# RV32M1 Series Reference Manual

Supports: RV32M1

Document Number: RV32M1RM
Rev. 1.1, 11/27/2018

# Contents

**Section number** **Title** **Page**

## Chapter 1
## About This Manual

1.1 Audience ..... 47

1.2 Organization ..... 47

1.3 Module descriptions ..... 47

1.3.1 Example: chip-specific information that supersedes content in the same chapter ..... 48

1.3.2 Example: chip-specific information that refers to a different chapter ..... 49

1.4 Register descriptions ..... 50

1.5 Conventions ..... 51

1.5.1 Numbering systems ..... 51

1.5.2 Typographic notation ..... 51

1.5.3 Special terms ..... 52

## Chapter 2
## Introduction

2.1 Overview ..... 53

2.2 Block diagram ..... 53

2.3 Module functional categories ..... 54

2.4 Ordering information ..... 57

## Chapter 3
## Core Overview

3.1 Core modules ..... 59

3.1.1 ARM Cortex-M0+ core ..... 59

3.1.2 ARM Cortex-M4F Core ..... 60

3.1.3 RISC-V RI5CY core ..... 62

3.1.4 RISC-V ZERO-RISCY core ..... 96

3.2 Nested Vectored Interrupt Controller (NVIC) modules ..... 113

3.2.1 Cortex-M0+ Nested Vectored Interrupt Controller (NVIC) ..... 113

3.2.2 Cortex-M4 Nested Vectored Interrupt Controller (NVIC) configuration ..... 119

3.3 Asynchronous Wake-up Interrupt Controller (AWIC)..... 126
3.3.1 AWIC overview..... 126
3.3.2 Wake-up sources..... 126
3.4 Event unit..... 128
3.4.1 Introduction..... 128
3.4.2 Memory map and register descriptions..... 129
3.4.3 Interrupt assignment to RI5CY..... 148
3.4.4 Interrupt assignment to ZERO-RISCY..... 150

## Chapter 4
## Peripheral Bridge (AIPS-Lite)

4.1 Chip-specific AIPS-Lite information..... 151
4.1.1 Memory maps..... 151
4.2 Memory map/register definition..... 151
4.3 Functional description..... 151
4.3.1 Access support..... 151

## Chapter 5
## Crossbar Switch (AXBS)

5.1 Chip-specific AXBS information..... 153
5.1.1 Crossbar switch master assignments - with system MPU..... 153
5.1.2 Crossbar switch slave assignments - with system MPU..... 153
5.2 Introduction..... 154
5.2.1 Features..... 154
5.3 Memory Map / Register Definition..... 155
5.3.1 AXBS0 register descriptions..... 155
5.4 Functional Description..... 162
5.4.1 General operation..... 162
5.4.2 Register coherency..... 163
5.4.3 Arbitration..... 164
5.5 Initialization/application information..... 167

## Chapter 6
## Miscellaneous Control Module for CM4F (MCM0)

6.1 Introduction....169
6.1.1 Features....169
6.2 Memory map/register descriptions....169
6.2.1 MCM register descriptions....169
6.3 Functional description....178
6.3.1 Interrupts....178
6.3.2 Determining source of the interrupt....179

## Chapter 7
## Miscellaneous Control Module for CM0+ (MCM1)

7.1 Introduction....181
7.1.1 Features....181
7.2 Memory map/register descriptions....181
7.2.1 MCM register descriptions....181

## Chapter 8
## Miscellaneous System Control Module (MSCM)

8.1 Chip-specific MSCM information....187
8.2 Overview....187
8.3 Chip Configuration and Boot....187
8.4 MSCM Memory Map/Register Definition....188
8.4.1 CPU Configuration Memory Map and Registers....188
8.4.2 MSCM register descriptions....188

## Chapter 9
## Extended Resource Domain Controller (XRDC)

9.1 Chip-specific XRDC information....233
9.1.1 XRDC configuration....233
9.1.2 XRDC register configurations....233
9.2 Introduction....239
9.2.1 Features....240

9.2.2 Block diagram.....241
9.2.3 Modes of operation.....242
9.3 External signal description.....243
9.4 Memory map/register definition.....243
9.4.1 XRDC register descriptions.....244
9.5 Functional description.....299
9.5.1 Manager (XRDC_MGR).....299
9.5.2 Master Domain Assignment Controller (XRDC_MDAC).....299
9.5.3 Special 4-State Model.....301
9.5.4 DxACP evaluation.....301
9.5.5 Exclusive Access Lock.....303
9.5.6 Memory Region Controller (XRDC_MRC).....305
9.5.7 Peripheral Access Controller (XRDC_PAC).....309
9.6 Initialization information.....311
9.7 Application information.....311
9.7.1 Master domain assignments.....311
9.7.2 Memory region descriptor management.....312
9.7.3 Domain error capture management.....312

## Chapter 10
## Semaphores2 (SEMA42)

10.1 Introduction.....315
10.1.1 Multi-core programming 101: software gates.....315
10.1.2 Features.....317
10.2 Memory map/register definition.....318
10.2.1 SEMA420 register descriptions.....319
10.2.2 SEMA421 register descriptions.....324
10.3 Functional description.....330

## Chapter 11
## Memory-Mapped Divide and Square Root (MMDVSQ)

11.1 Introduction....333
11.1.1 Features....333
11.1.2 Block diagram....334
11.1.3 Modes of operation....335
11.2 External signal description....336
11.3 Memory map and register definition....336
11.3.1 MMDVSQ register descriptions....336
11.4 Functional description....343
11.4.1 Algorithms....343
11.4.2 Execution times....347
11.4.3 Software interface....348

## Chapter 12
## ARM Core Debug

12.1 Introduction....351
12.2 Debug system block diagram....351
12.2.1 Debug components....352
12.2.2 JTAG-to-SWD change sequence....354
12.3 Debug port pin descriptions....354
12.4 System TAP connection....355
12.5 JTAG/SWD status and control registers....355
12.5.1 MDM-AP status registers....357
12.5.2 MDM-AP Control Register....359
12.5.3 MDM-AP Core Status Register....360
12.5.4 MDM-AP Core Clock Status Register....360
12.5.5 MDM-AP System Clock Status Register....361
12.5.6 MDM-AP System Power Status Register....362
12.5.7 MDM-AP PCC0_CGC0 Register....363
12.5.8 MDM-AP PCC0_CGC1 Register....363
12.5.9 MDM-AP PCC0_CGC2 Register....363

12.5.10 MDM-AP PCC0_CGC3 Register ... 363
12.5.11 MDM-AP PCC0_CGC4 Register ... 364
12.5.12 MDM-AP PCC1_CGC0 Register ... 364
12.5.13 MDM-AP PCC1_CGC1 Register ... 364
12.5.14 MDM-AP PCC1_CGC2 Register ... 364
12.5.15 MDM-AP PCC1_CGC3 Register ... 365
12.5.16 MDM-AP PCC1_CGC4 Register ... 365
12.6 Debug resets ... 365
12.7 SWD Multi-Drop ... 366
12.8 ITM ... 366
12.9 Core trace connectivity with ETM ... 367
12.10 Embedded Trace Macrocell v3.5 (ETM) ... 367
12.11 TPIU ... 368
12.12 DWT ... 368
12.13 Micro Trace Buffer (MTB) ... 369
12.14 Debug in low-power modes ... 369
12.15 Debug module state in low power modes ... 370
12.16 Debug and security ... 371

**Chapter 13
RISC-V Core Debug**

13.1 Introduction ... 373
13.2 Memory map for RISC-V debug port ... 373
13.3 Advanced debug interface ... 374
13.3.1 Error register ... 375
13.3.2 DEBUG_PATH_SELECTION register ... 375
13.3.3 POWER_UP register ... 376

**Chapter 14
Micro Trace Buffer (MTB)**

14.1 Introduction ... 377

14.1.1 Overview....377
14.1.2 Features....380
14.1.3 Modes of operation....381
14.2 External signal description....381
14.3 Memory map and register definition....382
14.3.1 MTB register descriptions....382
14.3.2 DWT register descriptions....400
14.3.3 ROM register descriptions....413

## Chapter 15
## JTAG Controller (JTAGC)

15.1 Introduction....421
15.1.1 Block diagram....421
15.1.2 Features....422
15.1.3 Modes of operation....422
15.2 External signal description....423
15.2.1 TCK—Test clock input....424
15.2.2 TDI—Test data input....424
15.2.3 TDO—Test data output....424
15.2.4 TMS—Test mode select....424
15.3 Register description....424
15.3.1 Instruction register....424
15.3.2 Bypass register....425
15.3.3 Device identification register....425
15.3.4 Boundary scan register....426
15.4 Functional description....426
15.4.1 JTAGC reset configuration....427
15.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port....427
15.4.3 TAP controller state machine....427
15.4.4 JTAGC block instructions....429

15.4.5 Boundary scan....432
15.5 Initialization/Application information....432

## Chapter 16
## Memory Map

16.1 Introduction....433
16.2 System memory map....433
16.3 Flash memory map....435
16.4 Flash access control introduction....436
16.5 SRAM memory map....436
16.6 Peripheral bridge memory maps....437
16.6.1 ARM Cortex-M0+/RISC-V ZERO-RISCY peripheral bridge memory maps....437
16.6.2 ARM Cortex-M4RISC-V RI5CY peripheral bridge memory maps....441
16.7 Private Peripheral Bus (PPB) memory map....445
16.7.1 ARM Cortex-M0+ PPB memory map....445
16.7.2 ARM Cortex-M4 PPB memory map....446

## Chapter 17
## Flash Memory Module (FTFE)

17.1 Chip-specific FTFE information....449
17.1.1 Flash Option (FOPT) customization....449
17.2 External signal description....451
17.3 Memory map and registers....451
17.3.1 IFR descriptions....452
17.3.2 Register descriptions....456
17.4 Functional description....481
17.4.1 Primary Program flash memory swap....481
17.4.2 Flash Program/Erase Protection....482
17.4.3 Flash Access Protection....483
17.4.4 Interrupts....484
17.4.5 Flash Operation in Low-Power Modes....485

17.4.6 Flash memory reads and ignored writes..... 485
17.4.7 Read while write (RWW)..... 486
17.4.8 Flash Program and Erase.....486
17.4.9 Flash Command Operations.....486
17.4.10 Margin Read Commands..... 493
17.4.11 Flash command descriptions.....494
17.4.12 Security..... 527
17.4.13 Reset Sequence..... 529

## Chapter 18
## Flash Memory Controller (FMC)

18.1 Chip-specific FMC information.....531
18.1.1 FMC buffers control.....531
18.1.2 Flash Access Control (FAC) Function.....531
18.2 Introduction.....538
18.2.1 Overview.....538
18.2.2 Features..... 538
18.3 Modes of operation..... 539
18.4 External signal description.....539
18.5 Functional description.....539
18.5.1 Default configuration..... 539
18.5.2 Configuration options..... 540
18.5.3 Wait states..... 540
18.5.4 Speculative reads.....540
18.6 Initialization and application information.....541

## Chapter 19
## Flash security

19.1 Introduction.....543
19.2 Flash Security..... 543
19.3 Security Interactions with other Modules..... 544

19.3.1 Security Interactions with Debug....544

## Chapter 20
## External Bus Interface (FlexBus)

20.1 Chip-specific FlexBus information....545
20.1.1 FlexBus clocking....545
20.1.2 FlexBus signal multiplexing....545
20.1.3 FlexBus CSCR0 reset value....547
20.1.4 FlexBus Security....547
20.1.5 FlexBus line transfers....547
20.2 Introduction....547
20.3 Signal descriptions....549
20.4 Memory Map/Register Definition....551
20.4.1 FB register descriptions....552
20.5 Functional description....561
20.5.1 Address and data bus configurations....561
20.5.2 Address comparison....561
20.5.3 Address driven on address bus....562
20.5.4 Connecting address/data lines....562
20.5.5 Bit ordering....562
20.5.6 Global chip-select....562
20.5.7 Data transfer signals....563
20.5.8 Signal transitions....563
20.5.9 Data-byte alignment and physical connections....563
20.5.10 Address/data bus multiplexing....565
20.5.11 Data transfer states....566
20.5.12 FlexBus Timing Examples....567
20.5.13 Burst cycles....586
20.5.14 Misaligned operands....595
20.5.15 Extended Transfer Start/Address Latch Enable....596

20.5.16 Bus errors ... 597
20.6 Initialization/Application Information ... 598
20.6.1 Initializing a chip-select ... 598
20.6.2 Reconfiguring a chip-select ... 598

## Chapter 21
## AHB Low Power Cache Controller (AHB_LPCAC)

21.1 Chip-specific LPCAC information ... 601
21.1.1 Cache controls ... 601
21.2 Introduction ... 601
21.2.1 Overview ... 601
21.3 Signal descriptions ... 602
21.4 Memory map and Input Control description ... 602
21.4.1 Memory regions ... 602
21.4.2 Input controls ... 602
21.5 Functional description ... 603
21.5.1 Cache Functional description ... 603

## Chapter 22
## AHB Low Power Local Memory Controller (AHB_LPLMEM)

22.1 Chip-specific LPLMEM information ... 605
22.1.1 Cache controls ... 605
22.2 Introduction ... 605
22.2.1 Overview ... 605
22.3 Signal descriptions ... 606
22.4 Memory map and Input Control description ... 606
22.4.1 Memory regions ... 606
22.4.2 Input controls ... 606
22.5 Functional description ... 606
22.5.1 Cache Functional description ... 607

## Chapter 23
## Signal Multiplexing and Signal Descriptions

23.1 Signal Multiplexing Introduction....609
23.2 Clock gating....609
23.3 Pinouts....610
23.3.1 RV32M1 Subfamily Pinout....610
23.3.2 Pin properties....619
23.3.3 Pinouts diagram....629
23.4 Module Signal Description Tables....630
23.4.1 Core Modules....630
23.4.2 System Modules....631
23.4.3 Memories and Memory Interfaces....632
23.4.4 Clock Modules....633
23.4.5 Communication Interfaces....634
23.4.6 Analog....640
23.4.7 Human-Machine Interfaces (HMI)....641
23.4.8 Timer Modules....641
23.4.9 Security Modules....643

## Chapter 24
## Port Control and Interrupts (PORT)

24.1 Introduction....645
24.1.1 Overview....645
24.1.2 Features....645
24.1.3 Modes of operation....646
24.2 External signal description....646
24.2.1 Detailed signal description....647
24.3 Memory map and register definition....647
24.3.1 PORTA register descriptions....647
24.3.2 PORTB register descriptions....664
24.3.3 PORTC register descriptions....673
24.3.4 PORTD register descriptions....687

24.3.5 PORTE register descriptions....701
24.4 Functional description....716
24.4.1 Pin control....716
24.4.2 Global pin control....717
24.4.3 Global interrupt control....717
24.4.4 External interrupts....718

## Chapter 25
## General-Purpose Input/Output (GPIO)

25.1 Chip-specific GPIO information....721
25.1.1 GPIO signals....721
25.2 Introduction....721
25.2.1 Features....721
25.2.2 Modes of operation....722
25.2.3 GPIO signal descriptions....722
25.3 Memory map and register definition....723
25.3.1 GPIO register descriptions....723
25.4 FGPIO memory map and register definition....730
25.4.1 FGPIOE register descriptions....731
25.5 Functional description....737
25.5.1 General-purpose input....737
25.5.2 General-purpose output....737
25.5.3 IOPORT....738

## Chapter 26
## Reset and Boot

26.1 Introduction....739
26.2 Reset....740
26.2.1 Voltage monitor reset sources....740
26.2.2 External system reset sources....742
26.2.3 Internal system reset sources....743

26.2.4 Debug resets....746
26.3 Boot....747
26.3.1 Boot sources....747
26.3.2 Flash Option (FOPT) customization....747
26.3.3 Boot sequence....750

## Chapter 27
## Kinetis ROM Bootloader

27.1 Chip-specific information....753
27.1.1 Also see the Kinetis Bootloader Reference Manual....753
27.1.2 Kinetis bootloader peripheral pinmux....753
27.1.3 Bootloader Memory Access....754
27.2 Introduction....754
27.3 Functional Description....756
27.3.1 The Kinetis Bootloader Configuration Area (BCA)....756
27.3.2 Start-up Process....758
27.3.3 Bootloader Entry Point / API Tree....760
27.3.4 Bootloader Protocol....762
27.3.5 Bootloader Packet Types....767
27.3.6 Bootloader Command API....775
27.3.7 Bootloader Exit state....799
27.4 Kinetis Flash Driver API....799
27.4.1 Flash Driver Entry Point....800
27.4.2 Flash driver API Tree....800
27.4.3 Quick demo using Kinetis Flash Driver API....801
27.4.4 Flash driver data structures....802
27.4.5 Flash driver API....803
27.5 Peripherals Supported....816
27.5.1 LPI2C Peripheral....816
27.5.2 LPSPI Peripheral....818

27.5.3 LPUART Peripheral....821
27.5.4 USB peripheral....823
27.6 Get/SetProperty Command Properties....827
27.6.1 Property Definitions....829
27.7 ROM API....831
27.7.1 ROM API....831
27.7.2 ROM API RAM usage....832
27.8 Security....833
27.8.1 Introduction....833
27.8.2 Notation....834
27.8.3 Use cases....835
27.8.4 Security fields....836
27.8.5 Signed image structure....839
27.8.6 SB file formats....846
27.8.7 Using SB files....858
27.8.8 Security considerations....862
27.8.9 Bootable section contents....864
27.9 Verifying the application in flash using CRC-32....870
27.10 Kinetis Bootloader Status Error Codes....871

## Chapter 28
## Clock Distribution

28.1 Introduction....875
28.2 Clock control modules....875
28.2.1 System Clock Generation (SCG) module....876
28.2.2 Peripheral Clock Control (PCC) module....877
28.3 SCG input clock sources....878
28.4 SCG system output clocks....878
28.5 SCG peripheral output clocks....879
28.6 Clock definitions....880

28.7 Clock gating ..... 881
28.8 Module clock assignments ..... 882

## Chapter 29
## System Clock Generator (SCG)

29.1 Chip-specific SCG information ..... 887
29.1.1 LPFLL configuration ..... 887
29.2 Introduction ..... 887
29.2.1 Features ..... 887
29.3 Memory Map/Register Definition ..... 889
29.3.1 SCG register descriptions ..... 890
29.4 Functional description ..... 927
29.4.1 SCG Clock Mode Transitions ..... 927

## Chapter 30
## Peripheral Clock Controller (PCC)

30.1 Chip-specific PCC information ..... 931
30.1.1 Peripheral source to the PCC ..... 931
30.2 Introduction ..... 931
30.3 Features ..... 931
30.4 Functional description ..... 932
30.5 Memory map and register definition ..... 933
30.5.1 PCC0 register descriptions ..... 933
30.5.2 PCC1 register descriptions ..... 995

## Chapter 31
## Power Management

31.1 Introduction ..... 1025
31.2 Power supply and power domain summary ..... 1025
31.2.1 Power supply ..... 1025
31.2.2 Power domains ..... 1028
31.3 On-chip regulator summary ..... 1030
31.3.1 DCDC regulator ..... 1031

31.3.2 LPPMC regulator ... 1031
31.3.3 IOREG regulator ... 1031
31.3.4 USB regulator ... 1031
31.4 Typical power supply schematic ... 1032
31.4.1 Typical power supply schematic 1 ... 1032
31.4.2 Typical power supply schematic 2 ... 1032
31.4.3 Typical power supply schematic 3 ... 1033
31.5 Power up state ... 1034
31.6 Multi-Core power mode description ... 1034
31.6.1 Core power structure overview ... 1034
31.6.2 Power mode combinations ... 1035
31.6.3 Recommended power mode combination ... 1039
31.7 Power mode description ... 1040
31.7.1 RUN mode ... 1040
31.7.2 Wait mode ... 1040
31.7.3 Stop mode ... 1041
31.7.4 Standby (LLS) mode ... 1042
31.7.5 Shutdown (VLLSx) mode ... 1042
31.8 Entering and exiting power modes ... 1043
31.9 Power mode transitions ... 1044
31.10 Power modes shutdown sequencing ... 1045
31.11 Flash program restrictions ... 1046
31.12 Module operation in low power modes ... 1046

## Chapter 32
## Multi System Mode Controller (MSMC)

32.1 Chip-specific MSMC information ... 1051
32.1.1 SRAM blocks with corresponding control bit ... 1051
32.1.2 Power mode transition in dual core application ... 1051
32.2 Introduction ... 1052

32.3 Modes of operation.... 1053
32.4 Memory map and register descriptions.... 1054
32.4.1 SMC0 register descriptions.... 1055
32.4.2 SMC1 register descriptions.... 1076
32.5 Functional description.... 1097
32.5.1 Power mode transitions.... 1097
32.5.2 Run modes.... 1102
32.5.3 Wait modes.... 1104
32.5.4 Stop modes.... 1105
32.5.5 Debug in low power modes.... 1108

## Chapter 33
## System Power Manager (SPM)

33.1 Chip-specific SPM information.... 1111
33.1.1 VDDIO voltage monitor.... 1111
33.2 Introduction.... 1111
33.3 Features.... 1111
33.4 Memory map and register descriptions.... 1113
33.4.1 SPM register descriptions.... 1113
33.5 Functional Description.... 1150
33.5.1 Low-voltage detect (LVD) system.... 1150
33.5.2 High-voltage detect (HVD) system.... 1152
33.5.3 Stop and VLPx Modes.... 1152
33.5.4 I/O retention.... 1153
33.5.5 Regulators.... 1153

## Chapter 34
## Low-Leakage Wakeup Unit (LLWU)

34.1 Chip-specific LLWU information.... 1159
34.1.1 Wake-up sources for Cortex-M4 core (CPU0).... 1159
34.1.2 Wake-up sources for Cortex-M0+ core (CPU1).... 1161

34.2 Introduction....1163
34.2.1 Features....1163
34.2.2 Modes of operation....1163
34.2.3 Block diagram....1164
34.3 LLWU signal descriptions....1165
34.4 Memory map/register definition....1166
34.4.1 LLWU0 register descriptions....1166
34.4.2 LLWU1 register descriptions....1185
34.5 Functional description....1204
34.5.1 LLS mode....1204
34.5.2 VLLS modes....1205
34.5.3 Initialization....1205

## Chapter 35
## System Integration Module (SIM)

35.1 Introduction....1207
35.1.1 Overview....1207
35.1.2 Features....1207
35.2 Memory Map and Registers....1207
35.2.1 SIM register descriptions....1207
35.3 Application information....1219

## Chapter 36
## Interrupt Multiplexer (INTMUX)

36.1 About this module....1221
36.1.1 Introduction....1221
36.1.2 Features....1221
36.1.3 Block diagram....1221
36.2 Memory Map and register definition....1222
36.2.1 INTMUX0 register descriptions....1222
36.2.2 INTMUX1 register descriptions....1228

36.3 Functional Description....1233
36.3.1 Configuring Output Channels....1233
36.3.2 INTMUX Vectors....1234

## Chapter 37
## Trigger MUX (TRGMUX)

37.1 Chip-specific TRGMUX information....1235
37.1.1 CPU0 Trigger Multiplexer input sources....1235
37.1.2 CPU0 Trigger Multiplexer outputs....1237
37.1.3 CPU1 Trigger Multiplexer input sources....1238
37.1.4 CPU1 Trigger Multiplexer outputs....1240
37.2 Introduction....1241
37.3 Features....1241
37.4 Memory map and register definition....1241
37.4.1 TRGMUX0 register descriptions....1242
37.4.2 TRGMUX1 register descriptions....1279

## Chapter 38
## Enhanced Direct Memory Access (eDMA)

38.1 Chip-specific eDMA information....1319
38.2 Introduction....1319
38.2.1 eDMA system block diagram....1319
38.2.2 Block parts....1320
38.2.3 Features....1321
38.3 Modes of operation....1322
38.4 Memory map/register definition....1323
38.4.1 TCD memory....1323
38.4.2 TCD initialization....1323
38.4.3 TCD structure....1323
38.4.4 Reserved memory and bit fields....1324
38.4.5 DMA0 register descriptions....1324

38.4.6 DMA1 register descriptions....1382
38.5 Functional description....1431
38.5.1 eDMA basic data flow....1431
38.5.2 Fault reporting and handling....1434
38.5.3 Channel preemption....1437
38.5.4 Performance....1437
38.6 Initialization/application information....1441
38.6.1 eDMA initialization....1441
38.6.2 Programming errors....1443
38.6.3 Arbitration mode considerations....1444
38.6.4 Performing DMA transfers....1444
38.6.5 Monitoring transfer descriptor status....1448
38.6.6 Channel Linking....1450
38.6.7 Dynamic programming....1451
38.6.8 Suspend/resume a DMA channel with active hardware service requests....1455

## Chapter 39
## Direct Memory Access Multiplexer (DMAMUX)

39.1 Chip-specific DMAMUX information....1457
39.1.1 ARM Cortex-M0+ DMAMUX configuration....1457
39.1.2 ARM Cortex-M4 DMAMUX configuration....1459
39.2 Introduction....1461
39.2.1 Overview....1461
39.2.2 Features....1462
39.2.3 Modes of operation....1462
39.3 External signal description....1463
39.4 Memory map/register definition....1463
39.4.1 DMAMUX0 register descriptions....1463
39.4.2 DMAMUX1 register descriptions....1465
39.5 Functional description....1467

39.5.1 DMA channels with periodic triggering capability....1467
39.5.2 Always-enabled DMA sources....1470
39.6 Initialization/application information....1471
39.6.1 Reset....1471
39.6.2 Enabling and configuring sources....1471

## Chapter 40
## Messaging Unit (MU)

40.1 Overview....1475
40.1.1 Features....1476
40.1.2 Modes of Operation....1476
40.2 Register Definition....1476
40.2.1 MUA register descriptions....1477
40.2.2 MUB register descriptions....1491
40.3 Functional Description....1505
40.3.1 Processor A Side Memory-Mapping....1505
40.3.2 Processor B Side Memory-Mapping....1506
40.3.3 MU Messaging....1506
40.3.4 Low Power Modes....1508
40.3.5 Event Update Timing....1509
40.3.6 Interrupts....1509
40.3.7 Interrupt Messaging Protocols....1510
40.3.8 Exclusive Access to Shared Memory....1513
40.3.9 Packet Data Transfers....1515
40.3.10 Resets....1515
40.4 Software Restrictions....1516
40.4.1 General Restrictions....1516
40.4.2 Processor Restrictions....1517

## Chapter 41
## Watchdog timer (WDOG)

41.1 Chip-specific WDOG information....1519
41.1.1 WDOG clocks....1519
41.1.2 WDOG low-power modes....1519
41.2 Introduction....1520
41.2.1 Features....1520
41.2.2 Block diagram....1521
41.3 Memory map and register definition....1521
41.3.1 WDOG0 register descriptions....1521
41.3.2 WDOG1 register descriptions....1528
41.4 Functional description....1534
41.4.1 Clock source....1535
41.4.2 Watchdog refresh mechanism....1536
41.4.3 Configuring the Watchdog....1538
41.4.4 Using interrupts to delay resets....1539
41.4.5 Backup reset....1539
41.4.6 Functionality in debug and low-power modes....1540
41.4.7 Fast testing of the watchdog....1540
41.5 Application Information....1542
41.5.1 Disable Watchdog....1542
41.5.2 Disable Watchdog after Reset....1542
41.5.3 Configure Watchdog....1543
41.5.4 Refreshing the Watchdog....1543

## Chapter 42
## External Watchdog Monitor (EWM)

42.1 Chip-specific EWM information....1545
42.1.1 EWM clocks....1545
42.1.2 EWM low-power modes....1545
42.1.3 EWM_OUT pin state in low power modes....1545
42.2 Introduction....1546

42.2.1 Features ... 1546
42.2.2 Modes of Operation ... 1547
42.2.3 Block Diagram ... 1547
42.3 EWM Signal Descriptions ... 1548
42.4 Memory Map/Register Definition ... 1549
42.4.1 EWM register descriptions ... 1549
42.5 Functional Description ... 1554
42.5.1 The EWM_OUT_b Signal ... 1554
42.5.2 EWM_OUT_b pin state in low power modes ... 1555
42.5.3 The EWM_in Signal ... 1555
42.5.4 EWM Counter ... 1556
42.5.5 EWM Compare Registers ... 1556
42.5.6 EWM Refresh Mechanism ... 1556
42.5.7 Counter clock prescaler ... 1557

## Chapter 43
## Cyclic Redundancy Check (CRC)

43.1 Introduction ... 1559
43.1.1 Features ... 1559
43.1.2 Block diagram ... 1559
43.1.3 Modes of operation ... 1560
43.2 Memory map and register descriptions ... 1560
43.2.1 CRC register descriptions ... 1560
43.3 Functional description ... 1565
43.3.1 CRC initialization/reinitialization ... 1565
43.3.2 CRC calculations ... 1565
43.3.3 Transpose feature ... 1566
43.3.4 CRC result complement ... 1568

## Chapter 44
## Standalone TRNG

44.1 Standalone True Random Number Generator (SA-TRNG)....1569
44.1.1 Standalone True Random Number Generator Block Diagram....1569
44.1.2 TRNG Functional Description....1570
44.1.3 SA-TRNG hardware functional description....1571
44.1.4 Another TRNG usage example....1573
44.1.5 TRNG register descriptions....1573

## Chapter 45
## Cryptographic Acceleration Unit (CAU3)

45.1 Introduction....1625
45.2 Block Diagram....1627
45.3 Overview....1628
45.4 Features....1629
45.5 CAU3 register descriptions....1630
45.5.1 CAU3 Memory map....1630
45.5.2 Processor Core Type (PCT)....1631
45.5.3 Memory Configuration (MCFG)....1632
45.5.4 Control Register (CR)....1634
45.5.5 Status Register (SR)....1638
45.5.6 Debug Control/Status Register (DBGCSR)....1641
45.5.7 Debug PC Breakpoint Register (DBGPBR)....1644
45.5.8 Debug Memory Command Register (DBGMCMD)....1645
45.5.9 Debug Memory Address Register (DBGMADR)....1647
45.5.10 Debug Memory Data Register (DBGMDR)....1648
45.5.11 Semaphore Register (SEMA4)....1649
45.5.12 Semaphore Ownership Register (SMOWNR)....1651
45.5.13 Address Remap Register (ARR)....1653
45.5.14 CryptoCore General Purpose Registers (CC_R0 - CC_R29)....1654
45.5.15 General Purpose R30 (CC_R30)....1655
45.5.16 General Purpose R31 (CC_R31)....1656

45.5.17 Program Counter (CC_PC)..... 1657
45.5.18 Start Command Register (CC_CMD)..... 1658
45.5.19 Condition Flag (CC_CF)..... 1659
45.5.20 Mode Register (PublicKey) (MDPK)..... 1660
45.5.21 Command Register (COM)..... 1662
45.5.22 Control Register (CTL)..... 1664
45.5.23 Clear Written Register (CW)..... 1666
45.5.24 Status Register (STA)..... 1668
45.5.25 Error Status Register (ESTA)..... 1670
45.5.26 PKHA A Size Register (PKASZ)..... 1672
45.5.27 PKHA B Size Register (PKBSZ)..... 1673
45.5.28 PKHA N Size Register (PKNSZ)..... 1674
45.5.29 PKHA E Size Register (PKESZ)..... 1675
45.5.30 PKHA Revision ID 1 (PKHA_VID1)..... 1676
45.5.31 PKHA Revision ID 2 (PKHA_VID2)..... 1677
45.5.32 CHA Revision ID (CHA_VID)..... 1678
45.5.33 PKHA Clock Control Register (PKHA_CCR)..... 1679
45.5.34 Global Status Register (GSR)..... 1681
45.5.35 Clock Linear Feedback Shift Register (CKLFSR)..... 1683
45.5.36 PKHA A0 Register (PKA0_0 - PKA0_31)..... 1684
45.5.37 PKHA A1 Register (PKA1_0 - PKA1_31)..... 1685
45.5.38 PKHA A2 Register (PKA2_0 - PKA2_31)..... 1686
45.5.39 PKHA A3 Register (PKA3_0 - PKA3_31)..... 1687
45.5.40 PKHA B0 Register (PKB0_0 - PKB0_31)..... 1689
45.5.41 PKHA B1 Register (PKB1_0 - PKB1_31)..... 1690
45.5.42 PKHA B2 Register (PKB2_0 - PKB2_31)..... 1691
45.5.43 PKHA B3 Register (PKB3_0 - PKB3_31)..... 1692
45.5.44 PKHA N0 Register (PKN0_0 - PKN0_31)..... 1694
45.5.45 PKHA N1 Register (PKN1_0 - PKN1_31)..... 1695

45.5.46 PKHA N2 Register (PKN2_0 - PKN2_31)....1696
45.5.47 PKHA N3 Register (PKN3_0 - PKN3_31)....1697
45.5.48 PKHA E Register (PKE_0 - PKE_127)....1698
45.6 Functional description....1700
45.6.1 CryptoCore States....1700
45.6.2 Memory Map....1701
45.6.3 Access to Cryptographic Routines....1702
45.6.4 Integrity checks....1703
45.6.5 DMA and Address Remapping....1703
45.6.6 Semaphore Operation....1705
45.6.7 Debug Resources....1707
45.6.8 Virtual External Registers....1709
45.6.9 Security Violation....1711
45.6.10 Module Reset....1712
45.6.11 Handling Exceptions....1713
45.6.12 Access to Memory Mapped Registers....1715
45.6.13 Low Power Operation....1717
45.7 Public-key hardware accelerator (PKHA) functionality....1719
45.7.1 Modular math....1720
45.7.2 About Montgomery values....1720
45.7.3 Non-modular Math....1722
45.7.4 Elliptic-Curve Math....1722
45.7.5 PKHA Mode Register....1725
45.7.6 PKHA functions....1737
45.7.7 Special values for common ECC domains....1771
45.8 Application/initialization information....1790
45.8.1 Code example....1790
45.8.2 Assembler equate values....1792

## Chapter 46

## Analog-to-Digital Converter (ADC)

46.1 Chip-specific LPADC information....1797

46.1.1 LPADC0 channel assignments....1797

46.1.2 Triggers....1799

46.1.3 Voltage reference options....1799

46.1.4 Functional clock options....1800

46.1.5 Direct Memory Access (DMA) support....1800

46.2 Introduction....1800

46.2.1 Features....1801

46.2.2 Block diagram....1801

46.2.3 Modes of operation....1802

46.3 Signal descriptions....1803

46.3.1 Analog Power (VDDA)....1803

46.3.2 Analog Ground (VSSA)....1804

46.3.3 Analog Channel Inputs (CHnA and CHnB)....1804

46.4 LPADC register descriptions....1804

46.4.1 LPADC Memory map....1804

46.4.2 Version ID Register (VERID)....1806

46.4.3 Parameter Register (PARAM)....1808

46.4.4 LPADC Control Register (CTRL)....1809

46.4.5 LPADC Status Register (STAT)....1810

46.4.6 Interrupt Enable Register (IE)....1812

46.4.7 DMA Enable Register (DE)....1813

46.4.8 LPADC Configuration Register (CFG)....1814

46.4.9 LPADC Pause Register (PAUSE)....1817

46.4.10 LPADC FIFO Control Register (FCTRL)....1818

46.4.11 Software Trigger Register (SWTRIG)....1819

46.4.12 LPADC Offset Trim Register (OFSTRIM)....1820

46.4.13 Trigger Control Register (TCTRL0 - TCTRL3)....1822

46.4.14 LPADC Command Low Buffer Register (CMDL1 - CMDL15)....1823
46.4.15 LPADC Command High Buffer Register (CMDH1 - CMDH4)....1825
46.4.16 LPADC Command High Buffer Register (CMDH5 - CMDH15)....1828
46.4.17 Compare Value Register (CV1 - CV4)....1831
46.4.18 LPADC Data Result FIFO Register (RESFIFO)....1832
46.5 Functional description....1834
46.5.1 Voltage reference....1837
46.5.2 Power control....1837
46.5.3 Clock operation....1838
46.5.4 Trigger detect and command execution....1838
46.5.5 Pause option....1839
46.5.6 Result FIFO operation....1840
46.5.7 Compare function....1840

## Chapter 47
## Low Power Comparator (LPCMP)

47.1 Chip-specific LPCMP information....1843
47.1.1 LPCMP input connections....1843
47.1.2 LPCMP external references....1843
47.2 Introduction....1844
47.3 Features....1844
47.4 LPCMP Block Diagram....1845
47.5 LPCMP0 register descriptions....1846
47.5.1 LPCMP0 Memory map....1847
47.5.2 Version ID Register (VERID)....1847
47.5.3 Parameter Register (PARAM)....1848
47.5.4 Comparator Control Register 0 (CCR0)....1849
47.5.5 Comparator Control Register 1 (CCR1)....1850
47.5.6 Comparator Control Register 2 (CCR2)....1852
47.5.7 DAC Control Register (DCR)....1854

47.5.8 Interrupt Enable Register (IER)..... 1855
47.5.9 Comparator Status Register (CSR)..... 1856
47.6 LPCMP1 register descriptions..... 1857
47.6.1 LPCMP1 Memory map..... 1857
47.6.2 Version ID Register (VERID)..... 1858
47.6.3 Parameter Register (PARAM)..... 1859
47.6.4 Comparator Control Register 0 (CCR0)..... 1860
47.6.5 Comparator Control Register 1 (CCR1)..... 1861
47.6.6 Comparator Control Register 2 (CCR2)..... 1863
47.6.7 DAC Control Register (DCR)..... 1865
47.6.8 Interrupt Enable Register (IER)..... 1866
47.6.9 Comparator Status Register (CSR)..... 1867
47.7 LPCMP Function Description..... 1868
47.7.1 Functional Block Diagram..... 1868
47.7.2 Functional Modes..... 1870
47.7.3 Hysteresis..... 1879
47.7.4 Initialization..... 1880
47.7.5 Low-Pass Filter..... 1881
47.7.6 Interrupts..... 1882
47.7.7 DMA Support..... 1882
47.7.8 Low Power Mode Operation..... 1883

## Chapter 48
## 12-bit Low Power Digital-to-Analog Converter (LPDAC)

48.1 Chip-specific LPDAC information..... 1885
48.1.1 12-bit LPDAC Overview..... 1885
48.1.2 12-bit LPDAC Output..... 1885
48.1.3 12-bit LPDAC Reference..... 1885
48.2 Introduction..... 1886
48.3 Features..... 1886

48.4 Block diagram....1886
48.5 LPDAC register descriptions....1887
48.5.1 LPDAC Memory map....1888
48.5.2 Version Identifier Register (VERID)....1888
48.5.3 Parameter Register (PARAM)....1889
48.5.4 DAC Data Register (DATA)....1890
48.5.5 DAC Global Control Register (GCR)....1891
48.5.6 DAC FIFO Control Register (FCR)....1893
48.5.7 DAC FIFO Pointer Register (FPR)....1894
48.5.8 FIFO Status Register (FSR)....1895
48.5.9 DAC Interrupt Enable Register (IER)....1897
48.5.10 DAC DMA Enable Register (DER)....1898
48.5.11 DAC Reset Control Register (RCR)....1899
48.5.12 DAC Trigger Control Register (TCR)....1900
48.6 Functional description....1901
48.6.1 Buffer mode....1902
48.6.2 FIFO mode....1902
48.6.3 Swing back mode....1902
48.6.4 Interrupts....1903
48.6.5 DMA operation....1903
48.6.6 Low-power mode operation....1903

## Chapter 49
## Voltage Reference (VREF)

49.1 Chip-specific VREF information....1905
49.1.1 VREF Overview....1905
49.2 Introduction....1905
49.2.1 Overview....1906
49.2.2 Features....1907
49.2.3 Modes of Operation....1907

49.2.4 VREF Signal Descriptions ... 1907
49.3 Memory Map and Register Definition ... 1908
49.3.1 VREF register descriptions ... 1908
49.4 Functional Description ... 1912
49.4.1 Voltage Reference Disabled, SC[VREFEN] = 0 ... 1912
49.4.2 Voltage Reference Enabled, SC[VREFEN] = 1 ... 1913
49.4.3 Internal voltage regulator ... 1914
49.5 Initialization/Application Information ... 1915

## Chapter 50
## Low Power Interrupt Timer (LPIT)

50.1 Introduction ... 1917
50.1.1 Overview ... 1917
50.1.2 Block Diagram ... 1918
50.2 Modes of operation ... 1919
50.3 Memory Map and Registers ... 1920
50.3.1 LPIT0 register descriptions ... 1920
50.3.2 LPIT1 register descriptions ... 1935
50.4 Functional description ... 1950
50.4.1 LPIT programming model ... 1951
50.4.2 Initialization ... 1952
50.4.3 Timer Modes ... 1953
50.4.4 Trigger Control for Timers ... 1954
50.4.5 Channel Chaining ... 1954
50.4.6 Detailed timing ... 1955

## Chapter 51
## Timer/PWM Module (TPM)

51.1 Chip-specific TPM information ... 1969
51.1.1 TPM Instantiation Information ... 1969
51.1.2 Global Timebase ... 1969

51.1.3 TPM Interrupts....1969
51.2 Introduction....1970
51.2.1 TPM Philosophy....1970
51.2.2 Features....1970
51.2.3 Modes of operation....1971
51.2.4 Block diagram....1971
51.3 TPM Signal Descriptions....1972
51.3.1 TPM_EXTCLK — TPM External Clock....1973
51.3.2 TPM_CHn — TPM Channel (n) I/O Pin....1973
51.4 Memory Map and Register Definition....1973
51.4.1 TPM0 register descriptions....1973
51.4.2 TPM1 register descriptions....1997
51.4.3 TPM2 register descriptions....2018
51.4.4 TPM3 register descriptions....2042
51.5 Functional description....2064
51.5.1 Clock domains....2064
51.5.2 Prescaler....2064
51.5.3 Counter....2065
51.5.4 Input Capture Mode....2068
51.5.5 Output Compare Mode....2069
51.5.6 Edge-Aligned PWM (EPWM) Mode....2070
51.5.7 Center-Aligned PWM (CPWM) Mode....2072
51.5.8 Combine PWM mode....2074
51.5.9 Combine Input Capture mode....2077
51.5.10 Input Capture Filter....2078
51.5.11 Deadtime insertion....2080
51.5.12 Quadrature Decoder mode....2081
51.5.13 Registers Updated from Write Buffers....2085
51.5.14 DMA....2086

51.5.15 Output triggers ... 2086
51.5.16 Reset Overview ... 2087
51.5.17 TPM Interrupts ... 2087

## Chapter 52
## Time Stamp Timer Module (TSTMR)

52.1 Chip-specific TSTMR information ... 2089
52.2 Introduction ... 2089
52.2.1 Features ... 2089
52.3 TSTMR Memory map and register definition ... 2089
52.3.1 TSTMRA register descriptions ... 2089
52.3.2 TSTMRB register descriptions ... 2092
52.4 Functional description ... 2095

## Chapter 53
## Low-Power Timer (LPTMR)

53.1 Chip-specific LPTMR information ... 2097
53.1.1 LPTMRx prescaler/glitch filter clocking options ... 2097
53.1.2 LPTMRx pulse counter input options ... 2097
53.2 Introduction ... 2098
53.2.1 Features ... 2098
53.2.2 Modes of operation ... 2098
53.3 LPTMR signal descriptions ... 2099
53.3.1 Detailed signal descriptions ... 2099
53.4 Memory map and register definition ... 2100
53.4.1 LPTMR0 register descriptions ... 2100
53.4.2 LPTMR1 register descriptions ... 2105
53.4.3 LPTMR2 register descriptions ... 2110
53.5 Functional description ... 2116
53.5.1 LPTMR power and reset ... 2116
53.5.2 LPTMR clocking ... 2116

53.5.3 LPTMR prescaler/glitch filter....2117
53.5.4 LPTMR compare....2118
53.5.5 LPTMR counter....2118
53.5.6 LPTMR hardware trigger....2119
53.5.7 LPTMR interrupt....2119

## Chapter 54
## Real Time Clock (RTC)

54.1 Chip-specific RTC information....2121
54.1.1 RTC_CLKOUT signal....2121
54.1.2 Number of tamper inputs....2121
54.2 Introduction....2122
54.2.1 Features....2122
54.2.2 Modes of operation....2122
54.2.3 RTC signal descriptions....2123
54.3 Register definition....2124
54.3.1 RTC register descriptions....2124
54.4 Functional description....2148
54.4.1 Power, clocking, and reset....2148
54.4.2 Time counter....2149
54.4.3 Compensation....2150
54.4.4 Time alarm....2151
54.4.5 Update mode....2151
54.4.6 Monotonic counter....2151
54.4.7 Tamper detect....2152
54.4.8 Register lock....2152
54.4.9 Access control....2152
54.4.10 Interrupt....2153

## Chapter 55
## Low Power Inter-Integrated Circuit (LPI2C)

55.1 Chip-specific LPI2C information ..... 2155
55.1.1 LPI2C instantiations ..... 2155
55.2 Introduction ..... 2156
55.2.1 Features ..... 2157
55.2.2 Block Diagram ..... 2159
55.2.3 Modes of operation ..... 2159
55.2.4 Signal Descriptions ..... 2160
55.2.5 Wiring options ..... 2160
55.3 Memory Map and Registers ..... 2162
55.3.1 LPI2C0 register descriptions ..... 2162
55.3.2 LPI2C1 register descriptions ..... 2201
55.3.3 LPI2C2 register descriptions ..... 2240
55.3.4 LPI2C3 register descriptions ..... 2279
55.4 Functional description ..... 2318
55.4.1 Clocking and Resets ..... 2318
55.4.2 Master Mode ..... 2319
55.4.3 Slave Mode ..... 2325
55.4.4 Interrupts and DMA Requests ..... 2327
55.4.5 Peripheral Triggers ..... 2329

## Chapter 56
## Low Power Universal Asynchronous Receiver/Transmitter (LPUART)

56.1 Chip-specific LPUART information ..... 2331
56.1.1 LPUART overview ..... 2331
56.1.2 LPUART Instantiation ..... 2331
56.2 Introduction ..... 2332
56.2.1 Features ..... 2332
56.2.2 Modes of operation ..... 2333
56.2.3 Signal Descriptions ..... 2333
56.2.4 Block diagram ..... 2334

56.3 Register definition....2335
56.3.1 LPUART0 register descriptions....2335
56.3.2 LPUART1 register descriptions....2360
56.3.3 LPUART2 register descriptions....2385
56.3.4 LPUART3 register descriptions....2410
56.4 Functional description....2435
56.4.1 Baud rate generation....2435
56.4.2 Transmitter functional description....2436
56.4.3 Receiver functional description....2439
56.4.4 Additional LPUART functions....2446
56.4.5 Infrared interface....2447
56.4.6 Interrupts and status flags....2448
56.4.7 Peripheral Triggers....2449

## Chapter 57
## Low Power Serial Peripheral Interface (LPSPI)

57.1 Chip-specific LPSPI information....2451
57.1.1 LPSPI instantiations....2451
57.2 Introduction....2451
57.2.1 Features....2453
57.2.2 Block Diagram....2454
57.2.3 Modes of operation....2454
57.2.4 Signal Descriptions....2455
57.2.5 Wiring options....2455
57.3 Memory Map and Registers....2457
57.3.1 LPSPI0 register descriptions....2457
57.3.2 LPSPI1 register descriptions....2479
57.3.3 LPSPI2 register descriptions....2501
57.3.4 LPSPI3 register descriptions....2523
57.4 Functional description....2545

57.4.1 Clocking and resets....2545
57.4.2 Master Mode....2546
57.4.3 Slave Mode....2552
57.4.4 Interrupts and DMA Requests....2554
57.4.5 Peripheral Triggers....2555

## Chapter 58
## Flexible I/O (FlexIO)

58.1 Chip-specific FlexIO information....2557
58.1.1 FlexIO overview....2557
58.1.2 FlexIO Instantiation....2558
58.2 Introduction....2558
58.2.1 Overview....2558
58.2.2 Features....2558
58.2.3 Block Diagram....2559
58.2.4 Modes of operation....2560
58.2.5 FlexIO Signal Descriptions....2560
58.3 Memory Map and Registers....2560
58.3.1 FLEXIO register descriptions....2560
58.4 Functional description....2589
58.4.1 Clocking and Resets....2589
58.4.2 Shifter operation....2590
58.4.3 Timer Operation....2595
58.4.4 Pin operation....2599
58.4.5 Interrupts and DMA Requests....2600
58.4.6 Peripheral Triggers....2601
58.5 Application Information....2601
58.5.1 UART Transmit....2601
58.5.2 UART Receive....2602
58.5.3 SPI Master....2604

58.5.4 SPI Slave....2606
58.5.5 I2C Master....2608
58.5.6 I2S Master....2610
58.5.7 I2S Slave....2611
58.5.8 Camera Interface....2613
58.5.9 Motorola 68K/Intel 8080 Bus Interface....2614
58.5.10 Low Power State Machine....2615

## Chapter 59
## Inter-IC Sound (I2S)

59.1 Chip-specific I2S information....2619
59.1.1 Instantiation information....2619
59.1.2 I2S/SAI operation in low power modes....2619
59.2 Introduction....2620
59.2.1 Features....2620
59.2.2 Block diagram....2621
59.2.3 Modes of operation....2621
59.3 External signals....2622
59.4 Memory map and register definition....2623
59.4.1 I2S register descriptions....2623
59.5 Functional description....2652
59.5.1 SAI clocking....2653
59.5.2 SAI resets....2654
59.5.3 Synchronous modes....2655
59.5.4 Frame sync configuration....2656
59.5.5 Data FIFO....2657
59.5.6 Word mask register....2661
59.5.7 Interrupts and DMA requests....2661

## Chapter 60
## Smart Card Interface Module (EMV SIM)

60.1 Chip-specific EMV SIM information ... 2665
60.1.1 EMV_SIM overview ... 2665
60.1.2 EMV_SIM Instantiation ... 2665
60.2 Introduction ... 2665
60.2.1 Features ... 2665
60.3 Block Diagram ... 2666
60.4 Design Overview ... 2667
60.5 Signal Description ... 2669
60.6 Memory Map and Registers ... 2669
60.6.1 EMVSIM register descriptions ... 2669
60.7 Functional Description ... 2697
60.7.1 Initialization ... 2697
60.7.2 Smart Card Interface and Control ... 2699
60.7.3 EMV SIM Receiver ... 2702
60.7.4 EMV SIM Transmitter ... 2706
60.7.5 LRC and CRC ... 2708
60.7.6 Message Handling ... 2710
60.7.7 Protocol Timers ... 2712
60.7.8 Answer To Reset (ATR) Detection ... 2715

## Chapter 61
## Universal Serial Bus Full Speed Controller (USBFS)

61.1 Chip-specific USB information ... 2721
61.1.1 USB wakeup ... 2721
61.1.2 LPUART over USB capability ... 2721
61.1.3 USB Power Distribution ... 2722
61.1.4 USB controller configuration ... 2724
61.1.5 Keep Alive Mode and IRC48M operation ... 2724
61.2 Introduction ... 2726
61.2.1 References ... 2726

61.2.2 USB—Overview ... 2727
61.2.3 USBFS Features ... 2728
61.3 Functional description ... 2728
61.3.1 Data Structures ... 2728
61.3.2 On-chip transceiver required external components ... 2728
61.4 Programmers interface ... 2729
61.4.1 Buffer Descriptor Table ... 2729
61.4.2 USB data transfers—Receive (Rx) and Transmit (Tx) ... 2731
61.4.3 Addressing BDT entries ... 2731
61.4.4 Buffer Descriptors (BDs) ... 2732
61.4.5 USB transaction ... 2734
61.5 Memory map/Register definitions ... 2736
61.5.1 USBFS memory mapping ... 2736
61.5.2 USB register descriptions ... 2736
61.6 Keep Alive mode ... 2776

## Chapter 62
## USB Voltage Regulator (USBVREG)

62.1 Chip-specific USBVREG information ... 2779
62.1.1 USB Voltage Regulator Configuration ... 2779
62.2 Introduction ... 2779
62.2.1 Features ... 2779
62.3 Memory Map and Registers ... 2780
62.3.1 USBVREG register descriptions ... 2780

## Chapter 63
## Ultra Secured Digital Host Controller (uSDHC)

63.1 Overview ... 2783
63.1.1 Features ... 2786
63.1.2 Modes and Operations ... 2787
63.2 External Signals ... 2787

63.2.1 Signals Overview ... 2788
63.3 Clocks ... 2789
63.4 Functional Description ... 2789
63.4.1 Data Buffer ... 2789
63.4.2 DMA AHB Interface ... 2794
63.4.3 Register Bank with IP Bus Interface ... 2802
63.4.4 Clock & Reset Manager ... 2805
63.4.5 Clock Generator ... 2806
63.4.6 SDIO Card Interrupt ... 2806
63.4.7 Card Insertion and Removal Detection ... 2808
63.4.8 Power Management and Wake Up Events ... 2809
63.4.9 MMC fast boot ... 2810
63.5 Initialization/Application of uSDHC ... 2812
63.5.1 Command Send & Response Receive Basic Operation ... 2812
63.5.2 Card Identification Mode ... 2813
63.5.3 Card Access ... 2818
63.5.4 Switch Function ... 2830
63.5.5 ADMA Operation ... 2832
63.5.6 Fast Boot Operation ... 2834
63.6 Commands for MMC/SD/SDIO ... 2837
63.7 Software Restrictions ... 2842
63.7.1 Initialization Active ... 2842
63.7.2 Software Polling Procedure ... 2843
63.7.3 Suspend Operation ... 2843
63.7.4 Data Length Setting ... 2843
63.7.5 (A)DMA Address Setting ... 2843
63.7.6 Data Port Access ... 2844
63.7.7 Change Clock Frequency ... 2844
63.7.8 Multi-block Read ... 2844

63.8 uSDHC Memory Map/Register Definition....2844
63.8.1 uSDHC register descriptions....2845

## Chapter 64
## 2.4 GHz Multi-Protocol Radio

64.1 Introduction....2903
64.2 Radio System Integration Module....2904
64.2.1 Introduction....2904
64.2.2 Radio Power....2907
64.2.3 Radio Clocks....2914
64.2.4 Radio Stop Modes....2920
64.2.5 Radio Deep Sleep....2925
64.2.6 Wi-Fi Coexistence....2931
64.2.7 RF Early Warning....2934
64.2.8 Radio Interrupts....2935
64.2.9 Radio Configuration....2938
64.2.10 Radio Resets....2939
64.2.11 Radio Gasket Bypass....2940
64.2.12 Radio Version ID....2941
64.2.13 Memory Map and Register Definition....2941
64.3 Transceiver Digital....2968
64.3.1 Transmitter Digital Module....2968
64.3.2 PLL Frequency Synthesizer....2990
64.3.3 Receiver Digital Module....3039
64.3.4 Bit Streaming Mode....3190
64.3.5 Transceiver Sequence Manager....3196
64.3.6 Transceiver DMA and Packet RAM Debug Modes....3340
64.3.7 2.4 GHz PHY....3364
64.3.8 Wake-On-Radio....3373
64.3.9 Cyclic Redundancy Check and Data Whitening Module (CRCW)....3448

64.3.10 Other Transceiver Memory Map and Register Definition..... 3457

64.4.1 Introduction..... 3510
64.4.2 Functional description..... 3512
64.5 Link Layer..... 3513
64.5.1 BLE Link Layer..... 3513
64.5.2 802.15.4 Link Layer Controller..... 3642
64.5.3 Generic_FSK Link Layer Controller..... 3840

# Chapter 1
# About This Manual

## 1.1 Audience

This reference manual is intended for system software and hardware developers and applications programmers who want to develop products with this device. It assumes that the reader understands operating systems, microprocessor system design, and basic principles of software and hardware.

## 1.2 Organization

This manual has two main sets of chapters.

1. Chapters in the first set contain information that applies to all components on the chip.
2. Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
   - Examples of these groupings are clocking, timers, and communication interfaces.
   - Each grouping includes chapters that provide a technical description of individual modules.

## 1.3 Module descriptions

Each module chapter has two main parts:

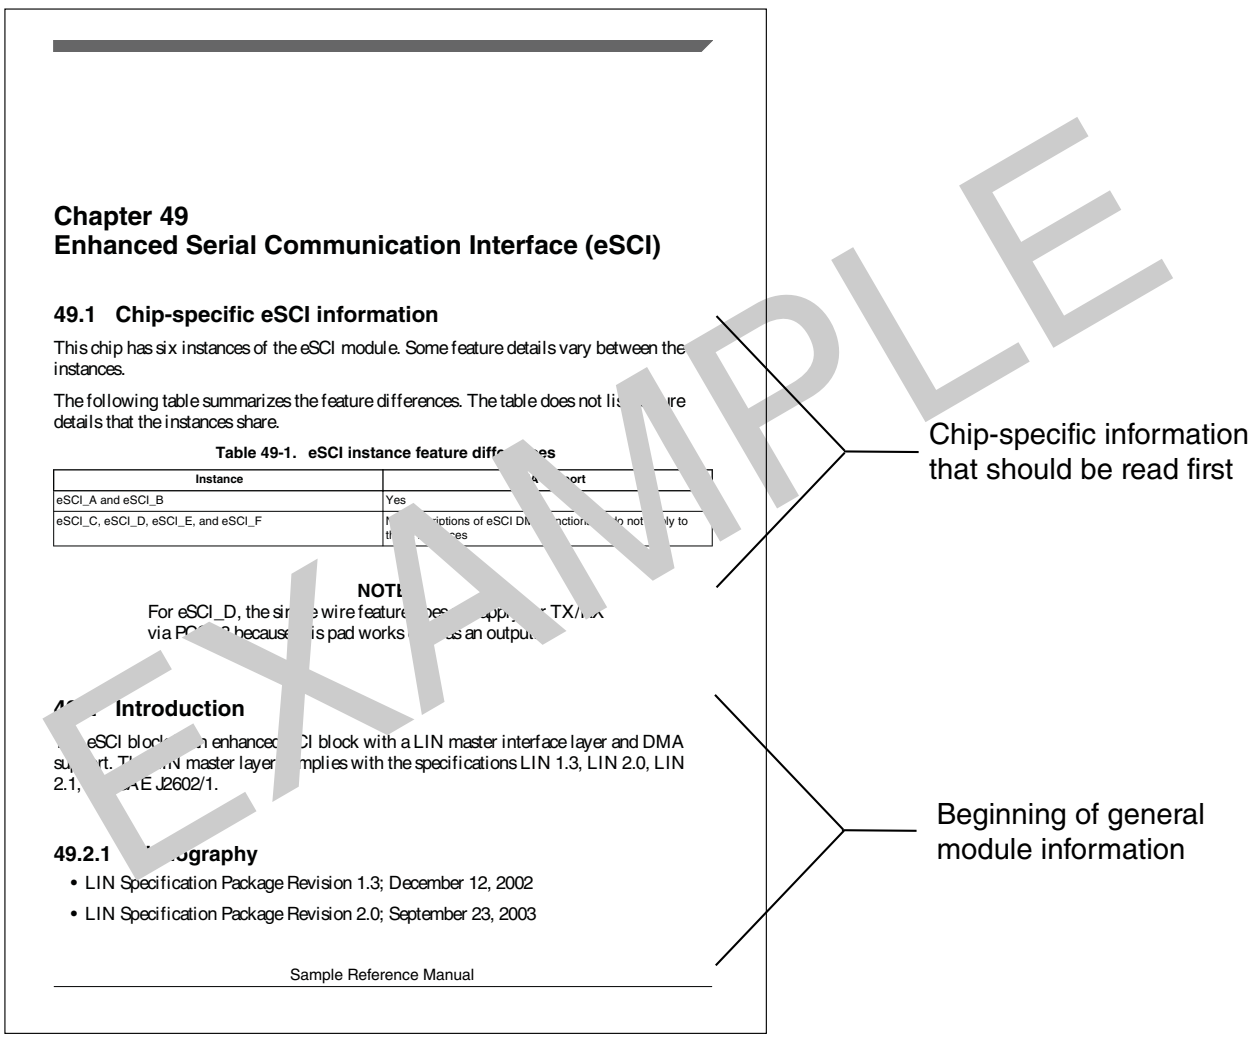
- **Chip-specific:** The first section, *Chip-specific [module name] information*, includes the number of module instances on the chip and possible implementation differences between the module instances, such as differences in FIFO depths or the number of

channels supported. It may also include functional connections between the module instances and other modules. Read this section *first* because its content is crucial to understanding the information in other sections of the chapter.

- **General:** The subsequent sections provide general information about the module, including its signals, registers, and functional description.

**NOTE**

If there is a conflict between the chip-specific module information (first section) and the general module information (subsequent sections), the chip-specific information supersedes the general information.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

| Instance | [illegible] Support |
|---|---|
| eSCI_A and eSCI_B | Yes |
| eSCI_C, eSCI_D, eSCI_E, and eSCI_F | [illegible] descriptions of eSCI DMA functions do not apply to these instances |

NOTE

For eSCI_D, the single wire feature does support TX/RX via PC[illegible] because this pad works as an output

49.[illegible] Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 [illegible]ography

- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003

Sample Reference Manual

Chip-specific information that should be read first

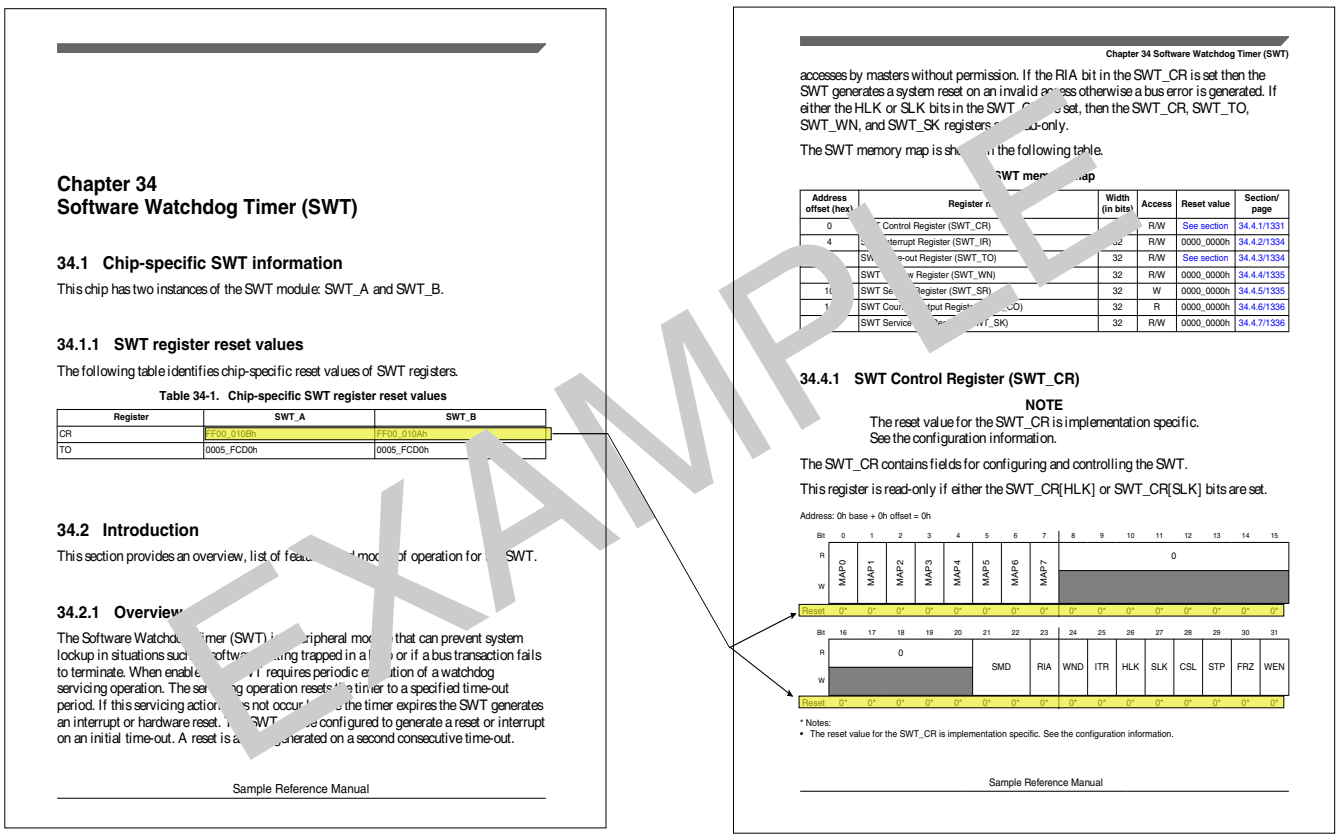
Beginning of general module information

EXAMPLE

**Figure 1-1. Example: chapter chip-specific information and general module information**

## 1.3.1 Example: chip-specific information that supersedes content in the same chapter

The example below shows chip-specific information that supersedes general module information presented later in the chapter. In this case, the chip-specific register reset values supersede the reset values that appear in the register diagram.



Chapter 34
Software Watchdog Timer (SWT)

34.1 Chip-specific SWT information

This chip has two instances of the SWT module: SWT_A and SWT_B.

34.1.1 SWT register reset values

The following table identifies chip-specific reset values of SWT registers.

Table 34-1. Chip-specific SWT register reset values

| Register | SWT_A | SWT_B |
|---|---|---|
| CR | FF00_010Bh | FF00_010Ah |
| TO | 0005_FCD0h | 0005_FCD0h |

34.2 Introduction

This section provides an overview, list of feat... mod... of operation for ... SWT.

34.2.1 Overview

The Software Watchd... imer (SWT) i... ripheral mo... that can prevent system lockup in situations suc... softw... ing trapped in a l... or if a bus transaction fails to terminate. When enable... T requires periodic e... tion of a watchdog servicing operation. The se... g operation resets ... timer to a specified time-out period. If this servicing actio... s not occur ... the timer expires the SWT generates an interrupt or hardware reset. ... SWT ... e configured to generate a reset or interrupt on an initial time-out. A reset is a... enerated on a second consecutive time-out.

Sample Reference Manual

Chapter 34 Software Watchdog Timer (SWT)

accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid a... ss otherwise a bus error is generated. If either the HLK or SLK bits in the SWT_C... set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers ... d-only.

The SWT memory map is sh... n the following table.

SWT mem... ap

| Address offset (hex) | Register n... | Width (in bits) | Access | Reset value | Section/ page |
|---|---|---|---|---|---|
| 0 | ... Control Register (SWT_CR) | | R/W | See section | 34.4.1/1331 |
| 4 | ... terrupt Register (SWT_IR) | ...2 | R/W | 0000_0000h | 34.4.2/1334 |
| | SW... e-out Register (SWT_TO) | 32 | R/W | See section | 34.4.3/1334 |
| | SWT ... w Register (SWT_WN) | 32 | R/W | 0000_0000h | 34.4.4/1335 |
| 10 | SWT Se... Register (SWT_SR) | 32 | W | 0000_0000h | 34.4.5/1335 |
| 1... | SWT Coun... tput Regis... CO) | 32 | R | 0000_0000h | 34.4.6/1336 |
| | SWT Service ... T_SK) | 32 | R/W | 0000_0000h | 34.4.7/1336 |

34.4.1 SWT Control Register (SWT_CR)

NOTE
The reset value for the SWT_CR is implementation specific.
See the configuration information.

The SWT_CR contains fields for configuring and controlling the SWT.

This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 0h offset = 0h

| Bit | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | MAP0 | MAP1 | MAP2 | MAP3 | MAP4 | MAP5 | MAP6 | MAP7 | 0 | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* |

| Bit | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | SMD | RIA | WND | ITR | HLK | SLK | CSL | STP | FRZ | WEN | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* | 0* |

* Notes:
- The reset value for the SWT_CR is implementation specific. See the configuration information.

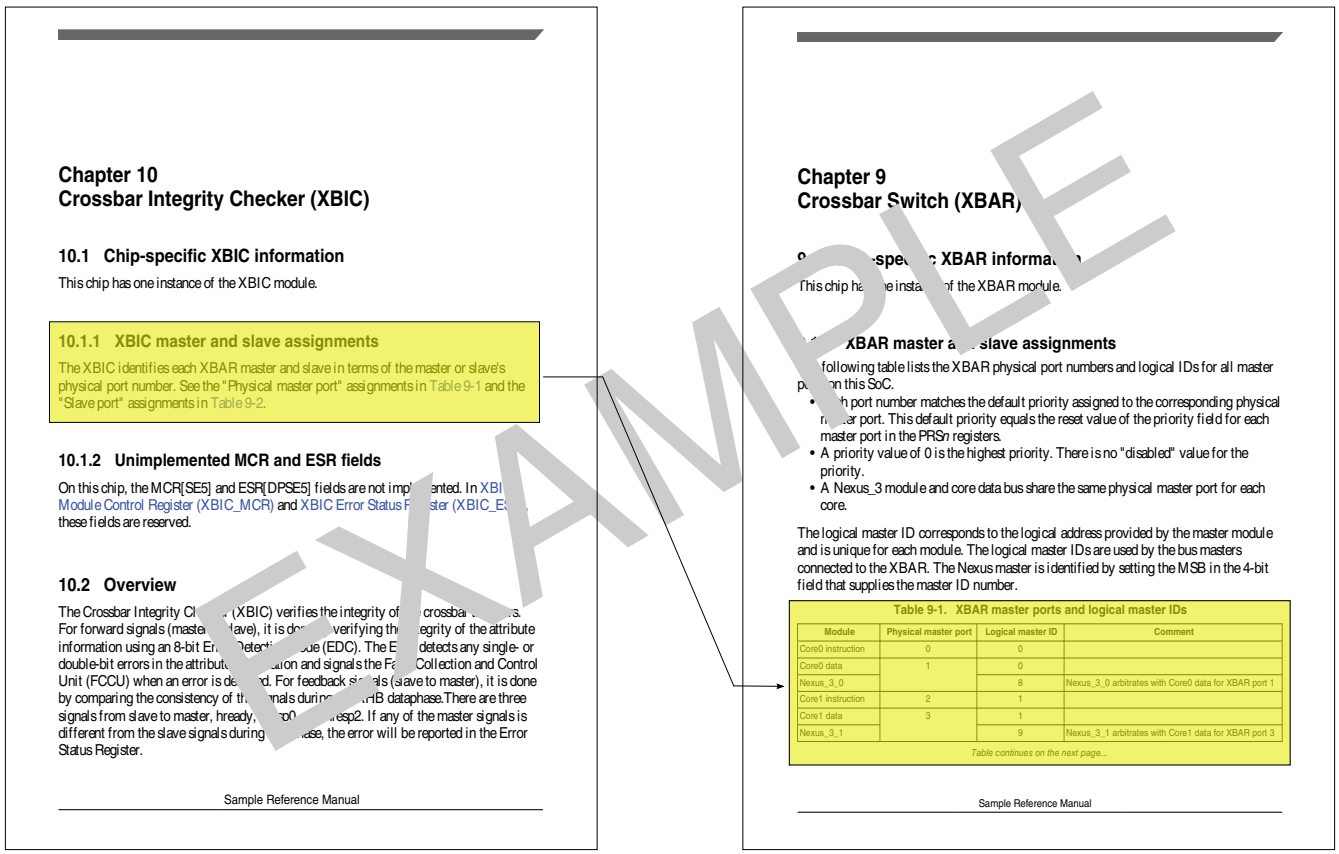
Sample Reference Manual

EXAMPLE

**Figure 1-2. Example: chip-specific information that supersedes content in the same chapter**

## 1.3.2 Example: chip-specific information that refers to a different chapter

The chip-specific information below refers to another chapter's chip-specific information. In this case, read both sets of chip-specific information before reading further in the chapter.



Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC master and slave assignments

The XBIC identifies each XBAR master and slave in terms of the master or slave's physical port number. See the "Physical master port" assignments in Table 9-1 and the "Slave port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBI Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_E these fields are reserved.

10.2 Overview

The Crossbar Integrity Ch (XBIC) verifies the integrity of crossba s. For forward signals (maste lave), it is do verifying th egrity of the attribute information using an 8-bit Er Detecti ue (EDC). The E detects any single- or double-bit errors in the attribut tion and signals the Fa Collection and Control Unit (FCCU) when an error is de d. For feedback si ls (slave to master), it is done by comparing the consistency of th nals duri hB dataphase.There are three signals from slave to master, hready, so0 esp2. If any of the master signals is different from the slave signals during ase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9 -spe c XBAR informa n

This chip ha e insta of the XBAR module.

XBAR master a slave assignments

following table lists the XBAR physical port numbers and logical IDs for all master p on this SoC.

- h port number matches the default priority assigned to the corresponding physical r er port. This default priority equals the reset value of the priority field for each master port in the PRSn registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical master port for each core.

The logical master ID corresponds to the logical address provided by the master module and is unique for each module. The logical master IDs are used by the bus masters connected to the XBAR. The Nexus master is identified by setting the MSB in the 4-bit field that supplies the master ID number.

Table 9-1. XBAR master ports and logical master IDs

| Module | Physical master port | Logical master ID | Comment |
|---|---|---|---|
| Core0 instruction | 0 | 0 | |
| Core0 data | 1 | 0 | |
| Nexus_3_0 | | 8 | Nexus_3_0 arbitrates with Core0 data for XBAR port 1 |
| Core1 instruction | 2 | 1 | |
| Core1 data | 3 | 1 | |
| Nexus_3_1 | | 9 | Nexus_3_1 arbitrates with Core1 data for XBAR port 3 |

Table continues on the next page...

Sample Reference Manual

EXAMPLE

**Figure 1-3. Example: chip-specific information that refers to a different chapter**

## 1.4 Register descriptions

Module chapters present register information in:

- Memory maps including:
  - Addresses
  - The name and acronym/abbreviation of each register
  - The width of each register (in bits)
  - Each register's reset value
  - The page number on which each register is described
- Register figures
- Field-description tables
- Associated text

The register figures show the field structure using the conventions in the following figure.

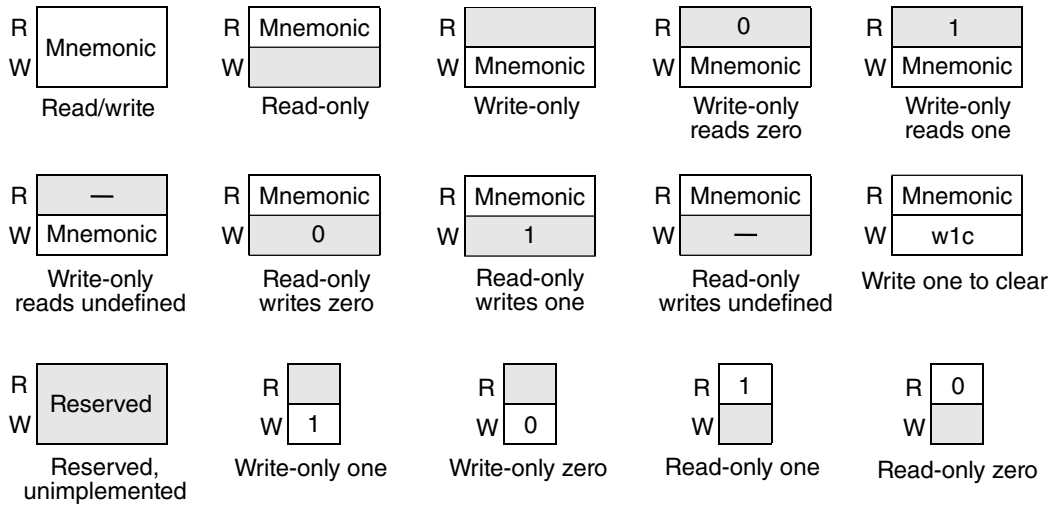


**Figure 1-4. Register figure conventions**

# 1.5 Conventions

## 1.5.1 Numbering systems

The following suffixes identify different numbering systems:

| This suffix | Identifies a |
|---|---|
| b | Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix *0b*. |
| d | Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix. |
| h | Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix *0x*. |

## 1.5.2 Typographic notation

The following typographic notation is used throughout this document:

| Example | Description |
|---|---|
| *placeholder*, x | Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers. |
| `code` | Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type |

*Table continues on the next page...*

| Example | Description |
|---|---|
| | is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR. |
| SR[SCM] | A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR). |
| REVNO[6:4], XAD[7:0] | Numbers in brackets and separated by a colon represent either:<br>• A subset of a register's named field<br>For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register.<br>• A continuous range of individual signals of a bus<br>For example, XAD[7:0] refers to signals 7–0 of the XAD bus. |

## 1.5.3 Special terms

The following terms have special meanings:

| Term | Meaning |
|---|---|
| asserted | Refers to the state of a signal as follows:<br>• An active-high signal is asserted when high (1).<br>• An active-low signal is asserted when low (0). |
| deasserted | Refers to the state of a signal as follows:<br>• An active-high signal is deasserted when low (0).<br>• An active-low signal is deasserted when high (1).<br><br>In some cases, deasserted signals are described as *negated*. |
| reserved | Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior.<br>• Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field.<br>• Consider undefined locations in memory to be reserved. |
| w1c | Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared." |

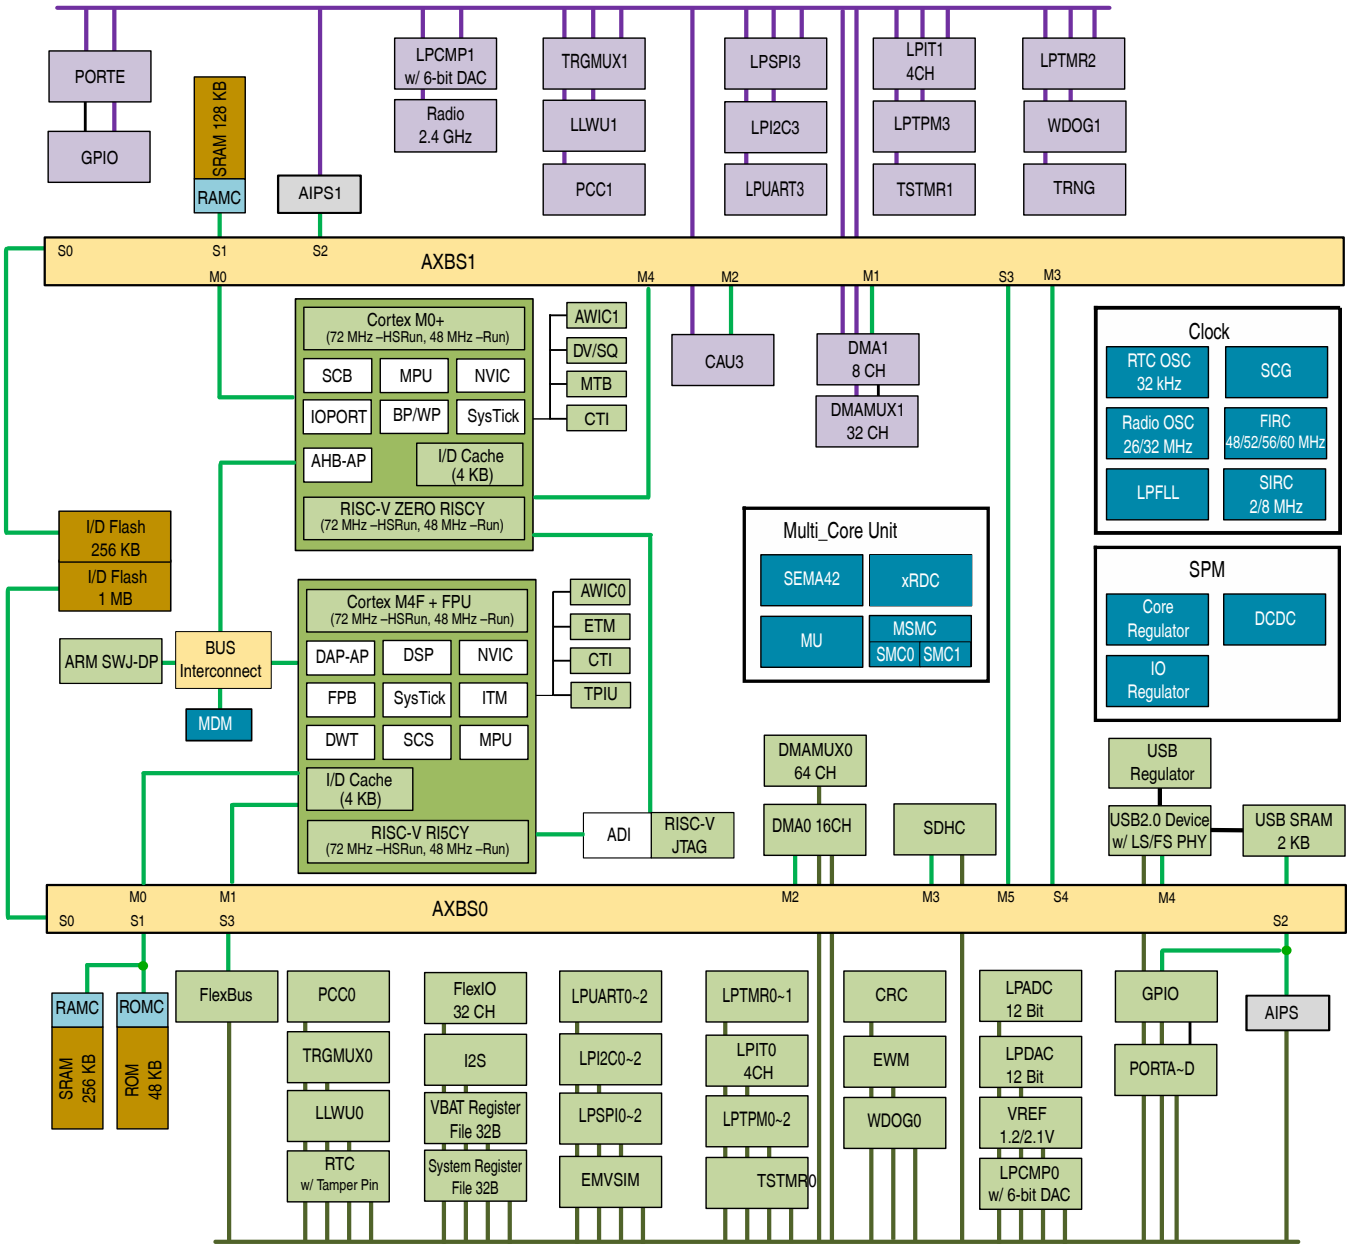
# Chapter 2
# Introduction

## 2.1 Overview

This chapter provides high-level descriptions of the modules available on the devices covered by this document.

## 2.2 Block diagram

The figure below shows a top-level block diagram.



Note: When a core needs access the other AXBS domain resources, the corresponding MUx_CCR[CLKE] bit must be set. AXBS keeps active even if another core enters low power mode (and CPO).

**Figure 2-1. Block diagram**

## 2.3 Module functional categories

The modules on this device are grouped into functional categories in the following table.

**Table 2-1. Module functional categories**

| Module category | Description |
|---|---|
| Processor cores | The available core modules are:<br>• ARM® Cortex®-M0+ core |

*Table continues on the next page...*

## Table 2-1. Module functional categories (continued)

| Module category | Description |
|---|---|
| | • Debug Watchpoint and Trace (DWT)<br>• ARM® Memory Protection Unit (MPU-ARM)<br>• Micro Trace Buffer (MTB)<br>• Nested Vectored Interrupt Controller (NVIC)<br>• ARM® Cortex®-M4F core<br>  • Digital Signal Processing (DSP) features<br>  • Debug Watchpoint and Trace (DWT)<br>  • Flash Patch Breakpoint (FPB)<br>  • Single precision Floating Point Unit (sFPU)<br>  • Instruction Trace Module (ITM)<br>  • ARM® Memory Protection Unit (MPU-ARM)<br>  • Nested Vectored Interrupt Controller (NVIC)<br>• RISC-V RI5CY core<br>• RISC-V ZERORISCY core |
| Platform | The available platform modules are:<br>• Peripheral Bridges (AIPS)<br>• Crossbar Switch (AXBS)<br>• Asynchronous Wake-up Interrupt Controller (AWIC)<br>• Boundary Scan<br>• Cache memory - Instruction/Data (CACHE-I/D)<br>• Cross Trigger Interface (CTI)<br>• Debug Access Port (DAP)<br>• Miscellaneous Control Module for CM0+ (MCM)<br>• Miscellaneous Control Module for CM4F (MCM)<br>• Miscellaneous System Control Module (MSCM)<br>• Extended Resource Domain Controller (XRDC)<br>• Semaphore Module (SEMA42)<br>• Memory Mapped Division and Square Root (MMDVSQ)<br>• Serial Wire Debug - Version 2.0 w/ Multi-Drop (SWD)<br>• Trace Port Interface Unit (TPIU) |
| Debug | The available debug modules are:<br>• Micro Trace Buffer (MTB)<br>• JTAG Controller (JTAGC)<br>• Advanced Debug Interface(ADI) |

## 2.4 Ordering information

The following table summarizes the part numbers of the devices covered by this document.

**Table 2-2. Ordering information**

| Product | | Memory | | Radio | | | Package | |
|---|---|---|---|---|---|---|---|---|
| Part Number | Marking | Flash (MB) | SRAM (KB) | BLE | GENFSK | 802.15.4 | Pin Count | Package |
| RV32M1 | RV32M1 | 1.25 | 384 | Yes | Yes | Yes | 176 | VFBGA |

# Chapter 3
# Core Overview

## 3.1 Core modules

This device has one ARM Cortex M0+ core, one ARM Cortex M4F core, one RISC-V RI5CY core and one RISC-V ZERORISCY core.

### 3.1.1 ARM Cortex-M0+ core

#### 3.1.1.1 Buses, interconnects, and interfaces

The ARM Cortex-M0+ core has two bus interfaces:

- Single 32-bit AMBA-3 AHB-Lite system interface that provides connections to peripherals and all system memory, which includes flash memory and RAM
- Single 32-bit I/O port bus interfacing to the GPIO with 1-cycle loads and stores

#### 3.1.1.2 System tick timer

The CLKSOURCE field in SysTick Control and Status register selects either the core clock (when CLKSOURCE = 1) or a divide-by-16 of the core clock (when CLKSOURCE = 0) and the divide-by-16 clock can be gated by SIM_MISC2[systick_clk_en]. Because the timing reference is a variable frequency, the TENMS field in the SysTick Calibration Value Register is always 0.

#### 3.1.1.3 Debug facilities

This device supports standard ARM 2-pin SWD debug port and JTAG.

#### 3.1.1.4 CM0+ core caches

CM0+ domain includes one 4 KB of combined data and instructions cache to minimize the performance impact on memory access latencies for I/D bus, and minimize the power consumption because of flash access.

Features of each cache are:

- 2-way, 8 sets, and 64 lines (pages)
- Each line is 1 word of 32-bit
- Entire cache can be flushed at once

##### 3.1.1.4.1 Cache operation in low power

The caches are powered down in VLLS0/1 modes. Under LLS and VLLS2/3 modes, caches are optionally powered down and controlled by SMC1_SRAMDSR[31] bit in MSMC module. In Run mode, the SMC1_SRAMLPR[31] bit can be used to put cache into power retention state. The caches must be disabled and then flushed before being powered down. This affects the time for the system to enter new mode but not the wakeup time.

##### 3.1.1.4.2 Control

The CM0+ cache controller, LPLMEM, supports write-through mode. The memory space below 0x2000_0000 is cacheable, and caches can be enabled by MCM1_CPCR2[DCC] under Run mode.

#### 3.1.1.5 Core privilege levels

The core on this device is implemented with both privileged and unprivileged levels. The ARM documentation uses different terms from this document to distinguish between privilege levels.

| If you see this term... | it also means this term... |
|---|---|
| Privileged | Supervisor |
| Unprivileged or user | User |

### 3.1.2 ARM Cortex-M4F Core

### 3.1.2.1 Buses, interconnects, and interfaces

The ARM Cortex-M4 core has four buses as described in the following table.

| Bus name | Description |
|---|---|
| Instruction code (ICODE) bus | The ICODE and DCODE buses are muxed. This muxed bus is called the CODE bus and is connected to the crossbar switch via a single master port. In addition, the CODE bus is also tightly coupled to the lower half of the system RAM (SRAM_L). |
| Data code (DCODE) bus | |
| System bus | The system bus is connected to a separate master port on the crossbar. In addition, the system bus is tightly coupled to the upper half system RAM (SRAM_U). |
| Private peripheral (PPB) bus | The PPB provides access to these modules:<br>• ARM modules such as the NVIC, ETM, ITM, DWT, FPB, and ROM table |

### 3.1.2.2 System Tick Timer

The System Tick Timer's clock source is always the core clock, FCLK. This results in the following:

- The CLKSOURCE bit in SysTick Control and Status register is always set to select the core clock.
- Because the timing reference (FCLK) is a variable frequency, the TENMS bit in the SysTick Calibration Value Register is always zero.
- The NOREF bit in SysTick Calibration Value Register is always set, implying that FCLK is the only available source of reference timing.

### 3.1.2.3 Debug facilities

This device has extensive debug capabilities including run control and tracing capabilities. The standard ARM debug port supports JTAG and multi-drop SWD interfaces.

### 3.1.2.4 CM4F core caches

CM4F domain includes one 4 KB of combined data and instructions cache to minimize the performance impact on memory access latencies for I/D bus, and minimize the power consumption because of flash access.

Features of each cache are:

- 2-way, 8 sets, and 16 lines (pages)

- Each line is 4 words of 128-bit
- Entire cache can be flushed at once

#### 3.1.2.4.1 Low power

The caches are powered down in VLLS0/1 modes. Under LLS and VLLS2/3 modes, caches are optional powered down and controlled by SMC0_SRAMDSR[31] bit in MSMC module. In Run mode, SMC0_SRAMLPR[31] bit can be used to put cache into power retention state. The caches must be disabled and then flushed before being powered down. This affects the time for the system to enter new mode but not the wakeup time.

#### 3.1.2.4.2 Control

The CM4F cache controller, LPCAC, supports write-through mode. The memory space below 0x2000_0000 is cacheable, and caches can be enabled by MCM0_CPCR2[DCC] under Run mode.

### 3.1.2.5 Core privilege levels

The ARM documentation uses different terms than this document to distinguish between privilege levels.

| If you see this term... | it also means this term... |
|---|---|
| Privileged | Supervisor |
| Unprivileged or user | User |

## 3.1.3 RISC-V RI5CY core

### 3.1.3.1 Introduction

RI5CY is a 4-stage in-order 32b RISC-V processor core. The ISA of RI5CY was extended to support multiple additional instructions including hardware loops, post-increment load and store instructions and additional ALU instructions that are not part of the standard RISC-V ISA.

The following figure shows a block diagram of the core.

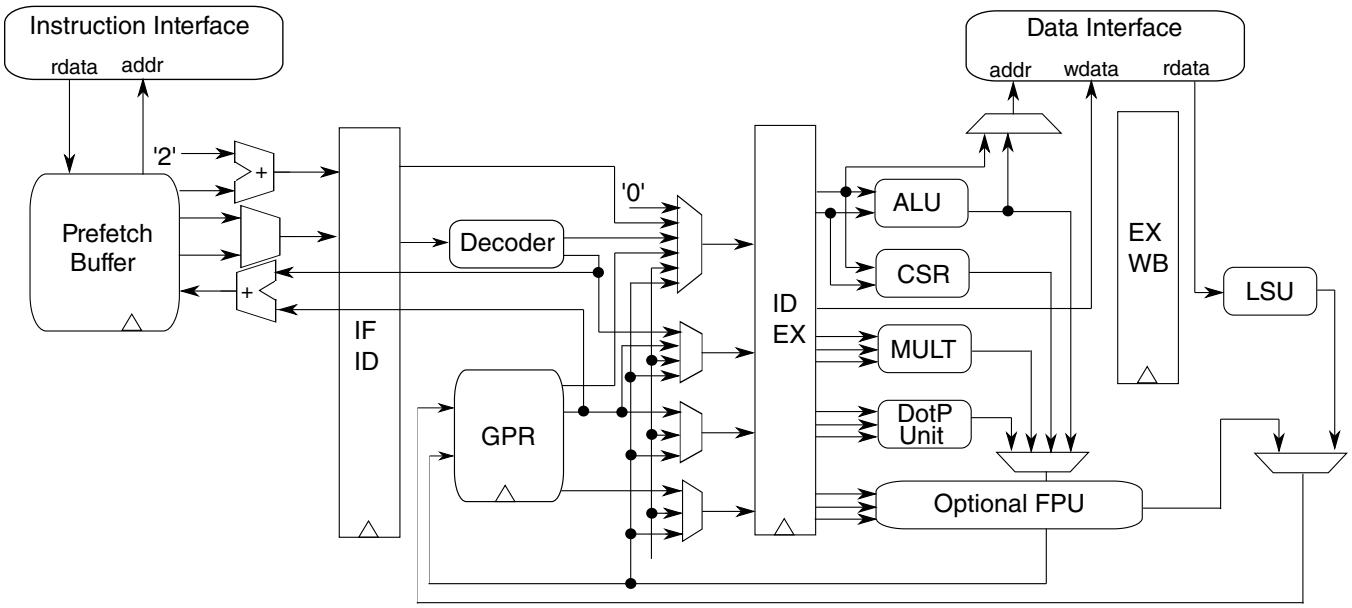

**Figure 3-1. Block diagram**

RI5CY supports the following instructions:

- Full support for RV32I Base Integer Instruction Set
- Full support for RV32C Standard Extension for Compressed Instructions
- Full support for RV32M Integer Multiplication and Division Instruction Set Extension
- Specific extensions
  - Post-Incrementing load and stores
  - Multiply-Accumulate extensions
  - ALU extensions
  - Hardware Loops

### 3.1.3.2 Post-Incrementing Load and Store Instructions

Post-incrementing load and store instructions perform a load/store operation from/to the data memory while at the same time increasing the base address by the specified offset. For the memory access, the base address without offset is used.

Post-incrementing load and stores reduce the number of required instructions to execute code with regular data access patterns, which can typically be found in loops. These post-incrementing load/store instructions allow the address increment to be embedded in the memory access instructions and get rid of separate instructions to handle pointers. Coupled with hardware loop extension, this instructions allow to reduce the loop overhead significantly.

### 3.1.3.3 Multiply-Accumulate

RI5CY uses a single-cycle 32-bit x 32-bit multiplier with a 32-bit result. All instructions of the RISC-V M instruction set extension are supported.

The multiplications with upper-word result (MSP of 32-bit x 32-bit multiplication), take 4 cycles to compute. The division and remainder instructions take between 2 and 32 cycles. The number of cycles depends on the operand values.

Additionally, RI5CY supports non-standard extensions for multiply-accumulate and half-word multiplications with an optional post-multiplication shift.

### 3.1.3.4 ALU extensions

RI5CY supports advanced ALU operations that allow to perform multiple instructions that are specified in the base instruction set in one single instruction and thus increases efficiency of the core. For example, those instructions include zero-/sign-extension instructions for 8-bit and 16-bit operands, simple bit manipulation/counting instructions and min/max/avg instructions.

The ALU does also support saturating, clipping, and normalizing instructions which make fixed-point arithmetic more efficient.

### 3.1.3.5 Hardware loop extensions

To increase the efficiency of small loops, RI5CY supports hardware loops. Hardware loops make it possible to execute a piece of code multiple times, without the overhead of branches or updating a counter. Hardware loops involve zero stall cycles for jumping to the first instruction of a loop.

A hardware loop is defined by its start address (pointing to the first instruction in the loop), its end address (pointing to the instruction that will be executed last in the loop) and a counter that is decremented every time the loop body is executed. RI5CY contains two hardware loop register sets to support nested hardware loops, each of them can store these three values in separate flip flops which are mapped in the CSR address space. If the end address of the two hardware loops is identical, loop 0 has higher priority and only the loop counter for hardware loop 0 is decremented. As soon as the counter of loop 0 reaches 1 at an end address, meaning it is decremented to 0 now, loop 1 is activated too. In this case, both counters will be decremented and the core jumps to the start of loop 1.

In order to use hardware loops, the compiler needs to setup the loop beforehand with the following instructions. Note that the minimum loop size is two instructions.

For debugging and context switches, the hardware loop registers are mapped into the CSR address space and thus it is possible to read and write them via csrr and csrw instructions. Since hardware loop registers could be overwritten when processing interrupts, the registers have to be saved in the interrupt routine together with the general purpose registers.

### 3.1.3.6 RI5CY Memory map and register descriptions

Performance Counters in RI5CY are placed inside the Control and Status Registers and can be accessed with csrr and csrw instructions.

**RI5CY memory map**

| Absolute address (hex) | Register name | Width (in bits) | Access | Reset value | Section/ page |
|---|---|---|---|---|---|
| 0 | User Status (RI5CY_USTATUS) | 32 | R/W | 0000_0000h | 3.1.3.6.1/ 66 |
| 5 | User Trap-Vector Base Address (RI5CY_UTVEC) | 32 | R/W | 0000_0000h | 3.1.3.6.2/ 67 |

### 3.1.3.6.9 Performance Counter Counter Register n (RI5CY_PCCR*n*)

PCCR registers support both saturating and wrap-around arithmetic. This is controlled by the saturation bit in PCMR.

| Register | Name | Description |
|---|---|---|
| PCCR0 | CYCLES | Counts the number of cycles the core was active (not sleeping) |
| PCCR1 | INSTR | Counts the number of instructions executed |
| PCCR2 | LD_STALL | Number of load data hazards |
| PCCR3 | JR_STALL | Number of jump register data hazards |
| PCCR4 | IMISS | Cycles waiting for instruction fetches, i.e. number of instructions wasted due to non-ideal caching |
| PCCR5 | LD | Number of data memory loads executed. Misaligned accesses are counted twice |
| PCCR6 | ST | Number of data memory stores executed. Misaligned accesses are counted twice |
| PCCR7 | JUMP | Number of unconditional jumps (j, jal, jr, jalr) |
| PCCR8 | BRANCH | Number of branches.<br>Counts taken and not taken branches |
| PCCR9 | BTAKEN | Number of taken branches. |
| PCCR10 | RVC | Number of compressed instructions executed |

In the FPGA, RTL simulation and Virtual-Platform there are individual counters for each event type, i.e. PCCR0-10 each represent a separate register. To save area in the ASIC, there is only one counter and one counter register. Accessing PCCR0-10 will access the same counter register in the ASIC.

The following figure shows how events are first masked with the PCER register and then ORed together to increase the one performance counter PCCR.

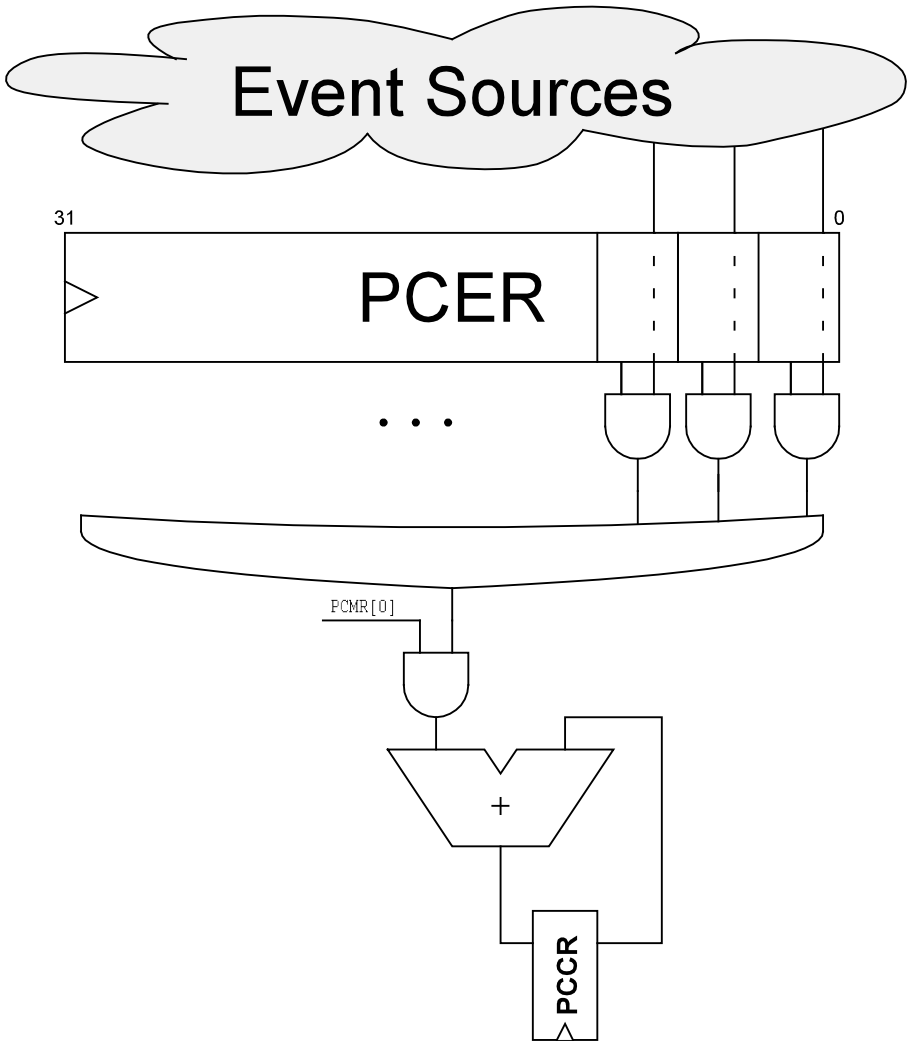

**Figure 3-2. Events and PCCR, PCMR and PCER on the ASIC**

Address: 0h base + 780h offset + (1d × i), where i=0d to 10d

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

## RI5CY_PCCR*n* field descriptions

| Field | Description |
|---|---|
| Counter | Counter<br><br>See register descriptions for details. |

### 3.1.3.6.10 Performance Counter Event Register (RI5CY_PCER)

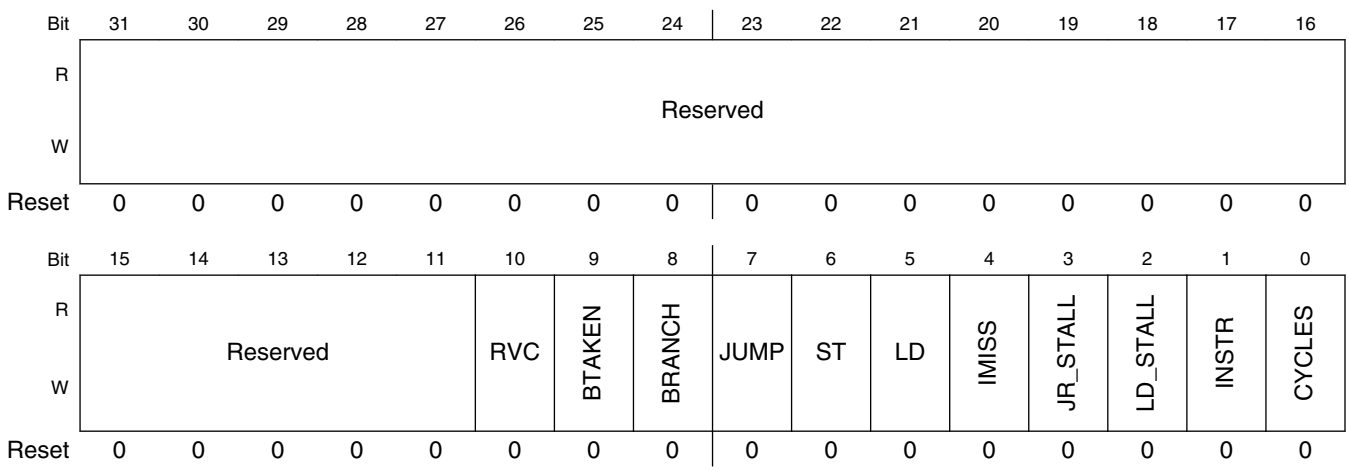
Each bit in the PCER register controls one performance counter. If the bit is 1, the counter is enabled and starts counting events. If it is 0, the counter is disabled and its value won't change.

In the ASIC there is only one counter register, thus all counter events are masked by PCER and ORed together, i.e. if one of the enabled event happens, the counter will be increased. If multiple non-masked events happen at the same time, the counter will only be increased by one.

In order to be able to count separate events on the ASIC, the program can be executed in a loop with different events configured.

In the FPGA or RTL simulation version, each event has its own counter and can be accessed separately.

Address: 0h base + 7A0h offset = 7A0h



**RI5CY_PCER field descriptions**

| Field | Description |

| PRVLVL | Privilege Level<br><br>This field indicates current privilege level of RI5CY core.<br><br>00 User level<br>11 Machine level |

## 3.1.3.7 Exceptions and Interrupts

RI5CY supports interrupts, exceptions on illegal instructions.

**Table 3-1. Interrupt/Exception Offset Vector Table**

| Offset address | Description |
|---|---|
| 0x00-0x7C | Interrupts 0 – 31 |
| 0x80 | Reset |
| 0x84 | Illegal Instruction |
| 0x88 | ECALL Instruction Executed |
| 0x8C | LSU Error (Invalid Memory Access) |

The base address of the interrupt vector table is given by the boot address. The most significant 3 bytes of the boot address given to the core are used for the first instruction fetch of the core and as the basis of the interrupt vector table. The core starts fetching at the address made by concatenating the most significant 3 bytes of the boot address and the reset value (0x80) as the least significant byte. The boot address can be changed after the first instruction was fetched to change the interrupt vector table address. It is assumed that the boot address is supplied via a register to avoid long paths to the instruction fetch unit.

#### 3.1.3.7.1 Interrupts

Interrupts can only be enabled/disabled on a global basis and not individually. It is assumed that there is an event/interrupt controller outside of the core that performs masking and buffering of the interrupt lines. The global interrupt enable is done via the CSR register MSTATUS.

Multiple interrupts requests are assumed to be handled by event/interrupt controller. When an interrupt is taken, the core gives an acknowledge signal to the event/interrupt controller as well as the interrupt id taken.

#### 3.1.3.7.2 Exceptions

The illegal instruction exception and ecall instruction exceptions cannot be disabled and are always active.

#### 3.1.3.7.3 Handling

RI5CY does support nested interrupt/exception handling. Exceptions inside interrupt/ exception handlers cause another exception, thus exceptions during the critical part of your exception handlers, i.e. before having saved the MEPC and MESTATUS registers, will cause those register to be overwritten. Interrupts during interrupt/exception handlers are disabled by default, but can be explicitly enabled if desired.

Upon executing an mret instruction, the core jumps to the program counter saved in the CSR register MEPC and restores the MPIE value of the register MSTATUS to IE. When entering an interrupt/exception handler, the core sets MEPC to the current program counter and saves the current value of MIE in MPIE of the MSTATUS register.

### 3.1.3.8 Debug Unit

### 3.1.3.8.1 Address Map

**Table 3-2. Debug Unit Address Map**

| Address | Name | Description |
|---|---|---|
| 0x0000-0x007F | Debug Registers | Always accessible, even when the core is running |
| 0x400-0x47F | GPR (x0-x31) | General Purpose Registers<br>Only accessible if the core is halted |
| 0x2000-0x20FF | Debug Registers | Only accessible if the core is halted |
| 0x4000-0x7FFF | CSR | Control and Status Registers<br>Only accessible if the core is halted |

**NOTE**

Addresses are intended for a bus system with 32-bit wide words.

Addresses have to be aligned to word-boundaries.

### 3.1.3.8.2 Debug memory map and register descriptions

**Debug memory map**

| Absolute address (hex) | Register name | Width (in bits) | Access | Reset value | Section/ page |

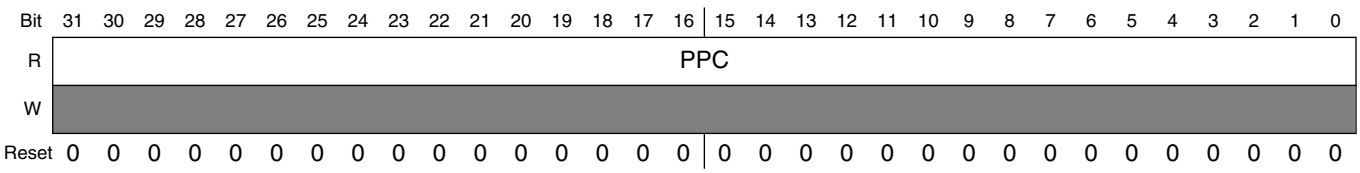
| NPC | NPC<br><br>Next PC to be executed. |

#### 3.1.3.8.2.8 Debug Previous Program Counter (Debug_PPC)

Address: F900_0000h base + 2004h offset = F900_2004h



**Debug_PPC field descriptions**

| Field | Description |
|---|---|
| PPC | PPC<br><br>Previous PC, already executed. |

### 3.1.3.8.3 Control and Status Registers

These registers can only be accessed when core is in debug mode.

| Address | Name | Description |
|---|---|---|
| 0x4000 | CSR 0 = 0x000 | CSR |
| ... | ... | ... |
| 0x7FFC | CSR 4095 = 0xFFF | CSR |

## 3.1.3.9 Instruction Set Extensions

### 3.1.3.9.1 Post-Incrementing Load and Store Instructions

Post-Incrementing load and store instructions perform a load, or a store, respectively, while at the same time incrementing the address that was used for the memory access. Since it is a post-incrementing scheme, the base address is used for the access and the modified address is written back to the register-file. There are versions of those instructions that use immediates and those that use registers as offsets. The base address always comes from a register.

#### 3.1.3.9.1.1 Load operations

**Table 3-3. Load operations**

| Mnemonic | Description |
|---|---|
| **Register-Immediate Loads with Post-Increment** | |

*Table continues on the next page...*

**Table 3-3. Load operations (continued)**

| Mnemonic | Description |
|---|---|
| **p.lb rD, Imm(rs1!)** | rD = Sext(Mem8(rs1)) rs1 += Imm[11:0] |
| **p.lbu rD, Imm(rs1!)** | rD = Zext(Mem8(rs1)) rs1 += Imm[11:0] |
| **p.lh rD, Imm(rs1!)** | rD = Sext(Mem16(rs1)) rs1 += Imm[11:0] |
| **p.lhu rD, Imm(rs1!)** | rD = Zext(Mem16(rs1)) rs1 += Imm[11:0] |
| **p.lw rD, Imm(rs1!)** | rD = Mem32(rs1) rs1 += Imm[11:0] |
| **Register-Register Loads with Post-Increment** | |
| **p.lb rD, rs2(rs1!)** | rD = Sext(Mem8(rs1)) rs1 += rs2 |
| **p.lbu rD, rs2(rs1!)** | rD = Zext(Mem8(rs1)) rs1 += rs2 |
| **p.lh rD, rs2(rs1!)** | rD = Sext(Mem16(rs1)) rs1 += rs2 |
| **p.lhu rD, rs2(rs1!)** | rD = Zext(Mem16(rs1)) rs1 += rs2 |
| **p.lw rD, rs2(rs1!)** | rD = Mem32(rs1) rs1 += rs2 |
| **Register-Register Loads** | |
| **p.lb rD, rs2(rs1)** | rD = Sext(Mem8(rs1 + rs2)) |
| **p.lbu rD, rs2(rs1)** | rD = Zext(Mem8(rs1 + rs2)) |
| **p.lh rD, rs2(rs1)** | rD = Sext(Mem16(rs1 + rs2)) |
| **p.lhu rD, rs2(rs1)** | rD = Zext(Mem16(rs1 + rs2)) |
| **p.lw rD, rs2(rs1)** | rD = Mem32(rs1 + rs2) |

### 3.1.3.9.1.2 Store operations

**Table 3-4. Store operations**

| Mnemonic | Description |
|---|---|
| **Register-Immediate Stores with Post-Increment** | |
| **p.sb rs2, Imm(rs1!)** | Mem8(rs1) = rs2 rs1 += Imm[11:0] |
| **p.sh rs2, Imm(rs1!)** | Mem16(rs1) = rs2 rs1 += Imm[11:0] |
| **p.sw rs2, Imm(rs1!)** | Mem32(rs1) = rs2 rs1 += Imm[11:0] |
| **Register-Register Stores with Post-Increment** | |
| **p.sb rs2, rs3(rs1!)** | Mem8(rs1) = rs2 rs1 += rs3 |
| **p.sh rs2, rs3(rs1!)** | Mem16(rs1) = rs2 rs1 += rs3 |
| **p.sw rs2, rs3(rs1!)** | Mem32(rs1) = rs2 rs1 += rs3 |
| **Register-Register Stores** | |
| **p.sb rs2, rs3(rs1)** | Mem8(rs1 + rs3) = rs2 |
| **p.sh rs2 rs3(rs1)** | Mem16(rs1 + rs3) = rs2 |
| **p.sw rs2, rs3(rs1)** | Mem32(rs1 + rs3) = rs2 |

#### 3.1.3.9.2 Hardware loops

RI5CY supports 2 levels of nested hardware loops. The loop has to be setup before entering the loop body. For this purpose, there are two methods, either the long commands that separately set start- and end-addresses of the loop and the number of iterations, or the short command that does all of this in a single instruction. The short command has a limited range for the number of instructions contained in the loop and the loop must start in the next instruction after the setup instruction.

Loop number 0 has higher priority than loop number 1 in a nested loop configuration, meaning that loop 0 represents the inner loop.

A hardware loop is subject to the following constraints:

- Minimum of 2 instructions in the loop body.
- Loop counter has to be bigger than 0, since the loop body is always entered at least once.

##### 3.1.3.9.2.1 Operations

**Table 3-5. Hardware loops operations**

| Mnemonic | | Description |
|---|---|---|
| **Long Hardware Loop Setup instructions** | | |
| **lp.starti** | **L, uimmL** | lpstart[L] = PC + (uimmL << 1) |
| **lp.endi** | **L, uimmL** | lpend[L] = PC + (uimmL << 1) |
| **lp.count** | **L, rs1** | lpcount[L] = rs1 |
| **lp.counti** | **L, uimmL** | lpcount[L] = uimmL |
| **Short Hardware Loop Setup Instructions** | | |
| **lp.setup** | **L, rs1, uimmL** | lpstart[L] = pc + 4<br>lpend[L] = pc + (uimmL << 1) lpcount[L] = rs1 |
| **lp.setupi** | **L, uimmS, uimmL** | lpstart[L] = pc + 4<br>lpend[L] = pc + (uimmS << 1) lpcount[L] = uimmL |

#### 3.1.3.9.3 ALU

The ALU extensions are split into several subgroups that belong together.

- Bit manipulation instructions are useful to work on single bits or groups of bits within a word, see Bit manipulation operations.

- General ALU instructions try to fuse common used sequences into a single instruction and thus increase the performance of small kernels that use those sequence, see General ALU operations.
- Immediate branching instructions are useful to compare a register with an immediate value before taking or not a branch, see Immediate branching operations.

#### 3.1.3.9.3.1 Bit manipulation operations

**Table 3-6. Bit manipulation operations**

| Mnemonic | | Description |
|---|---|---|
| **p.extract** | **rD, rs1, Is3, Is2** | rD = Sext((rs1 & ((1 << Is3) – 1) << Is2) >> Is2)<br>Note: Is3 + Is2 must be <= 32 |
| **p.extractu** | **rD, rs1, Is3, Is2** | rD = Zext((rs1 & ((1 << Is3) – 1) << Is2) >> Is2)<br>Note: Is3 + Is2 must be <= 32 |
| **p.extractr** | **rD, rs1, rs2** | rD = Sext((rs1 & ((1 << rs2[9:5]) – 1) << rs2[4:0]) >> rs2[4:0])<br>Note: rs2[9:5]+ rs2[4:0] must be <= 32 |
| **p.extractur** | **rD, rs1, rs2** | rD = Zext((rs1 & ((1 << rs2[9:5]) – 1) << rs2[4:0]) >> rs2[4:0])<br>Note: rs2[9:5]+ rs2[4:0] must be <= 32 |
| **p.insert** | **rD, rs1, Is3, Is2** | rD = rD \| (rs1[Is3:0] << Is2)<br>Note: Is3 + Is2 must be <= 32, the rest of the bits of rD are passed through and are not modified |
| **p.insertr** | **rD, rs1, rs2** | rD = rD \| (rs1[Is3:0] << rs2[4:0])<br>Note: rs2[9:5]+ rs2[4:0] must be <= 32, the rest of the bits of rD are passed through and are not modified |
| **p.bclr** | **rD, rs1, Is3, Is2** | rD = rs1 & ~(((1 << (Is3+1)) – 1) << Is2)<br>Note: Is3 + Is2 must be <= 32 |
| **p.bclrr** | **rD, rs1, rs2** | rD = rs1 & ~(((1 << (rs2[9:5]+1)) – 1) << rs2[4:0])<br>Note: rs2[9:5]+ rs2[4:0] must be <= 32 |
| **p.bset** | **rD, rs1, Is3, Is2** | rD = rs1 \| (((1 << (Is3+1)) – 1) << Is2)<br>Note: Is3 + Is2 must be <= 32 |
| **p.bsetr** | **rD, rs1, rs2** | rD = rs1 \| (((1 << (rs2[9:5]+1)) – 1) << rs2[4:0])<br>Note: rs2[9:5]+ rs2[4:0] must be <= 32 |
| **p.ff1** | **rD, rs1** | rD = bit position of the first bit set in rs1, starting from LSB. If bit 0 is set, rD will be 0. If only bit 31 is set, rD will be 31.<br>If rs1 is 0, rD will be 32. |
| **p.fl1** | **rD, rs1** | rD = bit position of the last bit set in rs1, starting from MSB. If bit 31 is set, rD will be 31. If only bit 0 is set, rD will be 0.<br>If rs1 is 0, rD will be 32. |
| **p.clb** | **rD, rs1** | rD = count leading bits of rs1<br>Note: This is the number of consecutive 1's or 0's from MSB.<br>Note: If rs1 is 0, rD will be 0. |
| **p.cnt** | **rD, rs1** | rD = Population count of rs1, i.e. number of bits set in rs1 |
| **p.ror** | **rD, rs1, rs2** | rD = RotateRight(rs1, rs2) |

### 3.1.3.9.3.2 General ALU operations

**Table 3-7. General ALU operations**

| Mnemonic | | Description |
|---|---|---|
| **p.abs** | **rD, rs1** | rD = rs1 < 0 ? –rs1 : rs1 |
| **p.slet** | **rD, rs1, rs2** | rD = rs1 <= rs2 ? 1 : 0 Note: Comparison issigned |
| **p.sletu** | **rD, rs1, rs2** | rD = rs1 <= rs2 ? 1 : 0<br>Note: Comparison is unsigned |
| **p.min** | **rD, rs1, rs2** | rD = rs1 < rs2 ? rs1 : rs2 Note: Comparison is signed |
| **p.minu** | **rD, rs1, rs2** | rD = rs1 < rs2 ? rs1 : rs2 Note: Comparison isunsigned |
| **p.max** | **rD, rs1, rs2** | rD = rs1 < rs2 ? rs2 : rs1 Note: Comparison is signed |
| **p.maxu** | **rD, rs1, rs2** | rD = rs1 < rs2 ? rs2 : rs1 Note: Comparison isunsigned |
| **p.exths** | **rD, rs1** | rD = Sext(rs1[15:0]) |
| **p.exthz** | **rD, rs1** | rD = Zext(rs1[15:0]) |
| **p.extbs** | **rD, rs1** | rD = Sext(rs1[7:0]) |
| **p.extbz** | **rD, rs1** | rD = Zext(rs1[7:0]) |

| **p.subuNr** | **rD, rs1, rs2** | rD = (rD – rs1) >> rs2[4:0]<br>Note: Logical shift right. |
| **p.subRNr** | **rD, rs1, rs2** | rD = (rD – rs1+ 2^(rs2[4:0]-1)) >>> rs2[4:0]<br>Note: Arithmetic shift right. |
| **p.subuRNr** | **rD, rs1, rs2** | rD = (rD – rs1+ 2^(rs2[4:0]-1))) >> rs2[4:0]<br>Note: Logical shift right. |

#### 3.1.3.9.3.3 Immediate branching operations

**Table 3-8. Immediate branching operations**

| Mnemonic | Description |
|---|---|
| **p.beqimm rs1, Imm5, Imm12** | Branch to PC + (Imm12 << 1) if rs1 is equal to Imm5. Imm5 is signed. |
| **p.bneimm rs1, Imm5, Imm12** | Branch to PC + (Imm12 << 1) if rs1 is not equal to Imm5.<br>Imm5 is signed. |

### 3.1.3.9.4 Multiply-Accumulate

RI5CY uses a single-cycle 32-bit x 32-bit multiplier with a 32-bit result. All instructions of the RISC-V M instruction set extension are supported.

The multiplications with upper-word result (MSP of 32-bit x 32-bit multiplication), take 4 cycles to compute. The division and remainder instructions take between 2 and 32 cycles. The number of cycles depends on the operand values.

Additionally, RI5CY supports non-standard extensions for multiply-accumulate and half-word multiplications with an optional post-multiplication shift.

### 3.1.3.9.4.1 MAC operations

**Table 3-9. MAC operations**

| Mnemonic | | Description |
|---|---|---|
| 32-Bit x 32-Bit Multiplication Operations | | |
| **p.mac** | **rD, rs1, rs2** | rD = rD + rs1 * rs2 |
| **p.msu** | **rD, rs1, rs2** | rD = rD - rs1 * rs2 |
| 16-Bit x 16-Bit Multiplication | | |
| **p.muls** | **rD, rs1, rs2** | rD[31:0] = Sext(rs1[15:0]) * Sext(rs2[15:0]) |
| **p.mulhhs** | **rD, rs1, rs2** | rD[31:0] = Sext(rs1[31:15]) * Sext(rs2[31:15]) |

### 3.1.3.9.5 Vectorial

Vectorial instructions perform operations in a SIMD-like manner on multiple sub-word elements at the same time. This is done by segmenting the data path into smaller parts when 8 or 16-bit operations should be performed.

Vectorial instructions are available in two flavors:

- 8-Bit, to perform four operations on the 4 bytes inside a 32-bit word at the same time
- 16-Bit, to perform two operations on the 2 half-words inside a 32-bit word at the same time

Additionally, there are three modes that influence the second operand:

1. Normal mode, vector-vector operation. Both operands, from rs1 and rs2, are treated as vectors of bytes or half-words.
2. Scalar replication mode (.sc), vector-scalar operation. Operand 1 is treated as a vector, while operand 2 is treated as a scalar and replicated two or four times to form a complete vector. The LSP is used for this purpose.
3. Immediate scalar replication mode (.sci), vector-scalar operation. Operand 1 is treated as vector, while operand 2 is treated as a scalar and comes from an immediate. The immediate is either sign- or zero-extended, depending on the operation. If not specified, the immediate is sign-extended.

#### 3.1.3.9.5.1 Vectorial ALU operations

**Table 3-10. Vectorial ALU operations**

| Mnemonic | Description |
|---|---|
| General ALU Instructions | |
| **pv.add[.sc,.sci]{.h,.b}** | rD[i] = rs1[i] + op2[i] |
| **pv.sub[.sc,.sci]{.h,.b}** | rD[i] = rs1[i] - op2[i] |
| **pv.avg[.sc,.sci]{.h,.b}** | rD[i] = (rs1[i] + op2[i]) >> 1 Note: Arithmetic right shift |
| **pv.avgu[.sc,.sci]{.h,.b}** | rD[i] = (rs1[i] + op2[i]) >> 1 |
| **pv.min[.sc,.sci]{.h,.b}** | rD[i] = rs1[i] < op2[i] ? rs1[i] : op2[i] |
| **pv.minu[.sc,.sci]{.h,.b}** | rD[i] = rs1[i] < op2[i] ? rs1[i] : op2[i]<br>Note: Immediate is zero-extended, comparison is unsigned |

#### 3.1.3.9.5.2 Vectorial comparison operations

Vectorial comparisons are done on individual bytes (.b) or half-words (.h), depending on the chosen mode. If the comparison result is true, all bits in the corresponding byte/half-word are set to 1. If the comparison result is false, all bits are set to 0.

The default mode (no .sc, .sci) compares the lowest byte/half-word of the first operand with the lowest byte/half-word of the second operand, and so on. If the mode is set to scalar replication (.sc), always the lowest byte/half-word of the second operand is used for comparisons, thus instead of a vector comparison a scalar comparison is performed. In the immediate scalar replication mode (.sci), the immediate given to the instruction is used for the comparison.

**Table 3-11. Vectorial comparison operations**

| Mnemonic | | Description |
|---|---|---|
| **pv.cmpeq[.sc,.sci]{.h,.b}** | **rD, rs1, {rs2, Imm6}** | rD[i] = rs1[i] == op2 ? ‘1 : ‘0 |
| **pv.cmpne[.sc,.sci]{.h,.b}** | **rD, rs1, {rs2, Imm6}** | rD[i] = rs1[i] != op2 ? ‘1 : ‘0 |
| **pv.cmpgt[.sc,.sci]{.h,.b}** | **rD, rs1, {rs2, Imm6}** | rD[i] = rs1[i] > op2 ? ‘1 : ‘0 |
| **pv.cmpge[.sc,.sci]{.h,.b}** | **rD, rs1, {rs2, Imm6}** | rD[i] = rs1[i] >=op2 ? ‘1 : ‘0 |

## 3.1.4 RISC-V ZERO-RISCY core

### 3.1.4.1 Introduction

ZERO-RISCY is a 2-stage in-order 32b RISC-V processor core. ZERO-RISCY has been designed to be small and efficient.

The following figure shows a block diagram of the core.

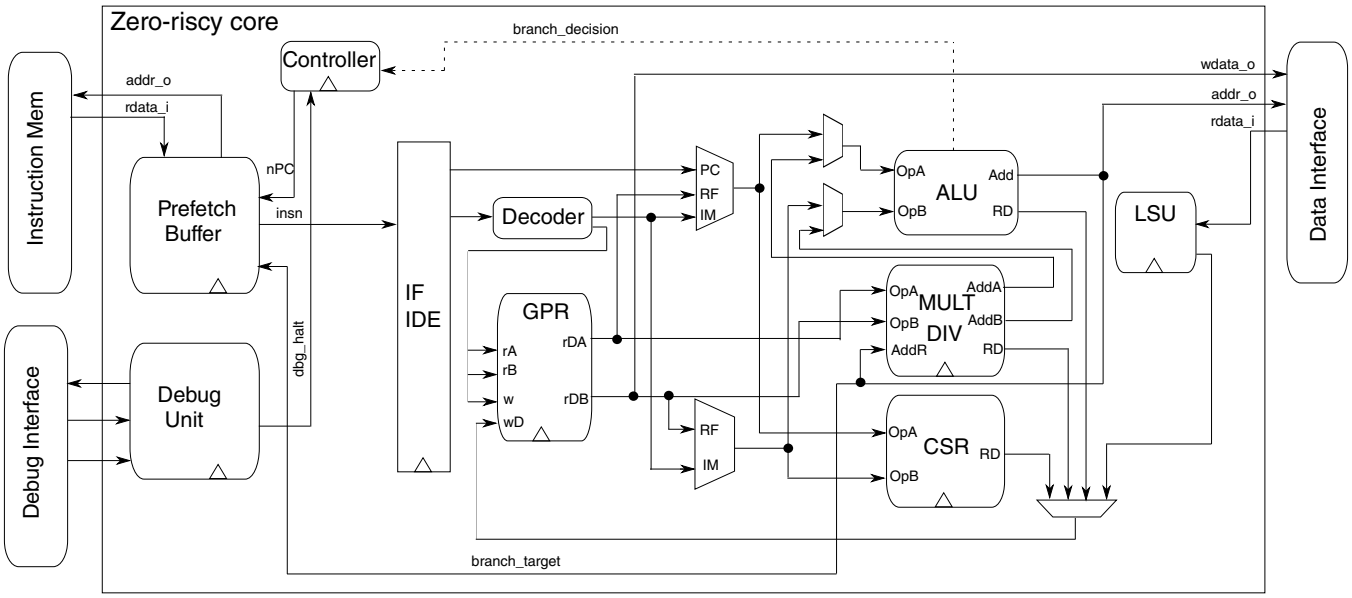

**Figure 3-3. Block diagram**

ZERO-RISCY supports the following instructions:

- Full support for RV32I Base Integer Instruction Set
- Full support for RV32E Base Integer Instruction Set
- Full support for RV32C Standard Extension for Compressed Instructions
- Full support for RV32M Integer Multiplication and Division Instruction Set Extension

## 3.1.4.2 ZERO-RISCY memory map and register descriptions

Performance Counters in ZERO-RISCY are placed inside the Control and Status Registers and can be accessed with csrr and csrw instructions.

**ZERO_RISCY memory map**

| Absolute address (hex) | Register name | Width (in bits) | Access | Reset value | Section/ page |
|---|---|---|---|---|---|
| 300 | Machine Status (ZERO_RISCY_MSTATUS) | 32 | R/W | 0000_1800h | 3.1.4.2.1/ 98 |
| 305 | Machine Trap-Vector Base Address (ZERO_RISCY_MTVEC) | 32 | R | 0103_FF00h | 3.1.4.2.2/ 99 |

### 3.1.4.2.5 Performance Counter Counter Register n (ZERO_RISCY_PCCR*n*)

PCCR registers support both saturating and wrap-around arithmetic. This is controlled by the saturation bit in PCMR.

**Table 3-12. PCCR registers**

| Register | Name | Description |
|---|---|---|
| PCCR0 | CYCLES | Counts the number of cycles the core is active (not sleeping) |
| PCCR1 | INSTR | Counts the number of instructions executed |
| PCCR2 | - | Reserved |
| PCCR3 | - | Reserved |
| PCCR4 | IMISS | Cycles waiting for instruction fetches, i.e. number of instructions wasted due to non-ideal caching |
| PCCR5 | LD | Number of data memory loads executed. Misaligned accesses are counted twice |
| PCCR6 | ST | Number of data memory stores executed. Misaligned accesses are counted twice |
| PCCR7 | JUMP | Number of unconditional jumps (j, jal, jr, jalr) |
| PCCR8 | BRANCH | Number of branches.<br>Counts taken and not taken branches |
| PCCR9 | BTAKEN | Number of taken branches. |
| PCCR10 | RVC | Number of compressed instructions executed |

In the FPGA, RTL simulation and Virtual-Platform there are individual counters for each event type, i.e. PCCR0-10 each represent a separate register. To save area in the ASIC, there is only one counter and one counter register. Accessing PCCR0-10 will access the same counter register in the ASIC.

The following figure shows how events are first masked with the PCER register and then ORed together to increase the one performance counter PCCR.

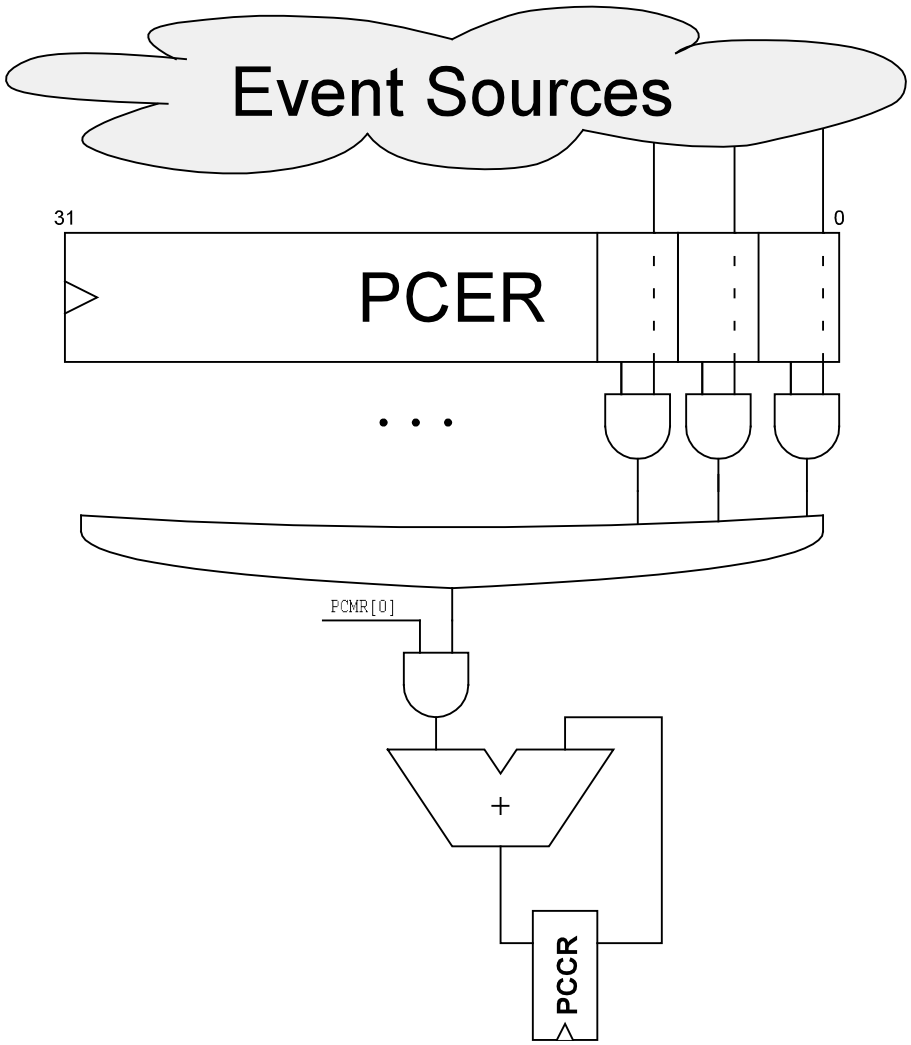

**Figure 3-4. Events and PCCR, PCMR and PCER on the ASIC**

Address: 0h base + 780h offset + (1d × i), where i=0d to 31d

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

## ZERO_RISCY_PCCR*n* field descriptions

| Field | Description |
|---|---|
| Counter | Counter<br><br>See register descriptions for details. |

### 3.1.4.2.6 Performance Counter Event Register (ZERO_RISCY_PCER)

Each bit in the PCER register controls one performance counter. If the bit is 1, the counter is enabled and starts counting events. If it is 0, the counter is disabled and its value won't change.

In the ASIC there is only one counter register, thus all counter events are masked by PCER and ORed together, i.e. if one of the enabled event happens, the counter will be increased. If multiple non-masked events happen at the same time, the counter will only be increased by one.

In order to be able to count separate events on the ASIC, the program can be executed in a loop with different events configured.

In the FPGA or RTL simulation version, each event has its own counter and can be accessed separately.

See PCCR Registers table for details of each bit field in this register.

Address: 0h base + 7A0h offset = 7A0h

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

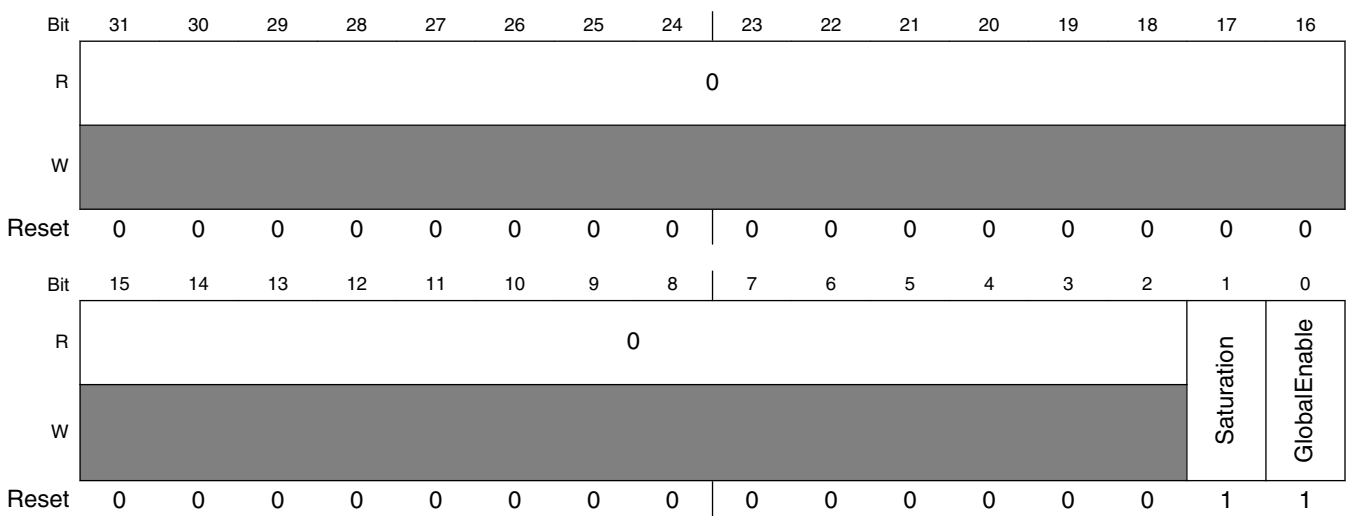
| 1<br>INSTR | INSTR<br><br>It counts the number of instructions executed. |
| 0<br>CYCLES | CYCLES<br><br>It counts the number of cycles that the core is active (not sleeping) |

## 3.1.4.2.7 Performance Counter Mode Register (ZERO_RISCY_PCMR)

Address: 0h base + 7A1h offset = 7A1h



**ZERO_RISCY_PCMR field descriptions**

| Field | Description |
|---|---|
| 31–2<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

*Table continues on the next page...*

**ZERO_RISCY_PCMR field descriptions (continued)**

| Field | Description |
|---|---|
| 1<br>Saturation | Saturation<br><br>If this bit is set, saturating arithmetic is used in the performance counter counters. After reset, this bit is set. |
| 0<br>GlobalEnable | Global Enable<br><br>Activate/deactivate all performance counters. If this bit is 0, all performance counters are disabled. After reset, this bit is set. |

### 3.1.4.3 Exceptions and Interrupts

ZERO-RISCY supports interrupts, exceptions on illegal instructions.

**Table 3-13. Interrupt/Exception Offset Vector Table**

| Address | Description |
|---|---|
| 0x00-0x7C | Interrupts 0 – 31 |
| 0x80 | Reset |
| 0x84 | Illegal Instruction |
| 0x88 | ECALL Instruction Executed |
| 0x8C | LSU Error (Invalid Memory Access) |

The base address of the interrupt vector table is given by the boot address. The most significant 3 bytes of the boot address given to the core are used for the first instruction fetch of the core and as the basis of the interrupt vector table. The core starts fetching at the address made by concatenating the most significant 3 bytes of the boot address and the reset value (0x80) as the least significant byte. The boot address can be changed after the first instruction was fetched to change the interrupt vector table address. It is assumed that the boot address is supplied via a register to avoid long paths to the instruction fetch unit.

#### 3.1.4.3.1 Interrupts

Interrupts can only be enabled/disabled on a global basis and not individually. It is assumed that there is an event/interrupt controller outside of the core that performs masking and buffering of the interrupt lines. The global interrupt enable is done via the CSR register MSTATUS.

Multiple interrupts requests are assumed to be handled by event/interrupt controller. When an interrupt is taken, the core gives an acknowledge signal to the event/interrupt controller as well as the interrupt id taken.

#### 3.1.4.3.2 Exceptions

The illegal instruction exception and ecall instruction exceptions cannot be disabled and are always active.

#### 3.1.4.3.3 Handling

ZERO-RISCY does support nested interrupt/exception handling. Exceptions inside interrupt/exception handlers cause another exception, thus exceptions during the critical part of your exception handlers, i.e. before having saved the MEPC and MESTATUS registers, will cause those register to be overwritten.

Interrupts during interrupt/exception handlers are disabled by default, but can be explicitly enabled if desired.

Upon executing an mret instruction, the core jumps to the program counter saved in the CSR register MEPC and restores the MPIE value of the register MSTATUS to IE. When entering an interrupt/exception handler, the core sets MEPC to the current program counter and saves the current value of MIE in MPIE of the MSTATUS register.

### 3.1.4.4 Debug Unit

#### 3.1.4.4.1 Address Map

**Table 3-14. Debug Unit Address Map**

| Address | Name | Description |
|---|---|---|
| 0x0000-0x007F | Debug Registers | Always accessible, even when the core is running |
| 0x400-0x47F | GPR (x0-x31) | General Purpose Registers<br>Only accessible if the core is halted |
| 0x2000-0x20FF | Debug Registers | Only accessible if the core is halted |
| 0x4000-0x7FFF | CSR | Control and Status Registers<br>Only accessible if the core is halted |

**NOTE**

Addresses are intended for a bus system with 32-bit wide words.

Addresses have to be aligned to word-boundaries.

### 3.1.4.4.2 ZERO-RISCY memory map and register descriptions

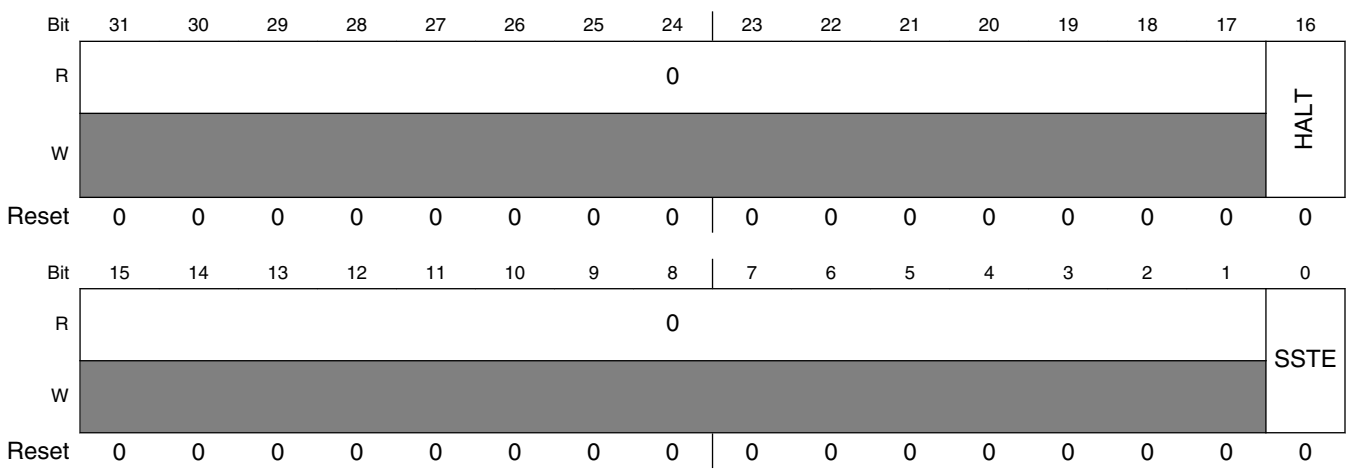
Performance Counters in ZERO-RISCY are placed inside the Control and Status Registers and can be accessed with csrr and csrw instructions.

**DBG memory map**

| Absolute address (hex) | Register name | Width (in bits) | Access | Reset value | Section/ page |
|---|---|---|---|---|---|
| F900_8000 | Debug Control (DBG_CTRL) | 32 | R/W | 0000_0000h | 3.1.4.4.2.1/ 107 |
| F900_8004 | Debug Hit (DBG_HIT) | 32 | R/W | 0000_0000h | 3.1.4.4.2.2/ 108 |
| F900_8008 | Debug Interrupt Enable (DBG_IE) | 32 | R/W | 0000_0000h | 3.1.4.4.2.3/ 109 |
| F900_800C | Debug Cause (DBG_CAUSE) | 32 | R | 0000_0000h | 3.1.4.4.2.4/ 110 |
| F900_8040 | Debug Hardware Breakpoint Control Register n (DBG_BPCTRL0) | 32 | R/W | 0000_0000h | 3.1.4.4.2.5/ 111 |
| F900_8044 | Debug Hardware Breakpoint Data Register n (DBG_BPDATA0) | 32 | R/W | 0000_0000h | 3.1.4.4.2.6/ 112 |
| F900_8048 | Debug Hardware Breakpoint Control Register n (DBG_BPCTRL1) | 32 | R/W | 0000_0000h | 3.1.4.4.2.5/ 111 |
| F900_804C | Debug Hardware Breakpoint Data Register n (DBG_BPDATA1) | 32 | R/W | 0000_0000h | 3.1.4.4.2.6/ 112 |
| F900_A000 | Debug Next Program Counter (DBG_NPC) | 32 | R/W | 0000_0000h | 3.1.4.4.2.7/ 112 |
| F900_A004 | Debug Previous Program Counter (DBG_PPC) | 32 | R | 0000_0000h | 3.1.4.4.2.8/ 113 |

### 3.1.4.4.2.1 Debug Control (DBG_CTRL)

Address: F900_8000h base + 0h offset = F900_8000h

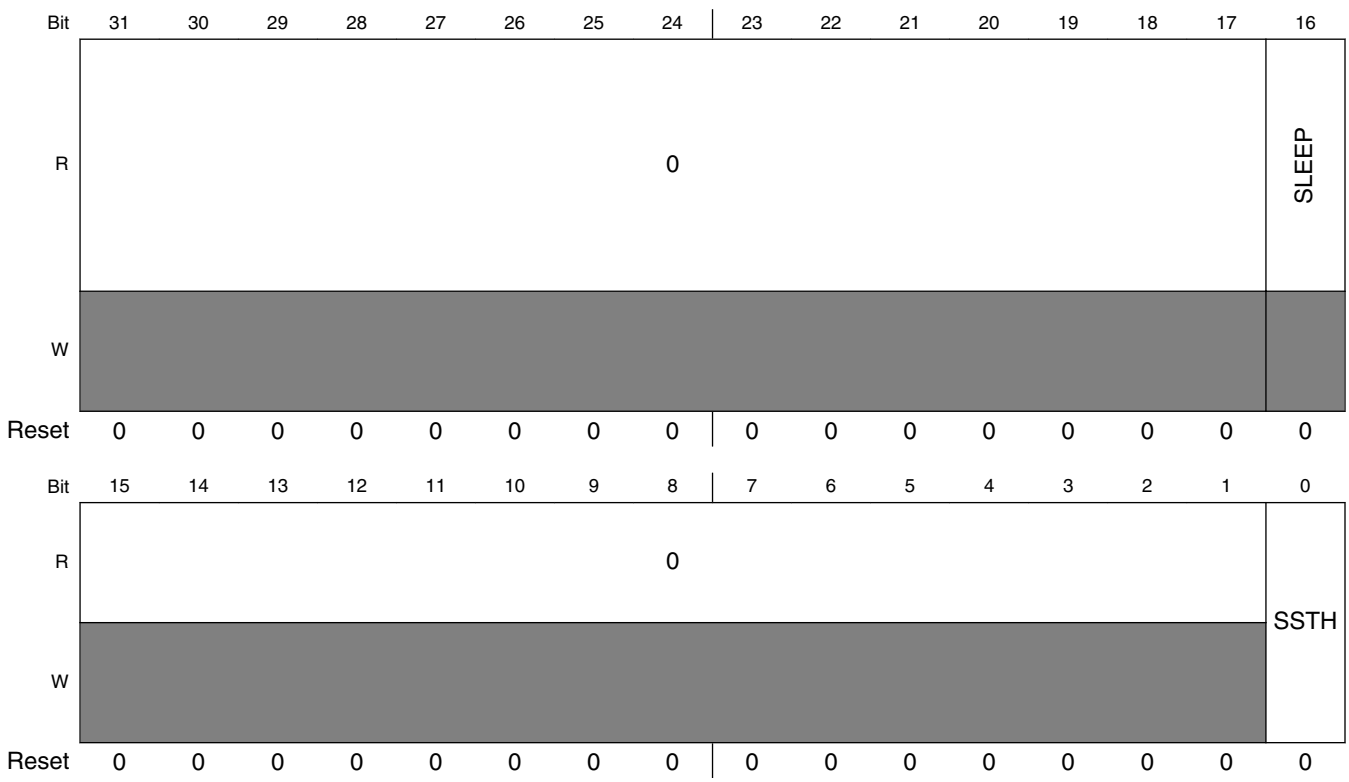


**DBG_CTRL field descriptions**

| Field | Description |
|---|---|
| 31–17<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 16<br>HALT | HALT<br><br>When 1 written, core enters debug mode, when 0 written, core exits debug mode. When read, 1 means core is in debug mode<br><br>0 Core is not in debug mode.<br>1 Core is in debug mode. |
| 15–1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 0<br>SSTE | Single-step enable<br><br>When single-step is enabled, writing 0 to HALT will cause the core to step by one step.<br><br>0 Single-step is disabled.<br>1 Single-step is enabled. |

## 3.1.4.4.2.2 Debug Hit (DBG_HIT)

Address: F900_8000h base + 4h offset = F900_8004h



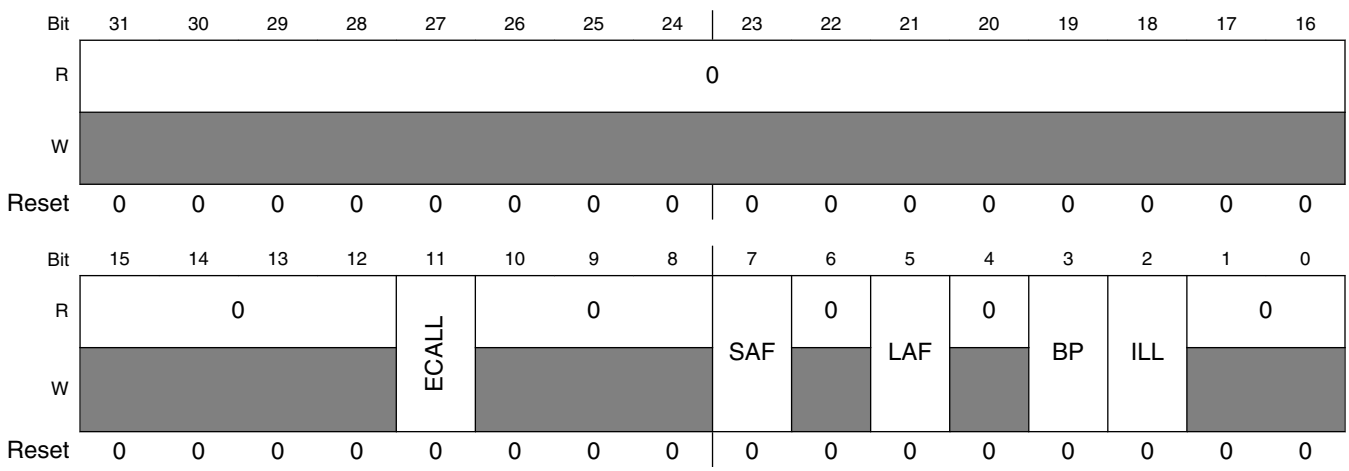
**DBG_HIT field descriptions**

| Field | Description |
|---|---|
| 31–17<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 16<br>SLEEP | SLEEP<br><br>Set when the core is in a sleeping state and waits for an event. |
| 15–1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 0<br>SSTH | SSTH<br><br>Single-step hit, sticky bit that must be cleared by external debugger. |

### 3.1.4.4.2.3 Debug Interrupt Enable (DBG_IE)

This register provides the ability for interrupts to cause traps. When enabled, exceptions cause traps, otherwise normal exceptions.

Address: F900_8000h base + 8h offset = F900_8008h



**DBG_IE field descriptions**

| Field | Description |
|---|---|
| 31–12<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 11<br>ECALL | ECALL Enable<br><br>0 Environment call does not cause trap.<br>1 Environment call causes trap. |
| 10–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 7<br>SAF | SAF<br><br>When 1 is written to the LAF, this bit is also set. |

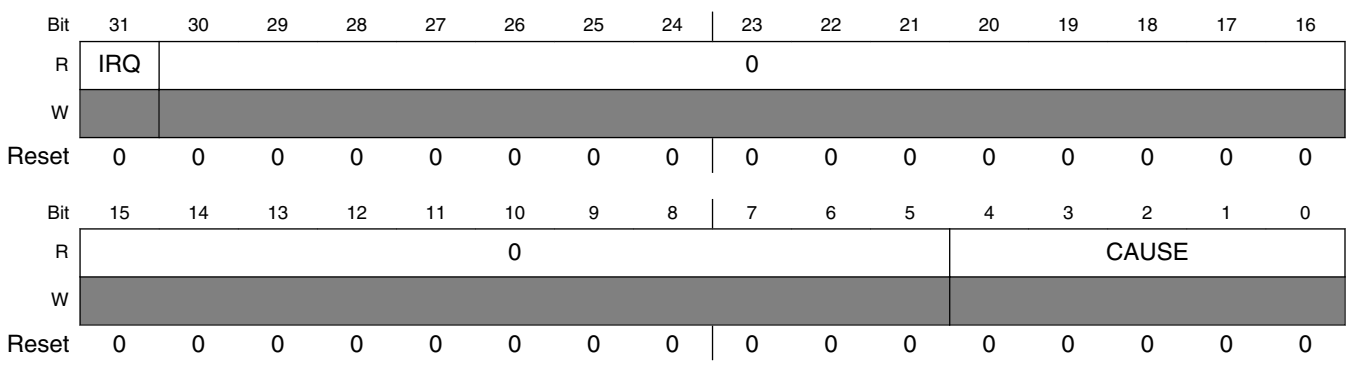
*Table continues on the next page...*

**DBG_IE field descriptions (continued)**

| Field | Description |
|---|---|
| | 0 Store access fault does not cause trap.<br>1 Store access fault causes trap. |
| 6<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 5<br>LAF | LAF<br><br>When 1 is written to the SAF, this bit is also set.<br><br>0 Load access fault does not cause trap.<br>1 Load access fault causes trap. |
| 4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 3<br>BP | BP<br><br>0 EBREAK instruction does not cause trap.<br>1 EBREAK instruction causes trap. |
| 2<br>ILL | ILL<br><br>0 Illegal instruction does not cause trap.<br>1 Illegal instruction causes trap. . |
| Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 3.1.4.4.2.4 Debug Cause (DBG_CAUSE)

Address: F900_8000h base + Ch offset = F900_800Ch



**DBG_CAUSE field descriptions**

| Field | Description |
|---|---|
| 31<br>IRQ | IRQ<br><br>0 Core in debug mode is caused by core exceptions.<br>1 Core in debug mode is caused by interrupts. . |
| 30–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

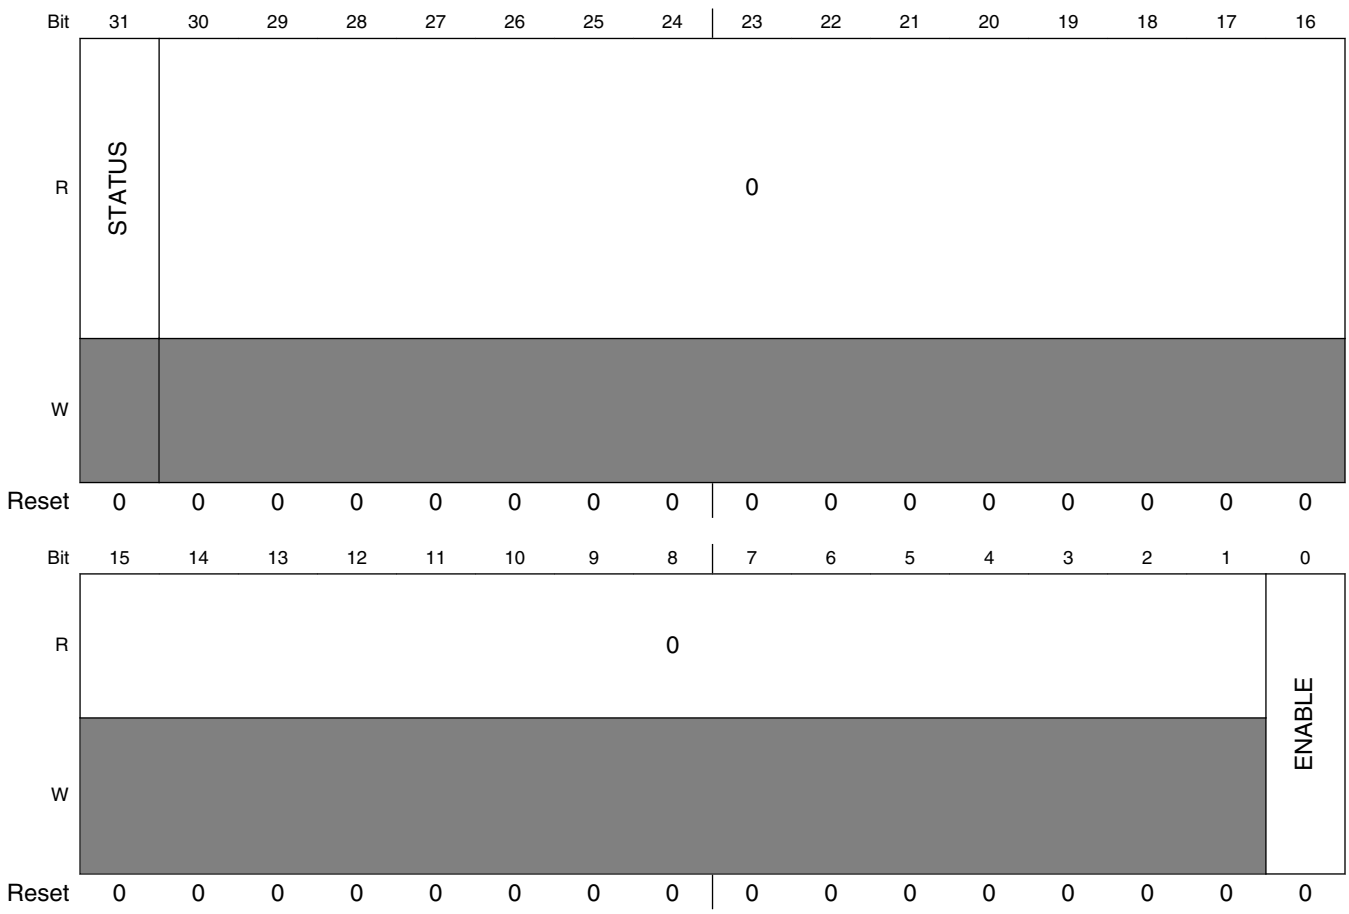
*Table continues on the next page...*

**DBG_CAUSE field descriptions (continued)**

| Field | Description |
|---|---|
| CAUSE | Exception/interrupt number<br><br>If IRQ is 1, this field is the number of interrupt that causes core to enter debug mode. If IRQ is 0, this field is the code of exception that causes core to enter debug mode.<br><br>00010 Illegal instruction<br>00011 EBREAK<br>00101 LSU load fault<br>00111 LSU store fault<br>01011 ECALL |

### 3.1.4.4.2.5 Debug Hardware Breakpoint Control Register n (DBG_BPCTRL*n*)

Address: F900_8000h base + 40h offset + (8d × i), where i=0d to 1d



**DBG_BPCTRL*n* field descriptions**

| Field | Description |
|---|---|
| 31<br>STATUS | STATUS<br><br>High when break point hits. |

*Table continues on the next page...*

**DBG_BPCTRL*n* field descriptions (continued)**

| Field | Description |
|---|---|
| | 0 Breakpoint does not hit.<br>1 Breakpoint hits. |
| 30–1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 0<br>ENABLE | Break point enable bit<br><br>When 1 is written and core's PC hits DBG_BPDATA, core enters debug mode.<br><br>0 Breakpoint is disabled.<br>1 Breakpoint is enabled. |

### 3.1.4.4.2.6 Debug Hardware Breakpoint Data Register n (DBG_BPDATA*n*)

Address: F900_8000h base + 44h offset + (8d × i), where i=0d to 1d

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | PC | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | PC | | | | | | | | | | | | | | | 0 |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**DBG_BPDATA*n* field descriptions**

| Field | Description |
|---|---|
| 31–1<br>PC | PC<br><br>Set break point PC value. |
| 0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 3.1.4.4.2.7 Debug Next Program Counter (DBG_NPC)

Values of PPC and NPC when entering debug mode:

| Reason | PPC | NPC | GDB Sigval |
|---|---|---|---|
| ebreak | ebreak instruction | next instruction | TRAP |
| ecall | ecall instruction | IVT entry | TRAP |
| illegal instruction | illegal instruction | IVT entry | ILL |
| invalid mem access | load/store instruction | IVT entry | SEGV |
| interrupt | last instruction | IVT entry | INT |
| halt | last instruction | next instruction | TRAP |
| single-step | last instruction | next instruction | TRAP |

Address: F900_8000h base + 2000h offset = F900_A000h

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | NPC | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**DBG_NPC field descriptions**

| Field | Description |
|---|---|
| NPC | NPC<br><br>Next PC to be executed. When written core jumps to PC. |

### 3.1.4.4.2.8 Debug Previous Program Counter (DBG_PPC)

Address: F900_8000h base + 2004h offset = F900_A004h

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PPC | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**DBG_PPC field descriptions**

| Field | Description |
|---|---|
| PPC | PPC<br><br>Previous PC, already executed. |

### 3.1.4.4.3 Control and Status Registers

These registers can only be accessed when core is in debug mode.

| Address | Name | Description |
|---|---|---|
| 0x4000 | CSR 0 = 0x000 | CSR |
| ... | ... | ... |
| 0x7FFC | CSR 4095 = 0xFFF | CSR |

## 3.2 Nested Vectored Interrupt Controller (NVIC) modules

This section introduces the NVIC modules in this device.

## 3.2.1 Cortex-M0+ Nested Vectored Interrupt Controller (NVIC)

This section summarizes how the module has been configured in the chip. Full documentation for this module is provided by Arm and can be found at **arm.com**.

### 3.2.1.1 Cortex M0+ interrupt priority levels

This device supports 4 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 2 bits. For example, IPR0 is shown below:

| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | IRQ3 | | 0 | 0 | 0 | 0 | 0 | 0 | IRQ2 | | 0 | 0 | 0 | 0 | 0 | 0 | IRQ1 | | 0 | 0 | 0 | 0 | 0 | 0 | IRQ0 | | 0 | 0 | 0 | 0 | 0 | 0 |
| W | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

### 3.2.1.2 Non-maskable interrupt

The non-maskable interrupt request to the NVIC is controlled by the external NMI_b signal. The pin the NMI_b signal is multiplexed on, must be configured for the Non-Maskable Interrupt function to generate the non-maskable interrupt request.

### 3.2.1.3 Cortex-M0+ interrupt channel assignments

The interrupt source assignments are defined in the following table.

- Vector number — the value stored on the stack when an interrupt is serviced.
- IRQ number — non-core interrupt source count, which is the vector number minus 16.

The IRQ number is used within ARM's NVIC documentation.

**Table 3-16. Interrupt vector assignments**

| Address | Vector | IRQ[1] | NVIC non-IPR register number [2] | NVIC IPR register number [3] | Source module | Source description |
|---|---|---|---|---|---|---|
| **ARM Core System Handler Vectors** | | | | | | |
| 0x0000_0000 | 0 | – | – | – | ARM Cortex-M0+ | Initial Stack Pointer |
| 0x0000_0004 | 1 | – | – | – | ARM Cortex-M0+ | Initial Program Counter |
| 0x0000_0008 | 2 | – | – | – | ARM Cortex-M0+ | Non-Maskable Interrupt (NMI) |

*Table continues on the next page...*

## Table 3-16. Interrupt vector assignments (continued)

| Address | Vector | IRQ[1] | NVIC non-IPR register number [2] | NVIC IPR register number [3] | Source module | Source description |
|---|---|---|---|---|---|---|
| 0x0000_000C | 3 | – | – | – | ARM Cortex-M0+ | Hard Fault |
| 0x0000_0010 | 4 | – | – | – | — | — |
| 0x0000_0014 | 5 | – | – | – | — | — |
| 0x0000_0018 | 6 | – | – | – | — | — |
| 0x0000_001C | 7 | – | – | – | — | — |
| 0x0000_0020 | 8 | – | – | – | — | — |
| 0x0000_0024 | 9 | – | – | – | — | — |
| 0x0000_0028 | 10 | – | – | – | — | — |
| 0x0000_002C | 11 | – | – | – | ARM Cortex-M0+ | Supervisor Call (SVCall) |
| 0x0000_0030 | 12 | – | – | – | — | — |
| 0x0000_0034 | 13 | – | – | – | — | — |
| 0x0000_0038 | 14 | – | – | – | ARM Cortex-M0+ | Pendable request for system service (PendableSrvReq) |
| 0x0000_003C | 15 | – | – | – | ARM Cortex-M0+ | System Tick timer (SysTick) |
| **Non-Core Vectors** | | | | | | |
| 0x0000_0040 | 16 | 0 | 0 | 0 | Cross Trigger Interface 1 (CTI1) | CTI1 interrupt |
| 0x0000_0044 | 17 | 1 | 0 | 0 | Direct Memory Controller 1 (DMA1) | DMA1 channel 0 or 4 transfer complete |
| 0x0000_0048 | 18 | 2 | 0 | 0 | Direct Memory Controller 1 (DMA1) | DMA1 channel 1 or 5 transfer complete |
| 0x0000_004C | 19 | 3 | 0 | 0 | Direct Memory Controller 1 (DMA1) | DMA1 channel 2 or 6 transfer complete |
| 0x0000_0050 | 20 | 4 | 0 | 1 | Direct Memory Controller 1 (DMA1) | DMA1 channel 3 or 7 transfer complete |

## Table 3-16. Interrupt vector assignments (continued)

| Address | Vector | IRQ[1] | NVIC non-IPR register number [2] | NVIC IPR register number [3] | Source module | Source description |
|---|---|---|---|---|---|---|
| 0x0000_0068 | 26 | 10 | 0 | 2 | Cryptographic Acceleration Unit version 3 (CAU3) | Task Complete |
| 0x0000_006C | 27 | 11 | 0 | 2 | Cryptographic Acceleration Unit version 3 (CAU3) | Security Violation |
| 0x0000_0070 | 28 | 12 | 0 | 3 | True Random Number Generator (TRNG) | TRNG interrupt |
| 0x0000_0074 | 29 | 13 | 0 | 3 | Low-Power Periodic Interrupt Timer 1 (LPIT1) | LPIT1 interrupt |
| 0x0000_0078 | 30 | 14 | 0 | 3 | Low-Power Timer 2 (LPTMR2) | LPTMR2 interrupt |
| 0x0000_007C | 31 | 15 | 0 | 3 | Timer / Pulse Width Modulation Module 3 (TPM3) | TPM3 interrupt |
| 0x0000_0080 | 32 | 16 | 0 | 4 | Low-Power Inter-Integrated Circuit 3 (LPI2C3) | LPI2C3 interrupt |
| 0x0000_0084 | 33 | 17 | 0 | 4 | 2.4GHz Radio (RF0) | RF0 Programmable Interrupt 0 |
| 0x0000_0088 | 34 | 18 | 0 | 4 | 2.4GHz Radio (RF0) | RF0 Programmable Interrupt 1 |
| 0x0000_008C | 35 | 19 | 0 | 4 | Low-Power Serial Peripheral Interface 3 (LPSPI3) | LPSPI3 interrupt |
| 0x0000_0090 | 36 | 20 | 0 | 5 | Low-Power Universal Asynchronous Receiver/ Transmitter 3 (LPUART3) | LPUART3 interrupt |
| 0x0000_0094 | 37 | 21 | 0 | 5 | PORTE | PORTE interrupt |
| 0x0000_0098 | 38 | 22 | 0 | 5 | Low-Power Comparator 1 (LPCMP1) | LPCMP1 interrupt |
| 0x0000_009C | 39 | 23 | 0 | 5 | Real Time Clock (RTC) - RTC and Tamper Functions | RTC interrupt |
| 0x0000_00A0 | 40 | 24 | 0 | 6 | Interrupt Multiplexer 0 (INTMUX0) | INTMUX0 Source |

*Table continues on the next page...*

**Table 3-16. Interrupt vector assignments (continued)**

| Address | Vector | IRQ[1] | NVIC non-IPR register number [2] | NVIC IPR register number [3] | Source module | Source description |
|---|---|---|---|---|---|---|
| 0x0000_00A4 | 41 | 25 | 0 | 6 | Interrupt Multiplexer 1 (INTMUX1) | INTMUX1 Source |
| 0x0000_00A8 | 42 | 26 | 0 | 6 | Interrupt Multiplexer 2 (INTMUX2) | INTMUX2 Source |
| 0x0000_00AC | 43 | 27 | 0 | 6 | Interrupt Multiplexer 3 (INTMUX3) | INTMUX3 Source |
| 0x0000_00B0 | 44 | 28 | 0 | 7 | Interrupt Multiplexer 4 (INTMUX4) | INTMUX4 Source |
| 0x0000_00B4 | 45 | 29 | 0 | 7 | Interrupt Multiplexer 5 (INTMUX5) | INTMUX5 Source |
| 0x0000_00B8 | 46 | 30 | 0 | 7 | Interrupt Multiplexer 6 (INTMUX6) | INTMUX6 Source |
| 0x0000_00BC | 47 | 31 | 0 | 7 | Interrupt Multiplexer 7 (INTMUX7) | INTMUX7 Source |

1. Indicates the NVIC's interrupt source number.
2. Indicates the NVIC's ISER, ICER, ISPR, ICPR, and IABR register number used for this IRQ. The equation to calculate this value is: IRQ div 32
3. Indicates the NVIC's IPR register number used for this IRQ. The equation to calculate this value is: IRQ div 4
4. The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit stop mode on an LLS recovery.

**NOTE**

Interrupt Vector handlers must be placed in Flash / RAM memory local to the core that will execute the functions. Vector fetches from the non-local memory are possible but not recommended. Under certain conditions, a hard fault exception can be thrown if these conditions are not met.

### 3.2.1.4 Interrupt Multiplexer n (INTMUXn) input assignments

In systems with a larger number of peripherals, the number of interrupts allowed for the ARM Cortex-M0+ Nested Vectored Interrupt Controller (NVIC) is not sufficient. In order to provide the interrupts from all of the implemented peripherals to the M0+ NVIC

module, an interrupt multiplexer is instantiated. This module takes the interrupts that will not fit in the M0+ NVIC and muxes them onto dedicated NVIC channels. This allows the remainging interrupts to be selected and sent to the NVIC for processing.

The following sections describe the Interrupt Multiplexer (INTMUX) assignments for this device. These assignments are used for all of the implemented interrupt multplexers for this device.

**Table 3-17. INTMUXn input assignments**

| INTMUXn Input | Source module | Source description |
|---|---|---|
| 0 | External Watchdog Monitor (EWM) | EWM interrupt |
| 1 | Flash Controller (FTFE) | Command Complete |
| 2 | Flash Controller (FTFE) | Read Collision |
| 3 | System Power Manager (SPM) | SPM interrupt |
| 4 | System Clock Generator (SCG) | SCG interrupt |
| 5 | Low-Power Periodic Interrupt Timer 0 (LPIT0) | LPIT0 interrupt |
| 6 | Low-Power Timer 0 (LPTMR0) | LPTMR0 interrupt |
| 7 | Low-Power Timer 1 (LPTMR1) | LPTMR1 interrupt |
| 8 | Timer/PWM Module 0 (TPM0 - (6ch)) | TPM0 interrupt |
| 9 | Timer/PWM Module 1 (TPM1 - (2ch)) | TPM1 interrupt |
| 10 | Timer/PWM Module 2 (TPM2 - (6ch)) | TPM2 interrupt |
| 11 | Euro Mastercard Visa Secure Identity Module 0 (EMVSIM0) | EMVSIM0 interrupt |
| 12 | Flexible Input/Output 0 (FlexIO0) | FlexIO0 Interrupt |
| 13 | Low-Power Inter-Integrated Circuit 0 (LPI2C0) | LPI2C0 interrupt |
| 14 | Low-Power Inter-Integrated Circuit 1 (LPI2C1) | LPI2C1 interrupt |
| 15 | Low-Power Inter-Integrated Circuit 2 (LPI2C2) | LPI2C2 interrupt |
| 16 | Inter-IC Sound 0 (I2S0) | I2S0 interrupt |
| 17 | Ultra Secured Digital Host Controller 0 (uSDHC0) | uSDHC0 interrupt |
| 18 | Low-Power Serial Peripheral Interface 0 (LPSPI0) | LPSPI0 interrupt |
| 19 | Low-Power Serial Peripheral Interface 1 (LPSPI1) | LPSPI1 interrupt |
| 20 | Low-Power Serial Peripheral Interface 2 (LPSPI2) | LPSPI2 interrupt |
| 21 | Low-Power Universal Asynchronous Receiver/ Transmitter 0 (LPUART0) | LPUART0 interrupt |
| 22 | Low-Power Universal Asynchronous Receiver/ Transmitter 1 (LPUART1) | LPUART1 interrupt |
| 23 | Low-Power Universal Asynchronous Receiver/ Transmitter 2 (LPUART2) | LPUART2 interrupt |
| 24 | Universal Serial Bus 0 (USB0) | USB0 interrupt |
| 25 | PORTA | PORTA interrupt |
| 26 | PORTB | PORTB interrupt |

*Table continues on the next page...*

**Table 3-17. INTMUXn input assignments (continued)**

| INTMUXn Input | Source module | Source description |
|---|---|---|
| 27 | PORTC | PORTC Interrupt |
| 28 | PORTD | PORTD interrupt |
| 29 | Low Power Analog-to-Digital Converter 0 (LPADC0) | LPADC0 interrupt |
| 30 | Low Power Comparator 0 (LPCMP0) | LPCMP0 interrupt |
| 31 | 12-bit Low Power Digital-to-Analog Converter 0 (LPDAC0) | LPDAC0 interrupt |

## 3.2.2 Cortex-M4 Nested Vectored Interrupt Controller (NVIC) configuration

This section summarizes how the module has been configured in the chip. Full documentation for this module is provided by Arm and can be found at **arm.com**.

### 3.2.2.1 Cortex M4F interrupt priority levels

This device supports 8 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 3 bits. For example, IPR0 is shown below:

| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | IRQ3 | | | 0 | 0 | 0 | 0 | 0 | IRQ2 | | | 0 | 0 | 0 | 0 | 0 | IRQ1 | | | 0 | 0 | 0 | 0 | 0 | IRQ0 | | | 0 | 0 | 0 | 0 | 0 |
| W | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

### 3.2.2.2 Non-maskable interrupt

The non-maskable interrupt request to the NVIC is controlled by the external NMI_b signal. The pin the NMI_b signal is multiplexed on, must be configured for the Non-Maskable Interrupt function to generate the non-maskable interrupt request.

### 3.2.2.3 Cortex-M4F interrupt channel assignments

The interrupt source assignments are defined in the following table.

- Vector number — the value stored on the stack when an interrupt is serviced.
- IRQ number — non-core interrupt source count, which is the vector number minus 16.

The IRQ number is used within ARM's NVIC documentation.

**Table 3-19. Interrupt vector assignments**

| Address | Vector | IRQ[1] | NVIC non-IPR register number [2] | NVIC IPR register number [3] | Source module | Source description |
|---|---|---|---|---|---|---|
| **ARM Core System Handler Vectors** | | | | | | |
| 0x0000_0000 | 0 | – | – | – | ARM Cortex-M4 | Initial Stack Pointer |
| 0x0000_0004 | 1 | – | – | – | ARM Cortex-M4 | Initial Program Counter |
| 0x0000_0008 | 2 | – | – | – | ARM Cortex-M4 | Non-Maskable Interrupt (NMI) |
| 0x0000_000C | 3 | – | – | – | ARM Cortex-M4 | Hard Fault |
| 0x0000_0010 | 4 | – | – | – | ARM Cortex-M4 | MemManage Fault |
| 0x0000_0014 | 5 | – | – | – | ARM Cortex-M4 | Bus Fault |
| 0x0000_0018 | 6 | – | – | – | ARM Cortex-M4 | Usage Fault |
| 0x0000_001C | 7 | – | – | – | — | — |
| 0x0000_0020 | 8 | – | – | – | — | — |
| 0x0000_0024 | 9 | – | – | – | — | — |
| 0x0000_0028 | 10 | – | – | – | — | — |
| 0x0000_002C | 11 | – | – | – | ARM Cortex-M4 | Supervisor Call (SVCall) |
| 0x0000_0030 | 12 | – | – | – | ARM Cortex-M4 | Debug Monitor |
| 0x0000_0034 | 13 | – | – | – | — | — |

*Table continues on the next page...*

**Table 3-19. Interrupt vector assignments (continued)**

| Address | Vector | IRQ[1] | NVIC non-IPR register number [2] | NVIC IPR register number [3] | Source module | Source description |
|---|---|---|---|---|---|---|
| 0x0000_01E0 | 120 | 104 | 3 | 26 | — | — |
| 0x0000_01E4 | 121 | 105 | 3 | 26 | — | — |
| 0x0000_01E8 | 122 | 106 | 3 | 26 | — | — |

1. Indicates the NVIC's interrupt source number.
2. Indicates the NVIC's ISER, ICER, ISPR, ICPR, and IABR register number used for this IRQ. The equation to calculate this value is: IRQ div 32
3. Indicates the NVIC's IPR register number used for this IRQ. The equation to calculate this value is: IRQ div 4
4. The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit stop mode on an LLS recovery.

**NOTE**

Interrupt Vector handlers must be placed in Flash / RAM memory local to the core that will execute the functions. Vector fetches from the non-local memory are possible but not recommended. Under certain conditions, a hard fault exception can be thrown if these conditions are not met.

## 3.3 Asynchronous Wake-up Interrupt Controller (AWIC)

This section summarizes how the module has been configured in the chip. Full documentation for this module is provided by Arm and can be found at **arm.com**.

### 3.3.1 AWIC overview

The AWIC block is used to detect asynchronous wake-up events in Stop and VLPS modes and signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.

### 3.3.2 Wake-up sources

The device uses the following internal and external inputs to the AWIC module. AWIC0 is AWIC in CM4F domain while AWIC1 is AWIC in CM0+ domain.

## Table 3-20. AWIC0 Stop and VLPS wakeup sources

| Wake-up source | Description |
|---|---|
| System resets | All available system resets sources are describted in SMC0 under MSMC chapter |
| SPM | All available interrupt in SPM, such as low/high voltage detect interrupt, low voltage detect/warnning interrupt, and etc. |
| Pin | PTA, PTB, PTC, PTD, PTE pin interrupts |
| LPUART0~3 | Functional when using clock source which is active in Stop and VLPS modes |
| LPI2C0~3 | Address match wakeup |
| LPSPI0~3 | Slave mode interrupt |
| I2S | Functional when using an external bit clock or external master clock |
| EMVSIM | Any enabled interrupt can be a source as long as the module remains clocked. |
| USB Controller | Wakeup |
| Secure Digital Hardware Controller (SDHC) | Wakeup |
| FlexIO | Functional when using clock source which is active in Stop and VLPS modes |
| LPTMR0~2 | Functional when using clock source which is active in Stop, VLPS and LLS/VLLS modes |
| TPM0~3 | Functional when using clock source which is active in Stop and VLPS modes |
| RTC | Functional in Stop, VLPS, LLS and VLLSx modes |
| LPIT0/1 | Any enabled interrupt can be a source as long as the module remains clocked. |
| Tamper detect | Interrupt |
| NMI | NMI is routed to CM4F or CM0+ automatically, only boot core has NMI |
| LPCMP0/1 | Interrupt in normal or trigger mode |
| LPDAC | Any enabled interrupt can be a source as long as the module remains clocked. |
| LPADC | The LPADC is functional when using internal clock source |
| LLWU0 | Any enabled interrupt can be a source as long as the module remains clocked. |
| MUA | Any enabled interrupt can be a source as long as the module remains clocked. |
| WDOG0 | Watchdog0 Interrupt |

## Table 3-21. AWIC1 Stop and VLPS wakeup sources

| Wake-up source | Description |
|---|---|
| System resets | All available system resets sources are describted in SMC1 under MSMC chapter |
| PortE | PTE pin interrupts |

*Table continues on the next page...*

**Table 3-21. AWIC1 Stop and VLPS wakeup sources (continued)**

| Wake-up source | Description |
|---|---|
| LPUART3 | Functional when using clock source which is active in Stop and VLPS modes |
| LPI2C03 | Address match wakeup |
| LPSPI3 | Any enabled interrupt can be a source as long as the module remains clocked. |
| 2.4GHz Radio | RF Programmable Interrupt 0 |
| 2.4GHz Radio | RF Programmable Interrupt 1 |
| LPTMR2 | Functional when using clock source which is active in Stop, VLPS and LLS/VLLS modes |
| TPM3 | Functional when using clock source which is active in Stop and VLPS modes |
| RTC | Functional in Stop,VLPS,LLS and VLLSx modes |
| LPIT1 | Any enabled interrupt can be a source as long as the module remains clocked. |
| NMI | NMI is routed to CM4F or CM0+ automatically, only boot core has NMI |
| LPCMP1 | Interrupt in normal or trigger mode |
| TRNG | TRNG has no stop wakeup capability |
| LLWU1 | Any enabled interrupt can be a source as long as the module remains clocked. |
| MUB | Any enabled interrupt can be a source as long as the module remains clocked. |
| WDOG1 | Watchdog1 Interrupt |
| INTMUX0~7 | All other wakeup sources availabe in AWIC0 can be selected through INTMUXn. Please refer to the INTMUXn description. |

# 3.4 Event unit

## 3.4.1 Introduction

RI5CY and ZERO-RISCY core both have an event unit to support vectorized interrupts of up to 32 lines and event triggering of up to 32 input lines. The interrupt and event lines are separately masked and buffered.

This is block diagram of event unit.

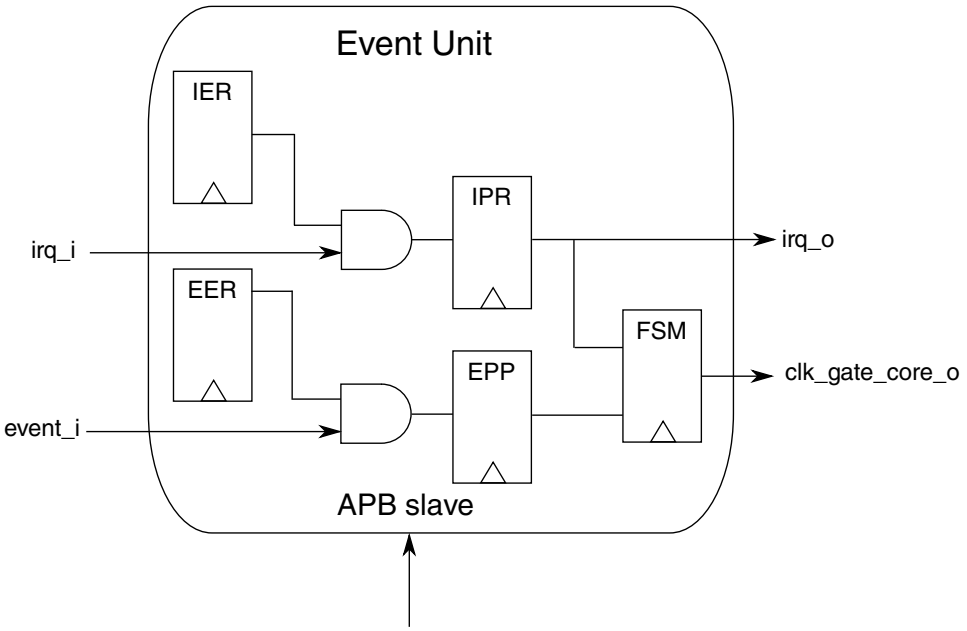

**Figure 3-5. Block diagram**

## 3.4.2 Memory map and register descriptions

### EVENT memory map

| Absolute address (hex) | Register name | Width (in bits) | Access | Reset value | Section/ page |
|---|---|---|---|---|---|
| 4101_F000 | Interrupt Enable Register (EVENT1_INTPTEN) | 32 | R/W | 0000_0000h | 3.4.2.1/131 |

## 3.4.2.1 Interrupt Enable Register (EVENTx_INTPTEN)

Address: Base address + 0h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | IEN | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTEN field descriptions**

| Field | Description |
|---|---|
| IEN | Interrupt n Enable<br><br>This bit enables interrupt. Each interrupt takes one bit. For example, interrupt 0 is in bit 0 while interrupt 31 is in bit 31.<br><br>0 Interrupt n is disabled.<br>1 Interrupt n is enabled. |

## 3.4.2.2 Interrupt Pending Register (EVENTx_INTPTPEND)

This register indicates the interrupts pending status. It can also be used to set or clear pending.

Address: Base address + 4h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | IPEND | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTPEND field descriptions**

| Field | Description |
|---|---|
| IPEND | Interrupt n Pending |

**EVENTx_INTPTPEND field descriptions (continued)**

| Field | Description |
|---|---|
| | This bit indicates whether interrupt is in pending. Each interrupt takes one bit. For example, interrupt 0 is in bit 0 while interrupt 31 is in bit 31.<br><br>0 Interrupt n is not pending.<br>1 Interrupt n is pending. |

### 3.4.2.3 Set Interrupt Pending Register (EVENTx_INTPTPENDSET)

This register sets the interrupts in pending status.

Address: Base address + 8h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | IPENDSET | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTPENDSET field descriptions**

| Field | Description |
|---|---|
| IPENDSET | Set Interrupt n Pending<br><br>This bit reads as 0 and write 1 to set interrupt in pending status. Each interrupt takes one bit. For example, interrupt 0 is in bit 0 while interrupt 31 is in bit 31.<br><br>0 Not set interrupt n in pending status<br>1 Set interrupt n in pending status. |

### 3.4.2.4 Clear Interrupt Pending Register (EVENTx_INTPTPENDCLEAR)

This register clear the interrupts out of pending status.

Address: Base address + Ch offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | IPENDCLEAR | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| W | w1c | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTPENDCLEAR field descriptions**

| Field | Description |
|---|---|
| IPENDCLEAR | Clear Interrupt n out of Pending<br><br>This bit reads as 0 and write 1 to clear interrupt out of pending status. Each interrupt takes one bit. For example, interrupt 0 is in bit 0 while interrupt 31 is in bit 31. |

**EVENTx_INTPTPENDCLEAR field descriptions (continued)**

| Field | Description |
|---|---|
| | 0 Not clear interrupt n out of pending status<br>1 Clear interrupt n out of pending status. |

### 3.4.2.5 Interrupt Secure Register (EVENTx_INTPTSECURE)

This register sets the secure feature for interrupt.

Address: Base address + 10h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | ISECURE | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTSECURE field descriptions**

| Field | Description |
|---|---|
| ISECURE | Set secure feature of Interrupt n<br><br>0 Set interrupt n out of security<br>1 Set interrupt n in secruity. |

### 3.4.2.6 Interrupt Priority 0 Register (EVENTx_INTPTPRI0)

This register sets 8-level priority of interrupt 0-7.

Address: Base address + 14h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IPRI7 | | | 0 | IPRI6 | | | 0 | IPRI5 | | | 0 | IPRI4 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IPRI3 | | | 0 | IPRI2 | | | 0 | IPRI1 | | | 0 | IPRI0 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTPRI0 field descriptions**

| Field | Description |
|---|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–28<br>IPRI7 | Interrupt 7 Priority<br><br>This bit sets the interrupt 7 priority |

*Table continues on the next page...*

## EVENTx_INTPTPRI0 field descriptions (continued)

| Field | Description |
|---|---|
| 27<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 26–24<br>IPRI6 | Interrupt 6 Priority<br><br>This bit sets the interrupt 6 priority |
| 23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 22–20<br>IPRI5 | Interrupt 5 Priority<br><br>This bit sets the interrupt 5 priority |
| 19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 18–16<br>IPRI4 | Interrupt 4 Priority<br><br>This bit sets the interrupt 4 priority |
| 15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 14–12<br>IPRI3 | Interrupt 3 Priority<br><br>This bit sets the interrupt 3 priority |
| 11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10–8<br>IPRI2 | Interrupt 2 Priority<br><br>This bit sets the interrupt 2 priority |
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 6–4<br>IPRI1 | Interrupt 1 Priority<br><br>This bit sets the interrupt 1 priority |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 3.4.2.7 Interrupt Priority 1 Register (EVENTx_INTPTPRI1)

This register sets 8-level priority of interrupt 8-15.

Address: Base address + 18h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IPRI15 | | | 0 | IPRI14 | | | 0 | IPRI13 | | | 0 | IPRI12 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IPRI11 | | | 0 | IPRI10 | | | 0 | IPRI9 | | | 0 | IPRI8 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTPRI1 field descriptions**

| Field | Description |
|---|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–28<br>IPRI15 | Interrupt 15 Priority<br><br>This bit sets the interrupt 15 priority |
| 27<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 26–24<br>IPRI14 | Interrupt 14 Priority<br><br>This bit sets the interrupt 14 priority |
| 23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 22–20<br>IPRI13 | Interrupt 13 Priority<br><br>This bit sets the interrupt 13 priority |
| 19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 18–16<br>IPRI12 | Interrupt 12 Priority<br><br>This bit sets the interrupt 12 priority |
| 15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

| 11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10–8<br>IPRI10 | Interrupt 10 Priority<br><br>This bit sets the interrupt 10 priority |

*Table continues on the next page...*

**EVENTx_INTPTPRI1 field descriptions (continued)**

| Field | Description |
|---|---|
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 6–4<br>IPRI9 | Interrupt 9 Priority<br><br>This bit sets the interrupt 9 priority |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| IPRI8 | Interrupt 8 Priority<br><br>This bit sets the interrupt 8 priority |

## 3.4.2.8 Interrupt Priority 2 Register (EVENTx_INTPTPRI2)

This register sets 8-level priority of interrupt 16-23.

Address: Base address + 1Ch offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IPRI23 | | | 0 | IPRI22 | | | 0 | IPRI21 | | | 0 | IPRI20 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IPRI19 | | | 0 | IPRI18 | | | 0 | IPRI17 | | | 0 | IPRI16 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTPRI2 field descriptions**

| Field | Description |
|---|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–28<br>IPRI23 | Interrupt 23 Priority<br><br>This bit sets the interrupt 23 priority |
| 27<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 26–24<br>IPRI22 | Interrupt 22 Priority<br><br>This bit sets the interrupt 22 priority |
| 23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 22–20<br>IPRI21 | Interrupt 21 Priority<br><br>This bit sets the interrupt 21 priority |
| 19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

*Table continues on the next page...*

**EVENTx_INTPTPRI2 field descriptions (continued)**

| Field | Description |
|---|---|
| 18–16<br>IPRI20 | Interrupt 20 Priority<br><br>This bit sets the interrupt 20 priority |
| 15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

| 6–4<br>IPRI17 | Interrupt 17 Priority<br><br>This bit sets the interrupt 17 priority |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| IPRI16 | Interrupt 16 Priority<br><br>This bit sets the interrupt 16 priority |

## 3.4.2.9 Interrupt Priority 3 Register (EVENTx_INTPTPRI3)

This register sets 8-level priority of interrupt 24-31.

Address: Base address + 20h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IPRI31 | | | 0 | IPRI30 | | | 0 | IPRI29 | | | 0 | IPRI28 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IPRI27 | | | 0 | IPRI26 | | | 0 | IPRI25 | | | 0 | IPRI24 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTPRI3 field descriptions**

| Field | Description |
|---|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–28<br>IPRI31 | Interrupt 31 Priority |

*Table continues on the next page...*

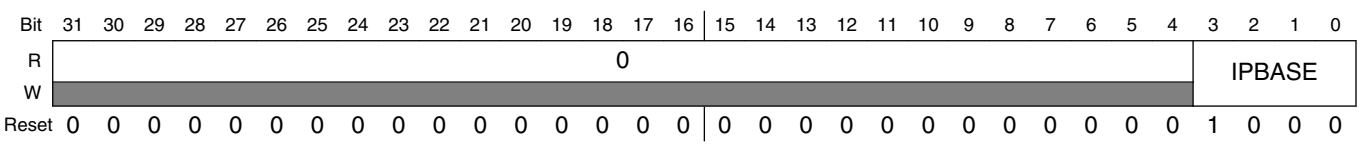
**EVENTx_INTPTPRI3 field descriptions (continued)**

| Field | Description |
|---|---|
| | This bit sets the interrupt 31 priority |
| 27<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 26–24<br>IPRI30 | Interrupt 30 Priority<br><br>This bit sets the interrupt 30 priority |
| 23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 22–20<br>IPRI29 | Interrupt 29 Priority<br><br>This bit sets the interrupt 29 priority |
| 19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 18–16<br>IPRI28 | Interrupt 28 Priority<br><br>This bit sets the interrupt 28 priority |
| 15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 14–12<br>IPRI27 | Interrupt 27 Priority<br><br>This bit sets the interrupt 27 priority |
| 11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10–8<br>IPRI26 | Interrupt 26 Priority<br><br>This bit sets the interrupt 26 priority |
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 6–4<br>IPRI25 | Interrupt 25 Priority<br><br>This bit sets the interrupt 25 priority |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| IPRI24 | Interrupt 24 Priority<br><br>This bit sets the interrupt 24 priority |

## 3.4.2.10 Interrupt Priority Base (EVENTx_INTPRIBASE)

This register sets base priority, the interrupt with which priority is lower than base priority cannot be handled.

Address: Base address + 24h offset



**EVENTx_INTPRIBASE field descriptions**

| Field | Description |
|---|---|
| 31–4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| IPBASE | Set interrupt base priority. |

## 3.4.2.11 Interrupt Active Register (EVENTx_INTPTENACTIVE)

Address: Base address + 28h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | IACTIVE | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTPTENACTIVE field descriptions**

| Field | Description |
|---|---|
| IACTIVE | Interrupt n Enable<br><br>This bit indicates whether each interrupt is active. Each interrupt takes one bit. For example, interrupt 0 is in bit 0 while interrupt 31 is in bit 31.<br><br>0 Interrupt n is not active.<br>1 Interrupt n is active.. |

## 3.4.2.12 Interrupt Active Priority 0 Register (EVENTx_INTACTPRI0)

This register indicates the priority of the active interrupts 0-7.

Address: Base address + 2Ch offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IAPRI7 | | | 0 | IAPRI6 | | | 0 | IAPRI5 | | | 0 | IAPRI4 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IAPRI3 | | | 0 | IAPRI2 | | | 0 | IAPRI1 | | | 0 | IAPRI0 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

## EVENTx_INTACTPRI0 field descriptions

| Field | Description |
|---|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–28<br>IAPRI7 | Interrupt 7 Active Priority<br><br>This bit indicates the interrupt 7 priority if it is active. |
| 27<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 26–24<br>IAPRI6 | Interrupt 6 Active Priority<br><br>This bit sets the interrupt 6 priority if it is active. |
| 23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 22–20<br>IAPRI5 | Interrupt 5 Active Priority<br><br>This bit indicates the interrupt 5 priority if it is active. |
| 19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 18–16<br>IAPRI4 | Interrupt 4 Active Priority<br><br>This bit indicates the interrupt 4 priority if it is active. |
| 15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 14–12<br>IAPRI3 | Interrupt 3 Active Priority<br><br>This bit indicates the interrupt 3 priority if it is active. |
| 11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10–8<br>IAPRI2 | Interrupt 2 Active Priority<br><br>This bit indicates the interrupt 2 priority if it is active. |
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 6–4<br>IAPRI1 | Interrupt 1 Active Priority<br><br>This bit indicates the interrupt 1 priority if it is active. |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| IAPRI0 | Interrupt 0 Active Priority<br><br>This bit indicates the interrupt 0 priority if it is active. |

### 3.4.2.13 Interrupt Active Priority 1 Register (EVENTx_INTACTPRI1)

This register indicates the priority of the active interrupts 8-15.

Address: Base address + 30h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IAPRI15 | | | 0 | IAPRI14 | | | 0 | IAPRI13 | | | 0 | IAPRI12 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IAPRI11 | | | 0 | IAPRI10 | | | 0 | IAPRI9 | | | 0 | IAPRI8 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTACTPRI1 field descriptions**

| Field | Description |
|---|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–28<br>IAPRI15 | Interrupt 15 Active Priority<br><br>This bit indicates the interrupt 15 priority if it is active. |
| 27<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 26–24<br>IAPRI14 | Interrupt 14 Active Priority<br><br>This bit sets the interrupt 14 priority if it is active. |
| 23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 22–20<br>IAPRI13 | Interrupt 13 Active Priority<br><br>This bit indicates the interrupt 13 priority if it is active. |
| 19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 18–16<br>IAPRI12 | Interrupt 12 Active Priority<br><br>This bit indicates the interrupt 12 priority if it is active. |
| 15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 14–12<br>IAPRI11 | Interrupt 11 Active Priority<br><br>This bit indicates the interrupt 11 priority if it is active. |
| 11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10–8<br>IAPRI10 | Interrupt 10 Active Priority<br><br>This bit indicates the interrupt 10 priority if it is active. |

*Table continues on the next page...*

**EVENTx_INTACTPRI1 field descriptions (continued)**

| Field | Description |
|---|---|
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 6–4<br>IAPRI9 | Interrupt 9 Active Priority<br><br>This bit indicates the interrupt 9 priority if it is active. |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| IAPRI8 | Interrupt 8 Active Priority<br><br>This bit indicates the interrupt 8 priority if it is active. |

## 3.4.2.14 Interrupt Active Priority 2 Register (EVENTx_INTACTPRI2)

This register indicates the priority of the active interrupts 16-23.

Address: Base address + 34h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IAPRI23 | | | 0 | IAPRI22 | | | 0 | IAPRI21 | | | 0 | IAPRI20 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IAPRI19 | | | 0 | IAPRI18 | | | 0 | IAPRI17 | | | 0 | IAPRI16 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_INTACTPRI2 field descriptions**

| Field | Description |
|---|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–28<br>IAPRI23 | Interrupt 23 Active Priority<br><br>This bit indicates the interrupt 23 priority if it is active. |
| 27<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 26–24<br>IAPRI22 | Interrupt 22 Active Priority<br><br>This bit sets the interrupt 22 priority if it is active. |
| 23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 22–20<br>IAPRI21 | Interrupt 21 Active Priority<br><br>This bit indicates the interrupt 21 priority if it is active. |

*Table continues on the next page...*

**EVENTx_INTACTPRI2 field descriptions (continued)**

| Field | Description |
|---|---|
| 19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 18–16<br>IAPRI20 | Interrupt 20 Active Priority<br><br>This bit indicates the interrupt 20 priority if it is active. |
| 15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 14–12<br>IAPRI19 | Interrupt 19 Active Priority<br><br>This bit indicates the interrupt 19 priority if it is active. |
| 11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10–8<br>IAPRI18 | Interrupt 18 Active Priority<br><br>This bit indicates the interrupt 18 priority if it is active. |
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 6–4<br>IAPRI17 | Interrupt 17 Active Priority<br><br>This bit indicates the interrupt 17 priority if it is active. |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| IAPRI16 | Interrupt 16 Active Priority<br><br>This bit indicates the interrupt 16 priority if it is active. |

## 3.4.2.15 Interrupt Active Priority 3 Register (EVENTx_INTACTPRI3)

This register indicates the priority of the active interrupts 24-31.

Address: Base address + 38h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IAPRI31 | | | 0 | IAPRI30 | | | 0 | IAPRI29 | | | 0 | IAPRI28 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | IAPRI27 | | | 0 | IAPRI26 | | | 0 | IAPRI25 | | | 0 | IAPRI24 | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

## EVENTx_INTACTPRI3 field descriptions

| Field | Description |
|---|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–28<br>IAPRI31 | Interrupt 31 Active Priority<br><br>This bit indicates the interrupt 31 priority if it is active. |
| 27<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 26–24<br>IAPRI30 | Interrupt 30 Active Priority<br><br>This bit sets the interrupt 30 priority if it is active. |
| 23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 22–20<br>IAPRI29 | Interrupt 29 Active Priority<br><br>This bit indicates the interrupt 29 priority if it is active. |
| 19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 18–16<br>IAPRI28 | Interrupt 28 Active Priority<br><br>This bit indicates the interrupt 28 priority if it is active. |
| 15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 14–12<br>IAPRI27 | Interrupt 27 Active Priority<br><br>This bit indicates the interrupt 27 priority if it is active. |
| 11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10–8<br>IAPRI26 | Interrupt 26 Active Priority<br><br>This bit indicates the interrupt 26 priority if it is active. |
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 6–4<br>IAPRI25 | Interrupt 25 Active Priority<br><br>This bit indicates the interrupt 25 priority if it is active. |

### 3.4.2.16 Event Enable Register (EVENTx_EVENTEN)

Address: Base address + 40h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | EEN | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_EVENTEN field descriptions**

| Field | Description |
|---|---|
| EEN | Event n Enable<br><br>This bit enables event. Each event takes one bit. For example, event 0 is in bit 0 while event 31 is in bit 31.<br><br>0 Event n is disabled.<br>1 Event n is enabled. |

### 3.4.2.17 Event Pending Register (EVENTx_EVENTPEND)

This register indicates the event pending status. It can also be used to set or clear events.

Address: Base address + 44h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | EPEND | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_EVENTPEND field descriptions**

| Field | Description |
|---|---|
| EPEND | Event n Pending<br><br>This bit indicates whether event is in pending. Each event takes one bit. For example, event 0 is in bit 0 while event 31 is in bit 31.<br><br>0 Event n is not pending.<br>1 Event n is pending. |

### 3.4.2.18 Set Event Pending Register (EVENTx_EVTPENDSET)

This register sets the event in pending status.

Address: Base address + 48h offset

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | EPENDSET | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| W | w1c | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_EVTPENDSET field descriptions**

| Field | Description |
|---|---|
| EPENDSET | Set Event n Pending<br><br>This bit reads as 0 and write 1 to set event in pending status. Each event takes one bit. For example, event 0 is in bit 0 while event 31 is in bit 31.<br><br>0 Not set event n in pending status<br>1 Set event n in pending status. |

### 3.4.2.19 Clear Event Pending Register (EVENTx_EVTPENDCLEAR)

This register clear the events out of pending status.

Address: Base address + 4Ch offset

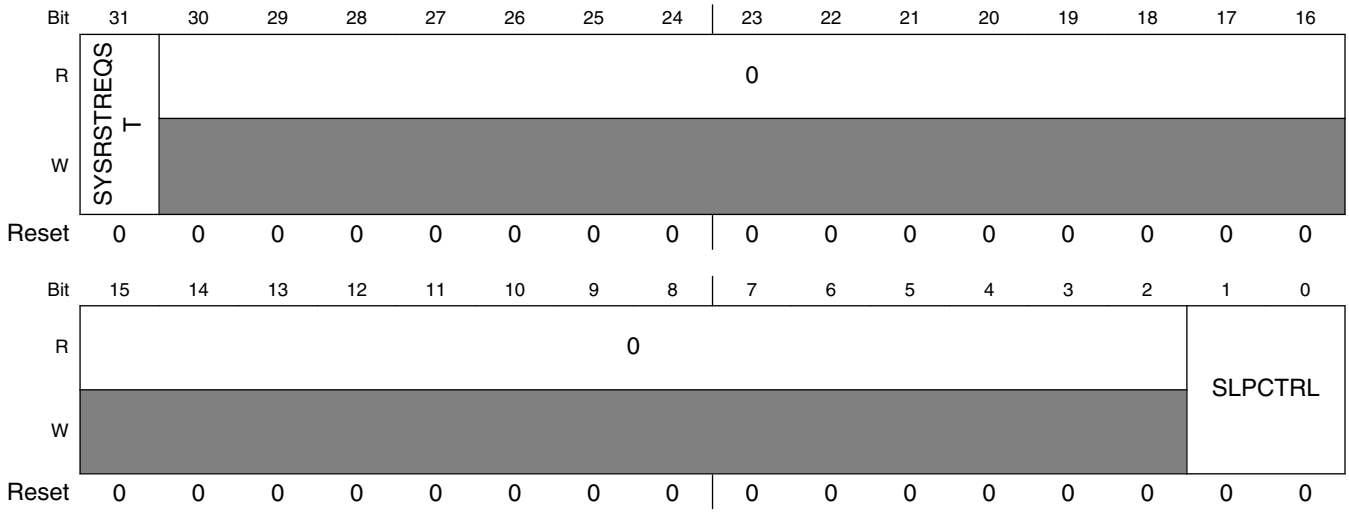
| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | EPENDCLEAR | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| W | w1c | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EVENTx_EVTPENDCLEAR field descriptions**

| Field | Description |
|---|---|
| EPENDCLEAR | Clear Event n out of Pending<br><br>This bit reads as 0 and write 1 to clear event out of pending status. Each event takes one bit. For example, event 0 is in bit 0 while event 31 is in bit 31.<br><br>0 Not clear event n out of pending status<br>1 Clear event n out of pending status. |

## 3.4.2.20 Sleep Control Register (EVENTx_SLPCTRL)

Address: Base address + 80h offset

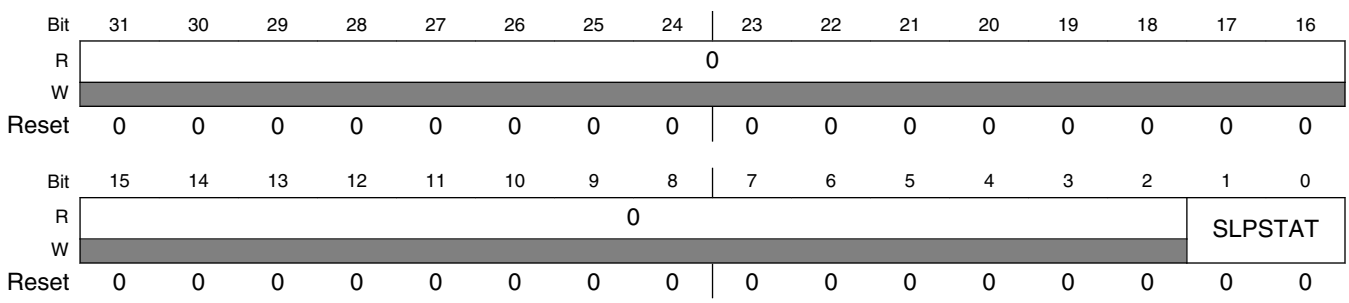


**EVENTx_SLPCTRL field descriptions**

| Field | Description |
|---|---|
| 31<br>SYSRSTREQST | System Reset Request<br><br>0 Do not send system reset request.<br>1 Send system reset request |
| 30–2<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| SLPCTRL | Sleep Mode Control<br><br>01 Sleep enable<br>10 Deep sleep enable |

## 3.4.2.21 Sleep Status Register (EVENTx_SLPSTATUS)

Address: Base address + 84h offset



**EVENTx_SLPSTATUS field descriptions**

| Field | Description |
|---|---|
| 31–2<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| SLPSTAT | Sleep Status<br><br>01 In sleep mode<br>10 In deep sleep mode |

## 3.4.3 Interrupt assignment to RI5CY

**Table 3-22. RI5CY interrupt assignment**

| Address | Vector | IRQ | Module | Description |
|---|---|---|---|---|
| **0x000F_FF00** | 0 | 0 | DMA0 | DMA0 Channel 0, 4, 8, 12 transfer complete |
| **0x000F_FF04** | 1 | 1 | DMA0 | DMA0 Channel 1, 5, 9, 13 transfer complete |

| **0x000F_FF44** | 17 | 17 | LPUART0 | |
| **0x000F_FF48** | 18 | 18 | PORTA | |
| **0x000F_FF4C** | 19 | 19 | TPM0 | |
| **0x000F_FF50** | 20 | 20 | DAC0 | |
| **0x000F_FF54** | 21 | 21 | LPADC0 | |
| **0x000F_FF58** | 22 | 22 | LPCMP0 | |
| **0x000F_FF5C** | 23 | 23 | RTC | |
| **0x000F_FF60** | 24 | 24 | RI5CY INTMUX | INTMUX Channel 0 |
| **0x000F_FF64** | 25 | 25 | RI5CY INTMUX | INTMUX Channel 1 |

*Table continues on the next page...*

**Table 3-22. RI5CY interrupt assignment (continued)**

| Address | Vector | IRQ | Module | Description |
|---|---|---|---|---|
| **0x000F_FF68** | 26 | 26 | RI5CY INTMUX | INTMUX Channel 2 |
| **0x000F_FF6C** | 27 | 27 | RI5CY INTMUX | INTMUX Channel 3 |
| **0x000F_FF70** | 28 | 28 | RI5CY INTMUX | INTMUX Channel 4 |
| **0x000F_FF74** | 29 | 29 | RI5CY INTMUX | INTMUX Channel 5 |
| **0x000F_FF78** | 30 | 30 | RI5CY INTMUX | INTMUX Channel 6 |
| **0x000F_FF7C** | 31 | 31 | RI5CY INTMUX | INTMUX Channel 7 |
| **0x000F_FF80** | 32 | - | RI5CY | Reset, Initial PC |
| **0x000F_FF84** | 33 | - | RI5CY | Illegal Instruction |
| **0x000F_FF88** | 34 | - | RI5CY | ECALL Instruction Executed |
| **0x000F_FF8C** | 35 | - | RI5CY | Load Store Unit Error |

Vector0-31: external interrupts, 8-level programmable priority.

Vector32-35: internal exceptions, fixed priority, the lower the vector number, the higher the priority.

The priority of the internal exception is higher than the external interrupts.

RI5CY INTMUX Source assignment:

**Table 3-23. RI5CY INTMUX Source assignment**

| INTMUX Input | Source Module | Description |
|---|---|---|
| 0 | EWM | |
| 1 | FTFE | FTFE command complete |
| 2 | FTFE | FTFE read collision |
| 3 | LLWU0 | |
| 4 | SPM | |
| 5 | WDOG0 | |

| 30 | RF0 | RF0 programmable interrupt 1 |
| 31 | | |

## 3.4.4 Interrupt assignment to ZERO-RISCY

**Table 3-24. ZERO-RISCY interrupt assignment**

| Address | Vector | IRQ | Module | Description |
|---|---|---|---|---|
| **0x0103_FF00 - 0x0103_FF7C** | 0 - 31 | 0 - 31 | same to vector16-47 of Cortex-M0+ | |
| **0x0103_FF80** | 32 | - | RI5CY | Reset, Initial PC |
| **0x0103_FF84** | 33 | - | RI5CY | Illegal Instruction |
| **0x0103_FF88** | 34 | - | RI5CY | ECALL Instruction Executed |
| **0x0103_FF8C** | 35 | - | RI5CY | Load Store Unit Error |

Vector0-31: external interrupts, 8-level programmable priority. Interrupt source module is the same to vector16-47 of Cortex-M0+.

Vector32-35: internal exceptions, fixed priority, the lower the vector number, the higher the priority.

The priority of the internal exception is higher than the external interrupts.

# Chapter 4
# Peripheral Bridge (AIPS-Lite)

## 4.1 Chip-specific AIPS-Lite information

This device contains two peripheral bridges.

### 4.1.1 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See AIPS0 Memory Map and AIPS1 Memory Map for the memory slot assignment for each module.

## 4.2 Memory map/register definition

The AIPS modules on this device do not contain any user-programmable registers.

## 4.3 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

### 4.3.1 Access support

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. All accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

# Chapter 5
# Crossbar Switch (AXBS)

## 5.1 Chip-specific AXBS information

### 5.1.1 Crossbar switch master assignments - with system MPU

The masters connected to the crossbar switch are assigned as follows:

**Table 5-1. CM4F/RI5CY crossbar master assignment**

| Master port number | Master module | Default Priority |
|---|---|---|
| 0 | ARM/RISC-V core code/data bus | 4 |
| 1 | ARM/RISC-V core system bus | 3 |
| 2 | DMA0 | 2 |
| 3 | uSDHC | 1 |
| 4 | USB | 0 |
| 5 | CM0+/ZERO-RISCY Domain Crossbar S3 | 5 |

**Table 5-2. CM0+/ZERO-RISCY crossbar master assignment**

| Master port number | Master module | Default Priority |
|---|---|---|
| 0 | ARM/RISC-V core unified bus | 2 |
| 1 | DMA1 | 1 |
| 2 | CAU3 | 0 |
| 3 | CM4F/RI5CY Domain Crossbar S4 | 4 |
| 4 | ZERO-RISCY data bus | 3 |

### 5.1.2 Crossbar switch slave assignments - with system MPU

The slaves connected to the crossbar switch are assigned as follows:

**Table 5-3. CM4F crossbar slave assignment**

| Slave port number | Slave module |
|---|---|
| 0 | Flash Memory Controller |
| 1 | SRAM backdoor/Boot ROM |
| 2 | Peripheral bridge 0 |
| 3 | FlexBus |
| 4 | CM0+ Domain Crossbar M3 |

**Table 5-4. CM0+ crossbar slave assignment**

| Slave port number | Slave module |
|---|---|
| 0 | Flash Memory Controller |
| 1 | SRAM Controller |
| 2 | Peripheral bridge 1/USB SRAM/RGPIO A~D |
| 3 | CM4F Domain Crossbar M5 |

## 5.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

### 5.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
  - Allows concurrent accesses from different masters to different slaves
  - Slave arbitration attributes configured on a slave-by-slave basis

- Up to single-clock 32-bit transfer
- Support for burst transfers of up to 16 beats of data
- Low-Power Park mode support

## 5.3 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to them will terminate with an error.

**NOTE**

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

All references to the crossbar switch registers are based on the physical port connections.

### 5.3.1 AXBS0 register descriptions

#### 5.3.1.1 AXBS0 Memory map

AXBS0 base address: 4000_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Priority Slave Registers (PRS0) | 32 | RW | 0050_1234h |
| 10h | Control Register (CRS0) | 32 | RW | 0000_0000h |
| 100h | Priority Slave Registers (PRS1) | 32 | RW | 0050_1234h |
| 110h | Control Register (CRS1) | 32 | RW | 0000_0000h |
| 200h | Priority Slave Registers (PRS2) | 32 | RW | 0050_1234h |
| 210h | Control Register (CRS2) | 32 | RW | 0000_0000h |
| 300h | Priority Slave Registers (PRS3) | 32 | RW | 0050_1234h |
| 310h | Control Register (CRS3) | 32 | RW | 0000_0000h |
| 400h | Priority Slave Registers (PRS4) | 32 | RW | 0050_1234h |
| 410h | Control Register (CRS4) | 32 | RW | 0000_0000h |
| 800h | Master General Purpose Control Register (MGPCR0) | 32 | RW | 0000_0000h |
| 900h | Master General Purpose Control Register (MGPCR1) | 32 | RW | 0000_0000h |
| A00h | Master General Purpose Control Register (MGPCR2) | 32 | RW | 0000_0000h |
| B00h | Master General Purpose Control Register (MGPCR3) | 32 | RW | 0000_0000h |
| C00h | Master General Purpose Control Register (MGPCR4) | 32 | RW | 0000_0000h |
| D00h | Master General Purpose Control Register (MGPCR5) | 32 | RW | 0000_0000h |

## 5.3.1.2 Priority Slave Registers (PRS0 - PRS4)

### 5.3.1.2.1 Offset

| Register | Offset |
|---|---|
| PRS0 | 0h |
| PRS1 | 100h |
| PRS2 | 200h |
| PRS3 | 300h |
| PRS4 | 400h |

### 5.3.1.2.2 Function

The priority registers (PRSn) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PRSn register can only be read; attempts to write to it have no effect on PRSn and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRSn is not updated.

**NOTE**

Valid values for the M*n* priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains fewer than three masters, only one bit is valid.
- If the chip contains fewer than five masters, only two bits are valid.
- If five or more masters are present, all three bits of the priority field are used.

### 5.3.1.2.3 Diagram

## 5.3.1.3 Control Register (CRS0 - CRS4)

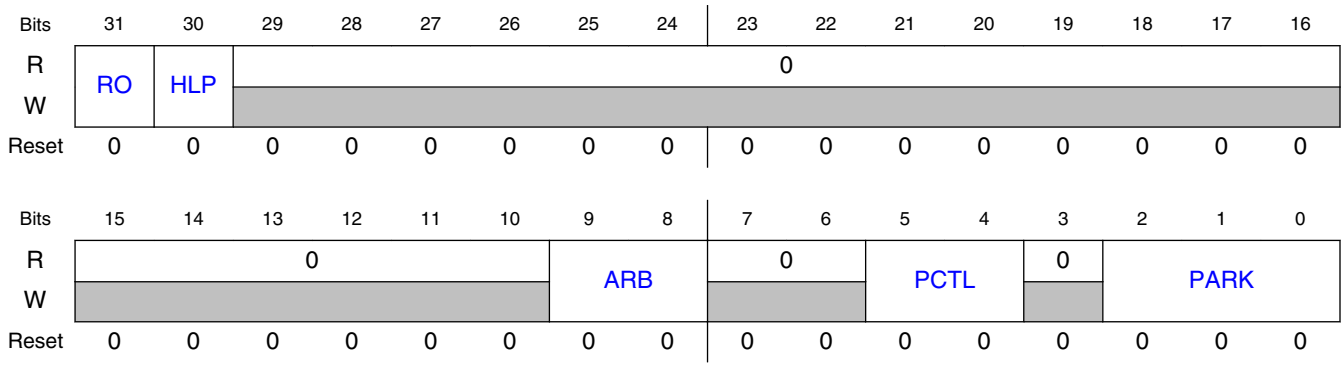
### 5.3.1.3.1 Offset

| Register | Offset |
|---|---|
| CRS0 | 10h |
| CRS1 | 110h |
| CRS2 | 210h |
| CRS3 | 310h |
| CRS4 | 410h |

### 5.3.1.3.2 Function

These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRSn[RO] is set, the PRSn can only be read; attempts to write to it have no effect and result in an error response.

## 5.3.1.3.3 Diagram



## 5.3.1.3.4 Fields

| Field | Function |
|---|---|
| 31<br>RO | Read Only<br>Forces the slave port's CSRn and PRSn registers to be read-only. After set, only a hardware reset clears it.<br>0b - The slave port's registers are writeable<br>1b - The slave port's registers are read-only and cannot be written. Attempted writes have no effect on the registers and result in a bus error response. |
| 30<br>HLP | Halt Low Priority<br>Sets the initial arbitration priority for low power mode requests . Setting this bit will not affect the request for low power mode from attaining highest priority once it has control of the slave ports.<br>0b - The low power mode request has the highest priority for arbitration on this slave port<br>1b - The low power mode request has the lowest initial priority for arbitration on this slave port |

### 5.3.1.4 Master General Purpose Control Register (MGPCR0 - MGPCR5)

#### 5.3.1.4.1 Offset

| Register | Offset |
|---|---|
| MGPCR0 | 800h |
| MGPCR1 | 900h |
| MGPCR2 | A00h |
| MGPCR3 | B00h |
| MGPCR4 | C00h |
| MGPCR5 | D00h |

#### 5.3.1.4.2 Function

The MGPCR controls only whether the master's undefined length burst accesses are allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters. The MGPCR can be accessed only in Supervisor mode with 32-bit accesses.

**NOTE**

If there are fewer than eight master ports, only the registers associated with those masters are present. Register addresses

associated with master ports that are not present are reserved. Please see this module's chip-specific information for which master ports are present on this module.

## 5.4 Functional Description

Information about general operation and arbitration can be found here.

### 5.4.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed- or undefined-length burst transfer it retains control of the slave port until that transfer completes. Based on MGPCR[AULB], the master either retains control of the slave port when doing undefined-length, incrementing burst transfers or loses the bus to a higher-priority master.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS*n*[PARK] . This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using CRS*n*[PCTL].

### 5.4.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

The MGPCRx[AULB] bits are the exception to this rule. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the slave bus cycle to write them will have already terminated successfully. If the MGPCRx[AULB] bits are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle is initiated by the master on that master port.

## 5.4.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

### 5.4.3.1 Arbitration during undefined length bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR[AULB] field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed-length burst accesses.

The following figure illustrates an example:

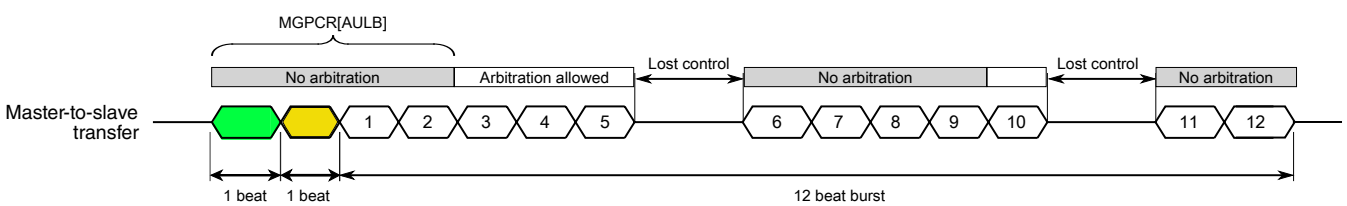

**Figure 5-1. Undefined length burst example**

In this example, a master runs an undefined length burst and the MGPCR[AULB] bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be a 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The crossbar does not allow an arbitration point until the fourth overall access, or the second beat of the second burst. At that point, all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. After the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the now

continued burst, or the ninth beat of the second burst from the master's perspective, is taken, all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third now continued burst, or the 10th beat of the second burst from the master's perspective. After the master regains control of the slave port, it is allowed to complete its final two beats of its burst without facing arbitration.

**Note**

Fixed-length burst accesses are not affected by the AULB bits. All fixed-length burst accesses lock out arbitration until the last beat of the fixed-length burst.

### 5.4.3.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRS*n*). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

**NOTE**

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

**Table 5-5. How the Crossbar Switch grants control of a slave port to a master**

| When | Then the Crossbar Switch grants control to the requesting master |
|---|---|
| Both of the following are true:<br>• The current master is not running a transfer.<br>• The new requesting master's priority level is higher than that of the current master. | At the next clock edge |
| Both of the following are true: | At the end of the burst transfer or locked transfer |

*Table continues on the next page...*

**Table 5-5. How the Crossbar Switch grants control of a slave port to a master (continued)**

| When | Then the Crossbar Switch grants control to the requesting master |
|---|---|
| • The current master is running a fixed length burst transfer or a locked transfer.<br>• The requesting master's priority level is higher than that of the current master. | |
| Both of the following are true:<br>• The current master is running an undefined length burst transfer.<br>• The requesting master's priority level is higher than that of the current master. | At the next arbitration point for the undefined length burst transfer<br><br>**NOTE:** Arbitration points for an undefined length burst are defined in the MGPCR for each master. |
| The requesting master's priority level is lower than the current master. | At the conclusion of one of the following cycles:<br>• An IDLE cycle<br>• A non-IDLE cycle to a location other than the current slave port |

### 5.4.3.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

#### 5.4.3.4 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

## 5.5 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

**NOTE**

- During configuration of the crossbar switch, all other masters must be idle.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS*n*[RO].

# Chapter 6
# Miscellaneous Control Module for CM4F (MCM0)

## 6.1 Introduction

The Miscellaneous Control Module (MCM) provides a myriad of miscellaneous control functions.

### 6.1.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Error status and interrupts for the core's floating-point unit (FPU)

## 6.2 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

### 6.2.1 MCM register descriptions

#### 6.2.1.1 MCM Memory map

MCM0 base address: E008_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 8h | Crossbar Switch (AXBS) Slave Configuration (PLASC) | 16 | RO | 001Fh |
| Ah | Crossbar Switch (AXBS) Master Configuration (PLAMC) | 16 | RO | 003Fh |

### 6.2.1.5 Interrupt Status and Control Register (ISCR)

#### 6.2.1.5.1 Offset

| Register | Offset |
|---|---|
| ISCR | 10h |

#### 6.2.1.5.2 Function

The MCM_ISCR register defines the configuration and reports status for a number of core-related interrupt exception conditions. It includes the enable and status bits associated with the core's floating-point exceptions, and bus errors associated with the core's cache write buffer. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these bits are ignored. Once set, the flags remain asserted until software clears the corresponding FPSCR bit.

## 6.3 Functional description

This section describes the functional description of MCM module.

### 6.3.1 Interrupts

The MCM's interrupt is generated if any of the following is true:

- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC)

- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC)
- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC)
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC)
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC)
- FPU invalid operation interrupt is enabled (FIOCE) and an invalid occurs (FIOC)

### 6.3.2 Determining source of the interrupt

To determine the exact source of the interrupt qualify the interrupt status flags with the corresponding interrupt enable bits.

1. From MCM_ISCR[31:16] && MCM_ISCR[15:0]
2. Search the result for asserted flags, which indicate the exact interrupt sources

# Chapter 7
# Miscellaneous Control Module for CM0+ (MCM1)

## 7.1 Introduction

The Miscellaneous Control Module (MCM) provides miscellaneous control functions.

### 7.1.1 Features

The MCM includes the following features:

# Chapter 8
# Miscellaneous System Control Module (MSCM)

## 8.1 Chip-specific MSCM information

The Core 0 and Core 1 in this chapter refer to the CPU0 (CM4F core) and CPU1 (CM0+ core) in other chapters.

## 8.2 Overview

The Miscellaneous System Control Module (MSCM) contains CPU configuration registers for Core 0 and Core 1, and on-chip memory controller registers.

## 8.3 Chip Configuration and Boot

The device's logical definition is controlled via chip-specific configuration bits, supported memory sizes and packing options. Collectively, these configuration bits define a reset configuration value (RCON).

Once the cores have fetched the needed reset vector(s), it is expected that core and system configuration information is read from a globally-accessible slave peripheral that properly converts the information into more appropriate values. More specifically, the cores access configuration information from a common set of peripheral addresses and the chip configuration logic properly evaluates based on the requesting processor and returns the appropriate value for the given processor, including core identification.

As an example, there is a single 32-bit read-only location for the core identification. A 32-bit read from this location returns a 4-character ASCII string: 0x434D3401("Cortex-M4").

The programming model associated with the core configuration information is included as part of the Miscellaneous System Control Module (MSCM). It specifically includes multiple views of the processor configuration; one view that is available generically to the cores, and other views that are available to any bus masters in the system.

## 8.4 MSCM Memory Map/Register Definition

### 8.4.1 CPU Configuration Memory Map and Registers

The CPU configuration portion of the MSCM module provides a set of memory-mapped read-only addresses defining the processor set-up. This portion of the MSCM programming model can only be accessed with privileged mode 32-bit read references; any other access type or size are terminated with an error. If the processor is logically not included in the chip configuration, then reads of its configuration registers return zeroes.

The CPU Configuration registers are organized based on the logical processor number (not any type of physical port number) and partitioned into the following equal sections:

**Table 8-1. CPU Configuration Register Sections**

| Offset addresses | Function |
|---|---|
| 0x000 - 0x01F | Defines the generic processor "x" configuration. This region is only accessible to the processor cores; reads by non-core bus masters are treated as read-as-zero (RAZ) accesses. |
| 0x020 - 0x03F | Defines the configuration information for processor 0 (CP0). This region is accessible to any bus master. |
| 0x040 - 0x05F | Defines the configuration information for processor 1 (CP1). This region is accessible to any bus master. For uniprocessor chip configurations, reads of this section are read as zero (RAZ). |

Attempted user mode or write accesses are terminated with an error.

### 8.4.2 MSCM register descriptions

#### 8.4.2.1 MSCM Memory map

MSCM base address: 4000_1000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Processor X Type Register (CPxTYPE) | 32 | RO | See description. |
| 4h | Processor X Number Register (CPxNUM) | 32 | RO | See description. |
| 8h | Processor X Master Register (CPxMASTER) | 32 | RO | See description. |
| Ch | Processor X Count Register (CPxCOUNT) | 32 | RO | 0000_0001h |
| 10h | Processor X Configuration Register 0 (CPxCFG0) | 32 | RO | See description. |
| 14h | Processor X Configuration Register 1 (CPxCFG1) | 32 | RO | See description. |
| 18h | Processor X Configuration Register 2 (CPxCFG2) | 32 | RO | See description. |
| 1Ch | Processor X Configuration Register 3 (CPxCFG3) | 32 | RO | See description. |

| 5Ch | Processor 1 Configuration Register 3 (CP1CFG3) | 32 | RO | 0000_0120h |
| 400h | On-Chip Memory Descriptor Register (OCMDR0) | 32 | RW | CB08_9000h |
| 404h | On-Chip Memory Descriptor Register (OCMDR1) | 32 | RW | C706_9000h |
| 408h | On-Chip Memory Descriptor Register (OCMDR2) | 32 | RW | C004_D000h |
| 40Ch | On-Chip Memory Descriptor Register (OCMDR3) | 32 | RW | D704_7000h |

## 8.4.2.2 Processor X Type Register (CPxTYPE)

#### 8.4.2.2.1 Offset

| Register | Offset |
|---|---|
| CPxTYPE | 0h |

#### 8.4.2.2.2 Function

The register provides a CPU-specific response indicating the personality of the core making the access. The 32-bit response includes 3 ASCII characters that define the CPU type, along with a byte that defines the logical revision number. The logical revision number follows ARM's rYpZ nomenclature.

**NOTE**

CPxTYPE value(s) for this device:

- If CPU0 is making the access = 0x434D3401
- If CPU1 is making the access = 0x434D3001
- If the read access is not from a CPU, then the value read is 0x00000000

#### 8.4.2.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 8.4.2.2.4 Fields

| Field | Function |
|---|---|
| 31-8<br>PERSONALITY | Processor x Personality<br>This read-only field defines the processor personality for CPUx<br>if CPUx = Cortex-M0+, then PERSONALITY = 0x43_4D_30 ("CM0+").<br>if CPUx = Cortex-M4, then PERSONALITY = 0x43_4D_34 ("CM4"). |
| 7-0 | Processor x Revision |

| Field | Function |
|---|---|
| RYPZ | This read-only field defines the processor revision for CPUx:<br>0x00 corresponds to the r0p0 core release.<br>0x01 corresponds to the r0p1 core release.<br>... |

## 8.4.2.3 Processor X Number Register (CPxNUM)

### 8.4.2.3.1 Offset

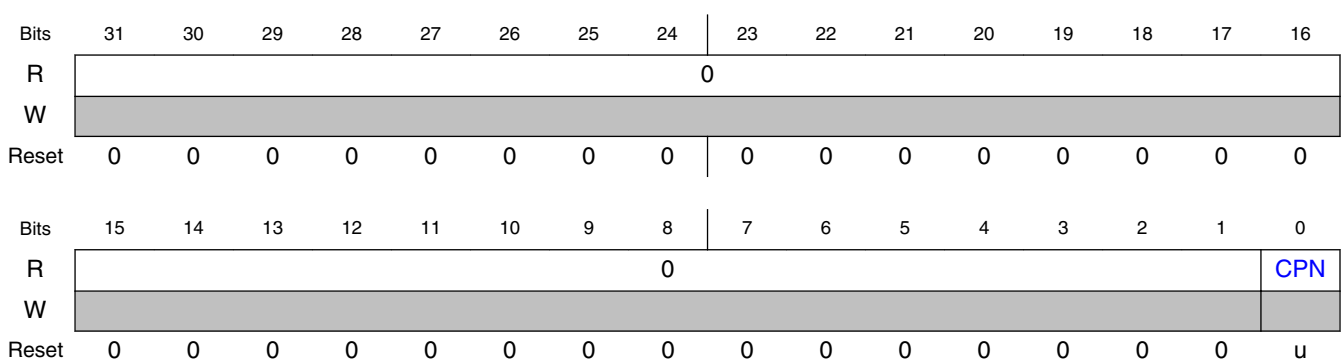
| Register | Offset |
|---|---|
| CPxNUM | 4h |

### 8.4.2.3.2 Function

The register provides a CPU-specific response indicating the logical processor number of the core making the access. The boot (or primary) core is assigned the number 0, while the secondary core is defined as number 1.

If the read access is not from a CPU, then the value read is 0x00000000.

### 8.4.2.3.3 Diagram



### 8.4.2.3.4 Fields

| Field | Function |
|---|---|
| 31-1 | Reserved |

*Table continues on the next page...*

| Field | Function |
|---|---|
| — | |
| 0<br>CPN | Processor x Number<br>This zero-filled word defines the logical processor number for CPUx<br>If boot (primary) core, then CPN = 0<br>For secondary core, CPN = 1 |

## 8.4.2.4 Processor X Master Register (CPxMASTER)

### 8.4.2.4.1 Offset

| Register | Offset |
|---|---|
| CPxMASTER | 8h |

### 8.4.2.4.2 Function

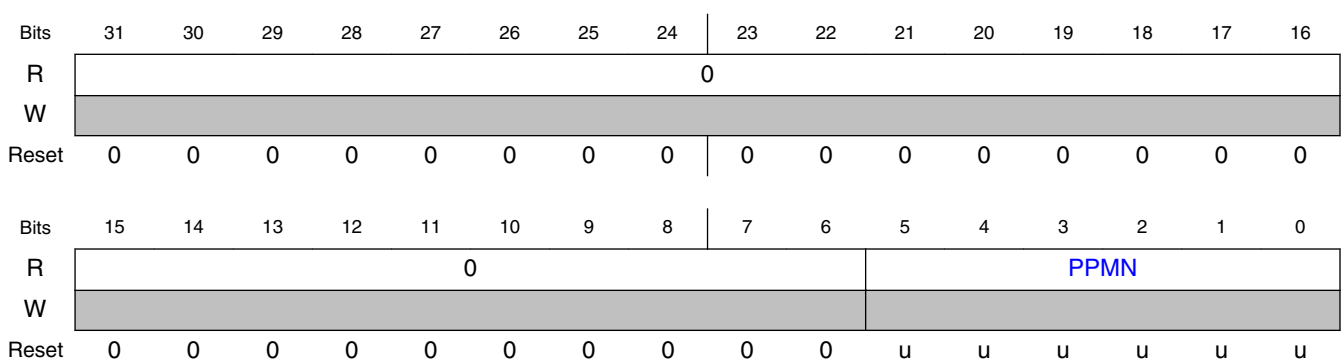
The register provides a CPU-specific response indicating the physical bus master number of the core that is making the access. The 32-bit response defines the physical master number for processor x.

- For CPU0, CPxMASTER = 0x00000000
- For CPU1, CPxMASTER = 0x00000020

**NOTE**

A privileged read from a CPU returns the appropriate processor information. Reads from a non-CPU bus master returns all zeroes. Attempted user mode or write accesses are terminated with an error.

### 8.4.2.4.3 Diagram



#### 8.4.2.4.4 Fields

## 8.4.2.9 Processor X Configuration Register 3 (CPxCFG3)

### 8.4.2.9.1 Offset

| Register | Offset |
|---|---|
| CPxCFG3 | 1Ch |

### 8.4.2.9.2 Function

The CPxCFG3 register provides a CPU-specific response detailing configuration information, in this case, information on processor options.

**NOTE**

Reset values for the Processor X Configuration Register 3:

- For CPU0 - CPxCFG3 = 0x00000121
- For CPU1 - CPxCFG3 = 0x00000120
- If the read access is not from a CPU, then the value read is 0x00000000

### 8.4.2.18.4 Fields

| Field | Function |
|---|---|
| 31-8<br>PERSONALITY | Processor 1 Personality<br>This read-only field defines the processor personality for CP1<br>CP1 = Cortex-M0+, then PERSONALITY = 0x43_4D_30 ("CM0+"). |
| 7-0<br>RYPZ | Processor 1 Revision<br>This read-only field defines the processor revision for CPU1:<br>0x00 corresponds to the r0p0 core release.<br>0x01 corresponds to the r0p1 core release.<br>... |

## 8.4.2.19 Processor 1 Number Register (CP1NUM)

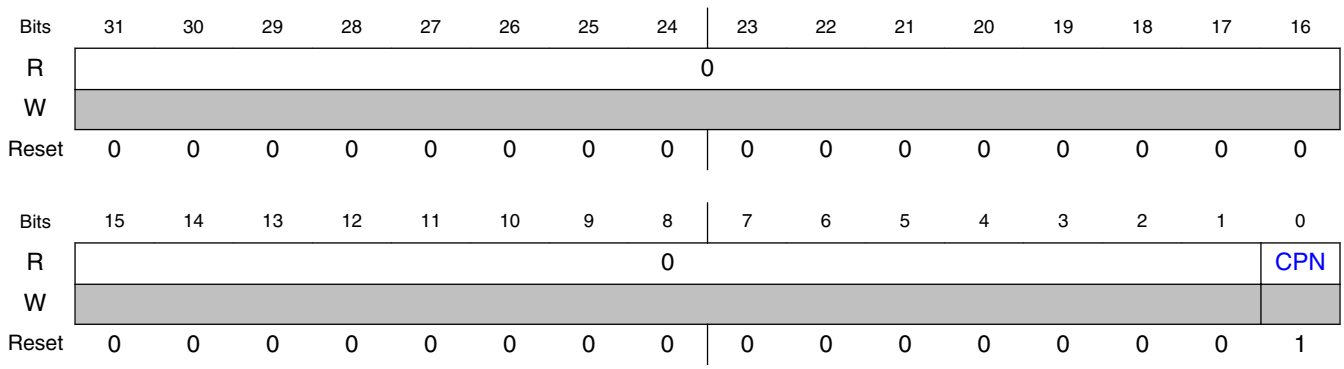
### 8.4.2.19.1 Offset

| Register | Offset |
|---|---|
| CP1NUM | 44h |

### 8.4.2.19.2 Function

The register provides the logical processor number of Processor 1. The boot (or primary) core is assigned the number 0, while the secondary core is defined as number 1.

### 8.4.2.19.3 Diagram



### 8.4.2.19.4 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>CPN | Processor 1 Number<br>This zero-filled word defines the logical processor number for CPU1<br>If boot (primary) core, then CPN = 0<br>For the secondary core, CPN = 1 |

## 8.4.2.20 Processor 1 Master Register (CP1MASTER)

### 8.4.2.20.1 Offset

| Register | Offset |
|---|---|
| CP1MASTER | 48h |

#### 8.4.2.20.2 Function

The register provides the physical bus master number of Processor 1.

#### 8.4.2.20.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 8.4.2.26 On-Chip Memory Descriptor Register (OCMDR0)

### 8.4.2.26.1 Offset

| Register | Offset |
|---|---|
| OCMDR0 | 400h |

### 8.4.2.26.2 Function

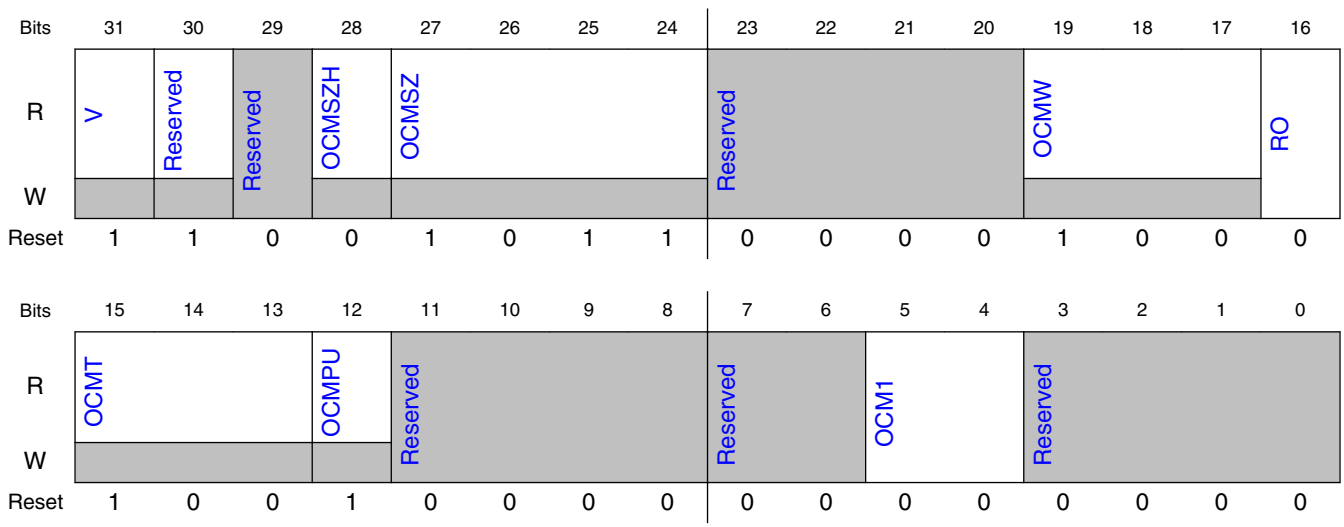
This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information about the attached memories, as well as configurable controls (where appropriate).

- Privileged 32-bit reads from a processor core or the debugger return the appropriate processor information.
- Reads from any other bus master return all zeroes.
- Privileged writes from a processor core or the debugger to writeable registers update the appropriate fields.
- Privileged writes from other bus masters are ignored.
- Attempted user mode accesses or any access with a size other than 32 bits are terminated with an error.

The following table describes the OCMDRn reset values and the associated memory type:

| OCMDRn | Reset Value | On-Chip Memory Type |
|---|---|---|
| OCMDR0 | 0xCB089000 | Program Flash |
| OCMDR1 | 0xC7069000 | Program Flash |
| OCMDR2 | 0xC004D000 | EEERAM |
| OCMDR3 | 0xD7047000 | ROM |

## 8.4.2.26.3 Diagram



## 8.4.2.26.4 Fields

| Field | Function |

## 8.4.2.28 On-Chip Memory Descriptor Register (OCMDR2)

### 8.4.2.28.1 Offset

| Register | Offset |
|---|---|
| OCMDR2 | 408h |

### 8.4.2.28.2 Function

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information about the attached memories, as well as configurable controls (where appropriate).

- Privileged 32-bit reads from a processor core or the debugger return the appropriate processor information.

- Reads from any other bus master return all zeroes.
- Privileged writes from a processor core or the debugger to writeable registers update the appropriate fields.
- Privileged writes from other bus masters are ignored.
- Attempted user mode accesses or any access with a size other than 32 bits are terminated with an error.

The following table describes the OCMDRn reset values and the associated memory type:

| OCMDRn | Reset Value | On-Chip Memory Type |
|---|---|---|
| OCMDR0 | 0xCB089000 | Program Flash |
| OCMDR1 | 0xC7069000 | Program Flash |
| OCMDR2 | 0xC004D000 | EEERAM |
| OCMDR3 | 0xD7047000 | ROM |

## 8.4.2.29 On-Chip Memory Descriptor Register (OCMDR3)

### 8.4.2.29.1 Offset

| Register | Offset |
|---|---|
| OCMDR3 | 40Ch |

### 8.4.2.29.2 Function

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information about the attached memories, as well as configurable controls (where appropriate).

- Privileged 32-bit reads from a processor core or the debugger return the appropriate processor information.
- Reads from any other bus master return all zeroes.
- Privileged writes from a processor core or the debugger to writeable registers update the appropriate fields.
- Privileged writes from other bus masters are ignored.
- Attempted user mode accesses or any access with a size other than 32 bits are terminated with an error.

The following table describes the OCMDRn reset values and the associated memory type:

| OCMDRn | Reset Value | On-Chip Memory Type |
|---|---|---|
| OCMDR0 | 0xCB089000 | Program Flash |
| OCMDR1 | 0xC7069000 | Program Flash |
| OCMDR2 | 0xC004D000 | EEERAM |

# Chapter 9
# Extended Resource Domain Controller (XRDC)

## 9.1 Chip-specific XRDC information

### 9.1.1 XRDC configuration

The XRDC implementation is distributed across multiple submodules instantiated throughout the device.

The following table shows the XRDC configurations for this device.

**Table 9-1. XRDC Configuration**

| Parameter | Number |
|---|---|
| DOMAIN_NUM | 2 |
| MDAC_NUM | 12 |
| MRC_NUM | 1 |
| PAC_NUM | 2 |

The following table shows the MDC and PID registers mapping for this device.

**Table 9-2. MDC and PID registers mapping**

| Master | MDAC | PID |
|---|---|---|
| CM4F C-BUS | MDAC0 | PID0 |
| CM4F S-BUS | MDAC1 | PID1 |
| CM0+ | MDAC32 | PID2 |

## 9.1.2 XRDC register configurations

### Table 9-3. MDAC configurations

| MDAC # | Master | xRDC MDAC register[1] | MDAC_REG_NUM | DEFAULT_DID | MDAC_CPU |
|---|---|---|---|---|---|
| MDAC0 | CM4F C-BUS[2] | MDA_W*_DFMT0 | 2 | 0 | 1 |
| MDAC1 | CM4F S-BUS[3] | MDA_W*_DFMT0 | 2 | 0 | 1 |
| MDAC2 | DMA0 | MDA_W*_DFMT1 | 1 | 0 | 0 |
| MDAC3 | uSDHC | MDA_W*_DFMT1 | 1 | 2 | 0 |
| MDAC4 | USB | MDA_W*_DFMT1 | 1 | 2 | 0 |
| MDAC16 | RI5CY C-BUS | MDA_W*_DFMT0 | 2 | 0 | 1 |
| MDAC17 | RI5CY S-BUS | MDA_W*_DFMT0 | 2 | 0 | 1 |
| MDAC32 | CM0+ | MDA_W*_DFMT0 | 2 | 1 | 1 |
| MDAC33 | DMA1 | MDA_W*_DFMT1 | 1 | 1 | 0 |
| MDAC34 | CAU3 | MDA_W*_DFMT1 | 1 | 1 | 0 |
| MDAC35 | ZERORISCY C-BUS | MDA_W*_DFMT0 | 2 | 1 | 1 |
| MDAC36 | ZERORISCY D-BUS | MDA_W*_DFMT0 | 2 | 1 | 1 |

1. The MDA_W*_DFMTn here refers to MDAC_W0_0_DFMT0 - MDA_W1_0_DFMT0.
2. Access address range: 0x0000_0000-0x1FFF_FFFF.
3. Access address range: 0x2000_0000-0xFFFF_FFFF.

### Table 9-4. MRC configurations

| MRC # | xRDC MRC register[1] | Slave Memory | REGION_NUM |
|---|---|---|---|
| MRC0 | MRGD_W*_0_0 | • CM4F flash<br>• CM4F ITCM SRAM<br>• Boot ROM<br>• CM4F DTCM SRAM<br>• FlexRAM<br>• FlexBus | 8 |
| MRC0 | MRGD_W*_0_1 | | |
| MRC0 | MRGD_W*_0_2 | | |
| MRC0 | MRGD_W*_0_3 | | |
| MRC0 | MRGD_W*_0_4 | | |
| MRC0 | MRGD_W*_0_5 | | |
| MRC0 | MRGD_W*_0_6 | | |
| MRC0 | MRGD_W*_0_7 | | |
| MRC1 | MRGD_W*_1_0 | • CM0+ flash<br>• CM0+ SRAM<br>• CM0+ PPB | 8 |
| MRC1 | MRGD_W*_1_1 | | |
| MRC1 | MRGD_W*_1_2 | | |
| MRC1 | MRGD_W*_1_3 | | |
| MRC1 | MRGD_W*_1_4 | | |
| MRC1 | MRGD_W*_1_5 | | |
| MRC1 | MRGD_W*_1_6 | | |
| MRC1 | MRGD_W*_1_7 | | |

1. The MRGD_W*_m_n here refers to MRGD_W0_m_n,MRGD_W1_m_n, MRGD_W2_m_n, MRGD_W3_m_n, MRGD_W4_m_n.

## Table 9-5. PAC configurations

| PAC # | xRDC PAC register | Peripheral | Slot | IP Bus |
|---|---|---|---|---|
| PAC0 | PDAC_W*_0_1 | Miscellaneous System Control Module (MSCM) | 1 | AIPS0 |
| PAC0 | PDAC_W*_0_4 | MAX CORE | 4 | AIPS0 |
| PAC0 | PDAC_W*_0_8 | Direct Memory Access 0 (DMA0) controller | 8 | AIPS0 |
| PAC0 | PDAC_W*_0_9 | Direct Memory Access 0 (DMA0) controller transfer control descriptors | 9 | AIPS0 |
| PAC0 | PDAC_W*_0_12 | External Bus Interface (FlexBus) | 12 | AIPS0 |
| PAC0 | PDAC_W*_0_20 | Resource Domain Controller (RDC) MGR | 20 | AIPS0 |
| PAC0 | PDAC_W*_0_21 | Resource Domain Controller (RDC) MDAC | 21 | AIPS0 |
| PAC0 | PDAC_W*_0_22 | Resource Domain Controller (RDC) PAC | 22 | AIPS0 |
| PAC0 | PDAC_W*_0_23 | Resource Domain Controller (RDC) MRC | 23 | AIPS0 |
| PAC0 | PDAC_W*_0_27 | Semaphore Unit (SEMA42) | 27 | AIPS0 |
| PAC0 | PDAC_W*_0_32 | System Mode Controller 0 (SMC0) | 32 | AIPS0 |
| PAC0 | PDAC_W*_0_33 | Direct memory Access Mutliplexer 0 (DMAMUX0) | 33 | AIPS0 |
| PAC0 | PDAC_W*_0_34 | External Watchdog Monitor (EWM) | 34 | AIPS0 |
| PAC0 | PDAC_W*_0_35 | Flash Memory Module (FTFE) | 35 | AIPS0 |
| PAC0 | PDAC_W*_0_36 | Low Leakage Wake-up Unit 0 (LLWU0) | 36 | AIPS0 |
| PAC0 | PDAC_W*_0_37 | Messaging Unit - Side A (MU-A) | 37 | AIPS0 |
| PAC0 | PDAC_W*_0_38 | System Integration Module (SIM) | 38 | AIPS0 |
| PAC0 | PDAC_W*_0_39 | USB Voltage Regulator (USBVREG) | 39 | AIPS0 |

*Table continues on the next page...*

## Table 9-5. PAC configurations (continued)

| PAC # | xRDC PAC register | Peripheral | Slot | IP Bus |
|---|---|---|---|---|

## 9.2 Introduction

The Extended Resource Domain Controller (XRDC) provides an integrated, scalable architectural framework for access control, system memory protection and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus masters, memory regions and slave peripherals to processing *domains* to support enforcement of robust operational environments. First, each bus mastering resource is assigned to a domain identifier (domainID, DID). For processors, there are additional fields that can optionally be used to assign it to multiple domains. Next, the access control policies for the individual domains are programmed into any number of slave memory region descriptors and slave peripheral domain access control registers. Finally, all accesses throughout the device are monitored concurrently to determine the validity of each and every access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is aborted and error information captured.

The access control scheme defined by the XRDC supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism, where:

PrivSecure > PrivNonsecure > UserSecure > UserNonsecure

with different access control policies based on read and write references. Combined with the user/privileged and secure/nonsecure attributes, a domainID is associated with every system bus transaction and forms the hardware basis for implementation of the XRDC's access control mechanisms.

Access to shared memory regions and slave peripherals can be dynamically controlled with the optional inclusion of a hardware semaphore. If a hardware semaphore is enabled for a given address space or peripheral, then writes to the targeted address space are only allowed if the requesting domain owns the semaphore. This capability allows the access control policy for a given resource to be dynamically revised based on hardware semaphore ownership.

### 9.2.1 Features

The key features of the XRDC include:

- Assignment of chip resources to processing "domains"
  - Processor cores, non-core bus masters, slave memories and slave peripherals
  - Each processing domain is assigned a unique domain identifier (domainID, DID)
  - DomainID is a new attribute associated with every system bus transaction
  - Used in conjunction with user/privileged, secure/nonsecure attributes
- Access rights to slave targets defined in region descriptor registers for memories and access control registers for peripherals
- Supports sharing of memory and peripherals with optional inclusion of hardware semaphores to dynamically determine access rights
- Built upon a 4-level hierarchical access control model
  - PrivSecure > PrivNonsecure > UserSecure > UserNonsecure

    - Encoded into a 3-bit per-domain access control policy (ACP) used throughout the XRDC
    - Certain processors do not support the PrivNonsecure state. For these cores, the model simplifies to a 3-state definition: PrivSecure > UserSecure > UserNonsecure
- Programming model and hardware implementation is distributed across multiple submodules
    - Supports a broad, highly-configurable architecture definition
    - Memory region descriptors support a format leveraged from earlier System Memory Protection Units (SMPU)

## 9.2.2 Block diagram

As previously noted, the XRDC implementation is distributed across multiple submodules instantiated throughout the device. The XRDC submodules include:

- XRDC_MGR
    - The Manager (MGR) submodule coordinates all programming model reads and writes
- XRDC_MDAC
    - The Master Domain Assignment Controller (MDAC) handles resource assignments and generation of the domain identifiers
- XRDC_MRC
    - The Memory Region Controller (MRC) implements the access controls for slave memories based on the pre-programmed region descriptor registers
- XRDC_PAC
    - The Peripheral Access Controller (PAC) implements the access controls for slave peripherals based on the pre-programmed domain access control registers
- XRDC_MSC
    - The Memory Slot Controller (MSC) implements the access controls for memory slots based on the pre-programmed domain access control registers

For chip-specific implementation details of this module's instances, see the chip specific information.

See Figure 9-1 for a simplified XRDC block diagram focusing on topology and connections.

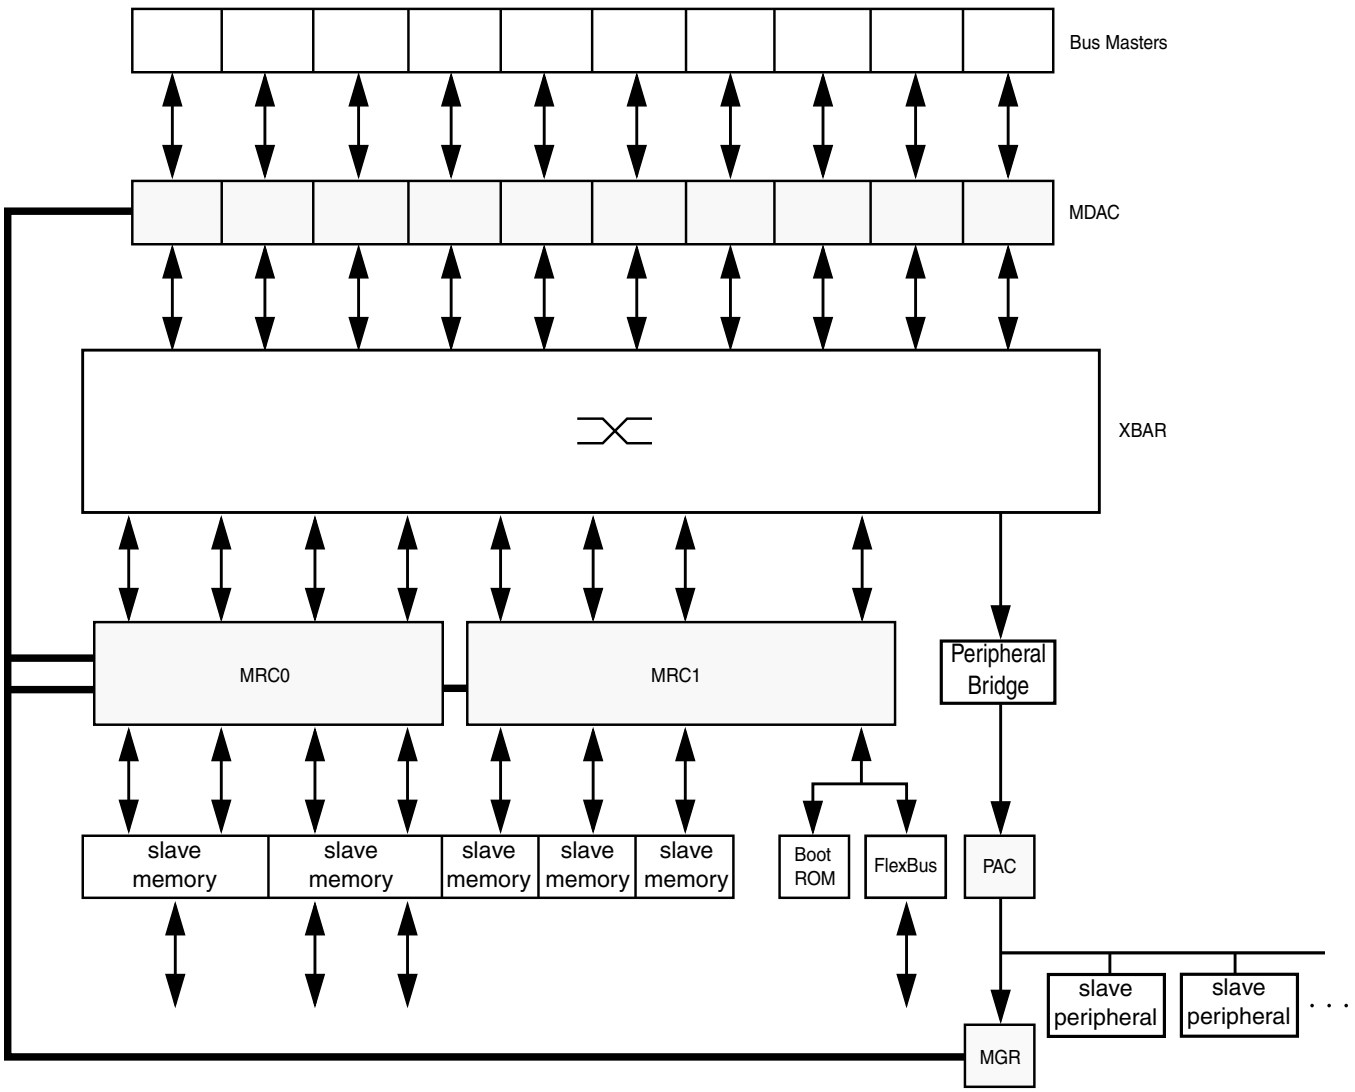

**Figure 9-1. Simplified XRDC Block Diagram**

## 9.2.3 Modes of operation

The XRDC module does not support any special modes of operation. As a memory-mapped device located in the core platform's clock domain, it responds based strictly on the memory addresses of the connected system buses. The slave peripheral bus is used to access the XRDC's distributed programming model; these references are only allowed if the requesting bus master is operating in the Privilege mode. Domain assignment and

access control functions are evaluated on a reference-by-reference basis using the addresses and attributes connected to the system bus port(s). The implementation of the XRDC_MRC submodule supports either AMBA-AHB or AMBA-AXI system bus protocols.

## 9.3 External signal description

The XRDC module does not directly support any external interfaces.

The *internal* interfaces include a standard 32-bit slave bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses and connections to the slave peripheral buses as shown in XRDC block diagram.

## 9.4 Memory map/register definition

The XRDC module supports a large number of architecturally-defined, program-visible registers distributed across four 4 Kbyte address slots. The actual registers present in any given device are application (and SoC) specific.

The register resources of the XRDC programming model can be accessed in privileged secure and privileged nonsecure modes. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error unless noted otherwise. The XRDC programming model is partitioned into 5 groups of registers:

- Basic hardware control and configuration
- Domain errors: location and details
- Master domain assignments
- Peripheral domain access controls
- Memory region descriptors

It should be noted that many of the programming model registers in the XRDC are organized as 2-dimensional data structures. These generic arrays contain "m" words representing the "columns" and "n" instances of the structure representing the "rows". These may be described as `structure[n][m]`. They appear in the address space of the programming model memory map in the standard C language row-major layout, that is,

the "m" words representing the "column" appear sequentially with the entire row replicated "n" times. The XRDC register structure uses the naming convention of *XRDC_<regname>_Wm_n*, where the column number "m" appears as a numeric suffix on the W (32-bit word) identifier, and the row identifier "n" appears as the final numerical suffix.

The architectural definition of the complete XRDC programming model is presented in this section. Each implementation is SoC-specific and highly dependent on the device requirements. For the reset values in this section, a "*" indicates an initial value determined by the hardware configuration.

## 9.4.1 XRDC register descriptions

### 9.4.1.1 XRDC Memory map

XRDC: 4001_4000h

| Offset | Register | Width (In bits) | Access | Reset value |

## 9.4.1.2 Control Register (CR)

### 9.4.1.2.1 Offset

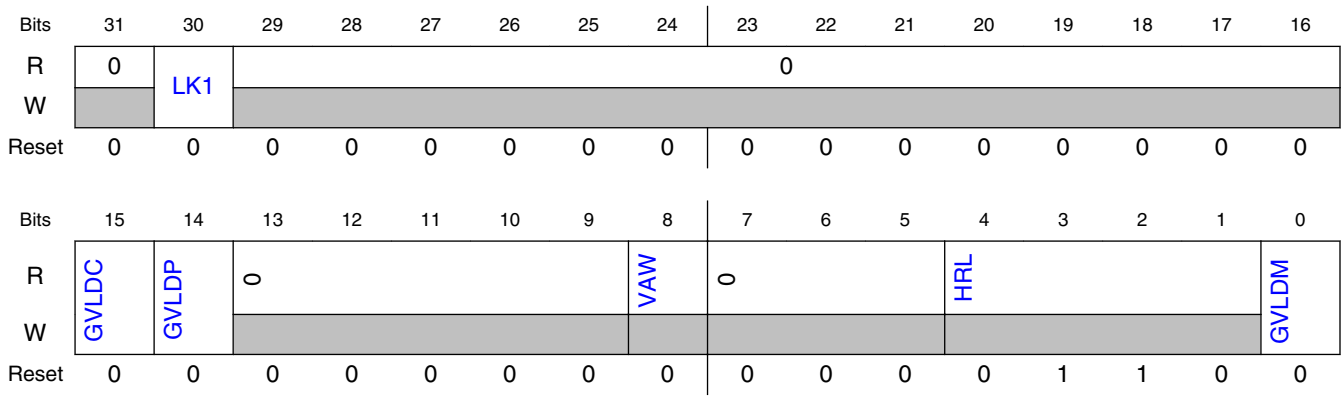
| Register | Offset |
|---|---|
| CR | 0h |

### 9.4.1.2.2 Function

This register provides read-only status about the XRDC and a global enable bit for the entire module's operation.

Access: Privileged Read/write

### 9.4.1.2.3 Diagram



### 9.4.1.2.4 Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved |
| 30<br>LK1 | 1-bit Lock<br>This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset.<br>0b - Register can be written by any secure privileged write.<br>1b - Register is locked (read-only) until the next reset. |
| 29-16<br>— | Reserved |
| 15<br>GVLDC | Global Valid for MRCs<br>XRDC global MRC enable/disable<br>0b - XRDC MRCs are disabled.<br>1b - XRDC MRCs are enabled. |
| 14<br>GVLDP | Global Valid for PACs/MSCs<br>XRDC global PAC/MSC enable/disable<br>0b - XRDC PACs/MSCs are disabled.<br>1b - XRDC PACs/MSCs are enabled. |
| 13-9<br>— | Reserved |
| 8<br>VAW | Virtualization aware<br>This field signals that the domain assignments support the optional inclusion of a logical partition identifier (also known as an operating system number).<br>0b - Implementation is not virtualization aware.<br>1b - Implementation is virtualization aware. |
| 7-5<br>— | Reserved |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 4-1<br>HRL | Hardware Revision Level<br>This read-only field specifies the XRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module. |
| 0<br>GVLDM | Global Valid MDACs(XRDC global enable/disable).<br>0b - XRDC MDACs are disabled.<br>1b - XRDC MDACs are enabled. |

### 9.4.1.3 Hardware Configuration Register 0 (HWCFG0)

#### 9.4.1.3.1 Offset

| Register | Offset |
|---|---|
| HWCFG0 | F0h |

#### 9.4.1.3.2 Function

This read-only register contains information on the XRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus masters along with the number of instances of memory region controllers (MRCs) and peripheral access controllers (PACs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: Privileged Read

#### 9.4.1.3.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 9.4.1.3.4 Fields

| Field | Function |
|---|---|
| 31-28<br>MID | Module ID |
| 27-24<br>NPAC | Number of PACs<br>This field defines the number of PACs minus 1 in the device. Add one to the field value to get the actual number of peripheral access controllers [1-4]. |
| 23-16<br>NMRC | Number of MRCs<br>This field defines the number of MRCs minus 1 in the device. Add one to the field value to get the actual number of memory region controllers [1-16]. |
| 15-8<br>NMSTR | Number of bus masters<br>This read-only field defines the number of bus masters minus 1 in the device. Add one to the field value to get the actual number of bus masters [1-64]. |
| 7-0<br>NDID | Number of domains<br>This read-only field defines the number of domains minus 1 in the device. Add one to the field value to get the actual number of domains [1-16]. |

### 9.4.1.4 Hardware Configuration Register 1 (HWCFG1)

#### 9.4.1.4.1 Offset

| Register | Offset |
|---|---|
| HWCFG1 | F4h |

#### 9.4.1.4.2 Function

This register contains information on the XRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: Privileged Read

#### 9.4.1.4.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

The XRDC_MDAC logic provides the needed PID for processor cores.<br>1b - Bus master 1 sources a process identifier register to the XRDC_MDAC logic. |
| 0<br>PIDP0 | Process identifier<br>Process identifier present from bus master 0. This field provides a bitmap to signal that bus master 0 sources a process identifier register to the XRDC_MDAC logic.<br>0b - Bus master 0 does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores.<br>1b - Bus master 0 sources a process identifier register to the XRDC_MDAC logic. |

## 9.4.1.6 Hardware Configuration Register 3 (HWCFG3)

### 9.4.1.6.1 Offset

| Register | Offset |
|---|---|
| HWCFG3 | FCh |

#### 9.4.1.6.2 Function

This register contains information on the XRDC's hardware configuration. Specifically, it provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus master. The HWCFG3 register is associated with bus masters [63-32], while the HWCFG2 register covers bus masters [31-0]. Attempted writes are error terminated.

Access: Privileged Read

#### 9.4.1.6.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PIDPn | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| R | PIDPn | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### 9.4.1.6.4 Fields

| Field | Function |
|---|---|
| 31-0<br>PIDPn | Process identifier<br>Process identifier present from bus master n, where n = [63-32]. This field provides a bitmap to signal that bus master n (where n is defined as 32 + bit number) sources a process identifier register to the XRDC_MDAC logic.<br>0 Bus master "n" does not source a process identifier register. The XRDC_MDAC logic provides the needed PID for processor cores.<br>1 Bus master "n" sources a process identifier register to the XRDC_MDAC logic. |

### 9.4.1.7 Master Domain Assignment Configuration Register (MDAC FG0 - MDACFG36)

#### 9.4.1.7.1 Offset

| Register | Offset |
|---|---|
| MDACFG0 | 100h |
| MDACFG1 | 101h |
| MDACFG2 | 102h |
| MDACFG3 | 103h |
| MDACFG4 | 104h |
| MDACFG16 | 110h |
| MDACFG17 | 111h |
| MDACFG32 | 120h |
| MDACFG33 | 121h |
| MDACFG34 | 122h |
| MDACFG35 | 123h |
| MDACFG36 | 124h |

#### 9.4.1.7.2 Function

This register defines the number of implemented domain assignment registers for bus master m, where m+1 can specify from 1 to 64 bus masters. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus master. Attempted writes are error terminated.

Typically, processor bus masters have one or more domain assignment registers, while non-processor masters have a single domain assignment register.

Access: Privileged Read

#### 9.4.1.7.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | NCM | 0 | | | NMDAR | | | |
| W | | | | | | | | |
| Reset | See Register reset values. | | | | | | | |

#### 9.4.1.7.4 Register reset values

| Register | Reset value |
|---|---|
| MDACFG0–MDACFG1 | 02h |
| MDACFG2–MDACFG4 | 81h |
| MDACFG5–MDACFG15 | Register not supported |
| MDACFG16–MDACFG32 | 02h |
| MDACFG18–MDACFG31 | Register not supported |
| MDACFG33–MDACFG34 | 81h |
| MDACFG35–MDACFG36 | 02h |
| MDACFG37–MDACFG62 | Register not supported |

#### 9.4.1.7.5 Fields

| Field | Function |
|---|---|
| 7<br>NCM | Non-CPU Master<br>This read-only field signals that bus master m is a non-CPU master. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus master.<br>0b - Bus master is a processor.<br>1b - Bus master is a non-processor. |
| 6-4<br>— | Reserved |
| 3-0<br>NMDAR | Number of master domain assignment registers for bus master m<br>This read-only field specifies the number of registers associated with the master domain assignment register for a given bus master. The value is limited to the range [0-8], where zero indicates a non-existent bus master and non-zero values indicate the number of implemented registers associated with this MDAm. |

### 9.4.1.8 Memory Region Configuration Register (MRCFG0 - MRCFG1)

#### 9.4.1.8.1 Offset

For r = 0 to 1:

| Register | Offset |
|---|---|
| MRCFGr | 140h + (r × 1h) |

#### 9.4.1.8.2 Function

This read-only register defines the number of implemented memory region descriptors for each MRCr, where r+1 can specify up to 16 instances. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. A zero value indicates a non-existent memory region controller instance. Attempted writes are error terminated.

Access: Privileged Read

| W | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |

#### 9.4.1.8.4 Fields

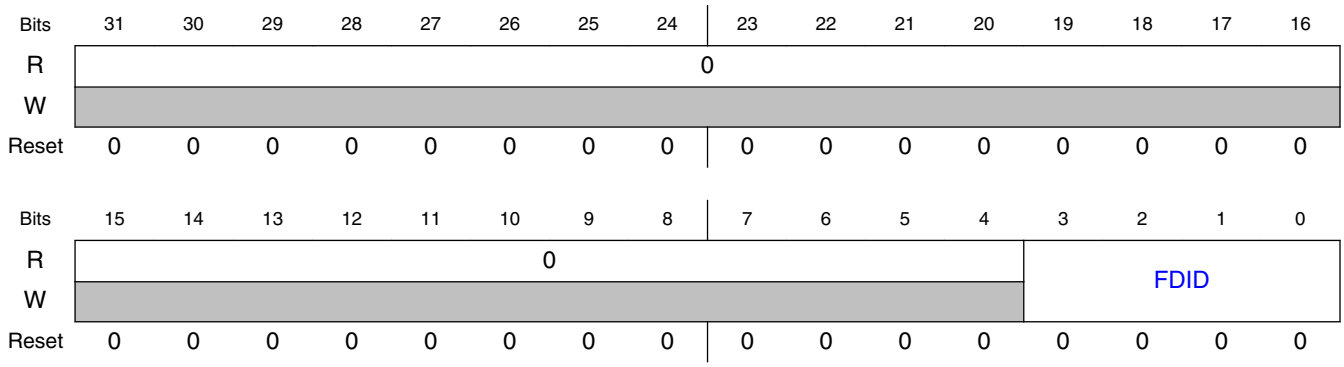
| Field | Function |
|---|---|
| 7-5<br>— | Reserved |
| 4-0<br>NMRGD | Number of memory region descriptors for memory region controller n<br>Number of memory region descriptors for MRCr. This field specifies the number of memory region descriptors associated with a given memory region controller instance. The value is limited to the range [0-16], where zero indicates a non-existent MRC instance and non-zero values indicate the number of implemented memory region descriptors [4, 8,12,16] associated with the XRDC_MRCr submodule. |

### 9.4.1.9 Fault Domain ID (FDID)

#### 9.4.1.9.1 Offset

| Register | Offset |
|---|---|
| FDID | 1FCh |

### 9.4.1.9.2 Diagram



### 9.4.1.9.3 Fields

| Field | Function |
|---|---|
| 31-4<br>— | Reserved |
| 3-0<br>FDID | Domain ID of Faulted Access<br>This field indicates the domainID of the fault that will be used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers. |

## 9.4.1.10 Domain Error Location Register (DERRLOC0 - DERRLOC2)

### 9.4.1.10.1 Offset

For d = 0 to 2:

| Register | Offset |
|---|---|
| DERRLOCd | 200h + (d × 4h) |

### 9.4.1.10.2 Function

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, which is indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information

for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i* register arrays. See Domain error capture management for more details.

When an access violation is detected by either a memory region controller (MRC) or a peripheral access controller (PAC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: Privileged Read

| 15-0<br>MRCINST | MRC instance<br>This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 0) corresponds to MRC instance 0. The most-significant bit of this field (bit 3) corresponds to MRC instance 3, and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs.<br>For each bit in this field:<br>• 0 - The memory region controller has not detected an access violation or is not physically present.<br>• 1 - The memory region controller has detected one or more access violations for this domain. |

## 9.4.1.11 Domain Error Word0 Register (DERR_W0_0 - DERR_W0_18)

### 9.4.1.11.1 Offset

| Register | Offset |
|---|---|
| DERR_W0_0 | 400h |
| DERR_W0_1 | 410h |
| DERR_W0_16 | 500h |
| DERR_W0_17 | 510h |
| DERR_W0_18 | 520h |

### 9.4.1.11.2 Function

This read-only register array provides the address of an access violation detected by either a memory region controller (MRC) or a peripheral access controller (PAC). These registers are organized as a word array, which is indexed by the violating submodule instance number. That is, the index, i, of this array is the instance number of the submodule that detected the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory-mapped error capture detail registers are organized as 20 sequential 16-byte entries. The first 16 register sets associated with the MRCs. The following register sets are associated with the PACs. Each 16-byte structure contains DERR_W0_i, DERR_W1_i, and DERR_W3_i.

The error capture registers in the MRC and PAC submodules contain physical registers for each domain, but are organized in the DERR_W0_i and DERR_W1_i registers to provide the information for the requesting domain only. Thus, the access violation exception handler for each domain only has visibility into the captured error information for its own domain. See Domain error capture management for more details.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MRC or PAC instance that is not physically present.

Access: Privileged Read

## 9.4.1.13 Domain Error Word3 Register (DERR_W3_0 - DERR_W3_18)

### 9.4.1.13.1 Offset

| Register | Offset |
|---|---|
| DERR_W3_0 | 40Ch |
| DERR_W3_1 | 41Ch |

*Table continues on the next page...*

| Register | Offset |
|---|---|
| DERR_W3_16 | 50Ch |
| DERR_W3_17 | 51Ch |
| DERR_W3_18 | 52Ch |

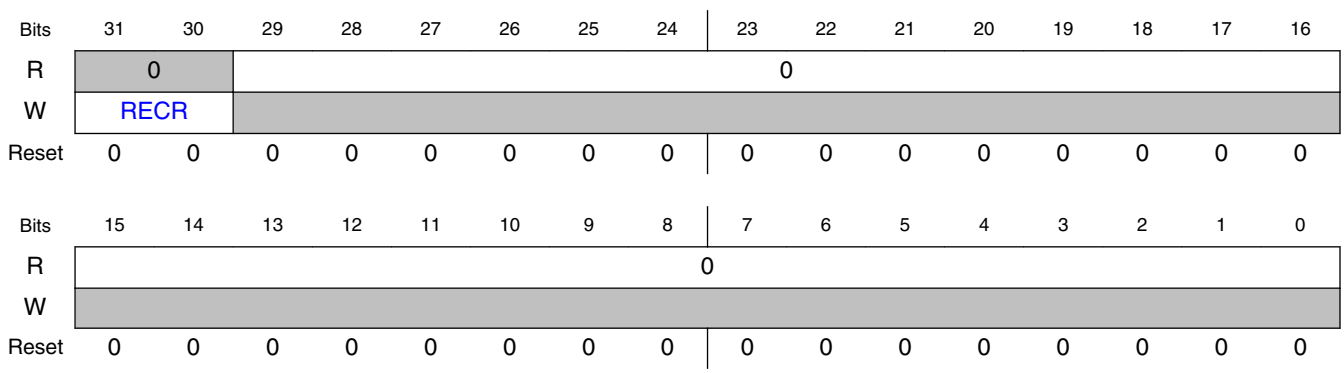
### 9.4.1.13.2 Function

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a memory region controller (MRC) or peripheral access controller (PAC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

### 9.4.1.13.3 Diagram



### 9.4.1.13.4 Fields

| Field | Function |
|---|---|
| 31-30<br>RECR | Rearm Error Capture Registers<br>This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured.<br>Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect. |
| 29-0<br>— | Reserved |

## 9.4.1.14 Process Identifier (PID0 - PID36)

### 9.4.1.14.1 Offset

| Register | Offset |
|---|---|
| PID0 | 700h |
| PID1 | 704h |
| PID16 | 740h |
| PID17 | 744h |
| PID32 | 780h |
| PID35 | 78Ch |
| PID36 | 790h |

### 9.4.1.14.2 Function

In the XRDC's access control definition, each processor has a corresponding process identifier (PID) which performs two important functions: the PID[5] bit defines the secure/nonsecure attribute associated with an executing task, and the entire value can be used to group tasks into different domains.

While certain processors include this register in their programming model definitions, others do not. This register is provided for those processors that do *not* include a PID register in their programming models. Secure privileged software saves and restores the PID as part of any context switch.

This data structure defines an array of 32-bit values, one per MDA module, that define the PID. Since this register resource is only applicable to processor cores, the data structure is typically sparsely populated. The HWCFG[2-3] registers provide a bitmap of the implemented PID*n* registers. This data structure is indexed using the corresponding MDA instance number.

For processors only supporting the 3-state access control model (PrivSecure, UserSecure, UserNonsecure), the nonsecure[n] output signal from the MDAC submodule is forced to zero while in privileged mode to enable precise state transitions between user and privileged modes. Specifically, the MDAC logic for bus master n forms the nonsecure attribute output signal as a function of 2 configuration bits: PIDm[TSM] and HWCFG{2,3}[n]. See Table 9-6.

When TSM is enabled, the output DID is a function of the mode:

TSM=1, mode = PrivSecure, DID_out= {2'b00, did_in[1:0]}

TSM=1, mode = UserSecure, if did_in=0,1, DID_out=2 else DID_out=did_in

TSM=1, mode = UserNonsecure, if did_in=0,1, DID_out=2 else DID_out=did_in

PrivNonsecure is an invalid mode when TSM=1.

Furthermore, when SP4SM is enabled, the MDAC doesn't use the MDA[DIDS,DID] fields. The MDAC tracks the access control mode and generates specific domainIDs. In PrivSec mode, the DID is forced to 0. In UserSecure and UserNonsecure modes, the DID is forced to 0 if DIDin is 0 or 1, and passes DIDin = DIDout for DIDs >=2.

Depending on the operating clock domain of each MDAC instance, there may be optional information stored in the corresponding PIDm register to properly implement the LK2 = 2 functionality.

Reads of the PID*n* register return the contents of this register, or the PID*n* value directly sourced from a processor. For non-processor bus masters, this register does not exist and any attempted read is error terminated.

**Table 9-6. Generation of the nonsecure_out[n] Attribute**

| Configuration {PID*n*[TSM], HWCFG{2,3}[n]} | local_nonsecure[n] | nonsecure_out[n] |
|---|---|---|
| 00b | nonsecure_in[n] | local_nonsecure[n] |
| 01b | nonsecure_in[n] | local_nonsecure[n] & ~priv_in[n] |
| 10b | PID*n*[5] | local_nonsecure[n] & ~priv_in[n] |
| 11b | pid_in[n][5] | local_nonsecure[n] & ~priv_in[n] |

| MDA_W1_35_DFMT0 | C64h |
| MDA_W0_36_DFMT0 | C80h |
| MDA_W1_36_DFMT0 | C84h |

### 9.4.1.15.2 Function

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus masters to domains. The number of implemented registers is defined by MDACFGm[NMDAR]. This per-master domain assignment is then repeated for each bus master (MDAm). Thus, m specifies the master number and r refers to the specific MDA register for a given bus master.

Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor masters typically support one or more Wr domain definitions, while non-processor masters support a single Wr.

The MDAC submodule is responsible for the generation of domain identifiers for every transaction from every bus master. If there is a single Wr for a given master, then the specified domain identifier is used directly. If there are multiple Wr values for a given master, then the MDAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor master. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in the following section, Master Domain Assignment (MDA_Wr_m_DFMT1).

| Field | Function |
|---|---|
| 31<br>VLD | Valid |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This field indicates the domain assignment is valid. It is further qualified by CR[GVLDM] = 1. If CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the XRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register.<br>0b - The Wr domain assignment is invalid.<br>1b - The Wr domain assignment is valid. |
| 30<br>LK1 | 1-bit Lock<br>This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset.<br>0b - Register can be written by any secure privileged write.<br>1b - Register is locked (read-only) until the next reset. |
| 29<br>DFMT | Domain format<br>Identifies this register's domain assignment.<br>**NOTE:** This bitfield access is ROZ<br>0b - Processor-core domain assignment<br>1b - Non-processor domain assignment |
| 28<br>— | Reserved |
| 27-22<br>— | Reserved |
| 21-16<br>PID | Process Identifier<br>This field specifies that the process identifier is to be combined with the PIDM field and included in the domain hit determination. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field. |
| 15-14<br>— | Reserved |
| 13-8<br>PIDM | Process Identifier Mask<br>This field provides a masking capability so that multiple process identifiers can be included as part of the domain hit determination. If a bit in the PIDM is set, then the corresponding bit of the PID is ignored in the comparison. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field. |
| 7-6<br>PE | Process identifier enable<br>This field controls the optional inclusion of the PID, qualified by PIDM, into the domain hit evaluation. It provides the ability to include inclusive or exclusive sets of masked PID values.<br>00b - No process identifier is included in the domain hit evaluation.<br>01b - No process identifier is included in the domain hit evaluation.<br>10b - The process identifier is included in the domain hit evaluation as defined by the expression: `partial_domain_hit = (PE == 2) && ((PID & ~PIDM) == (XRDC_PIDn[PID] & ~PIDM))`<br>11b - The process identifier is included in the domain hit evaluation as defined by the expression: `partial_domain_hit = (PE == 3) && ~((PID & ~PIDM) == (XRDC_PIDn[PID] & ~PIDM))` |
| 5-4<br>DIDS | DID Select<br>This field selects the source of the domain identifier.<br>00b - Use MDAm[3:0] as the domain identifier.<br>01b - Use the input DID as the domain identifier.<br>10b - Use MDAm[3:2] concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 11b - Reserved for future use. |
| 3-0<br>DID | Domain identifier<br>When the DIDB=1., this 4-bit field is the domain ID attribute that sent on accesses from the bus master connected to the MDAC. |

## 9.4.1.16 Master Domain Assignment (MDA_W0_2_DFMT1 - MDA_W0_34_DFMT1)

### 9.4.1.16.1 Offset

| Register | Offset |
|---|---|
| MDA_W0_2_DFMT1 | 840h |
| MDA_W0_3_DFMT1 | 860h |
| MDA_W0_4_DFMT1 | 880h |
| MDA_W0_33_DFMT1 | C20h |
| MDA_W0_34_DFMT1 | C40h |

### 9.4.1.16.2 Function

This register is identical to Master Domain Assignment (MDA_W0_0_DFMT0 - MDA_W1_36_DFMT0) except that the domain format field, DFMT, is 1. This format supports two different specifications of the DID for non-core bus masters.

Access: Privileged Read/write

### 9.4.1.17.2 Function

The PDAC_Wr_c_s registers provide a 3-dimensional data structure for defining access control policies per domain for each implemented slave peripheral. Refer to the Access control policies table below . There are 2 word-sized registers assigned for each peripheral "address slot" (Wr).

Each Wr within the PDAC*s* structure is a word-sized definition; a total of two words (64 bits) is needed to define the access control policies for all the domains.

These registers also allow an exclusive access lock to be optionally included in the access control evaluation for peripherals shared by multiple domains. If enabled, the state of the lock dynamically modifies the access control policies so that only the domain "owning" it has write permission into the peripheral. The write permissions for all other domains are revoked based on the lock state. If the lock is disabled, the DxACP fields are evaluated normally.

The PAC submodule uses the peripheral access address to select the appropriate PDAC*s* register, and then uses the domain identifier associated with the access to select the appropriate DxACP field. The selected DxACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See DxACP evaluation for more details. If allowed, the access proceeds, else an access violation is signaled, the transfer error terminated and the appropriate address and attribute information captured in the corresponding error detail registers.

Access: Privileged Read/write

## 9.4.1.19 Memory Region Descriptor (MRGD_W0_0_0 - MRGD_W0_1_7)

### 9.4.1.19.1 Offset

For m = 0 to 7; n = 0 to 1:

| Register | Offset |
|---|---|
| MRGD_W0_n_m | 2000h + (n × 200h) + (m × 20h) |

### 9.4.1.19.2 Function

The MRGD_W*o*_*n*_*m* registers provide a 3-dimensional data structure for defining access control policies (Table 9-8) per domain for each supported memory region. There are five word-size registers (W*o*) defined in each memory region. There are up to 16 memory region controllers (MRCs), *n*, each supporting up to 16 memory region descriptors (MRGD), *m*. The number of MRCs is defined by HWCFG0[NMRC].

Each instance of a MRC submodule can monitor up to 8 system buses concurrently.

**NOTE**

An AXI port counts as two system buses since the read address and write address channels operate independently.

Each W*o* within the MRGD*m* structure is a word-sized definition; a total of four words (128 bits, W0-W3) are needed to completely define the memory region descriptor.

XRDC uses a base address plus a size (0-modulo-size) to specify memory regions. This format provides addressing capabilities that are equivalent to those provided in the ARM Cortex-M processor core memory protection unit.

The region descriptor also allows an exclusive access lock to be optionally included in the access control evaluation for memory regions shared by multiple domains. If enabled, the state of the lock dynamically modifies the access control policies so that only the domain "owning" it has write permission into the region. The write permissions for all other domains are revoked based on the lock state. If the semaphore is not owned by any domain, the D*x*ACP fields are evaluated normally.

The MRC submodule evaluates multiple system bus access addresses versus the programmed address ranges to determine a region hit. Once a region hit has been determined, the MRC then uses the domain identifier associated with the access to select the appropriate D*x*ACP field from the corresponding MRGDn. The selected D*x*ACP field is then evaluated against the attributes associated with the memory transaction to determine the validity of the access. See Memory region descriptor hit determination and Memory region DxACP evaluation for more details. If allowed, the access proceeds, else an access violation is signaled, the transfer error terminated and the appropriate address and attribute information captured in the corresponding error detail registers.

## 9.5 Functional description

This section provides more details on the operation and implementation of the XRDC submodules.

### 9.5.1 Manager (XRDC_MGR)

The MGR submodule is responsible for coordinating XRDC's programming model reads and writes.

The complete programming model is large, requiring four 4-Kbyte slave peripheral address space slots, although most devices define a sparsely populated subset. Additionally, the programming model is distributed across the various submodule instances (MDAC, MRC, PAC). The MGR submodule provides the required hardware management for all programming model accesses, generating and distributing the appropriate address decodes and write data to the MDAC, MRC and PAC submodule instances, collecting and combining all the register read data buses and responses.

MGR implements the Control Register, all the read-only hardware configuration registers (HWCFG[0-3], MDACFGn, MRCFG) and the program-visible versions of the domain error capture registers. To support the domain error reporting functionality, the MGR submodule collects the individual captured error indicator output signals from all the submodule instances and remaps them so they are organized into a instance bitmap by domain as specified by the DERRLOCn register array.

### 9.5.2 Master Domain Assignment Controller (XRDC_MDAC)

The MDAC submodule is responsible for the generation of the domainID on every memory transaction for every bus master in the device. The resulting domainID and {nonsecure, privileged} signals are generated and then treated as address attributes and associated with each transaction as it moves through the system.

MDAC modules that drive the domainIDs (DIDs) for processor cores include an option of processor-identifier (PID) matching in order to select between DIDs. This is accomplished by first enabling PID checking by setting XRDC_MDA_Wm_n[PE] = [2,3]. With PID matching enabled, a domain hit is determined by matching XRDC_MDA_Wm_n[PID] with the PID input or PID in the XRDC_PID register. The PIDM field can be used to match specific groups of PIDs.

As a simple example, assume a system with two domainIDs.

- domainID 1 is for critical tasks (“critical” is system-specific and may refer to timing, safety, and so on.).
- domainID 2 is for non-critical tasks.
- Two domainIDs require two MDA_Wm_n registers, MDA_W0 and MDA_W1.

Further assume the processor’s task identifier defines whether a task is critical or non-critical as defined by system software.

- PIDs [0-15] are assigned to critical tasks.
- PIDs != [0-15] are assigned to noncritical tasks.

During startup, software initializes the MDA_W[0-1] registers. MDA_W0 defines DID = 1 for PIDs [0-15] and MDA_W1 defines DID = 2 for PIDs != [0-15].

1. MDA_W0 = 0x8000_0F81
    - VLD = 1
    - PID = 0x0
    - PIDM = 0xF
    - PE = 2
    - DIDS = 0
    - DID = 1
2. MDA_W1 = 0x8000_0FC2
    - VLD = 1
    - PID = 0x0
    - PIDM = 0xF
    - PE = 3
    - DIDS = 0
    - DID = 2

As the processor executes, it loads the appropriate task ID into its PID register as the task is started. The processor’s PID register value is input to the corresponding MDAC module and used by the MDA_Wm comparison logic. The system then dynamically generates two domainIDs and the downstream XRDC access check logic can distinguish and enforce different access control rights based on the different domainIDs.

A special mode is provided for driving the DID of non-processor masters. This is enabled with the DID bypass (DIDB) bit. The MDAC has a DID input that can be driven by a master and used directly as the DID output. This allows variability in the DID as dictated by the master and is intended to be used by DMA masters that masquerade as, (that is, drive the DID of) the master that programmed it.

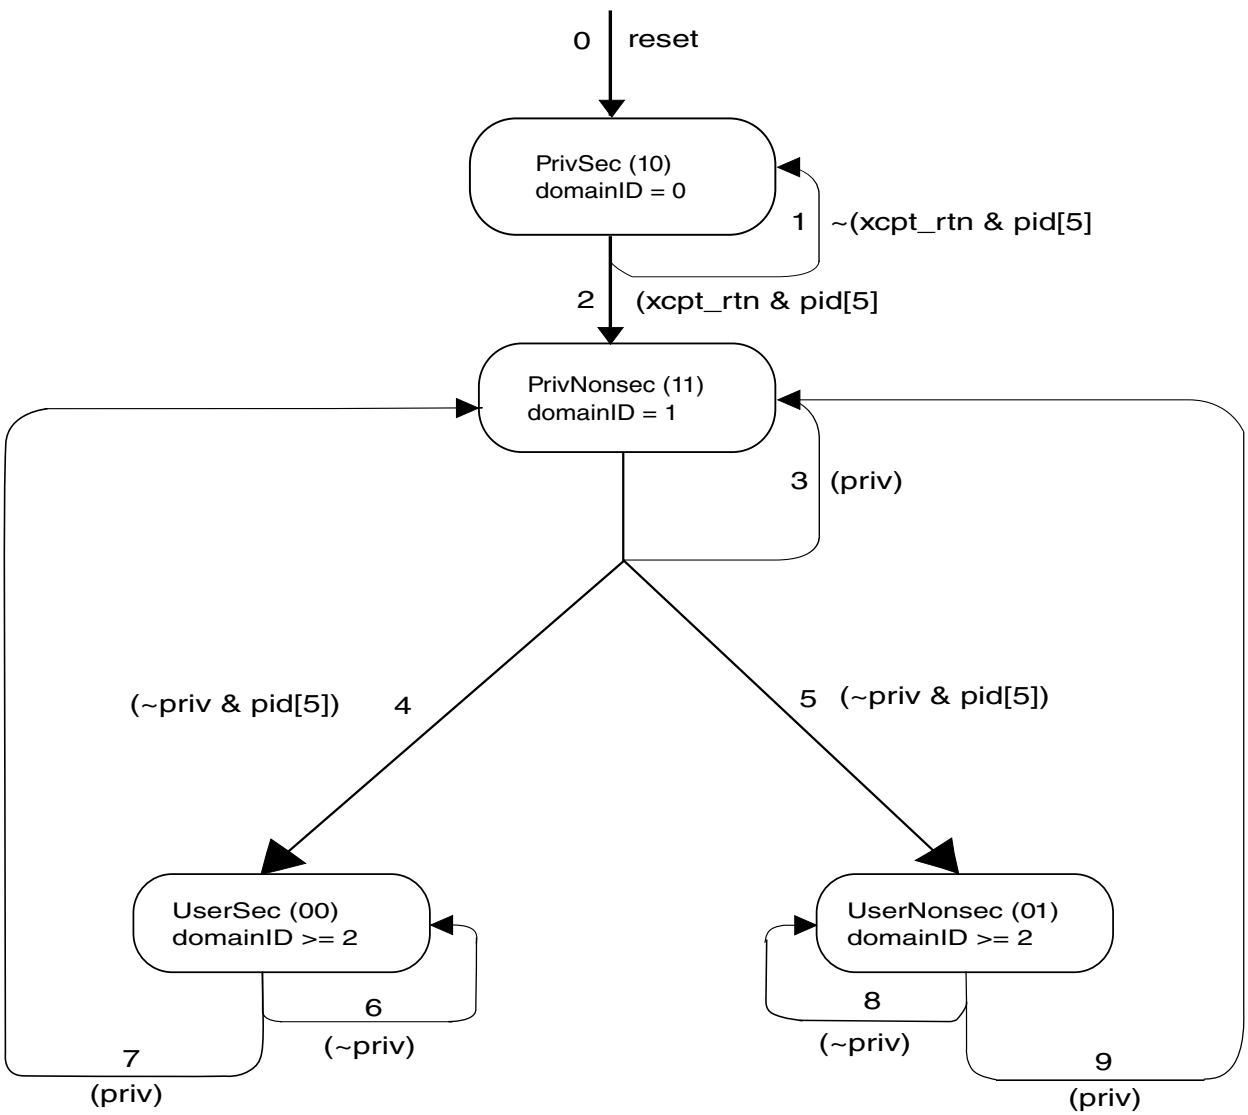
**NOTE**

Do not change the XRDC_MDAC configuration of a master while that master is active and XRDC_CR[GVLD] is set.

## 9.5.3 Special 4-State Model

When the special 4-state model (SP4SM) is enabled, a Mealy finite state machine in each processor MDACn tracks the current 2-bit access mode and generates specific domainIDs for specific modes.

The mode states and their transitions are shown in the diagram. In this configuration, the access mode states include PrivSecure (10), PrivNonsecure (11), UserSecure (00) and UserNonsecure (01).



### 9.5.4 DxACP evaluation

Fundamental to the XRDC's operation is the actual access violation check performed by the memory region (MRC) and peripheral access (PAC) controllers.

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the domain identifier as an address attribute through the system bus switching fabric(s). As transactions reach the slave memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or peripheral access control register. Once the appropriate register has been selected, the next function is the actual access evaluation.

For this step, the domainID of the current transaction selects the appropriate 3-bit DxACP (domain "x" access control policy) from the source register. The DxACP field defines the access rights for the domain based on the 4-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, user = 0/privileged = 1).

The 4-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged attributes. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as:

```
if {privileged, nonsecure} == 0b10, then level = PrivSecure
if {privileged, nonsecure} == 0b11, then level = PrivNonsecure
if {privileged, nonsecure} == 0b00, then level = UserSecure
if {privileged, nonsecure} == 0b01, then level = UserNonsecure
```

Recall the resulting hierarchical access control model specifies:

```
PrivSecure > PrivNonsecure > UserSecure > UserNonsecure
```

The XRDC's evaluation of the access control policy is defined by Table 9-9.

**Table 9-9. Domain x Access Control Policy Definition**

| Policy | Allowable Accesses | | | |
|---|---|---|---|---|
| | Secure Priv | Secure User | Nonsecure Priv | Nonsecure User |
| 111 | r, w | r, w | r, w | r, w |
| 110 | r, w | r, w | r, w | none |
| 101 | r, w | r, w | r | r |
| 100 | r, w | r, w | r | none |
| 011 | r, w | r, w | none | none |
| 010 | r, w | none | none | none |
| 001 | r | r | none | none |
| 000 | none | none | none | none |

Unimplemented domains default to an all-zero DxACP field providing no access rights.

After the DxACP evaluation is complete and the access error signal generated, the transaction is allowed to continue if it has sufficient access rights, else the access is aborted with the address and attribute information captured in the appropriate error registers.

Recall XRDC optionally supports the inclusion of a hardware semaphore to *dynamically alter* the access control policy of a memory region or peripheral access. See Hardware semaphores and dynamic access rights for details.

### 9.5.5 Exclusive Access Lock

The exclusive access lock is a hardware mechanism to dynamically modify the DxACP permission evaluation such that only one domain has access to a peripheral or memory region at any given time. Once an exclusive access lock is enabled, it is enabled until the next reset and the lock must be acquired by a domain to enable its access permissions. Only one domain can own the lock at a time and only the lock owner's access permissions are enabled, read and write permissions for all other domains are revoked. Some devices do not have exclusive access locks, see the appropriate section of the reference manual to determine if a device includes this feature.

Owning an exclusive access lock only enables permissions granted by the DxACP field, it does not grant permissions. Only domains with some read or write permissions (non-zero DxACP value) can acquire or release a lock. A lock can be held indefinitely. Typically a lock is released after required accesses are completed to allow other domains to acquire the lock as needed. In normal operation, only the domain that owns the lock can release it. There is a safeguarded means for a domain which does not own a lock to force a lock release.

The exclusive access lock is enabled, acquired and released by writing to the 2-bit EAL descriptor field. Neither the global configuration lock nor the descriptor lock apply to this field. The EAL field can be written to independently of the rest of the descriptor fields. Non-zero writes (01,10,11) to the EAL field do not affect other fields of the register. Likewise, a write of 00 does not affect the exclusive access lock and other fields of the register are updated. This convention eliminates the need to perform a read, modify, write operation to control the exclusive access lock. For devices without the exclusive access lock feature, the EAL field is a read only, reserved space and register writes are not affected by non-zero writes to the EAL field.

The EAL values are shown table below.

| EAL | Lock Enabled | Lock State | Access Permissions | Allowed Transitions |
|---|---|---|---|---|
| 00 | No | --- | Per DxACP evaluation | 01 disable lock |

*Table continues on the next page...*

| EAL | Lock Enabled | Lock State | Access Permissions | Allowed Transitions |
|---|---|---|---|---|
| | | | | 10 enable lock |
| 01 | No | --- | Per DxACP evaluation | None |
| 10 | Yes | Available | Write permissions revoked for all domains | 11 acquire lock |
| 11 | Yes | Not available | Per DxACP evaluation for the domain that owns the lock, write permissions revoked for all other domains | 10 release lock |

If EAL=11, the owner of the lock is indicated by the 4-bit, read only EALO field. The EALO field is used in the lock acquisition procedure to determine when the lock acquisition is successful. Domains with a DxACP field value of 000 can not acquire or release the lock.

The EAL field has a reset value of 00 which disables the exclusive access lock. The lock is disabled until the next reset by writing 0x01000000 to the W1 register (PAC/MSC) or W3 register (MRC) which sets EAL=01. Alternatively, the exclusive access lock is enabled until the next reset and set to the available state by writing 0x02000000 to the W1 register (PAC/MSC) or W3 register (MRC) which sets EAL=10.

Once the exclusive access lock is enabled, domains must acquire the lock to enable their access permissions. Only one domain can own the lock at a time. The procedure for acquiring the lock is as follows:

1. Set EAL = 11 by writing 0x03000000 to the W1 register (PAC/MSC) or W3 register (MRC)
2. Read EALO
3. If EALO = DID then the lock is acquired, else delay and repeat steps 1-3.

The DID value can be determined by reading the SR.

The exclusive access lock is released by writing 0x02000000 to the W1 register (PAC/MSC) or W3 register (MRC) which sets EAL=10. Only the domain that owns the lock (EALO=DID) may release the lock with the normal lock release write.

A lock can be forced to the available state (EAL=10) by a domain that does not own the lock through the forced lock release procedure. The procedure to force a exclusive access lock release is as follows:

1. Write 0x02000046 to W1 register (PAC/MSC) or W3 register (MRC)
2. Write 0x02000052 to W1 register (PAC/MSC) or W3 register (MRC)

Only the EAL field and the least significant byte of the forced release writes are significant and detected by hardware. The two writes must be consecutive, any intervening write to the register resets the sequence. No other register fields are affected by the forced release write. Once the lock is released, it can be acquired by any domain. As a convention, normal lock release writes should use 0x02000000 to clearly distinguish normal release writes from other configuration register writes and forced release writes.

### 9.5.6 Memory Region Controller (XRDC_MRC)

The XRDC's Memory Region Controller provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed *region descriptors* which define memory spaces and their associated access rights per domain identifier, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

The XRDC architectural framework supports up to 16 MRC instances, where each MRC instance can support {4, 8, 12, 16} region descriptors, concurrently monitoring up to 8 slave memory ports. Note, monitoring an AXI protocol port counts as two ports since there are independent read address and write address channels. Conversely, an AHB connection counts as a single port.

A partial, simplified one-dimensional block diagram of an instance of the MRC module is shown in Figure 9-2. In this figure, a single slave bus port is shown. When the remaining slave ports are considered, the MRC hardware's two-dimensional connection matrix, broadcasting each system bus slave port access across the implemented memory region descriptors, is the resulting structure with the basic access evaluation macro shown as the replicated submodule block. In Figure 9-2, the system bus fabric slave port is shown on the left, the memory region descriptor registers are in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and, based on the domainID associated with the reference, access violations.

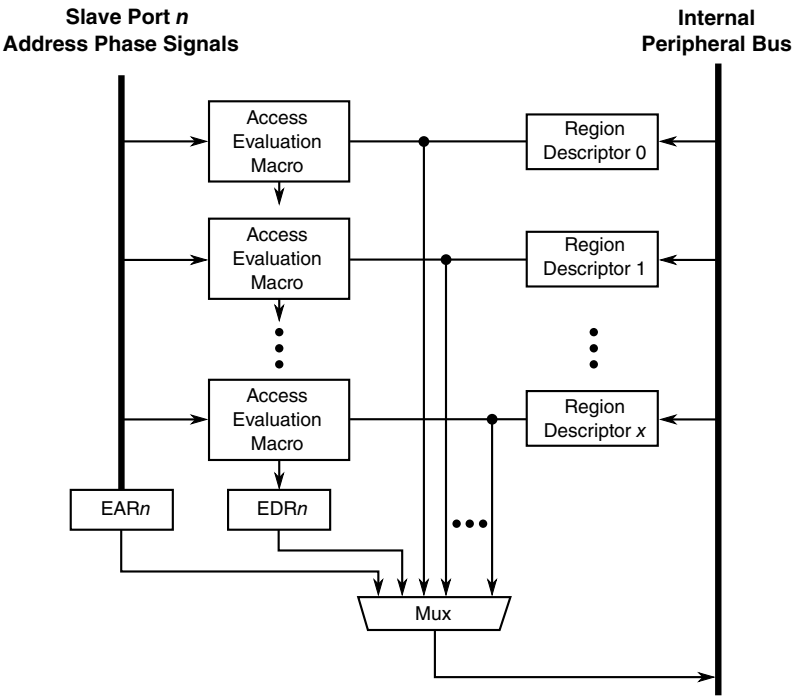


**Figure 9-2. MRC access evaluation macro hardware structure**

For each access, the MRC hardware performs a two-step evaluation process. First, the access is compared to all memory region descriptors to determine hit/miss status, and then, using the domainID associated with the reference plus the address attributes {write, nonsecure, privileged}, the access rights are examined using the method detailed in DxACP evaluation.

### 9.5.6.1 Memory region descriptor hit determination

To determine if the current reference hits in a given region, two magnitude comparators are used in conjunction with the region's start and end addresses. The boolean equation for this portion of the hit determination is defined as:

```
region_hit_n =
   ((addr >= start_addr) & (addr <= end_addr)) & valid
```

where `addr` is the current system reference address, `start_addr]` and `end_addr` are the start and end addresses, and `valid` is the valid bit, all from memory region descriptor n.

Note there are *no hardware checks* to verify that `end_addr ≥ start_addr`, and it is software's responsibility to properly load appropriate values into these fields of the region descriptor.

Also, the region hit determination is based only on an address comparison of the first byte being accessed; that is, the MRC does *not* check the size of the access to make sure it entirely fits within the region.

### 9.5.6.2 Memory region DxACP evaluation

For each region descriptor hit, the MRC logic then evaluates the access rights defined by the MRGD_Wm_n registers. Specifically, the domainID attribute selects the appropriate DxACP field from the MRGD_W{2,3}_n registers and then the {write, nonsecure, privileged} address attributes are compared with the access policy defined by the selected DxACP. See DxACP evaluation for additional details on this function.

While CR[GVLDC] = 1, and for each bus slave port being monitored, the MRC performs a **reduction-AND** of all the individual *(no_hit | error)* terms from each access evaluation macro. Recall as specified in Memory region descriptor hit determination, an *invalid* MRGD_Wm_n (MRGD_W3_n[VLD] = 0) forces the region_hit_n evaluation to be negated.

This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. If the access does not hit in *any* region descriptor, an access error is reported.
2. If the access hits in a single region descriptor and that region signals a domain violation, then an access error is reported.
3. If the access hits in multiple (overlapping) regions and one region signals a violation, then an access error is reported.

The third condition reflects that priority is given to access denying over access allowing for overlapping regions.

Unimplemented domain identifiers default to all-zero DxACP fields providing no access rights. Additionally, these fields are RAZ/WI.

### 9.5.6.3 MRC C code description

The functionality of the MRC evaluation is described in the C code of Listing 9-1 on page 308. This code begins with the description of the data structures corresponding to the MRC-associated registers (lines 1-12). Note the memory region descriptors are

described as a 3-dimensional unsigned 32-bit integer array indexed by the MRC instance number, the RGD number within the instance and then the word offset within the region descriptor.

The access evaluation consists of four basic functions: a check of the XRDC's global valid bit (lines 43-45), the address hit/miss determination (lines 73-78), the selection of the DxACP field and its evaluation (lines 80-96) and finally, the combination of all the individual MRGD_Wm_n hit and error indicators to determine the final state of the memory reference (lines 99-134).

**Listing 9-1. C code for MRGDn R,W,X Evaluation**

```

    }
    return(accError);
}
```

## 9.5.7 Peripheral Access Controller (XRDC_PAC)

The peripheral access controller performs an access control evaluation similar to that of the memory region controller (Memory Region Controller (XRDC_MRC), but using dedicated "memory region descriptors" with one unique PDAC_W[0-1]_n register per slave peripheral slot. The presence of a one and only one memory region descriptor per slave peripheral address space slot in the PAC simplifies the required functionality compared to the MRC.

The functionality of the PAC evaluation is described in the C code of Listing 9-2 on page 310. This code begins with the description of the data structures corresponding to the PAC-associated registers (lines 1-3). It then performs a check of the global valid bit (CR[GVLDP]) (lines 25-27), followed by the extraction of the peripheral slot number from the system address (line 32), then followed by the access of the selected PDAC_W[0-1]_n registers (lines 33-34). Next, a check of the optional inclusion of a hardware semaphore and its current state is performed (lines 37-46). Finally, if the access is still allowed, an evaluation of the appropriate DxACP permission field is made (line 48) as detailed in DxACP evaluation and the state of the peripheral access error control signal returned (line 52).

**Listing 9-2. PAC Evaluation C Code Description**

```

43                    (pac_ealo != 0)                        &&  // ealo != idle
44                    (pac_ealo != (did+1)))                 {   // ealo != did
45                   peripheral_access_error = 1;
46               } else {
47                   // perform the standard DxACP check
48                   peripheral_access_error = evaluate_DxACP(pdacw0, pdacw1, did,
\                                                   nonsecure, privileged, write);
```

```
49                  }
50              }
51                }
52                return peripheral_access_error;
53    }
```

## 9.6 Initialization information

Out of reset, CR[GVLDC, GVLDP, GVLDM] bits are cleared and XRDC disabled allowing secure privileged startup code to configure the entire programming model. The initialization process typically is performed in 3 steps:

1. Read the various hardware configuration registers (HWCFG{0-3}, MDACFGn, MRCFGn) to obtain the implemented hardware capabilities for the device.
2. Using the information retrieved in Step 1 coupled with the desired domain architecture, program all the register data structures for domain assignment (MDA_Wm_n), memory region descriptors (MRGD_Wm_n) and peripheral access control register (PDAC_Wm_n). There are individual valid bits included in all these registers which typically would be asserted. Additionally, there are also lock mechanisms available if register settings need to be configured and marked as read-only.
3. Once the XRDC programming model is loaded, the CR is written with GVLD {C, P, M} asserted. At that point, the XRDC is fully operational.

## 9.7 Application information

As described in Introduction, the XRDC architecture is intended to provide a broad, highly-capable framework for access control, system memory protection and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the core platform, highly configurable via hardware design parameters and software programmability. The considerable number of hardware design parameters allows the XRDC architecture to be a very scalable solution, able to service a wide spectrum of SoC devices from ultra-low end MCUs to multi-core high performance embedded microprocessors.

### 9.7.1 Master domain assignments

The typical use case related to master domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus master devices like DMA, etc. The definition of a domain may be static, based simply on the combination of a processor and other optional bus masters. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains. The maximum number of possible CPU domain definitions is limited by MDACFGn value. In particular, the optional inclusion of PID value(s) to be used to create multiple classes of CPU with different domain values.

For example, "critical" tasks, whether safety-critical, performance-critical, etc. can be grouped together in one domain and all other tasks into a second domain. Non-processor bus masters typically have a single MDA_Wm_n configuration register associated with them. The domainID and {nonsecure, privileged} attributes are usually statically assigned, unless the module can "inherit" attributes from a processor programming it (like certain modules like DMAs).

The MDA_Wm_n registers, along with the memory region descriptors and the peripheral domain access control registers all have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

### 9.7.2 Memory region descriptor management

There are two important concepts to consider in managing the memory region descriptors.

First, recall that the association between each MRCn instance and the slave memory regions it monitors is SoC-dependent. The device-specific configuration specifies the number of implemented memory region descriptors in a given instance and the specific port numbers associated with the slave memories being monitored.

Second, as detailed in Memory region DxACP evaluation, recall that, once the XRDC is enabled, *every memory reference must hit in one or more regions*, else an access violation is reported. These are also two other conditions were access errors are reported:

1. If the access hits in a single region descriptor and that region signals a domain violation, then an access error is reported.
2. If the access hits in multiple (overlapping) regions and *all* regions signal violations, then an access error is reported.

### 9.7.3 Domain error capture management

Recall when a domain access violation is detected by either a memory region controller or a peripheral access controller, address and attribute information of the offending access is captured. The DERRLOCn read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_n and DERR_W1_n, the DERRLOCn registers provide the instance number details.

These registers are organized as a word array, *indexed by the faulting domain number*, with the contents of each register providing a bitmap signaling the instance number(s) associated with all submodules containing captured error information for that domain.

It is recommended that the exception handler begin by reading the HWCFG1 register to determine its domainID. Next, it uses the just-retrieved domainID to index into the DERRLOCn array. The resulting DERRLOCn value is then examined to determine the instance number of the reporting MRC and/or PAC submodule.

There may be multiple access violations, across multiple instances, pending for a given domain. It is suggested that exception handler use a "find first one" instruction (alternatively known as "count leading zeroes") to quickly and efficiently find the instance number containing access violation details. Once the instance number has been determined, the captured error address (DERR_W0_n) and attribute information (DERR_W1_n) can easily be retrieved from the domain error registers. The 2-bit DERR_W1_n[EST] field provides information signaling whether one or more errors have been detected by the submodule instance. A special write to DERR_W3_n is required to reset (and rearm) the EST error capture state machine.

This process is repeated until all errors associated with a given domainID have been processed.

A graphical representation of this 2-step retrieval of the domain error address and attributes is shown in Figure 9-3.

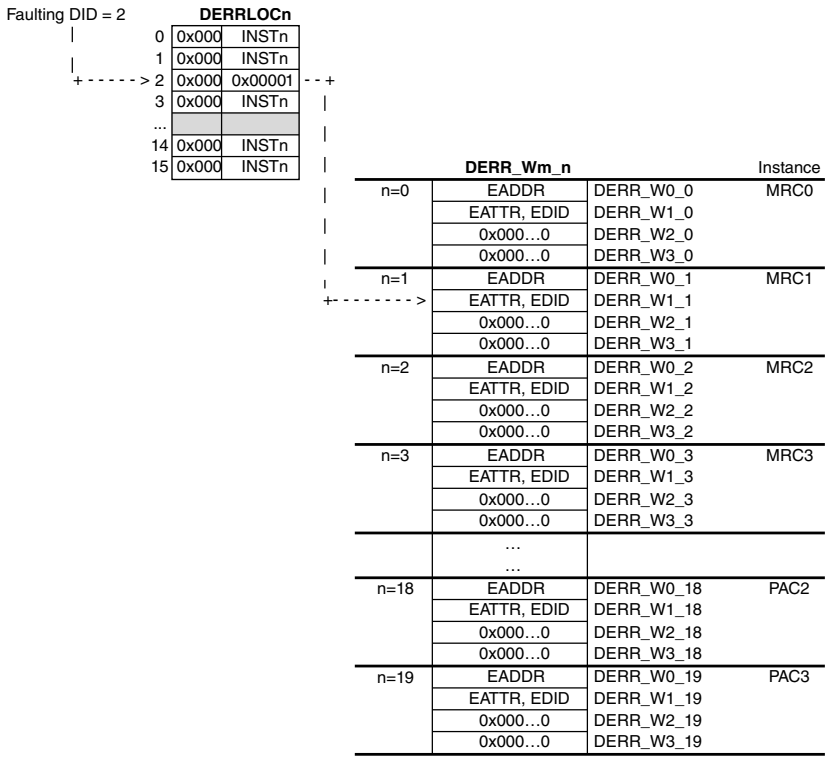

**Figure 9-3. Two-step retrieval of domain error address and attributes**

# Chapter 10
# Semaphores2 (SEMA42)

## 10.1 Introduction

The SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

### 10.1.1 Multi-core programming 101: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism that is then used by system software to control access to shared data structures, shared hardware resources, and so on. These gating mechanisms are used by the software to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and processors.

Consider the following description of a typical use-case. Processor X enters a section of code where shared data values are to be updated. It must first acquire a semaphore; this can be considered to be locking (or closing) a software gate. Once the gate has been locked, a properly architected software system does not allow other processes (or processors) to execute the same code segment or modify the shared data structure protected by the gate; in other words, other processes/processors are locked out. Many software implementations include a *spin-wait loop* within the lock function until the locking of the gate is accomplished. Once the lock has been obtained, processor X continues execution and updates the data values protected by the particular lock. Once the updates are complete, processor X unlocks (or opens) the software gate, allowing other processes/processors access to the updated data values.

There are three important rules that must be followed for a correctly implemented system solution:

1. All writes to shared data values or shared hardware resources must be protected by a gate variable.
2. Once a processor locks a gate, accesses to the shared data or resources by other processes/processors must be blocked. This is enforced by software conventions.
3. The processor that locks a particular gate is the only processor that can open (unlock) that gate.

Information in the hardware gate identifying the locking processor can be extremely useful for system-level debugging.

The Hennessy/Patterson text on computer architecture offers the following description of software gating.

"One of the major requirements of a shared-memory architecture multiprocessor is being able to coordinate processes that are working on a common task. Typically, a programmer will use *lock variables* to synchronize the processes.

The difficulty for the architect of a multiprocessor is to provide a mechanism to decide which processor gets the lock and to provide the operation that locks a variable. Arbitration is easy for shared-bus multiprocessors, since the bus is the only path to memory. The processor that gets the bus locks out all the other processors from memory. If the CPU and bus provide an atomic swap operation, programmers can create locks with the proper semantics. The adjective *atomic* is key, for it means that a processor can both read a location **and** set it to the locked value in the same bus operation, preventing any other processor from reading or writing memory." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*]

The classic text continues with a description of the steps required to lock/unlock a variable using an *atomic swap instruction*.

"Assume that 0 means unlocked and 1 means locked. A processor first reads the lock variable to test its state. A processor keeps reading and testing until the value indicates that the lock is unlocked. The processor then races against all other processes that were similarly "spin waiting" to see who can lock the variable first. All processes use a swap instruction that reads the old value and stores a 1 into the lock variable. The single winner will see the 0, and the losers will see a 1 that was placed there by the winner. (The losers will continue to set the variable to the locked value, but this does not matter.) The winning processor executes the code after the lock and then stores a 0 into the lock when

it exits, starting the race all over again. Testing the old value and then setting to a new value is why the atomic swap instruction is called *test and set* in some instruction sets." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*]

Next, consider the features, programming model, and functional operation of the hardware semaphore module.

## 10.1.2 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Supports 16 hardware-enforced gates in a multi-processor configuration, where up to 15 processors can be supported; cp*X* is meant to represent core processor *X*
  - Gates appear as an 16-entry byte-size array with read and write accesses.
    - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful.
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
    - The number of implemented gates is specified by a hardware configuration define.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      if gate = 0x0, then state = unlocked
      if gate = 0x1, then state = locked by processor (master) 0
      if gate = 0x2, then state = locked by processor (master) 1
      …
      if gate = 0xF, then state = locked by processor (master) 14
    - Uses the logical bus master number as a reference attribute plus the specified data patterns to validate all write operations.
    - Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.
  - Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.
- Memory-mapped IPS slave peripheral platform module

- Interface to the IPS bus for programming-model accesses

A simplified block diagram of the Semaphores module is shown in the following figure. In the diagram, the register blocks named gate0, gate1,…, gate (n-2), gate (n-1) include the finite state machines implementing the semaphore gates.

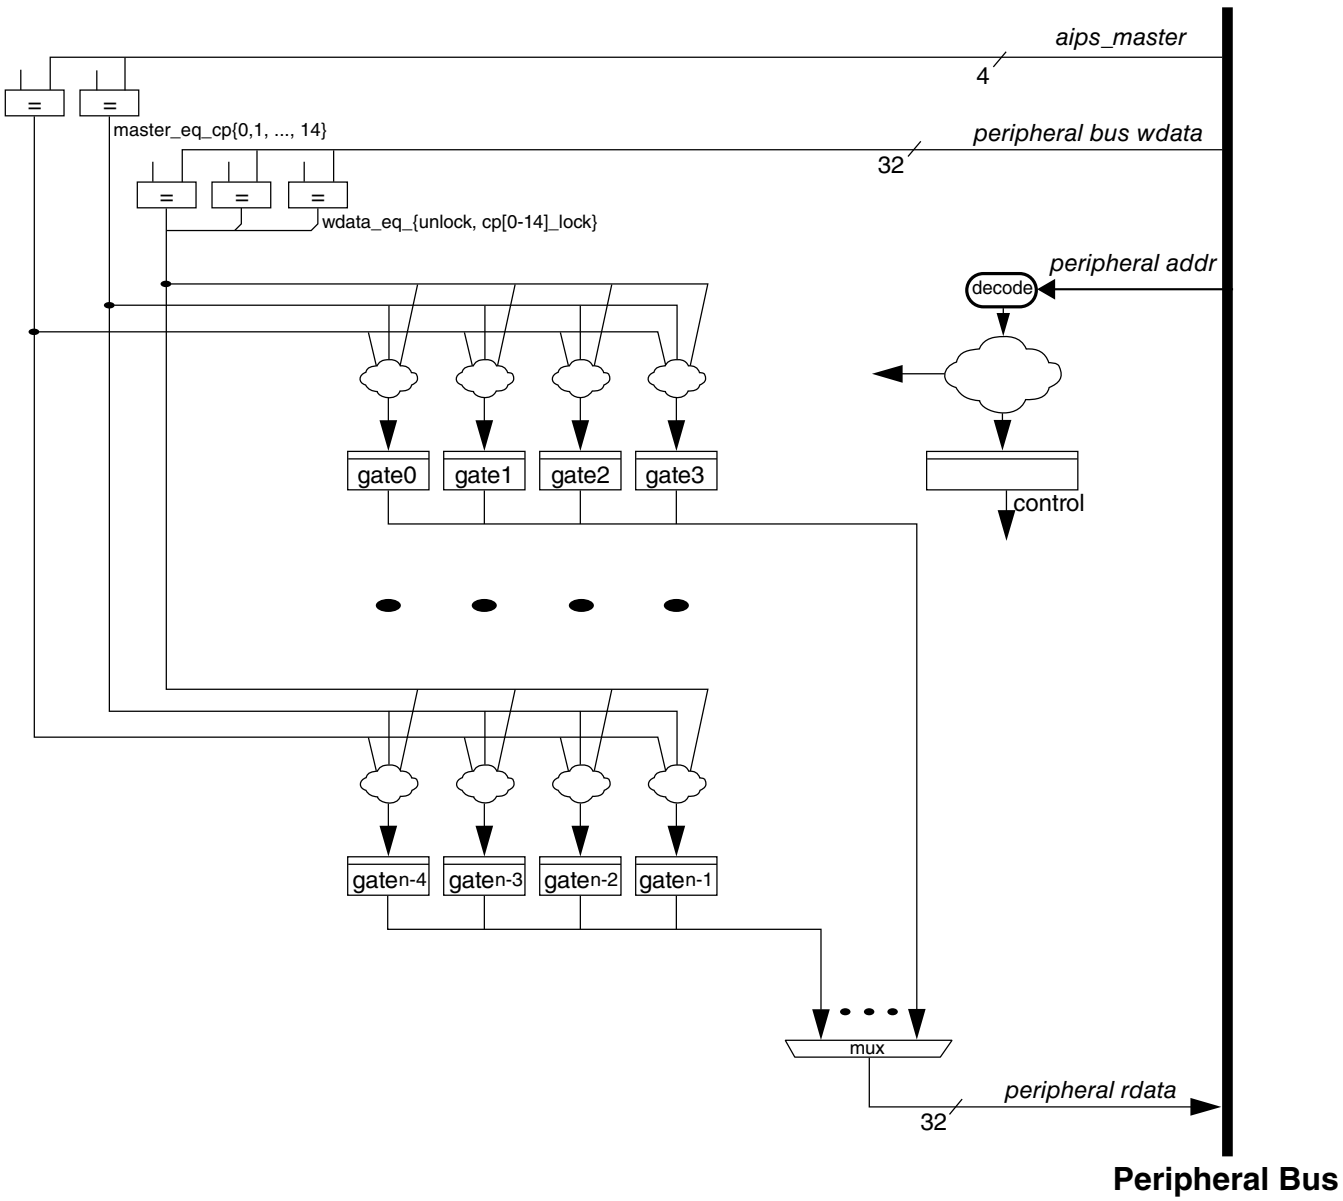

**Figure 10-1. Semaphores2 block diagram**

## 10.2 Memory map/register definition

Only Supervisor Mode accesses are allowed on these registers. User accesses will be terminated with an error.

## 10.2.1 SEMA420 register descriptions

| GATE8 | Bh |
| GATE15 | Ch |
| GATE14 | Dh |
| GATE13 | Eh |
| GATE12 | Fh |

#### 10.2.1.2.2 Function

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value (0x00) nor the appropriate lock value (processor_number + 1) are simply treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

#### 10.2.1.3.2 Function

**NOTE**

This section and the following section, Reset Gate Write (RSTGT_W), describe the same register. This section describes the general operation of the register and also shows how the register fields appear when the register is read. Reset Gate Write (RSTGT_W) shows how the register fields appear when the register is written.

Although the intent of the hardware gate implementation specifies a protocol where the locking domain must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same domain to force the clearing of the specified gate(s). The required access pattern is:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT[RSTGDP]) must be E2h; the least significant byte is a "don't_care" for this reference.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, the special gate reset sequence is aborted and no error signal is asserted.
3. Reads of the RSTGT location return information on the 2-bit state machine (RSTGT[RSTGSM]) that implements this function, the domain performing the reset (RSTGT[RSTGMS]), and the gate number(s) last cleared (RSTGT[RSTGTN]). Reads of the RSTGT register do not affect the secure reset finite state machine in any manner.

### 10.2.1.3.3 Diagram

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | ROZ | | RSTGSM | | RSTGMS | | | | RSTGTN | | | | | | | |
| W | | | | | | | | | | | | | | | | |

### 10.2.1.3.4 Fields

| Field | Function |
|---|---|
| 15-14<br>ROZ | ROZ<br>This field always returns the value 0 when read. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 13-12<br>RSTGSM | RSTGSM<br>Reset Gate Finite State Machine. Reads of the RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as:<br>00b - Idle, waiting for the first data pattern write.<br>01b - Waiting for the second data pattern write.<br>10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The "01" state persists for only one clock cycle. Software cannot observe this state.<br>11b - This state encoding is never used and therefore reserved. |
| 11-8<br>RSTGMS | RSTGMS<br>Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs.<br>The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information. |
| 7-0<br>RSTGTN | RSTGTN<br>Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write.<br>If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates. |

## 10.2.1.4 Reset Gate Write (RSTGT_W)

### 10.2.1.4.1 Offset

| Register | Offset |
|---|---|
| RSTGT_W | 42h |

### 10.2.1.4.2 Function

This section describes how the Reset Gate register fields appear when the register is written. See Reset Gate Read (RSTGT_R) for the description of the register's overall operation and how the register fields appear when the register is read.

#### 10.2.1.4.3 Diagram

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

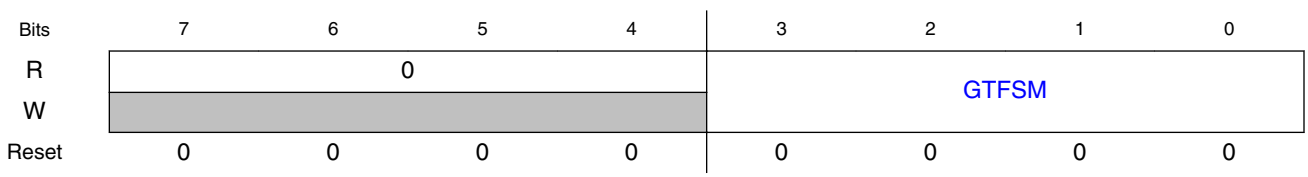
| GATE10 | 9h |
| GATE9 | Ah |
| GATE8 | Bh |
| GATE15 | Ch |
| GATE14 | Dh |
| GATE13 | Eh |
| GATE12 | Fh |

#### 10.2.2.2.2 Function

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value (0x00) nor the appropriate lock value (processor_number + 1) are simply treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

#### 10.2.2.2.3 Diagram



#### 10.2.2.2.4 Fields

### 10.2.2.3 Reset Gate Read (RSTGT_R)

#### 10.2.2.3.1 Offset

| Register | Offset |
|---|---|
| RSTGT_R | 42h |

#### 10.2.2.3.2 Function

**NOTE**

This section and the following section, Reset Gate Write (RSTGT_W), describe the same register. This section describes the general operation of the register and also shows how the register fields appear when the register is read. Reset Gate Write (RSTGT_W) shows how the register fields appear when the register is written.

Although the intent of the hardware gate implementation specifies a protocol where the locking domain must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same domain to force the clearing of the specified gate(s). The required access pattern is:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT[RSTGDP]) must be E2h; the least significant byte is a "don't_care" for this reference.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT[RSTGTN]) specifies the gate(s) to be

reset. This gate field can specify a single gate be cleared, or that all gates are to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, the special gate reset sequence is aborted and no error signal is asserted.

3. Reads of the RSTGT location return information on the 2-bit state machine (RSTGT[RSTGSM]) that implements this function, the domain performing the reset (RSTGT[RSTGMS]), and the gate number(s) last cleared (RSTGT[RSTGTN]). Reads of the RSTGT register do not affect the secure reset finite state machine in any manner.

### 10.2.2.3.3 Diagram

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 15-8<br>RSTGDP | RSTGDP<br>Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = E2h while the second write requires RSTGDP = 1Dh. |
| 7-0<br>RSTGTN | RSTGTN<br>Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write.<br>If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates. |

## 10.3 Functional description

Functional operation of the Semaphores module and specific details of the state machines of the SEMA42_GATEn registers are provided as follows.

As described previously, each of the SEMA42_GATEn registers implements a 4-bit, 16-state machine. A *simplified* diagram of the state transitions for each gate is shown in Figure 10-2.

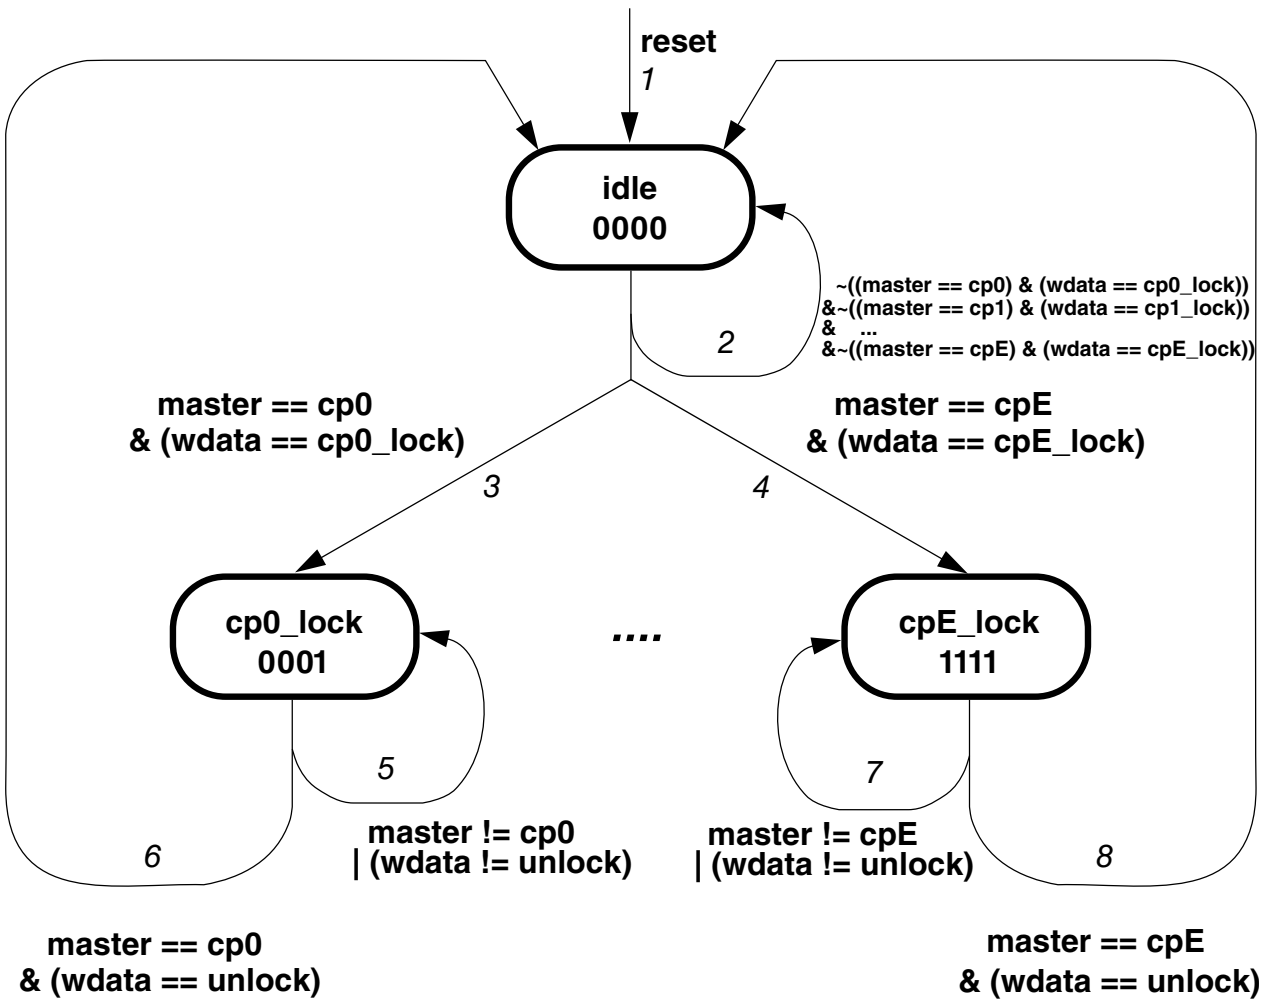

**Figure 10-2. SEMA42_GATEn state machine**

The bus master number is used to identify core processor *X* (cp*X*) where the notation cpE is used to represent core processor 14 (= 0xE). The platform passes the AHB bus master number through the peripheral bridge controller and drives a signal to the Semaphores module.

The state transitions for SEMA42_GATEn are defined in Table 10-1.

**Table 10-1. SEMA42_GATEn state transitions**

| Current State | Next State | Transition | Description |
|---|---|---|---|
| – | idle | 1 | Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state. |
| idle | idle | 2 | Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state. |
| idle | cp0_lock | 3 | When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state. |
| idle | cpE_lock | 4 | When a write of the "cpE_lock" value is initiated by processor 0xE, the gate transitions into the cpE_lock state. |
| cp0_lock | cp0_lock | 5 | Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value. |
| cp0_lock | idle | 6 | The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs. |
| cpE_lock | cpE_lock | 7 | Once in this state, the gate remains here if any attempted write is not from cpE with the unlock data value. |
| cpE_lock | idle | 8 | The gate returns to the idle (unlocked) state once a write from cpE with the unlock data value occurs. |

The following gate data values are used:

- The lock data value is (processor number + 1) where the processor number and the platform bus master number are the same.
- The unlock data value is 0x00.

# Chapter 11
# Memory-Mapped Divide and Square Root (MMDVSQ)

## 11.1 Introduction

ARM processor cores in the Cortex-M family implementing the ARMv6-M instruction set architecture do not include hardware support for integer divide operations. The affected processors include the Cortex-M0+ core. However, in certain deeply embedded application spaces, hardware support for this class of arithmetic operation (along with an unsigned square root function) is important to maximize system performance and minimize device power dissipation. Accordingly, the MMDVSQ module is included in select microcontrollers, to serve as a memory-mapped co-processor located in a special address space (within the system memory map) that is accessible only to the processor core.

The MMDVSQ module supports execution of the integer divide operations defined in the ARMv7-M instruction set architecture, plus an unsigned integer square root operation. The supported integer divide operations include 32/32 signed (SDIV) and unsigned (UDIV) calculations.

### 11.1.1 Features

The key features of the MMDVSQ include:

- Lightweight implementation of 32-bit integer divide and square root arithmetic operations
  - Supports 32/32 signed and unsigned divide (or remainder) calculations
  - Supports 32-bit unsigned square root calculations
- Simple programming model includes input data and result registers plus a control/status register
- Programming model interface optimized for activation from inline code or software library call

- "Fast Start" configuration minimizes the memory-mapped register write overhead
- Supports two methods to determine when result is valid, including software polling
- Configurable divide-by-zero response

• Pipelined design processes 2 bits per cycle with early termination exit for minimum execution time

## 11.1.2 Block diagram

A generic block diagram of the processor core and platform for this class of ultra low-end microcontrollers is shown in Figure 11-1. The MMDVSQ module's location as a memory-mapped co-processor is highlighted.

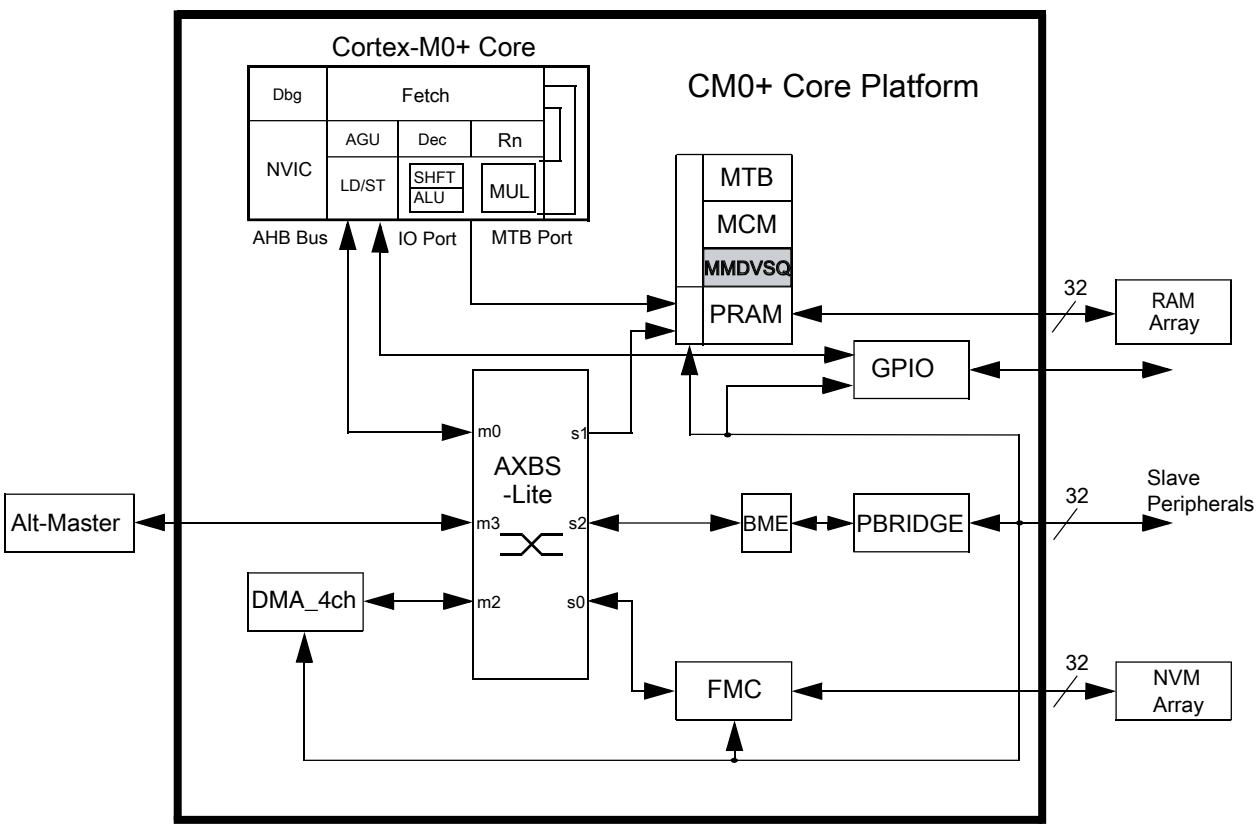

**Figure 11-1. Generic Cortex-M0+ Core Platform Block Diagram**

Next, a block diagram of the internal structure of the MMDVSQ module is presented. See Figure 11-2.

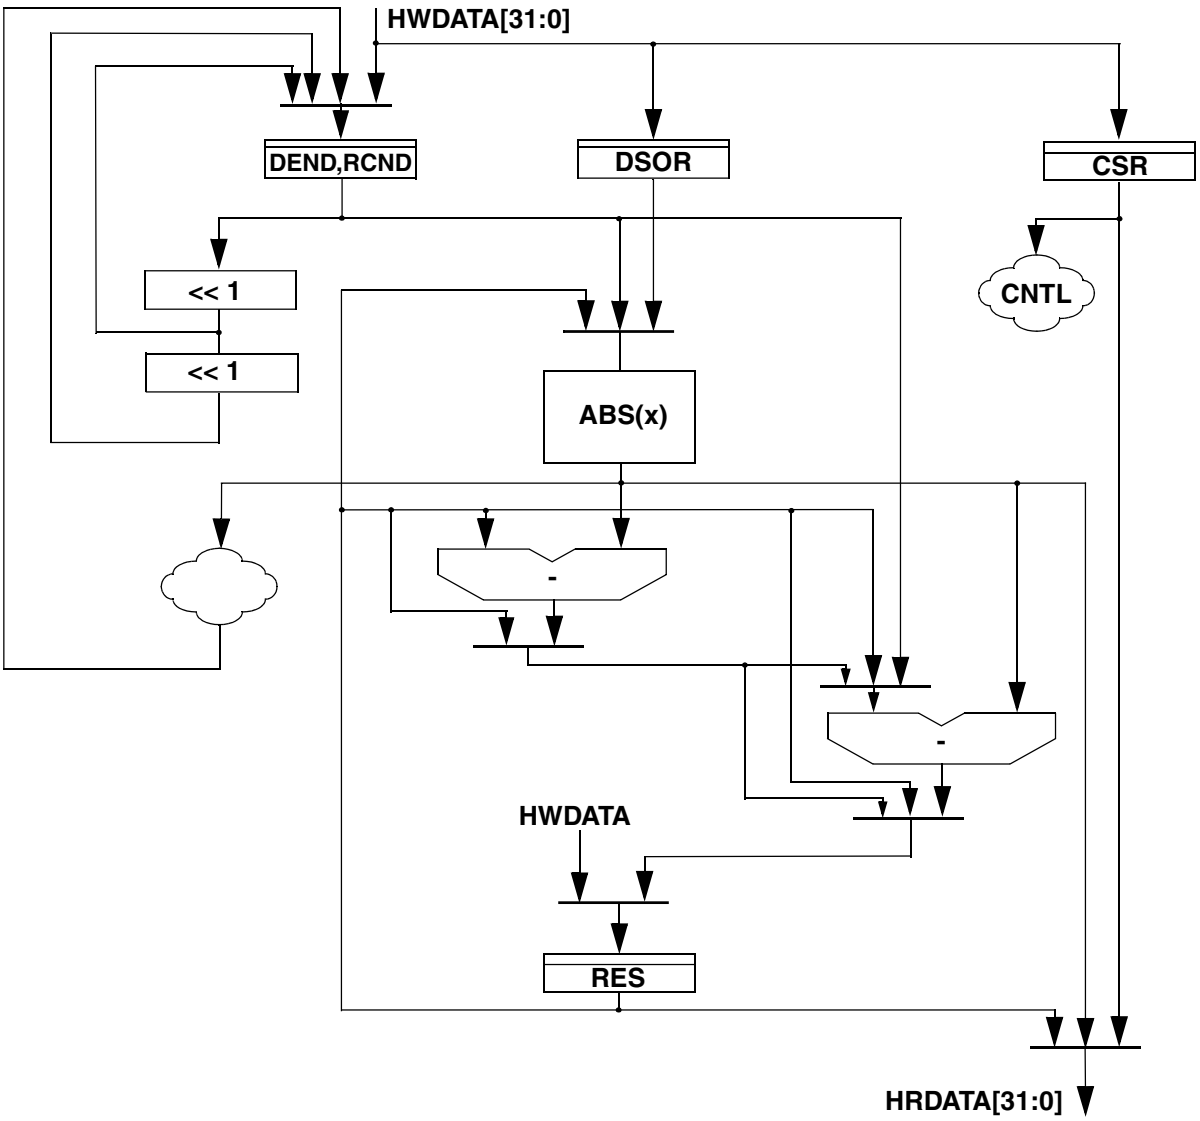

**Figure 11-2. MMDVSQ Block Diagram**

## 11.1.3 Modes of operation

The MMDVSQ module does not support any special modes of operation. As a memory-mapped device located on a crossbar slave AHB system bus port, MMDVSQ responds based strictly on memory addresses to its programming model.

All functionality associated with the MMDVSQ module resides in the core platform's clock domain; this includes its connections with the crossbar slave port. To minimize power dissipation, the design supports an architectural clock gate for the entire module, that is, the MMDVSQ is only clocked when responding to bus requests to its programming model or is busy performing a calculation.

## 11.2 External signal description

The MMDVSQ module does not directly support any external interfaces.

The internal interface includes a standard 32-bit AHB bus as shown in Figure 11-1.

## 11.3 Memory map and register definition

The MMDVSQ module supports a small number of program-visible registers used for passing input operands and retrieving the output result plus a configuration/status register.

The programming model occupies the first 20 bytes of a standard 4 Kb address slot. It can only be accessed via word-sized (32 bit) accesses. Attempted accesses using smaller data sizes, reading the write-only location or to reserved space are terminated with an error.

At any instant in time, the MMDVSQ can perform either a divide or square root calculation. The basic integer operations supported by the MMDVSQ are:

For divide:

```
MMDVSQ_RES = quotient  (MMDVSQ_DEND / MMDVSQ_DSOR)

MMDVSQ_RES = remainder (MMDVSQ_DEND % MMDVSQ_DSOR)
```

For square root:

```
MMDVSQ_RES = integer   (√MMDVSQ_RCND)
```

The register usage, based on the operation (divide, square root), is detailed in Table 11-1.

**Table 11-1. Register Usage = f(Divide, Square Root)**

| Register | Divide | Square Root | Description |
|---|---|---|---|
| Dividend (MMDVSQ_DEND) | Yes | No | Input dividend (numerator) for the divide |
| Divisor (MMDVSQ_DSOR) | Yes | No | Input divisor (denominator) for the divide |
| Control/Status (MMDVSQ_CSR) | Yes | Yes | Control for divide, status for divide and square root |
| Result (MMDVSQ_RES) | Yes | Yes | Output result |
| Radicand (MMDVSQ_RCND) | No | Yes | Input "square" data |

## 11.3.1 MMDVSQ register descriptions

### 11.3.1.1 MMDVSQ Memory map

MMDVSQ1 base address: F000_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Dividend Register (DEND) | 32 | RW | See description. |
| 4h | Divisor Register (DSOR) | 32 | RW | See description. |
| 8h | Control/Status Register (CSR) | 32 | RW | See description. |
| Ch | Result Register (RES) | 32 | RW | See description. |
| 10h | Radicand Register (RCND) | 32 | WO | See description. |

### 11.3.1.2 Dividend Register (DEND)

#### 11.3.1.2.1 Offset

| Register | Offset |
|---|---|
| DEND | 0h |

#### 11.3.1.2.2 Function

This register is loaded with the input dividend operand before a divide operation is initiated. The register is updated by the MMDVSQ hardware during the execution of a divide or square root calculation. Any memory access (read or write) of the DEND register while the module is busy during a calculation causes the access to be stalled (using wait states) until the calculation completes.

#### 11.3.1.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | DIVIDEND | | | | | | | | | | | | | | | |

| Field | Function |
|---|---|
| 31-0<br>DIVIDEND | Dividend<br>This is the input dividend operand for divide calculations. |

### 11.3.1.3 Divisor Register (DSOR)

#### 11.3.1.3.1 Offset

| Register | Offset |
|---|---|
| DSOR | 4h |

#### 11.3.1.3.2 Function

This register is loaded with the input divisor operand before a divide operation is initiated. If CSR[DFS] = 0, a write to this register inititates a divide operation. Any memory access (read or write) of the DSOR register while the module is busy during a calculation causes the access to be stalled (using wait states) until the calculation completes. If a divide operation is inititated with DSOR = 0, the hardware signals a divide-by-zero condition and sets RES = 0 and CSR[DZ] = 1. If CSR[DZE] = 1, an attempted read of the RES result is error terminated.

#### 11.3.1.3.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 11.3.1.3.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DIVISOR | Divisor<br>This is the input divisor operand for divide calculations. |

### 11.3.1.4 Control/Status Register (CSR)

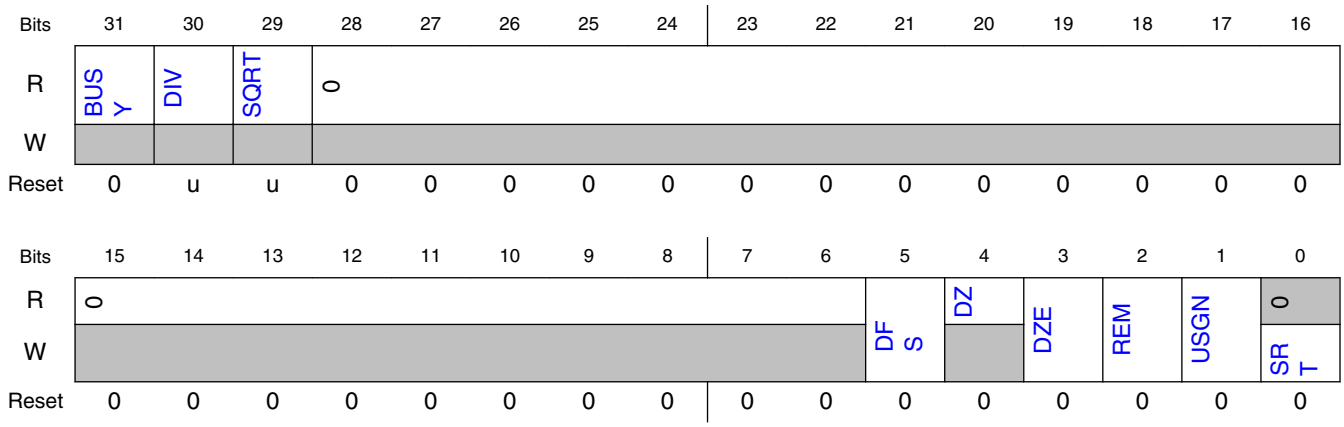
#### 11.3.1.4.1 Offset

| Register | Offset |
|---|---|
| CSR | 8h |

#### 11.3.1.4.2 Function

This register defines the operating configuration of divide operations and provides status information. The upper 3 bits provide busy status indicators, while the low-order byte defines the configuration for divide operations. The read-only status bits in CSR[31:29] are valid for both divide and square root operations; the configuration and status bit in CSR[5:0] are only valid for divides. A memory write access of the CSR register while the module is busy during a calculation causes the access to be stalled (using wait states) until the calculation completes.

### 11.3.1.4.3 Diagram



### 11.3.1.4.4 Fields

| Field | Function |
|---|---|
| 31<br>BUSY | BUSY<br>This read-only bit is asserted when the MMDVSQ is performing a divide or square root. When an operation is initiated, the hardware sets this flag. It remains asserted until the operation completes and the hardware automatically clears the indicator. This bit can be used to poll the DVSQ's execution status. The combined CSR[BUSY, DIV, SQRT] indicators provide an encoded module status:<br>• If 0b001, then MMDVSQ is idle and the last calculation was a square root<br>• If 0b010, then MMDVSQ is idle and the last calculation was a divide<br>• If 0b101, then MMDVSQ is busy processing a square root calculation<br>• If 0b110, then MMDVSQ is busy processing a divide calculation<br><br>The remaining encodings of CSR[BUSY, DIV, SQRT] are reserved.<br>0b - MMDVSQ is idle<br>1b - MMDVSQ is busy performing a divide or square root calculation |
| 30<br>DIV | DIVIDE<br>Current or last operation was a divide. This read-only indicator bit signals if the current or last operation performed by the MMDVSQ was a divide.<br>0b - Current or last MMDVSQ operation was not a divide<br>1b - Current or last MMDVSQ operation was a divide |
| 29<br>SQRT | SQUARE ROOT<br>Current or last operation was a square root. This read-only indicator bit signals if the current or last operation performed by the MMDVSQ was a square root.<br>0b - Current or last MMDVSQ operation was not a square root<br>1b - Current or last MMDVSQ operation was a square root |
| 28-6<br>— | Reserved |
| 5<br>DFS | Disable Fast Start<br>The MMDVSQ supports 2 mechanisms for initiating a divide operation. The default mechanism is a "fast start" where a write to the DSOR register begins the divide. Alternatively, the start mechanism can begin after a write to the CSR register with CSR[SRT] set. The CSR[DFS] indicator selects the divide start mechanism. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 0b - A divide operation is initiated by a write to the DSOR register<br>1b - A divide operation is initiated by a write to the CSR register with CSR[SRT] = 1 |
| 4<br>DZ | Divide-by-Zero<br>This read-only status indicator signals the last divide operation had a zero divisor, that is, DSOR = 0x0000_0000. For this case, RES is set to 0x0000_0000 and this indicator bit set. After a divide-by-zero operation, a read of the RES register returns either the zero result, or, if CSR[DZE] = 1, terminates the read with an error. The CSR[DZ] indicator is cleared by the hardware at the beginning of each operation.<br>0b - The last divide operation had a non-zero divisor, that is, DSOR != 0<br>1b - The last divide operation had a zero divisor, that is, DSOR = 0 |
| 3<br>DZE | Divide-by-Zero-Enable<br>This indicator configures the MMDVSQ's response to divide-by-zero calculations. If both CSR[DZ] and CSR[DZE] are set, then a subsequent read of the RES register is error terminated to signal the processor of the attempted divide-by-zero.<br>0b - Reads of the RES register return the register contents<br>1b - If CSR[DZ] = 1, an attempted read of RES register is error terminated to signal a divide-by-zero, else the register contents are returned |
| 2<br>REM | REMainder calculation<br>This indicator selects whether the quotient or the remainder is returned in the RES register. The combined CSR[REM] and CSR[USGN] bits define four possible divide operations:<br>• If CSR[REM, USGN] = 0b00, perform a signed divide, returning the quotient<br>• If CSR[REM, USGN] = 0b01, perform an unsigned divide, returning the quotient<br>• If CSR[REM, USGN] = 0b10, perform a signed divide, returning the remainder<br>• If CSR[REM, USGN] = 0b11, perform an unsigned divide, returning the remainder<br><br>0b - Return the quotient in the RES for the divide calculation<br>1b - Return the remainder in the RES for the divide calculation |
| 1<br>USGN | Unsigned calculation<br>This indicator selects whether a signed (default) or unsigned divide is performed. See the CSR[REM] description for the encoding of the four possible divide operations.<br>0b - Perform a signed divide<br>1b - Perform an unsigned divide |
| 0<br>SRT | Start<br>When written with a logical one and CSR[DFS] = 1, this flag initiates a divide operation. If written as a logical one with CSR[DFS] = 0, it is ignored. This bit always reads as a zero. The state of the register write data defines this bit's function.<br>0b - No operation initiated<br>1b - If CSR[DFS] = 1, then initiate a divide calculation, else ignore |

## 11.3.1.5 Result Register (RES)

### 11.3.1.5.1 Offset

| Register | Offset |
|---|---|
| RES | Ch |

#### 11.3.1.5.2 Function

This register is loaded with the result of the divide or square root calculation. It is updated by the MMDVSQ hardware at the completion of the calculation. When a square root operation is performed (on an unsigned 32-bit number), the result is limited to a 16-bit value with RES[31:16] = 0x0000. Any memory access (read or write) of the RES register while the module is busy during a calculation causes the access to be stalled (using wait states) until the calculation completes and the new result written into the register.

#### 11.3.1.5.3 Diagram

### 11.3.1.6 Radicand Register (RCND)

#### 11.3.1.6.1 Offset

| Register | Offset |
|---|---|
| RCND | 10h |

#### 11.3.1.6.2 Function

The write-only radicand register is loaded with the input "square" number. A memory write to the radicand register initiates a square root calculation. While the MMDVSQ module is busy performing a square root calculation, any memory write access to the RCND register causes the write access to be stalled (using wait states) until the square root calculation finishes. Any attempted read of the radicand register terminates with an error.

## 11.4 Functional description

This section details the algorithms, execution times of the MMDVSQ, and the software interface to the module.

### 11.4.1 Algorithms

This section provides more details on the integer divide and square root algorithms.

## 11.4.1.1 Integer divide including special cases

### 11.4.1.1.1 Overview

The MMDVSQ module implements a "shift, test, and restore" radix-2 algorithm for unsigned integer divide operations. When performing a signed divide calculation, negative input operands are converted into 2's complement positive numbers first, an unsigned divide performed, and the sign of the results based on the input operand signs, namely:

- The sign of the remainder is the same as the sign of the dividend
- The quotient is negated if the signs of the dividend and divisor are different

The hardware implementation processes two bits per machine cycle and includes "early termination" logic where the execution time is data dependent, based on the magnitude of the positive dividend. See Table 11-4 for more execution time details.

### 11.4.1.1.2 Special case: Overflow

There is a single "special overflow case" affecting signed integer divides. If the dividend = 0x8000_0000 and the divisor = 0xFFFF_FFFF, the result of this ($-2^{31}/-1$) operation cannot be expressed as a 32-bit 2's complement number. For this case, the MMDVSQ exactly follows the ARM Cortex-Mx definition and returns 0x8000_0000 (the lower 32 bits of the $+2^{31}$ result) as the quotient with no indication of the overflow condition. If the remainder is selected as the output of this calculation, it returns 0x0000_0000.

### 11.4.1.1.3 Special case: Divide-by-Zero

For both signed and unsigned divides, if the divisor is zero, the MMDVSQ hardware detects this condition and the CSR[DZ] indicator set. The quotient result is forced to 0x0000_0000. If the remainder is selected as the output of this calculation, it also returns 0x0000_0000. Additionally, if CSR[DZE] = 1, then an attempted read of the Result register (RES) is error terminated to provide a simple mechanism to signal software of the divide-by-zero condition.

### 11.4.1.2 Integer square root

#### 11.4.1.2.1 Overview

The unsigned square root algorithm begins by creating a 32-bit "one-hot" bit vector signaling the highest power of four of the contents of the Radicand register (RCND). It then iterates through an algorithm involving magnitude comparisons of the RCND register versus the working result plus bit vector summation, conditional decrementing of the radicand, a 1-bit right shift of the result, and a 2-bit right shift of the one-hot bit vector.

Processing two bits of the radicand per cycle, the result register finishes with the integer portion of the square root calculation. The module includes early termination logic so that the execution time is data dependent, based on the magnitude of the input radicand. See Table 11-5 for more execution time details. Since both algorithms share common hardware structures, the incremental cost of the square root logic is an extremely small delta to the basic divide hardware.

The square root algorithm was exhaustively compared (that is, all $2^{32}$ possible input values) against the standard GNU C library implementation, which converts the unsigned integer input into a double-precision floating-point number, calculates the double-precision square root and then converts it back into an unsigned integer. Each input value calculated identical square root results.

#### 11.4.1.2.2 Square root using Q notation

Consider the use of Q notation for square root calculations returning fractional values. The following description is taken from http://en.wikipedia.org/wiki/Q_(number_format).

*Q is a fixed point number format where the number of fractional bits (and optionally the number of integer bits) is specified. For example, a Q15 number has 15 fractional bits; a Q1.14 number has 1 integer bit and 14 fractional bits. Q format is often used in hardware that does not have a floating-point unit and in applications that require constant resolution.*

*Q format numbers are (notionally) fixed point numbers (but not actually a number itself); that is, they are stored and operated upon as regular binary numbers (i.e. signed integers), thus allowing standard integer hardware/ALU to perform rational number calculations. The number of integer bits, fractional bits and the underlying word size are to be chosen by the programmer on an application-specific basis - the programmer's choices of the foregoing will depend on the range and resolution needed for the numbers. The machine itself remains oblivious to the notional fixed point representation being*

*employed - it merely performs integer arithmetic the way it knows how. Ensuring that the computational results are valid in the Q format representation is the responsibility of the programmer.*

*The Q notation is written as Qm.n, where:*

- *Q designates that the number is in the Q format notation - the Texas Instruments representation for signed fixed-point numbers (the "Q" being reminiscent of the standard symbol for the set of rational numbers).*
- *m is the number of bits set aside to designate the two's complement integer portion of the number, exclusive of the sign bit (therefore if m is not specified it is taken as zero).*
- *n is the number of bits used to designate the fractional portion of the number, i.e. the number of bits to the right of the binary point. (If n = 0, the Q numbers are integers - the degenerate case).*

*Note that the most significant bit is always designated as the sign bit (the number is stored as a two's complement number) in order to allow standard arithmetic-logic hardware to manipulate Q numbers. Representing a signed fixed-point data type in Q format therefore always requires m+n+1 bits to account for the sign bit. Hence the smallest machine word size required to accommodate a Qm.n number is m+n+1, with the Q number left justified in the machine word.*

*For a given Qm.n format, using an m+n+1 bit signed integer container with n fractional bits:*

- *its range is $[-2^m, 2^m - 2^{-n}]$*
- *its resolution is $2^{-n}$*

For the unsigned integer format used in the MMDVSQ's square root calculation, an u(nsigned)Qm.n notation requires m+n bits (m+n = 32) for the input radicand. An uQm.n format produces an uQ(m/2).(n/2) square root. As examples, consider the following tables involving the square root of 2 and square root of "pi" calculations. As expected, as the number of fractional bits (n) increases, the error between the calculated square root and the "actual" result decreases.

**Table 11-2. Square Root of 2 Calculations (√2 = 1.4142135623)**

| RCND [Hex] | RCND Q format | Results [Hex] | RES Q Format | Decimal | % Error |
|---|---|---|---|---|---|
| 0x0000_0002 | uQ32.00 | 0x0000_0001 | uQ16.00 | 1.0 | -29.289% |
| 0x0002_0000 | uQ16.16 | 0x0000_016A | uQ08.08 | 1.4140625 | -0.011% |
| 0x0200_0000 | uQ08.24 | 0x0000_16A0 | uQ04.12 | 1.4140625 | -0.011% |
| 0x2000_0000 | uQ04.28 | 0x0000_5A82 | uQ02.14 | 1.4141845703 | -0.002% |
| 0x8000_0000 | uQ02.30 | 0x0000_B504 | uQ01.15 | 1.4141845703 | -0.002% |

**Table 11-3. Square Root of Pi Calculations (√Pi = 1.7724538509)**

| RCND [Hex] | RCND Q format | Results [Hex] | RES Q Format | Decimal | % Error |
|---|---|---|---|---|---|
| 0x0000_0003 | uQ32.0 | 0x0000_0001 | uQ16.00 | 1.0 | -43.581% |
| 0x0003_243F | uQ16.16 | 0x0000_01C5 | uQ08.08 | 1.76953125 | -0.165% |
| 0x0324_3F6A | uQ08.24 | 0x0000_1C5B | uQ04.12 | 1.772216769 | -0.013% |
| 0x3243_F6A8 | uQ04.28 | 0x0000_716F | uQ02.14 | 1.7723999023 | -0.003% |
| 0xC90F_DAA0 | uQ02.30 | 0x0000_E2DF | uQ01.15 | 1.7724304199 | -0.001% |

The application of the Q notation for square root calculations provides a powerful extension for these types of fractional numeric computations using fixed-point integer processing hardware.

## 11.4.2 Execution times

The MMDVSQ module includes early termination logic to finish both divide and square root calculations as quickly as possible, based on the magnitude of the input operand. Accordingly, the execution time for the calculations is data dependent as defined in Table 11-4 and Table 11-5. In this context, the execution time is defined from the register write to initiate the calculation until the result register has been updated and available to read. Stated differently, it represents the time CSR[BUSY] is asserted for a given calculation. In the following two tables, "x" signals a bit with a don't care value.

**Table 11-4. Divide Execution Times**

| CSR[USGN]<br>? DEND[31:0] // unsigned divide<br>: abs(DEND[31:0]) // signed divide | Execution Time with CSR[BUSY] = 1 [cycles] |

## 11.4.3 Software interface

The programming model of the MMDVSQ is organized to be similar to the input arguments passed to software libraries for integer divide and square root functions.

### 11.4.3.1 Operation activation and result retrieval

The MMDVSQ supports 2 mechanisms for initiating a divide operation:

- The default mechanism is a "fast start" where a write to the DSOR register begins the divide.
- Alternatively, the start mechanism can begin after a write to the CSR register with the CSR[SRT] set.

The CSR[DFS] indicator selects the divide start mechanism.

```
if CSR[DFS] = 0
   then a divide is initiated by a write to the DSOR register
   else a divide is initiated by a write to the CSR register with CSR[SRT] = 1
```

A square root calculation is initiated by a write to the RCND register.

For both divide and square root calculations, the result of the operation is retrieved by reading the RES register. A memory read of this register while the calculation is still being performed causes the access to be stalled via the insertion of bus wait states until the new result is loaded into the register. Note a stalled bus cycle cannot be interrupted, so if system interrupt latency is a concern, the processor should execute a simple wait loop, for example, polling CSR[BUSY], before reading the RES register. This code construct is fully interruptible, so interrupt latency is minimized.

### 11.4.3.2 Context save and restore

Given that multiple memory-mapped register accesses are needed for each divide and square root calculation, interrupts may occur during the required sequence of operations. As a result, the MMDVSQ's programming model can be saved at entry to an interrupt service routine (ISR) and then restored when redispatching to the interrupted task.

The module's context can be saved by reading the DEND, DSOR, CSR, and RES registers and storing them as part of the task state. There is one special consideration for the task state save. If the last calculation was a zero divide and the divide-by-zero enable is set (CSR[DZE] = 1), then a read of the RES register is error terminated. To avoid a zero-divide error termination during a context save, the following sequence can be used:

1. Read DEND, DSOR, and CSR registers and save the values as part of the task state.
2. Clear CSR[DZE].
3. Read the RES register and save its value as part of the task state.

When restoring the context, special care must be taken to not initiate another divide calculation. Specifically, CSR[DFS] must be set first before reloading the DEND and DSOR registers. For example, the following sequence can be used for the context reload:

1. Write 0x0000_0020 to the CSR to disable the fast start mechanism.
2. Reload DEND, DSOR, CSR, and RES registers from the saved state.

Since the original context save of the control/status register is guaranteed to have CSR[SRT] = 0, there is no divide operation initiated when this register is reloaded in step 2.

# Chapter 12
# ARM Core Debug

## 12.1 Introduction

The debug system of this device is based on the ARM CoreSight™ architecture, and is configured to provide the maximum flexibility as allowed by the restrictions of the pinout and other available resources.

The MCU has one CM4F core for customer application use (Core0), and one CM0+ core mainly for wireless application (Core1).

Debug provides register and memory accessibility from the external debugger interface, basic run/halt control. The CM4F core implements full trace ability, FPB function and 4 watch points. The CM0+ core supports ARM's Micro Trace Buffer (MTB) capability to provide simple program trace and has 4 breakpoints and 2 watch points. Three debug interfaces are supported:

- IEEE 1149.1 JTAG
- Multi-drop Serial Wire Debug (SWD) debug interface.
- ARM Real-Time Trace Interface

The debug interfaces provide the capability for debugger tools to interface to either CPU.

## 12.2 Debug system block diagram

The following diagram shows the ARM CoreSight™ debug configuration for this device.

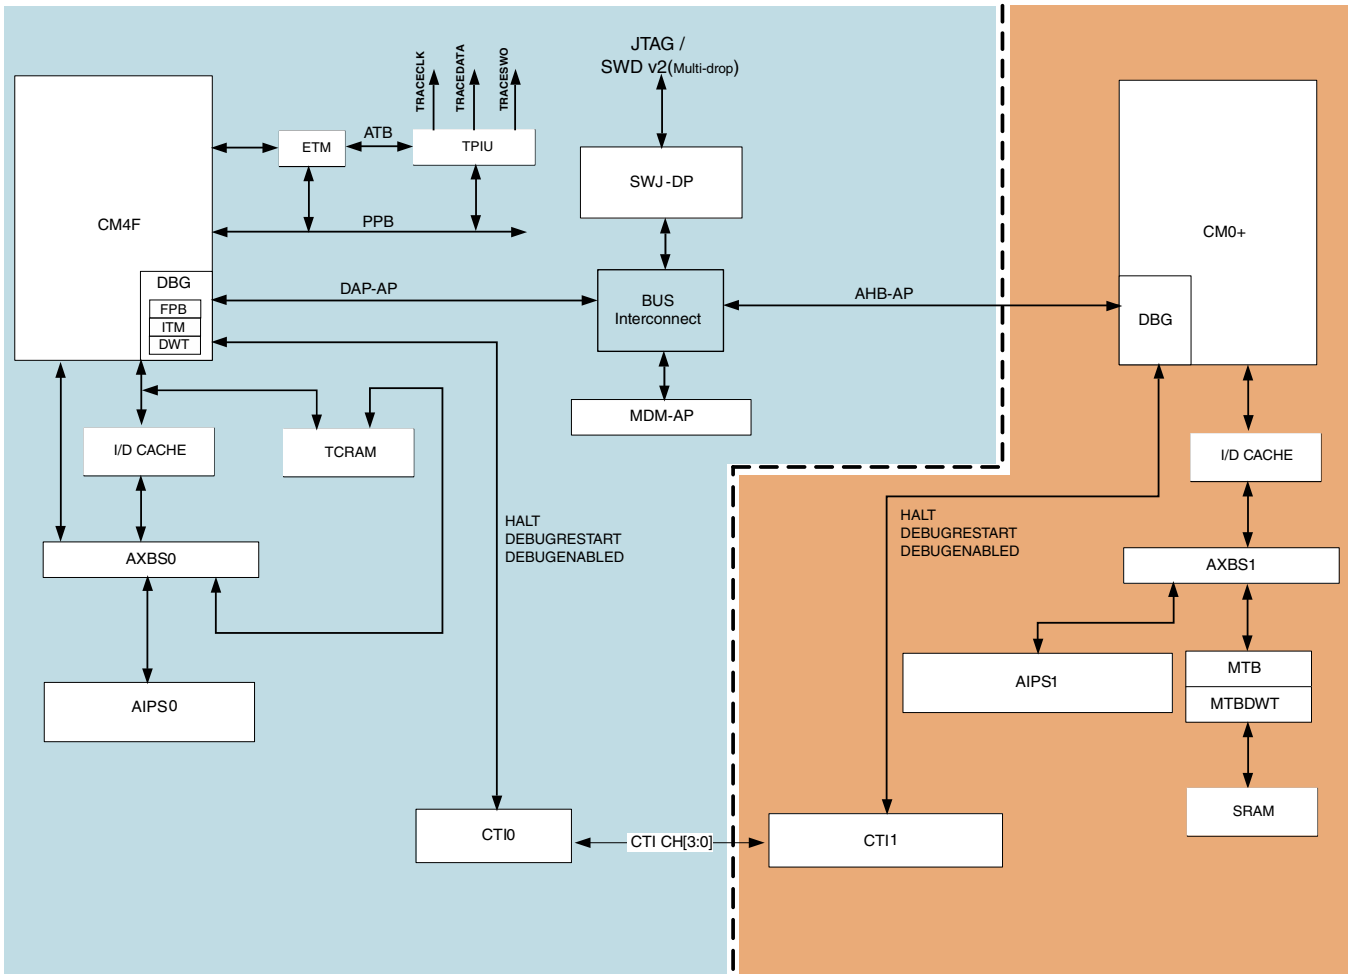

**Figure 12-1. Debug and trace block diagram**

## 12.2.1 Debug components

**Table 12-1. Debug components**

| Core | Module | Description |
|---|---|---|
| CM4F and CM0+ | SWJ-DP | Debug Port with support for SWD, JTAG |
| | CTI | Cross-triggering is achieved via the ARM-based Cross Trigger Interface (CTI0 and CTI1), which allows events on one Core to halt/start code execution and enable debug on the other Core, and vice versa. Each of the CTI modules has 4 output channels and 4 input channels:<br>• Each CTI can configure individual debug events of its Core (DebugStart, CPU halt etc) to 1 of 4 output channels. |

*Table continues on the next page...*

## Table 12-1. Debug components (continued)

| Core | Module | Description |
|---|---|---|
| | | • Each CTI can configure any of the input channels to trigger a CPU halt, Debug Enable, debug re-start.<br>• Thus, CTI0's 4 output channels are connected to CTI1's 4 input channels and vice versa |
| | MDM-AP | Provides centralized control and status registers for an external debugger to control the device. |
| CM4F | DAP-AP | |
| | ETM(Embedded Trace Macrocell) | ETMv3.5 Architecture |
| | ITM | S/W Instrumentation Messaging + Simple Data Trace Messaging + Watchpoint Messaging |
| | DWT (Data and Address Watchpoints) | 4 data and address watchpoints |
| | FPB (Flash Patch and Breakpoints) | The FPB implements hardware breakpoints and patches code and data from code space to system space.<br>The FPB unit contains two literal comparators for matching against literal loads from Code space, and remapping to a corresponding area in System space.<br>The FPB also contains six instruction comparators for matching against instruction fetches from Code space, and remapping to a corresponding area in System space. Alternatively, the six instruction comparators can individually<br>configure the comparators to return a Breakpoint Instruction (BKPT) to the processor core on a match, so providing hardware breakpoint capability. |
| | TPIU (Trace Port Inter face Unit) | Synchronous Mode (5-pin) = TRACE_D[3:0] + TRACE_CLKOUT<br>Synchronous Mode (3-pin) = TRACE_D[1:0] + TRACE_CLKOUT<br>Asynchronous Mode (1-pin) = TRACE_SWO (available on<br>JTAG_TDO) |
| CM0+ | AHB-AP | The AHB-AP2 module connects to the CM0+ core via a private AHB bus, allowing the debugger tool to set up watch points, breakpoints, instruction stepping, halting/ starting CPU execution |
| | MTB | Provides a simple execution trace capability for the Cortex-M0+ processor |

*Table continues on the next page...*

**Table 12-1. Debug components (continued)**

| Core | Module | Description |
|---|---|---|
| | MTBDWT | Supports triggering via TSTART and TSTOP control functions |

**Table 12-2. Debug access ports and AP numbers**

| Debug access ports | AP number |
|---|---|
| CM4F DAP-AP | AP 0 |
| MDM-AP | AP 1 |
| CM0+ AHB-AP | AP 2 |

### 12.2.2 JTAG-to-SWD change sequence

The following are JTAG to SWD change sequence:

1. Send more than 50 TCK cycles with TMS (SWDIO) =1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111_1001_1110_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) =1

**NOTE**

See ARM documentation for the CoreSight DAP Lite for the restrictions.

## 12.3 Debug port pin descriptions

The debug port pins default after POR to their SWD functionality.

**Table 12-3. Debug pin description**

| Pin name | Type | Description |
|---|---|---|
| JTAG_TCK / SWD_CLK | Input | JTAG Test Clock / Serial Wire Clock – This pin is the clock for debug logic when in the Serial Wire Debug mode. This pin is pulled down internally. |
| JTAG_TMS / SWD_DIO | Input / Output | JTAG Test Mode Select/ Serial Wire Data Input / Output – The SWD_DIO pin is used by an external debug tool for communication and device control. This pin is pulled up internally. |
| JTAG_TDI | Input | JTAG Test Data Input |
| JTAG_TDO/ TRACE_SWO | Output | JTAG Test Data Output / Trace output over a single pin |
| TRACE_CLK_OUT | Output | Trace clock out. |
| TRACE_DATA0~3 | Output | Trace data output |

## 12.4 System TAP connection

The system JTAG controller is connected in parallel to the ARM TAP controller. The system JTAG controller IR codes overlay the ARM JTAG controller IR codes without conflict. Refer to the IR codes table for a list of the available IR codes. The output of the TAPs (TDO) are muxed based on the IR code which is selected. This is fully JTAG compliant and appears to the JTAG chain as a single TAP. At power on reset, NXP's IDCODE (IR=4'b0000) is selected.

**Table 12-4. JTAG Instructions**

| Instruction | Code[3:0] | Instruction summary |
|---|---|---|
| IDCODE | 0000 | Selects device identification register for shift |
| SAMPLE/PRELOAD | 0010 | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation |
| SAMPLE | 0011 | Selects boundary scan register for shifting and sampling without disturbing functional operation |
| EXTEST | 0100 | Selects boundary scan register while applying preloaded values to output pins and asserting functional reset |
| HIGHZ | 1001 | Selects bypass register while three-stating all output pins and asserting functional reset |
| CLAMP | 1100 | Selects bypass register while applying preloaded values to output pins and asserting functional reset |
| ARM_IDCODE | 1110 | ARM JTAG-DP Instruction |
| BYPASS | 1111 | Selects bypass register for data operations |
| Factory debug reserved | 0101, 0110, 0111, 1000 | Intended for factory debug only |
| ARM JTAG-DP Reserved | 1000, 1010, 1011 | These instructions will go the ARM JTAG-DP controller. Refer to ARM JTAG-DP documentation for more information on these instructions. |

## 12.5 JTAG/SWD status and control registers

Through the ARM Debug Access Port (DAP), the debugger has access to the status and control elements, implemented as registers on the DAP bus as shown in the following figure.

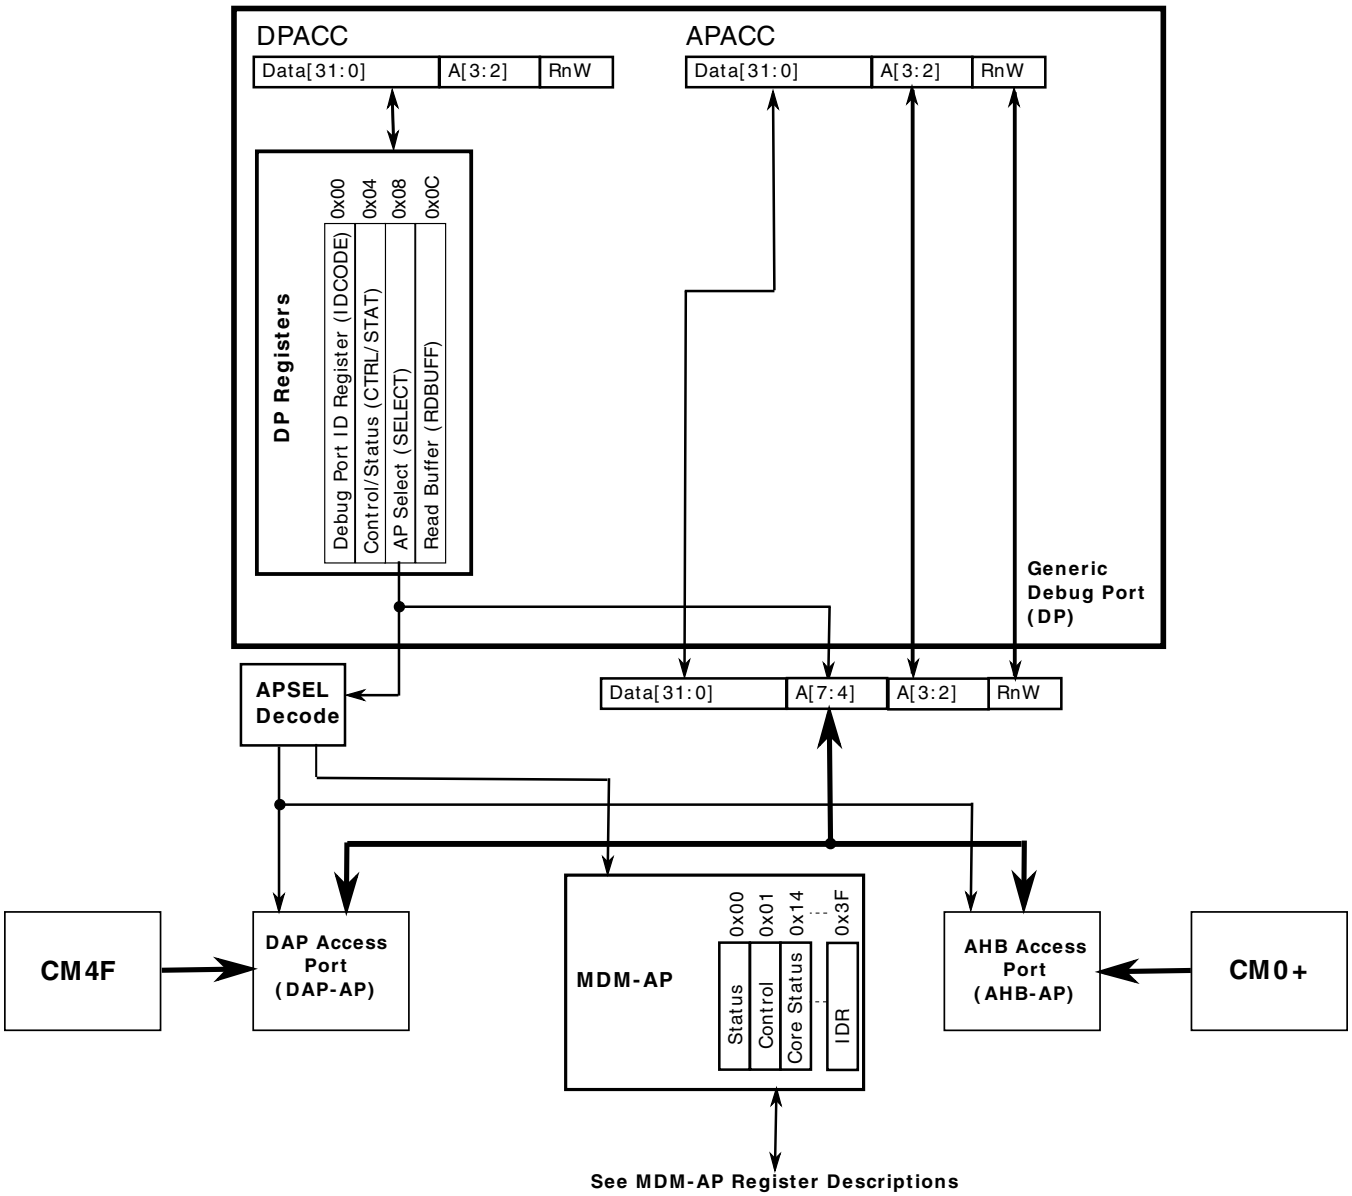

**Figure 12-2. MDM AP addressing**

These registers provide additional control and status for low power mode recovery and typical run-control scenarios. The status register bits also provide a means for the debugger to get updated status of the two cores, without having to initiate a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

It is important to note that these DAP control and status registers are not memory-mapped within the system memory map, and are only accessible via the Debug Access Port using SWD. The MDM-AP is accessible as Debug Access Port 1 with the available registers shown in the following table.

**Table 12-5. MDM-AP register summary**

| Address | Register | Description |
|---|---|---|
| 0x0100_0000 | Status | See MDM-AP Status Register |
| 0x0100_0004 | Control | See MDM-AP Control Register |
| 0x0100_0050 | Core Status | See MDM-AP Core Status Register |
| 0x0100_0054 | Core Clock Status | See MDM-AP Core Clock Status Register |
| 0x0100_0058 | System Clock Source Status | See MDM-AP System Clock Source Status Register |
| 0x0100_005C | System Power Status | See MDM-AP System Power Status Register |
| 0x0100_0070 ~ 0x0100_0080 | PCC0_CGC0~ PCC0_CGC4 | See MDM-AP PCC0_CGC0~4 Register |
| 0x0100_0084 ~ 0x0100_0094 | PCC1_CGC0~ PCC1_CGC4 | See MDM-AP PCC1_CGC0~4 Register |
| 0x0100_00FC | Identification Register | Read-only identification register that always reads as 0x001C_0040 |

## 12.5.1 MDM-AP status registers

**Table 12-6. MDM-AP status register assignments**

| Bit | Name | Description |
|---|---|---|
| 0 | Flash Mass Erase Acknowledge | The Flash Mass Erase Acknowledge bit is cleared after a Power-On Reset (POR) or when there is a new mass erase request before acknowledged. The Flash Mass Erase Acknowledge is set after Flash control logic has started the mass erase operation. When mass erase is disabled (via MEEN and SEC settings), an erase request due to setting of Flash Mass Erase in Progress bit is not acknowledged. If the system is not in reset status, the Flash Mass Erase is not acknowledged,either. |
| 1 | Flash Ready | Indicates Flash has been initialized and the debugger can be configured, even if the system is continuing to be held in reset by the debugger. |
| 2 | System Security | Indicates the security state. When secure, the debugger does not have access to the system bus or any memory-mapped peripherals. |
| 3 | System Reset | Indicates the system reset state.<br>0 System is in reset.<br>1 System is not in reset. |
| 4 | FSLACC | Flash security -Factory Security Level Access, see details from FSEC[FSLACC] in FTFE chapter |

*Table continues on the next page...*

## Table 12-6. MDM-AP status register assignments (continued)

| Bit | Name | Description |
|---|---|---|
| | | 0 indicates Factory access denied.<br>1 indicates Factory access granted |
| 5 | Mass Erase Enable | Indicates if the MCU can be mass erased or not<br>0 Mass erase is disabled.<br>1 Mass erase is enabled. |
| 6 | Backdoor Access Key Enable | Indicates if the MCU has the backdoor access key enabled.<br>0 Disabled<br>1 Enabled |
| 7 | LP Stop Mode Enabled | Decode of MSMC_SMCx_PMCTRL[STOPM] field to indicate that VLPS, LLS, or VLLSx are the selected power mode for the next time that the ARM Core enters Deep Sleep. This bit is used for debug operations in which Run to VLPS is attempted. Per the debug definition, the system actually enters the Stop state. A debugger should interpret a deep sleep indication (with SLEEPDEEP and SLEEPING asserted), in conjunction with LP Enabled bit asserted, as the debugger-VLPS status indication.<br>0 Low Power Stop Mode is not enabled.<br>1 Low Power Stop Mode is enabled. |
| 8 | Very Low Power Mode | Indicates that the current power mode is VLPS. This bit is not ‘sticky’ and should always represent whether VLPS is enabled or not. This bit is used to throttle SWD_CLK frequency up/down. |
| 9 | LLS Mode Exit | Indicates an exit from LLS mode has occurred. The debugger will lose communication while the system is in LLS (including access to this register). After communication is re-established, this bit indicates that the system is in LLS. Because the debug modules held their state during LLS, they do not need to be reconfigured. This bit is set during the LLS recovery sequence, and is cleared by a write of 1 to the LLS, VLLSx Status Acknowledge bit in MDM AP Control register. |
| 10 | VLLSx Modes Exit | This bit indicates an exit from VLLSx mode has occurred. The debugger will lose communication while the system is in VLLSx (including access to this register). After communication is reestablished, this bit indicates that the system is in VLLSx. Because the debug modules lose their state information during VLLSx modes, they need to be reconfigured. This bit is set during the VLLSx recovery sequence, and is cleared by a write of 1 to the LLS, VLLSx Status Acknowledge bit in MDM AP Control register. |
| 11 – 29 | Reserved for future use | Always read 0. |
| 30 | CM0+ Debug Restart Done | Indicates that the CM0+ debug restart procedure done<br>Set after CM0+ Debug Restart bit in MDM-AP Control Register is set |
| 31 | CM4F Debug Restart Done | Indicates that the CM4F debug restart procedure done<br>Set after CM4F Debug Restart bit in MDM-AP Control Register is set |

## 12.5.2 MDM-AP Control Register

**Table 12-7. MDM-AP control register assignments**

| Bit | Name | Secure[1] | Description |
|---|---|---|---|
| 0 | Flash Mass Erase in Progress | Y | Set to cause mass erase. Cleared by a Power-On Reset (POR) or when the mass erase is finished. When mass erase is disabled (via MEEN and SEC settings), the erase request does not occur and the Flash Mass Erase in Progress bit continues to assert until the next system reset. NOTE: When the reset pin has been disabled and security has been enabled by means of the FSEC register, a mass erase can be performed only by setting both the mass erase and system reset request bits in the MDM-AP register. |
| 1 | Debug Disable | N | Set to disable debug. Clear to allow debug operation. When set, it overrides the C_DEBUGEN bit within the DHCSR and force disables Debug logic. |
| 2 | Debug Request | N | Set to force the core to halt. If the core is in a Stop or Wait mode, then Debug Request bit can be used to wake the core to a halted state. |
| 3 | System Reset Request | Y | Set to force a system reset. The system remains held in reset until System Reset Request bit is cleared. |
| 4 | Core Hold Reset | N | Configuration bit to control core operation at the end of system reset sequencing.<br>0 Normal operation: At the end of system reset sequencing, release the core from reset (along with the rest of the system).<br>1 Suspend operation: At the end of reset sequencing, hold the core in reset. After the system enters this suspended state, clearing this control bit immediately releases the core from reset and CPU operation begins. |
| 5 | Debug Hold Request (DBGHOLDREQ) | N | Set to request the system to be held for any next system reset |
| 6 | Debug Hold Acknowledge (DBGHOLDACK) | N | Set to release system from hold after Debug Hold Request |
| 7 | LLS, VLLSx Status Acknowledge | N | Set this bit to acknowledge that the DAP LLS and VLLS Status bits have been read. This acknowledge automatically clears the status bits. This bit is used by the debugger to clear the sticky LLS and VLLSx mode entry status bits. This bit is asserted and cleared by the debugger. |
| 8 | Reserved for future use | N | |
| 9 | Inhibit Sleep | N | 1 = Device enters pseudo-sleep mode when debugger is attached<br>0 = Device enters full stop mode, and ignores attached debugger |
| 10-29 | Reserved for future use | N | |
| 30 | CM0+ Debug Restart | N | If CM0+ in halt state, set to bring CM0+ out of halt state after restart |
| 31 | CM4F Debug Restart | N | If CM4F in halt state, set to bring CM4F out of halt state after restart |

1. Register bit is writable in secure mode.

## 12.5.3 MDM-AP Core Status Register

**Table 12-8. MDM-AP Core Status register assignments**

| Bit | Name | Description |
|---|---|---|
| 0 | CM4F DEEPSLEEP Status | Set to indicate CM4F in DEEPSLEEP mode |
| 1 | CM4F SLEEP Status | Set to indicate CM4F in SLEEP mode |
| 2 | CM4F Reset Status | Set to indicate CM4F in Reset state |
| 3 | CM4F CPO Status | Set to indicate CM4F in Compute operation mode(CPO) |
| 4-6 | Reserved for future use | Always read 0 |
| 7 | CM4F Halted Status | Set to indicate CM4F in Halt state |
| 8 | CM0+ DEEPSLEEP Status | Set to indicate CM0+ in DEEPSLEEP mode |
| 9 | CM0+ SLEEP Status | Set to indicate CM0+ in SLEEP mode |
| 10 | CM0+ Reset Status | Set to indicate CM4F in Reset state |
| 11 | CM0+ CPO Status | Set to indicate CM0+ in Compute operation mode (CPO) |
| 12-14 | Reserved for future use | Always read 0 |
| 15 | CM0+ Halted Status | Set to indicate CM0+ in Halt state |
| 16-31 | Reserved for future use | Always read 0 |

## 12.5.4 MDM-AP Core Clock Status Register

**Table 12-9. MDM-AP Core Clock Status register assignments**

| Bit | Name | Description |
|---|---|---|
| 0 | CM4F Platform Clock Status | Set to indicate CM4F platform clock is enabled<br>Clear to indicate CM4F platform clock is disabled |
| 1 | CM4F Bus Clock Status | Set to indicate CM4F Bus clock is enabled<br>Clear to indicate CM4F Bus clock is disabled |
| 2 | CM4F Slow Clock Status | Set to indicate CM4F Slow clock is enabled<br>Clear to indicate CM4F Slow clock is disabled |

*Table continues on the next page...*

**Table 12-9. MDM-AP Core Clock Status register assignments (continued)**

| Bit | Name | Description |
|---|---|---|
| 3 | CM4F External Clock Status | Set to indicate Flexbus clock is enabled<br>Clear to indicate Flexbus clock is disabled |
| 4-7 | Reserved for future use | Always read 0 |
| 8 | CM0+ Platform Clock Status | Set to indicate CM0+ platform clock is enabled<br>Clear to indicate CM0+ platform clock is disabled |
| 9 | CM0+ Bus Clock Status | Set to indicate CM0+ bus clock is enabled<br>Clear to indicate CM0+ bus clock is disabled |
| 10 | CM0+ Slow Clock Status | Set to indicate CM0+ slow clock is enabled<br>Clear to indicate CM0+ slow clock is disabled |
| 11-31 | Reserved for future use | Always read 0 |

## 12.5.5 MDM-AP System Clock Status Register

**Table 12-10. MDM-AP System Clock Status register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-3 | DIVSLOW | Indicates DIVSLOW value |
| 4-7 | DIVBUS | Indicates DIVBUS value[1] |
| 8-11 | DIVEXT | Indicates DIVEXT value[1] |
| 12-15 | Reserved | Always read 0 |
| 16-19 | DIVCORE | Indicate DIVCOR value[1] |
| 20-23 | System Clock Source Status | 0010 RF OSC<br>0011 SIRC<br>0100 FIRC<br>0101 RTC OSC<br>0110 LPFLL |
| 24 | FIRC ON Status | Set to indicate FIRC clock alive |
| 25 | SIRC ON Status | Set to indicate SIRC clock alive |
| 26 | OSC ON Status | Set to indicate OSC clock alive |
| 27 | RTC32K ON Status | Set to indicate RTC32K clock alive |
| 28 | LPFLL ON Status | Set to indicate LPFLL clock alive |
| 29 | Reserved | Always read 0 |
| 30 | LPO_1KHz ON Status | Set to indicate LPO_1KHz clock alive |

*Table continues on the next page...*

**Table 12-10. MDM-AP System Clock Status register assignments (continued)**

| Bit | Name | Description |
|---|---|---|
| 31 | Reserved | Always read 0 |

1. This value is configured by SCG_RCCR in Run mode, SCG_VCCR in VLPR mode, and SCG_HCCR in HSRUN mode.

## 12.5.6 MDM-AP System Power Status Register

**Table 12-11. MDM-AP System Power Status register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-7 | System Power Mode Status[1] | 001xxxx - RUN mode<br>010xxxx - HSRUN mode<br>100xxxx - VLPR mode<br>0000000 - STOP mode<br>0000001 - VLPS mode<br>0000011 - LLS mode<br>0000111 - VLLS2/3 mode<br>0001111 – VLLS0/1 mode |
| 8 | PMC LDO Status | Set to indicate PMC LD regulator enabled |
| 9 | PMC DCDC Status | Set to indicate PMC DCDC regulator enabled |
| 10 | PMC IOREG Status | Set to indicate PMC IOREG regulator enabled |
| 11-12 | Reserved for future use | Always read 0 |
| 13 | USB VREGIN OK | Set to indicate USB VREGIN power available |
| 14 | VBAT OK | Set to indicate VBAT power supply available |
| 15 | VDDIO2 OK | Set to indicate VDDIO2 power supply available |
| 16 | Flash Disable Status | Flash accesses are disabled (and generate a bus error) and the flash memory is placed in a low-power state, see details from SIM_FCFG1[FLASHDIS]<br>Set to indicate Flash is enabled<br>Clear to indicate Flash is disabled |
| 17-19 | Flash Standby Status | Flash Standby, see details from FSTBDY register in FTFE chapter<br>Set to indicate Standby mode enabled for relative flash block if FTFE_FSTDBYCTL[STDBYDIS] is clear<br>Clear to indicate Standby mode not enabled for relative flash block |
| 20-23 | CM4F Stop Mode Configuration | 0001 – VLPS<br>0011 – LLS<br>0111 – VLLS2/3<br>1000 – VLLS0/1 |
| 24-27 | RF Power Mode Status | 1000 – RRUN |

*Table continues on the next page...*

**Table 12-11. MDM-AP System Power Status register assignments (continued)**

| Bit | Name | Description |
|---|---|---|
| | | 0011 – RLLS<br>0111 – RVLLS |
| 28-31 | CM0+ Stop Mode Configuration | 0001 – VLPS<br>0011 – LLS<br>0111 – VLLS2/3<br>1000 – VLLS0/1 |

1. it refers to MCU requested power mode, see details in system power mode table from power chapter.

## 12.5.7 MDM-AP PCC0_CGC0 Register

**Table 12-12. MDM-AP PCC0_CGC0 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-31 | PCC0_CGC[0:31] | Set to indicate corresponding clock gated |

## 12.5.8 MDM-AP PCC0_CGC1 Register

**Table 12-13. MDM-AP PCC0_CGC1 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-31 | PCC0_CGC[32:63] | Set to indicate corresponding clock gated |

## 12.5.9 MDM-AP PCC0_CGC2 Register

**Table 12-14. MDM-AP PCC0_CGC2 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-31 | PCC0_CGC[64:95] | Set to indicate corresponding clock gated |

## 12.5.10 MDM-AP PCC0_CGC3 Register

**Table 12-15. MDM-AP PCC0_CGC3 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-31 | PCC0_CGC[96:127] | Set to indicate corresponding clock gated |

## 12.5.11 MDM-AP PCC0_CGC4 Register

**Table 12-16. MDM-AP PCC0_CGC4 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-7 | PCC0_CGC[128:135] | Set to indicate corresponding clock gated |
| 8-31 | Reserved for future use | |

## 12.5.12 MDM-AP PCC1_CGC0 Register

**Table 12-17. MDM-AP PCC1_CGC0 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-31 | PCC1_CGC[0:31] | Set to indicate corresponding clock gated |

## 12.5.13 MDM-AP PCC1_CGC1 Register

**Table 12-18. MDM-AP PCC1_CGC1 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-31 | PCC1_CGC[32:63] | Set to indicate corresponding clock gated |

## 12.5.14 MDM-AP PCC1_CGC2 Register

**Table 12-19. MDM-AP PCC1_CGC2 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-31 | PCC1_CGC[64:95] | Set to indicate corresponding clock gated |

## 12.5.15 MDM-AP PCC1_CGC3 Register

**Table 12-20. MDM-AP PCC1_CGC3 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-31 | PCC1_CGC[96:127] | Set to indicate corresponding clock gated |

## 12.5.16 MDM-AP PCC1_CGC4 Register

**Table 12-21. MDM-AP PCC1_CGC4 register assignments**

| Bit | Name | Description |
|---|---|---|
| 0-7 | PCC1_CGC[128:135] | Set to indicate corresponding clock gated |
| 8-31 | Reserved for future use | |

# 12.6 Debug resets

The debug system receives the following sources of reset:

- Debug reset (the CDBGRSTREQ field within the DP CTRL/STAT register) that allows the debugger to reset the debug logic.
- System POR reset

Conversely, the debug system is capable of generating system reset using the following mechanism:

- A system reset in the MDM-AP control register which allows the debugger to hold the system in reset.
- SYSRESETREQ field in the NVIC Application Interrupt and Reset control register

## 12.7 SWD Multi-Drop

ARM Multi-drop SWD technology brings the benefits of SWD to complex, multi-device-based system by enabling simultaneous access to a number of devices through a single connection, providing complex-device developers with a low power 2-pin debug and trace solution.

The Multi-drop SWD is fully backwards compatible, retaining existing single point-to-point host equipment connections, and permits a device to power down completely while that device is not selected, reducing power consumption.

Each target must be configured with a unique combination of target ID and instance ID, to enable a debugger to select a single target to communicate with:

- The target ID is a 32-bit field that uniquely identifies the system accessed by the SWJ-DP.

**Table 12-22. Target ID**

| Bits | Value | Description |
|---|---|---|
| [31:28] | SIM_SDID[REVID] | The revision of the part. |
| [27:12] | 1011_0000_0010_0000 | Identifies the part. |
| [11:1] | 000_0000_1110 | Identifies the designer of the device. |
| [0] | 1 | Reserved. |

- The instance ID is the inverse of FTFE_FOPT[31:28]. It is used to distinguish between multiple instances of the same target in a system, for example, because the same chip is used more than once on a board.

## 12.8 ITM

The ITM is an application-driven trace source that supports "printf" style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. Software trace -- Software can write directly to ITM stimulus registers. This emits packets.
2. Hardware trace -- The DWT generates these packets, and the ITM emits them.

3. Time stamping -- Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M4 clock or the bitclock rate of the Serial Wire Viewer (SWV) output clocks the counter.
4. Global system timestamping. Timestamps can optionally be generated using a system-wide 48-bit count value. The same count value can be used to insert timestamps in the ETM trace stream, allowing coarse-grain correlation.

## 12.9 Core trace connectivity with ETM

The following figure assumes the device contains an ETM.

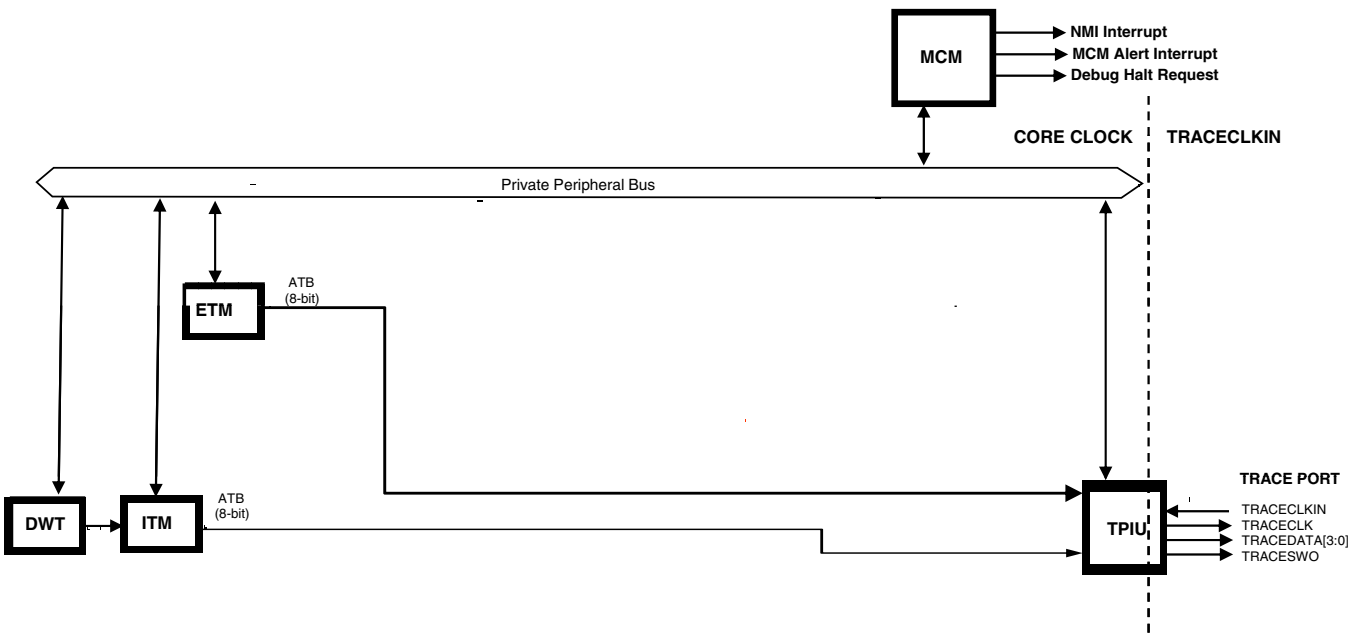

**Figure 12-3. Core Trace Connectivity with ETM only**

The following combinations paths are supported:

- ETM -> TPIU(4 pin or 2 pin parallel)
- ITM->TPIU(1 pin SWO, 2 pin or 4 pin parallel)
- ETM and ITM -> TPIU

## 12.10 Embedded Trace Macrocell v3.5 (ETM)

The Cortex-M4 Embedded Trace Macrocell (ETM-M4) is a debug component that enables a debugger to reconstruct program execution. The CoreSight ETM-M4 supports only instruction trace. You can use it with the Cortex-M4 Trace Port Interface Unit (M4-TPIU).

The main features of an ETM are:

- Tracing of 16-bit and 32-bit Thumb instructions
- Four EmbeddedICE watchpoint inputs
- Trace Start/Stop block with EmbeddedICE inputs
- One reduced function counter
- Two external inputs
- 24-byte FIFO queue
- Global timestamping

## 12.11 TPIU

The TPIU acts as a bridge between the on-chip trace data from the Embedded TraceMacrocell (ETM) and the Instrumentation Trace Macrocell (ITM), with separate IDs, to a data stream, encapsulating IDs where required, that is then captured by a Trace PortAnalyzer (TPA). The TPIU is specially designed for low-cost debug.

## 12.12 DWT

The DWT is a unit that performs the following debug functionality:

- It contains four comparators that you can configure as a hardware watchpoint, an ETM trigger, a PC sampler event trigger, or a data address sampler event trigger. The first comparator, DWT_COMP0, can also compare against the clock cycle counter, CYCCNT. The second comparator, DWT_COMP1, can also be used as a data comparator.
- The DWT contains counters for:
  - Clock cycles (CYCCNT)
  - Folded instructions
  - Load store unit (LSU) operations
  - Sleep cycles
  - CPI (all instruction cycles except for the first cycle)
  - Interrupt overhead

**NOTE**

An event is emitted each time a counter overflows.

- The DWT can be configured to emit PC samples at defined intervals, and to emit interrupt event information.

## 12.13 Micro Trace Buffer (MTB)

The Micro Trace Buffer (MTB) provides a simple execution trace capability for the Cortex-M0+ processor.

When enabled, the MTB records changes in program flow reported by the Cortex-M0+ processor, via the execution trace interface, into a configurable region of the SRAM. Subsequently, an off-chip debugger may extract the trace information, which would allow reconstruction of an instruction flow trace. The MTB does not include any form of load/store data trace capability or tracing of any other information.

In addition to providing the trace capability, the MTB also operates as a simple AHB-Lite SRAM controller. The system bus masters, including the processor, have read/write access to all of the SRAM via the AHB-Lite interface, allowing the memory to be also used to store program and data information. The MTB simultaneously stores the trace information into an attached SRAM and allows bus masters to access the memory. The MTB ensures that trace information write accesses to the SRAM take priority over accesses from the AHB-Lite interface.

The MTB includes trace control registers for configuring and triggering the MTB functions. The MTB also supports triggering via TSTART and TSTOP control functions in the MTB DWT module.

## 12.14 Debug in low-power modes

In low-power modes, in which the debug modules are kept static or powered off, the debugger cannot gather any debug data for the duration of the low-power mode.

- In the case that the debugger is held static, the debug port returns to full functionality as soon as the low-power mode exits and the system returns to a state with active debug.
- In the case that the debugger logic is powered off, the debugger is reset on recovery and must be reconfigured once the low-power mode is exited.

Power mode entry logic monitors Debug Power Up and System Power Up signals from the debug port as indications that a debugger is active. These signals can be changed in RUN, VLPR, WAIT and VLPW. When system attempts to enter any stop or low power mode, if debug signal is active and MDM-AP_Control[Inhibit Sleep] is enabled, FCLK continues to run to support core register access, but device enters pseudo-sleep mode. In these modes, in which FCLK is left active, the debug modules have access to core registers but not to system memory resources accessed via the crossbar.

With debug enabled, transitions from Run directly to VLPS result in the system entering Stop mode instead. Status bits within the MDM-AP Status register can be evaluated to determine this pseudo-VLPS state.

**NOTE**

With the debug enabled, transitions from Run --> VLPR --> VLPS are still possible.

In VLLS mode, all debug modules are powered off and reset at wakeup. In LLS mode, the debug modules retain their state but no debug activity is possible.

Waking up from a VLLSx mode causes all the debug controls and settings to be reset. To give time to the debugger to sync up with the HW, the MDM-AP Control register can be configured to hold the system in reset on recovery so that the debugger can regain control and reconfigure debug logic prior to the system exiting reset and resuming operation.

## 12.15 Debug module state in low power modes

The following table shows the state of the debug modules in low power modes. These terms are used: .

- FF = Full functionality. In VLPR and VLPW the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- Static = Module register states and associated memories are retained.
- OFF = Modules are powered off; module is in reset state upon wakeup.

**Table 12-23. Debug module state in low power modes**

| Module | STOP | VLPR | VLPW | VLPS | LLS | VLLSx |
|---|---|---|---|---|---|---|
| Debug Port | Static | FF | FF | Static | Static | OFF |
| AHB-AP | Static | FF | FF | Static | Static | OFF |
| DAP-AP | Static | FF | FF | Static | Static | OFF |
| ITM | Static | FF | FF | Static | Static | OFF |
| ETM | Static | FF | FF | Static | Static | OFF |
| DWT | Static | FF | FF | Static | Static | OFF |
| TPIU | Static | FF | FF | Static | Static | OFF |
| MTB | Static | FF | FF | Static | Static | OFF |

## 12.16 Debug and security

When flash security is enabled, the debug port capabilities are limited in order to prevent exploitation of secure data.

In the secure state, the debugger still has access to the MDM-AP status register and can determine the current secruity state of the device. In the case of a secure device, the debugger has the capability of only performing a mass erase or system reset operation. In the case of a secure device that has mass erase disabled (FSEC[MEEN] = 10), attempts to mass erase via the debug interface are blocked.

# Chapter 13
# RISC-V Core Debug

## 13.1 Introduction

RISC-V debug has separated JTAG ports and cannot access ARM CoreSight debug components. RI5CY core and ZERO-RISCY core both have interface to RISC-V debug. So RISC-V debug can configure debug registers in RI5CY core and ZERO-RISCY core to execute basic debug controls, which including run/halt, signal step, breakpoint etc.

For RISC-V debug registers, see RI5CY Debug Registers and ZERO-RISCY Debug Registers for more details.

## 13.2 Memory map for RISC-V debug port

0x0000_0000 – 0xF8FF_FFFF: system memory map, Debug port cannot access CM4/CM0P PPB modules except MCM2 in CM4/RI5CY platform.

0xF900_0000 – 0xF900_7FFF: RI5CY core registers, 0xF900_0000 + Address in the table.

**Table 13-1. RI5CY debug unit address map**

| Offset address | Name | Description |
|---|---|---|
| 0x0000-0x007F | Debug Registers | Always accessible, even when the core is running |
| 0x400-0x47F | GPR (x0-x31) | General Purpose Registers<br>Only accessible if the core is halted |
| 0x2000-0x20FF | Debug Registers | Only accessible if the core is halted |
| 0x4000-0x7FFF | CSR | Control and Status Registers<br>Only accessible if the core is halted |

0xF900_8000 – 0xF900_FFFF: ZERORISCY core registers, 0xF900_8000 + Address in the table.

**Table 13-2. ZERO-RISCY debug unit address map**

| Offset address | Name | Description |
|---|---|---|
| 0x0000-0x007F | Debug Registers | Always accessible, even when the core is running |
| 0x400-0x47F | GPR (x0-x31) | General Purpose Registers<br>Only accessible if the core is halted |
| 0x2000-0x20FF | Debug Registers | Only accessible if the core is halted |
| 0x4000-0x7FFF | CSR | Control and Status Registers<br>Only accessible if the core is halted |

0xF901_0000 – 0xF901_00FF: MDM-AP

## 13.3 Advanced debug interface

The Advanced Debug Interface (ADI) is a hardware module which creates an interface between a JTAG Test Access Port (TAP) and the system bus AXI. It is part of the system which allows software running on an SoC to be controlled and debugged by a software debugger such as GDB, running on a separate host PC. Here is block diagram of ADI.

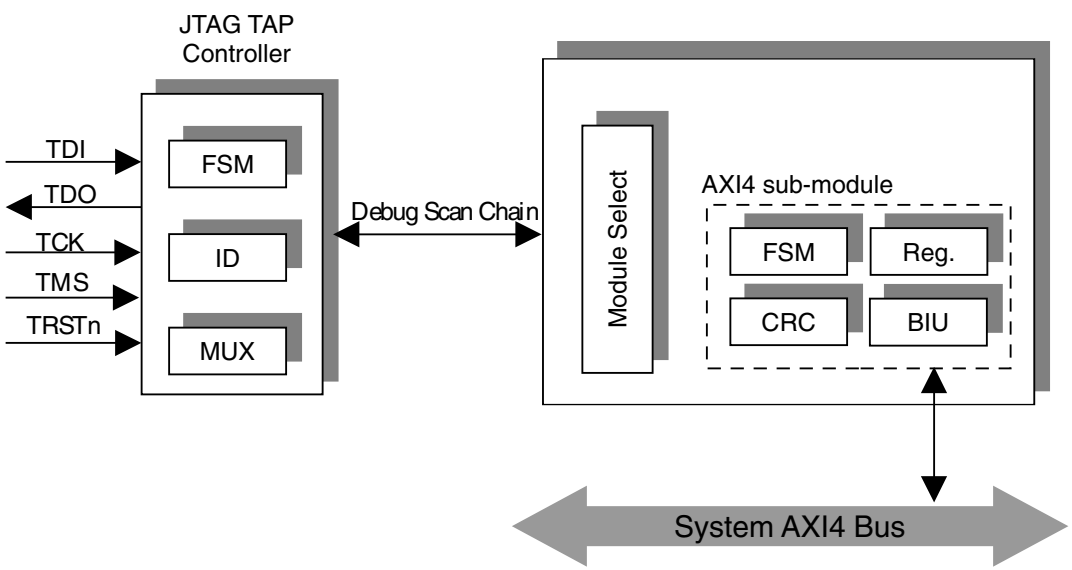

**Figure 13-1. ADI block diagram**

This is AXI4 module register summary in ADI.

**Table 13-3. ADI AXI4 register summary**

| Index | Register name |
|---|---|
| 0x0 | Error Register |
| 0x1 | DEBUG_PATH_SELECTION Register |
| 0x2 | POWER_UP Register |

## 13.3.1 Error register

The error register captures bus errors during transactions. If an error is present, then the error bit in the error register is set to '1', and the address of the failed access is stored in the rest of the error register. The error bit may only be reset by writing a '1' to the error bit.

Error Register format:

**Table 13-4. Error regiser format**

| Bit | Access | Description |
|---|---|---|
| 33:1 | R | When error bit = '1', contains the address of the failed transaction |
| 0 | R | Error bit. Set to '1' when a AXI4 error has occurred since the last time the error bit was reset. |
| 0 | W | Write as '1' to reset the error bit to '0' and re-enable error detection. |

## 13.3.2 DEBUG_PATH_SELECTION register

RISCV debug port can access system memory through CM4/RI5CY platform or CM0+/ ZERO-RISCY platform. The path for debug port to access system memory is configurable. The default path is determained by IFR boot configuration.

**Table 13-5. RISC-V debug port access path**

| BOOT CORE SEL | RI5CY_DIS | ZERORISCY_DIS | Path |
|---|---|---|---|
| 0 | 0 | 0 | ZERORISCY |
| 0 | 0 | 1 | RI5CY |
| 0 | 1 | 0 | ZERORISCY |
| 0 | 1 | 1 | RI5CY(NA) |
| 1 | 0 | 0 | RI5CY |
| 1 | 0 | 1 | RI5CY |

*Table continues on the next page...*

**Table 13-5. RISC-V debug port access path (continued)**

| BOOT CORE SEL | RI5CY_DIS | ZERORISCY_DIS | Path |
|---|---|---|---|
| 1 | 1 | 0 | ZERORISCY |
| 1 | 1 | 1 | RI5CY(NA) |

The user can change the path by writing DEBUG_PATH_SELECTION register in ADI. This register is a new addition to the ADI for this application. It's an AXI4 module register with index = 1.

DEBUG_PATH_SELECTION register format:

**Table 13-6. DEBUG_PATH_SELECTION register format**

| Bit | Access | Description |
|---|---|---|
| 1 | R/W | 0: Use default selection<br>1: Use bit 0 config |
| 0 | R/W | 0: RI5CY<br>1: ZERORISCY |

## 13.3.3 POWER_UP register

This register is to power up RISC-V debug components. The first step to debug RISC-V core is to write "1" to POWER_UP register.

POWER_UP register format:

**Table 13-7. POWER_UP register format**

| Bit | Access | Description |
|---|---|---|
| 0 | R/W | Write '1' to enable clock of RISC-V debug components |

# Chapter 14
# Micro Trace Buffer (MTB)

## 14.1 Introduction

Microcontrollers using the Cortex-M0+ processor core include support for a CoreSight Micro Trace Buffer to provide program trace capabilities.

The proper name for this function is the CoreSight Micro Trace Buffer for the Cortex-M0+ Processor; in this document, it is simply abbreviated as the MTB.

The simple program trace function creates instruction address change-of-flow data packets in a user-defined region of the system RAM. Accordingly, the system RAM controller manages requests from two sources:

- AMBA-AHB reads and writes from the system bus
- program trace packet writes from the processor

As part of the MTB functionality, there is a DWT (Data Watchpoint and Trace) module that allows the user to define watchpoint addresses, or optionally, an address and data value, that when triggered, can be used to start or stop the program trace recording.

This document details the functionality of both the MTB and DWT capabilities.

### 14.1.1 Overview

A generic block diagram of the processor core and platform for this class of ultra low-end microcontrollers is shown as follows:

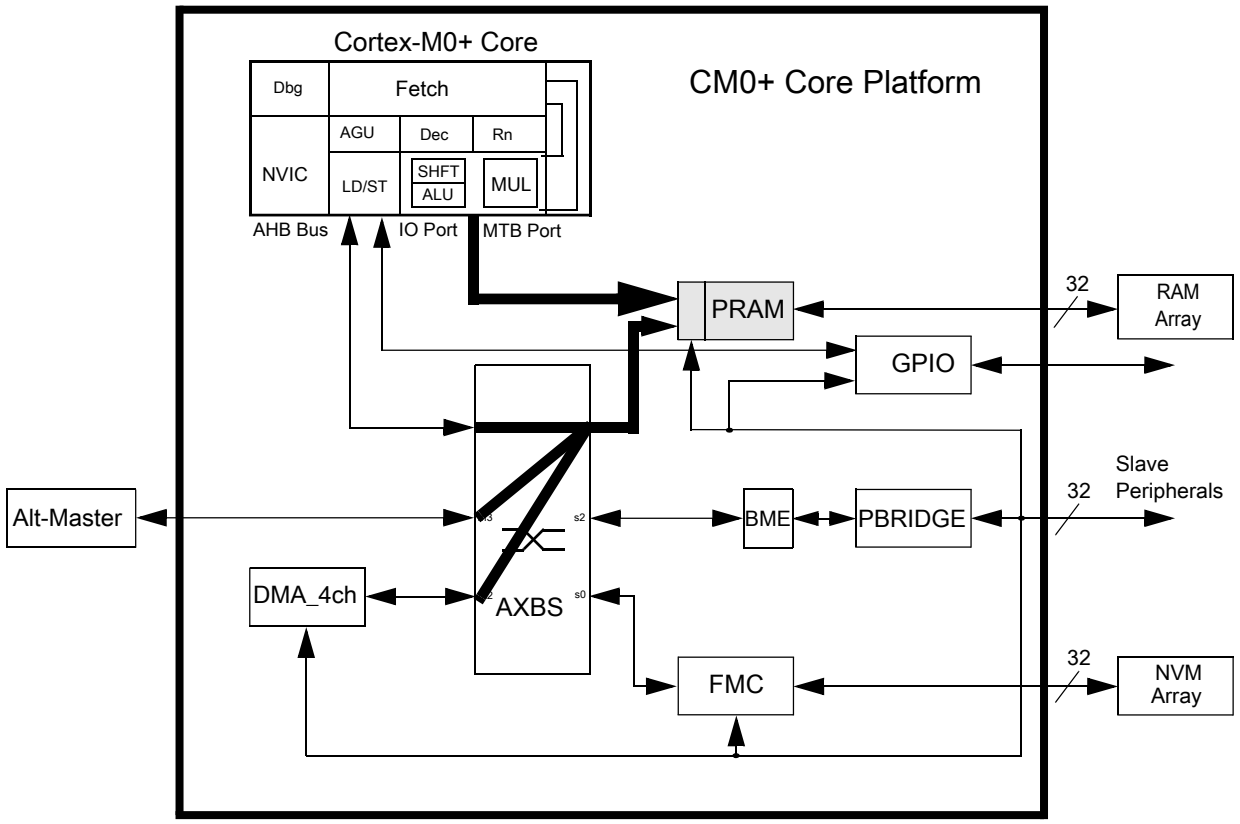

**Figure 14-1. Generic Cortex-M0+ core platform block diagram**

As shown in the block diagram, the platform RAM (PRAM) controller connects to two input buses:

- the crossbar slave port for system bus accesses
- a "private execution MTB port" from the core

The logical paths from the crossbar master input ports to the PRAM controller are highlighted along with the private execution trace port from the processor core. The private MTB port signals the instruction address information needed for the 64-bit program trace packets written into the system RAM. The PRAM controller output interfaces to the attached RAM array. In this document, the PRAM controller is the MTB controller.

The following information is taken from the ARM CoreSight Micro Trace Buffer documentation.

"The execution trace packet consists of a pair of 32-bit words that the MTB generates when it detects the processor PC value changes non-sequentially. A non-sequential PC change can occur during branch instructions or during exception entry.

The processor can cause a trace packet to be generated for any instruction.

The following figure shows how the execution trace information is stored in memory as a sequence of packets.

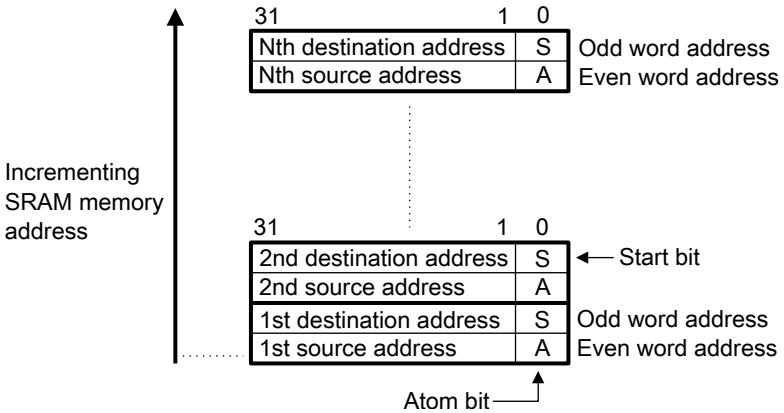

**Figure 14-2. MTB execution trace storage format**

The first, lower addressed, word contains the source of the branch, the address it branched from. The value stored only records bits[31:1] of the source address, because Thumb instructions are at least halfword aligned. The least significant bit of the value is the A-bit. The A-bit indicates the atomic state of the processor at the time of the branch, and can differentiate whether the branch originated from an instruction in a program, an exception, or a PC update in Debug state. When it is zero the branch originated from an instruction, when it is one the branch originated from an exception or PC update in Debug state. This word is always stored at an even word location.

The second, higher addressed word contains the destination of the branch, the address it branched to. The value stored only records bits[31:1] of the branch address. The least significant bit of the value is the S-bit. The S-bit indicates where the trace started. An S-bit value of 1 indicates where the first packet after the trace started and a value of 0 is used for other packets. Because it is possible to start and stop tracing multiple times in a trace session, the memory might contain several packets with the S-bit set to 1. This word is always stored in the next higher word in memory, an odd word address.

When the A-bit is set to 1, the source address field contains the architecturally-preferred return address for the exception. For example, if an exception was caused by an SVC instruction, then the source address field contains the address of the following instruction. This is different from the case where the A-bit is set to 0. In this case, the source address contains the address of the branch instruction.

For an exception return operation, two packets are generated:

- The first packet has the:
  - Source address field set to the address of the instruction that causes the exception return, BX or POP.

  - Destination address field set to bits[31:1] of the EXC_RETURN value. See the ARM v6-M Architecture Reference Manual.
  - The A-bit set to 0.

- The second packet has the:
  - Source address field set to bits[31:1] of the EXC_RETURN value.
  - Destination address field set to the address of the instruction where execution commences.
  - A-bit set to 1."

Given the recorded change-of-flow trace packets in system RAM and the memory image of the application, a debugger can read out the data and create an instruction-by-instruction program trace. In keeping with the low area and power implementation cost design targets, the MTB trace format is less efficient than other CoreSight trace modules, for example, the ETM (Embedded Trace Macrocell). Since each branch packet is 8 bytes in size, a 1 KB block of system RAM can contain 128 branches. Using the Dhrystone 2.1 benchmark's dynamic runtime as an example, this corresponds to about 875 instructions per KB of trace RAM, or with a zero wait state memory, this corresponds to approximately 1600 processor cycles per KB. This metric is obviously very sensitive to the runtime characteristics of the user code.

The DWT function (not shown in the core platform block diagram) monitors the processor address and data buses so that configurable watchpoints can be detected to trigger the appropriate response in the MTB recording.

### 14.1.2 Features

The key features of the MTB and DWT include:

- Memory controller for system RAM and Micro Trace Buffer for program trace packets
- Read/write capabilities for system RAM accesses, write-only for program trace packets
- Supports zero wait state response to system bus accesses when no trace data is being written
- Can buffer two AHB address phases and one data write for system RAM accesses
- Supports 64-bit program trace packets including source and destination instruction addresses
- Program trace information in RAM available to MCU's application code or external debugger
- Program trace watchpoint configuration accessible by MCU's application code or debugger
- Location and size of RAM trace buffer is configured by software

- Two DWT comparators (addresses or address + data) provide programmable start/ stop recording
- CoreSight compliant debug functionality

### 14.1.3 Modes of operation

The MTB and DWT functions do not support any special modes of operation. The MTB controller, as a memory-mapped device located on the platform's slave AHB system bus, responds strictly on the basis of memory addresses for accesses to its attached RAM array. The MTB private execution bus provides program trace packet write information to the RAM controller. Both the MTB and DWT modules are memory-mapped, so their programming models can be accessed.

All functionality associated with the MTB and DWT modules resides in the core platform's clock domain; this includes its connections with the RAM array.

## 14.2 External signal description

The MTB and DWT modules do not directly support any external interfaces.

The internal interface includes a standard AHB bus with a 32-bit datapath width from the appropriate crossbar slave port plus the private execution trace bus from the processor core. The signals in the private execution trace bus are detailed in the following table taken from the ARM CoreSight Micro Trace Buffer documentation. The signal direction is defined as viewed by the MTB controller.

**Table 14-1. Private execution trace port from the core to MTB**

| Signal | Direction | Description |
|---|---|---|
| LOCKUP | Input | Indicates the processor is in the Lockup state. This signal is driven LOW for cycles when the processor is executing normally and driven HIGH for every cycle the processor is waiting in the Lockup state. This signal is valid on every cycle. |
| IAESEQ | Input | Indicates the next instruction address in execute, IAEX, is sequential, that is non-branching. |
| IAEXEN | Input | IAEX register enable. |
| IAEX[30:0] | Input | Registered address of the instruction in the execution stage, shifted right by one bit, that is, PC >> 1. |
| ATOMIC | Input | Indicates the processor is performing non-instruction related activities. |
| EDBGRQ | Output | Request for the processor to enter the Debug state, if enabled, and halt. |

In addition, there are two signals formed by the DWT module and driven to the MTB controller: TSTART (trace start) and TSTOP (trace stop). These signals can be configured using the trace watchpoints to define programmable addresses and data values to affect the program trace recording state.

## 14.3 Memory map and register definition

The MTB and DWT modules each support a sparsely-populated 4 KB address space for their programming models. For each address space, there are a variety of control and configurable registers near the base address, followed by a large unused address space and finally a set of CoreSight registers to support dynamic determination of the debug configuration for the device.

Accesses to the programming model follow standard ARM conventions. Taken from the ARM CoreSight Micro Trace Buffer documentation, these are:

- Do not attempt to access reserved or unused address locations. Attempting to access these locations can result in UNPREDICTABLE behavior.
- The behavior of the MTB is UNPREDICTABLE if the registers with UNKNOWN reset values are not programmed prior to enabling trace.
- Unless otherwise stated in the accompanying text:
  - Do not modify reserved register bits
  - Ignore reserved register bits on reads
  - All register bits are reset to a logic 0 by a system or power-on reset
  - Use only word size, 32-bit, transactions to access all registers

### 14.3.1 MTB register descriptions

#### 14.3.1.1 MTB Memory map

MTB base address: F000_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | MTB Position Register (POSITION) | 32 | RW | See description. |
| 4h | MTB Master Register (MASTER) | 32 | RW | See description. |

*Table continues on the next page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 8h | MTB Flow Register (FLOW) | 32 | RW | See description. |

## 14.3.1.2 MTB Position Register (POSITION)

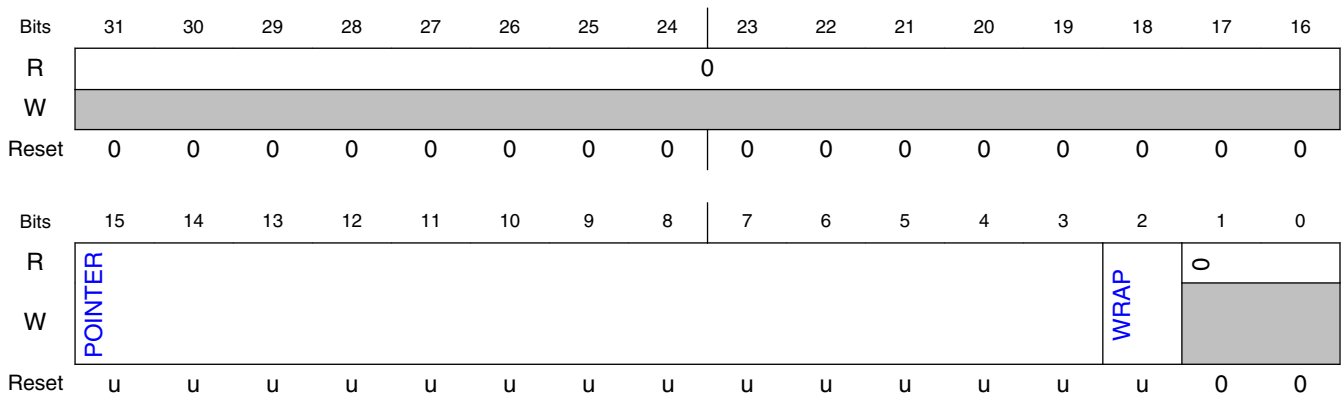
### 14.3.1.2.1 Offset

| Register | Offset |
|---|---|
| POSITION | 0h |

### 14.3.1.2.2 Function

The POSITION register contains the Trace Write Address Pointer and Wrap fields. This register can be modified by the explicit programming model writes. It is also automatically updated by the MTB hardware when trace packets are being recorded.

### 14.3.1.2.3 Diagram



### 14.3.1.2.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved<br>These bits must be treated as UNK/SBZP (unknown on reads, should-be-zero-or-preserved on writes). |
| 15-3<br>POINTER | Trace Packet Address Pointer<br>Because a packet consists of 2 words, the POINTER field is the address of the first word of a packet. This field contains bits[31:3] of the RAM address where the next trace packet is written. Therefore, it points to an unused location and is automatically incremented.<br>A debug agent can calculate the system memory map address for the current location in the MTB, using the following "generic" equation:<br>systemAddress = BASE+(POSITION & 0xFFFF_FFF8);<br>**NOTE:** The size of the RAM is parameterized and the most significant bits of the POINTER field are RAZ/WI.<br>For these devices, POSITION[31:16] == POSITION[POINTER[28:13] are RAZ/WI. Therefore, the active bits in this field are POSITION[15:3] == POSITION[POINTER[12:0]]. |
| 2<br>WRAP | WRAP<br>This field is set to 1 automatically when the POINTER value wraps (as determined by the MASTER[MASK] field in the MASTER Trace Control Register). A debug agent might use the WRAP field to determine whether the trace information above and below the pointer address is valid. |
| 1-0<br>— | Reserved<br>These bits must be treated as UNK/SBZP (unknown on reads, should-be-zero-or-preserved on writes). |

## 14.3.1.3 MTB Master Register (MASTER)

### 14.3.1.3.1 Offset

| Register | Offset |
|---|---|
| MASTER | 4h |

### 14.3.1.3.2 Function

The MASTER register contains the main program trace enable plus other trace controls. This register can be modified by the explicit programming model writes. MASTER[EN] and MASTER[HALTREQ] fields are also automatically updated by the MTB hardware.

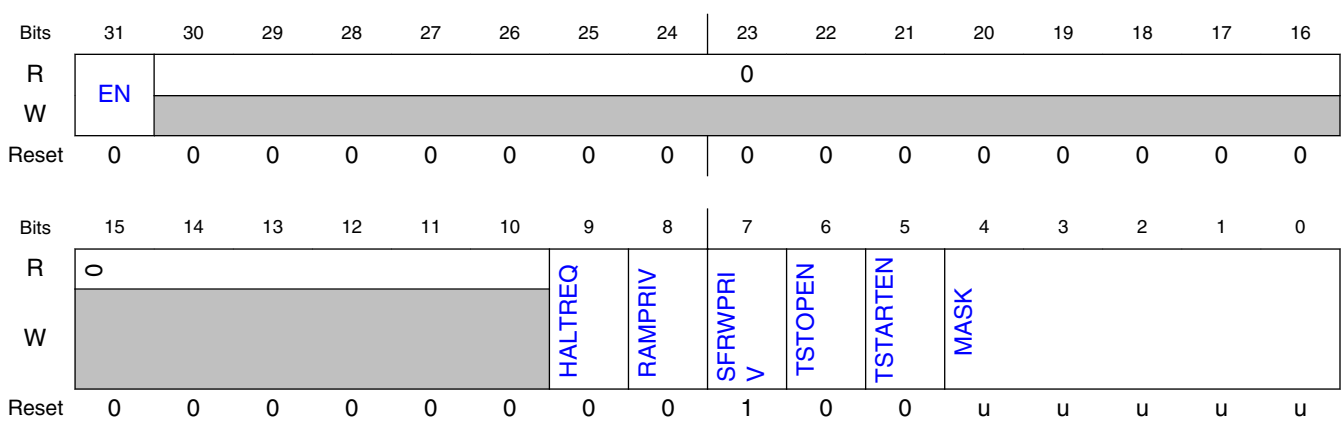
Before MASTER[EN] or MASTER[TSTARTEN] are set to 1, the software must initialize the POSITION and FLOW registers.

If FLOW[WATERMARK] is used to stop tracing or to halt the processor, MASTER[MASK] must still be set to a value that prevents POSITION[POINTER] from wrapping before it reaches the FLOW[WATERMARK] value.

**NOTE**

The format of this mask field is different than DWT_MASKn[MASK].

### 14.3.1.3.3 Diagram



#### 14.3.1.3.4 Fields

| Field | Function |
|---|---|
| 31<br>EN | Main Trace Enable<br>When this field is 1, trace data is written into the RAM memory location addressed by POSITION[POINTER]. The POSITION[POINTER] value auto increments after the trace data packet is written.<br>EN can be automatically set to 0 using the FLOW[WATERMARK] field and the FLOW[AUTOSTOP] bit.<br>EN is automatically set to 1 if TSTARTEN is 1 and the TSTART signal is HIGH.<br>EN is automatically set to 0 if TSTOPEN is 1 and the TSTOP signal is HIGH.<br>**NOTE:** If EN is set to 0 because FLOW[WATERMARK] is set, then it is not automatically set to 1 if TSTARTEN is 1 and the TSTART input is HIGH. In this case, tracing can only be restarted if FLOW[WATERMARK] or POSITION[POINTER] value is changed by software. |
| 30-10<br>— | Reserved<br>These bits must be treated as UNK/SBZP (unknown on reads, should-be-zero-or-preserved on writes). |
| 9<br>HALTREQ | Halt Request<br>This field is connected to the halt request signal of the trace logic, EDBGRQ. When HALTREQ is set to 1, the EDBFGRQ is asserted if DBGEN (invasive debug enable, one of the debug authentication interface signals) is also HIGH. HALTREQ can be automatically set to 1 using FLOW[WATERMARK]. |
| 8<br>RAMPRIV | RAM Privilege<br>If this field is 0, then user or privileged AHB read and write accesses to the RAM are permitted. If this field is 1, then only privileged AHB read and write accesses to the RAM are permitted and user accesses are RAZ/WI. The HPROT[1] signal determines if an access is a user or privileged mode reference. |
| 7<br>SFRWPRIV | Special Function Register Write Privilege<br>If this field is 0, then user or privileged AHB read and write accesses to the MTB Special Function Registers (programming model) are permitted. If this field is 1, then only privileged write accesses are permitted; user write accesses are ignored. The HPROT[1] signal determines if an access is user or privileged. Note MTB SFR read access are not controlled by this bit and are always permitted. |
| 6<br>TSTOPEN | Trace Stop Input Enable<br>If this field is 1 and the TSTOP signal is HIGH, then EN is set to 0. If a trace packet is being written to memory, the write is completed before tracing is stopped. |
| 5<br>TSTARTEN | Trace Start Input Enable<br>If this field is 1 and the TSTART signal is HIGH, then EN is set to 1. Tracing continues until a stop condition occurs. |
| 4-0<br>MASK | Mask<br>This value determines the maximum size of the trace buffer in RAM. It specifies the most-significant bit of the POSITION[POINTER] field that can be updated by automatic increment. If the trace tries to advance past this power of 2, the POSITION[WRAP] bit is set to 1, the POSITION[MASK+3:3] == POSITION[POINTER[MASK:0]] bits are set to 0, and the POSITION[14:MASK+3] == POSITION[POINTER[11:MASK+1]] bits remain unchanged.<br>This field causes the trace packet information to be stored in a circular buffer of size 2^[MASK+4] bytes, that can be positioned in memory at multiples of this size. As detailed in the POSITION description, typical "upper limits" for the MTB size are RAM_Size/4 or RAM_Size/2. Values greater than the maximum have the same effect as the maximum. |

## 14.3.1.4 MTB Flow Register (FLOW)

### 14.3.1.4.1 Offset

| Register | Offset |
|---|---|
| FLOW | 8h |

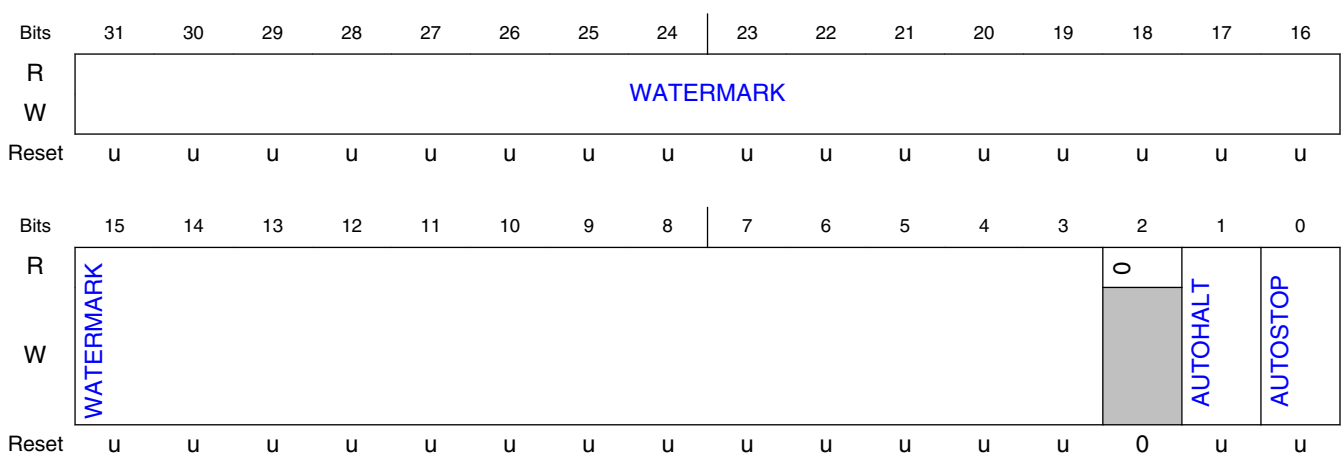
### 14.3.1.4.2 Function

The FLOW register contains the watermark address and the autostop/autohalt control bits. If tracing is stopped using the watermark autostop feature, it cannot be restarted until software clears the watermark autostop. This can be achieved in one of the following ways:

- Changing the POSITION[POINTER] field value to point to the beginning of the trace buffer, or
- Setting FLOW[AUTOSTOP] = 0.

A debug agent can use FLOW[AUTOSTOP] to fill the trace buffer once only without halting the processor.A debug agent can use FLOW[AUTOHALT] to fill the trace buffer once before causing the Cortex-M0+ processor to enter the Debug state. To enter Debug state, the Cortex-M0+ processor might have to perform additional branch type operations. Therefore, the FLOW[WATERMARK] field must be set below the final entry in the trace buffer region.

### 14.3.1.4.3 Diagram



#### 14.3.1.4.4 Fields

| Field | Function |
|---|---|
| 31-3<br>WATERMARK | WATERMARK[28:0]<br>This field contains an address in the same format as the POSITION[POINTER] field. When POSITION[POINTER] matches the WATERMARK field value, actions defined by the AUTOHALT and AUTOSTOP bits are performed. |
| 2<br>— | Reserved<br>These bits must be treated as UNK/SBZP (unknown on reads, should-be-zero-or-preserved on writes). |
| 1<br>AUTOHALT | AUTOHALT<br>If this field is 1 and WATERMARK is equal to POSITION[POINTER], then MASTER[HALTREQ] is automatically set to 1. If the DBGEN signal is HIGH, the MTB asserts this halt request to the Cortex-M0+ processor by asserting the EDBGRQ signal. |
| 0<br>AUTOSTOP | AUTOSTOP<br>If this field is 1 and WATERMARK is equal to POSITION[POINTER], then MASTER[EN] is automatically set to 0. This stops tracing. |

### 14.3.1.5 MTB Base Register (BASE)

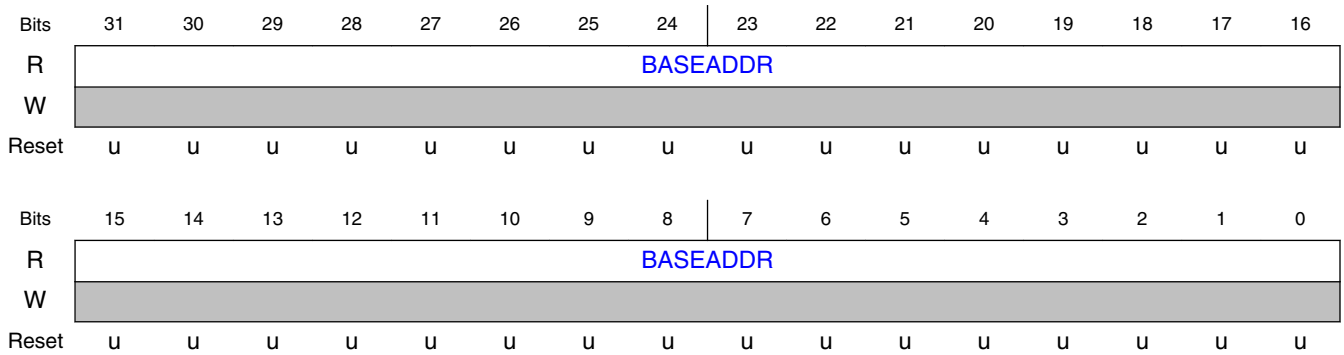
#### 14.3.1.5.1 Offset

| Register | Offset |
|---|---|
| BASE | Ch |

#### 14.3.1.5.2 Function

The read-only BASE Register indicates where the RAM is located in the system memory map. This register is provided to enable auto discovery of the MTB RAM location by a debug agent, and is defined by a hardware design parameter.

#### 14.3.1.5.3 Diagram



#### 14.3.1.5.4 Fields

| Field | Function |
|---|---|
| 31-0<br>BASEADDR | BASEADDR<br>This value is defined (hardwired): 0x09000000 |

### 14.3.1.6 Integration Mode Control Register (MODECTRL)

#### 14.3.1.6.1 Offset

| Register | Offset |
|---|---|
| MODECTRL | F00h |

#### 14.3.1.6.2 Function

This register enables the device to switch from a functional mode, or default behavior, into integration mode. It is hardwired to specific values used during the auto-discovery process by an external debug agent.

#### 14.3.1.6.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | MODECTRL | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |

| Field | Function |
|---|---|
| 31-0<br>TAGSET | TAGSET<br>Hardwired to 0x0000_0000 |

### 14.3.1.8 Claim TAG Clear Register (TAGCLEAR)

#### 14.3.1.8.1 Offset

| Register | Offset |
|---|---|
| TAGCLEAR | FA4h |

#### 14.3.1.8.2 Function

The read/write Claim Tag Clear Register is used to read the claim status on debug resources. A read indicates the claim tag status. Writing 1 to a specific bit clears the corresponding claim tag to 0. It is hardwired to specific values used during the auto-discovery process by an external debug agent.

#### 14.3.1.8.3 Diagram

## 14.3.1.11 Authentication Status Register (AUTHSTAT)

### 14.3.1.11.1 Offset

| Register | Offset |
|---|---|
| AUTHSTAT | FB8h |

### 14.3.1.11.2 Function

The Authentication Status Register reports the required security level and current status of the security enable bit pairs. Where functionality changes on a given security level, this change must be reported in this register. It is connected to specific signals used during the auto-discovery process by an external debug agent.

AUTHSTAT[3:2] indicates if nonsecure, noninvasive debug is enabled or disabled, while AUTHSTAT[1:0] indicates the enabled/disabled state of nonsecure, invasive debug. For both 2-bit fields, 0b10 indicates the functionality is disabled and 0b11 indicates it is enabled.

### 14.3.2.2.4 Fields

| Field | Function |
|---|---|
| 31-28<br>NUMCMP | Number of comparators<br>The DWT implements two comparators. |
| 27-0<br>DWTCFGCTRL | DWT configuration controls<br>This field is hardwired to 0xF00_0000, disabling all the remaining DWT functionality. The specific fields and their state are:<br>CTRL[27] = NOTRCPKT = 1, trace sample and exception trace is not supported<br>CTRL[26] = NOEXTTRIG = 1, external match signals are not supported<br>CTRL[25] = NOCYCCNT = 1, cycle counter is not supported<br>CTRL[24] = NOPRFCNT = 1, profiling counters are not supported<br>CTRL[22] = CYCEBTENA = 0, no POSTCNT underflow packets generated<br>CTRL[21] = FOLDEVTENA = 0, no folded instruction counter overflow events<br>CTRL[20] = LSUEVTENA = 0, no LSU counter overflow events<br>CTRL[19] = SLEEPEVTENA = 0, no sleep counter overflow events<br>CTRL[18] = EXCEVTENA = 0, no exception overhead counter events<br>CTRL[17] = CPIEVTENA = 0, no CPI counter overflow events<br>CTRL[16] = EXCTRCENA = 0, generation of exception trace disabled<br>CTRL[12] = PCSAMPLENA = 0, no periodic PC sample packets generated<br>CTRL[11:10] = SYNCTAP = 0, no synchronization packets<br>CTRL[9] = CYCTAP = 0, cycle counter is not supported<br>CTRL[8:5] = POSTINIT = 0, cycle counter is not supported<br>CTRL[4:1] = POSTPRESET = 0, cycle counter is not supported<br>CTRL[0] = CYCCNTENA = 0, cycle counter is not supported |

## 14.3.2.3 DWT Comparator Register (COMP0 - COMP1)

### 14.3.2.3.1 Offset

For a = 0 to 1:

| Register | Offset |
|---|---|
| COMPa | 20h + (a × 10h) |

### 14.3.2.3.2 Function

The COMPn registers provide the reference value for comparator n.

### 14.3.2.3.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | COMP | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | COMP | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 14.3.2.3.4 Fields

| Field | Function |
|---|---|
| 31-0<br>COMP | Reference value for comparison<br>If COMP0 is used for a data value comparator and the access size is byte or halfword, the data value must be replicated across all appropriate byte lanes of this register. For example, if the data is a byte-sized "x" value, then COMP[31:24] = COMP[23:16] = COMP[15:8] = COMP[7:0] = "x". Likewise, if the data is a halfword-size "y" value, then COMP[31:16] = COMP[15:0] = "y". |

## 14.3.2.4 DWT Comparator Mask Register (MASK0 - MASK1)

### 14.3.2.4.1 Offset

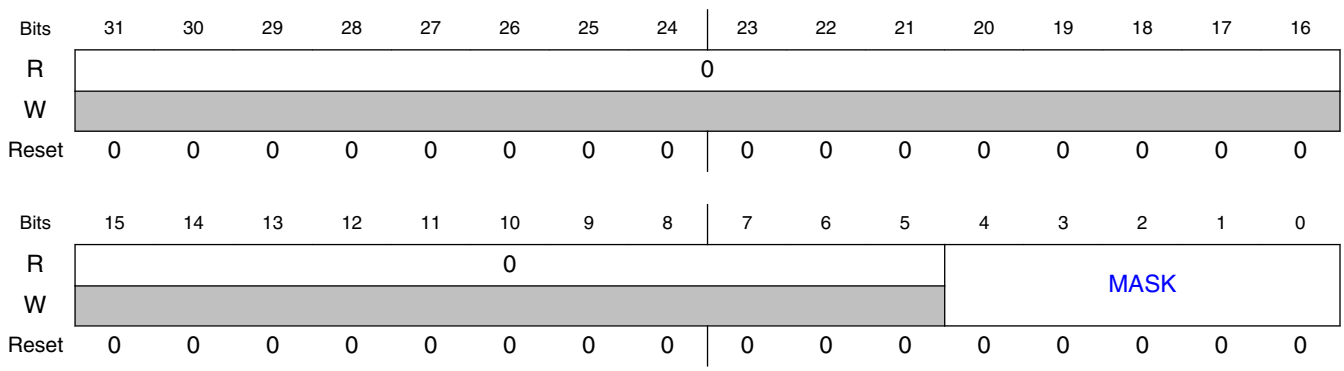
For a = 0 to 1:

| Register | Offset |
|---|---|
| MASKa | 24h + (a × 10h) |

### 14.3.2.4.2 Function

The MASKn registers define the size of the ignore mask applied to the reference address for address range matching by comparator n. Note the format of this mask field is different than the MTB_MASTER[MASK].

### 14.3.2.4.3 Diagram



### 14.3.2.4.4 Fields

| Field | Function |
|---|---|
| 31-5<br>— | Reserved |
| 4-0<br>MASK | MASK<br>The value of the ignore mask, 0-31 bits, is applied to address range matching. MASK = 0 is used to include all bits of the address in the comparison, except if MASK = 0 and the comparator is configured to watch instruction fetch addresses, address bit [0] is ignored by the hardware since all fetches must be at least halfword aligned. For MASK != 0 and regardless of watch type, address bits [x-1:0] are ignored in the address comparison.<br>Using a mask means the comparator matches on a range of addresses, defined by the unmasked most significant bits of the address, bits [31:x]. The maximum MASK value is 24, producing a 16 Mbyte mask. An attempted write of a MASK value > 24 is limited by the DWT hardware to 24.<br>If COMP0 is used as a data value comparator, then MASK0 should be programmed to zero. |

## 14.3.2.5 DWT Comparator Function Register 0 (FCT0)

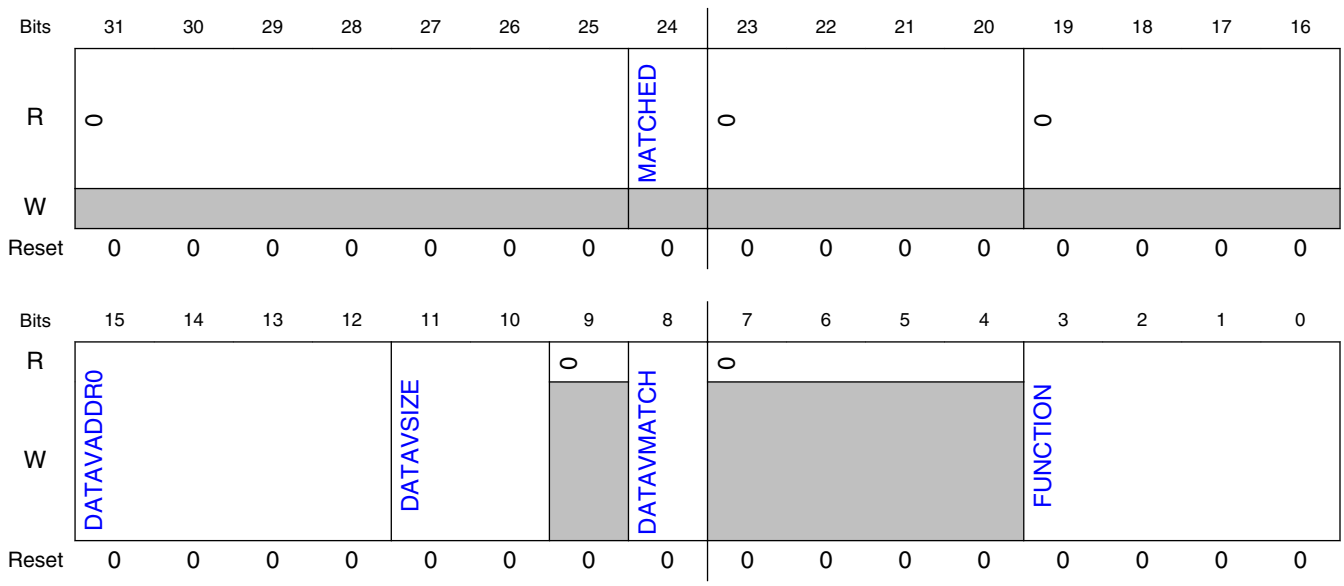
### 14.3.2.5.1 Offset

| Register | Offset |
|---|---|
| FCT0 | 28h |

### 14.3.2.5.2 Function

The FCTn registers control the operation of comparator n.

### 14.3.2.5.3 Diagram



### 14.3.2.5.4 Fields

| Field | Function |
|---|---|
| 31-25<br>— | Reserved |
| 24<br>MATCHED | Comparator match<br>If this read-only flag is asserted, it indicates the operation defined by the FUNCTION field occurred since the last read of the register. Reading the register clears this bit.<br>0b - No match.<br>1b - Match occurred. |
| 23-20<br>— | Reserved |
| 19-16<br>— | Reserved<br>Data Value Address 1. Reserved, RAZ/WI. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 15-12<br>DATAVADDR0 | Data Value Address 0<br>Since the DWT implements two comparators, the DATAVADDR0 field is restricted to values {0,1}. When the DATAVMATCH bit is asserted, this field defines the comparator number to use for linked address comparison.<br>If COMP0 is used as a data watchpoint and COMP1 as an address watchpoint, DATAVADDR0 must be set. |
| 11-10<br>DATAVSIZE | Data Value Size<br>For data value matching, this field defines the size of the required data comparison.<br>00b - Byte.<br>01b - Halfword.<br>10b - Word.<br>11b - Reserved. Any attempts to use this value results in UNPREDICTABLE behavior. |
| 9<br>— | Reserved<br>Data Value Address 1. Reserved, RAZ/WI. |
| 8<br>DATAVMATCH | Data Value Match<br>When this field is 1, it enables data value comparison. For this implementation, COMP0 supports address or data value comparisons; COMP1 only supports address comparisons.<br>0b - Perform address comparison.<br>1b - Perform data value comparison. |
| 7-4<br>— | Reserved<br>Data Value Address 1. Reserved, RAZ/WI. |
| 3-0<br>FUNCTION | Function<br>Selects the action taken on a comparator match. If COMP0 is used for a data value and COMP1 for an address value, then FCT1[FUNCTION] must be set to zero. For this configuration, MASK1 can be set to a non-zero value, so the combined comparators match on a range of addresses.<br>0000b - Disabled.<br>0001-0011b - Reserved. Any attempts to use this value results in UNPREDICTABLE behavior.<br>0100b - Instruction fetch.<br>0101b - Data operand read.<br>0110b - Data operand write.<br>0111b - Data operand (read + write).<br>1000-1111b - Reserved. Any attempts to use this value results in UNPREDICTABLE behavior. |

## 14.3.2.6 DWT Comparator Function Register 1 (FCT1)

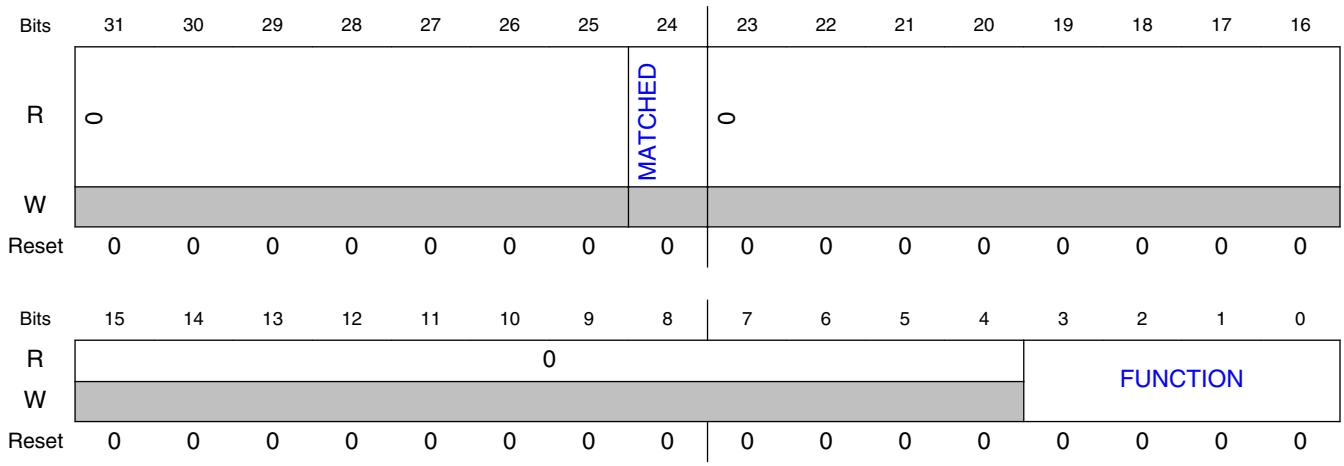
### 14.3.2.6.1 Offset

| Register | Offset |
|---|---|
| FCT1 | 38h |

### 14.3.2.6.2 Function

The FCTn registers control the operation of comparator n. Since the DWT only supports data value comparisons on comparator 0, there are several fields in the FCT1 register that are RAZ/WI (bits 12, 11:10, 8).

### 14.3.2.6.3 Diagram



### 14.3.2.6.4 Fields

| Field | Function |
|---|---|
| 31-25<br>— | Reserved |
| 24<br>MATCHED | Comparator match<br>If this read-only flag is asserted, it indicates the operation defined by the FUNCTION field occurred since the last read of the register. Reading the register clears this bit.<br>0b - No match.<br>1b - Match occurred. |
| 23-4<br>— | Reserved |
| 3-0<br>FUNCTION | Function<br>Selects the action taken on a comparator match. If COMP0 is used for a data value and COMP1 for an address value, then FCT1[FUNCTION] must be set to zero. For this configuration, MASK1 can be set to a non-zero value, so the combined comparators match on a range of addresses.<br>0000b - Disabled.<br>0001-0011b - Reserved. Any attempts to use this value results in UNPREDICTABLE behavior.<br>0100b - Instruction fetch.<br>0101b - Data operand read.<br>0110b - Data operand write.<br>0111b - Data operand (read + write).<br>1000-1111b - Reserved. Any attempts to use this value results in UNPREDICTABLE behavior. |

## 14.3.2.7 DWT Trace Buffer Control Register (TBCTRL)

### 14.3.2.7.1 Offset

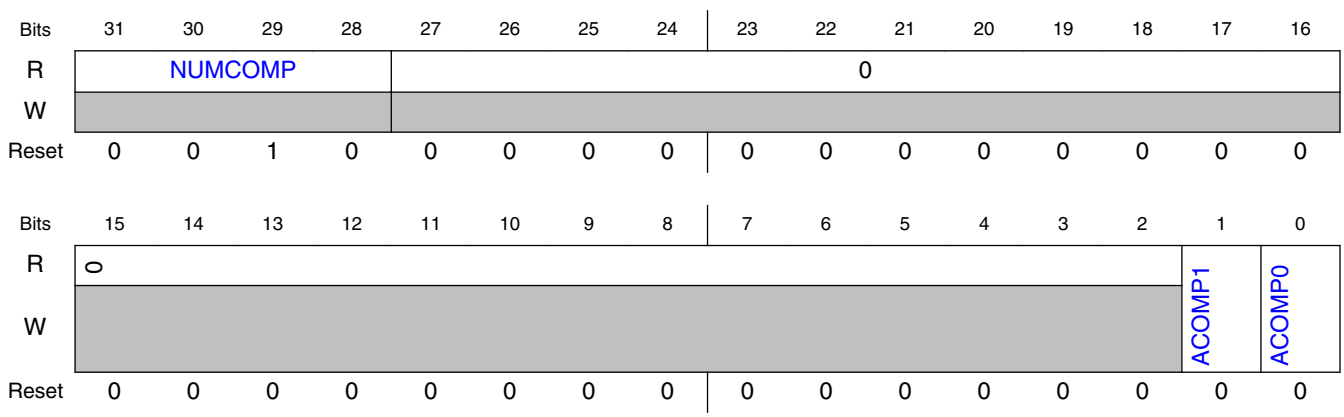
| Register | Offset |
|---|---|
| TBCTRL | 200h |

### 14.3.2.7.2 Function

The TBCTRL register defines how the watchpoint comparisons control the actual trace buffer operation.

Recall the MTB supports starting and stopping the program trace based on the watchpoint comparisons signaled via TSTART and TSTOP. The watchpoint comparison signals are enabled in the MTB's control logic by setting the appropriate enable bits, MTB_MASTER[TSTARTEN, TSTOPEN]. In the event of simultaneous assertion of both TSTART and TSTOP, TSTART takes priority.

### 14.3.2.7.3 Diagram



### 14.3.2.7.4 Fields

| Field | Function |
|---|---|

## 14.3.3 ROM register descriptions

### 14.3.3.1 ROM Memory map

The System ROM Table registers are also mapped into a sparsely-populated 4 KB address space.

For core configurations like that supported by Cortex-M0+, ARM recommends that a debugger identifies and connects to the debug components using the CoreSight debug infrastructure.

ARM recommends that a debugger follows the flow as shown in the following figure to discover the components in the CoreSight debug infrastructure. In this case, a debugger reads the peripheral and component ID registers for each CoreSight component in the CoreSight system.

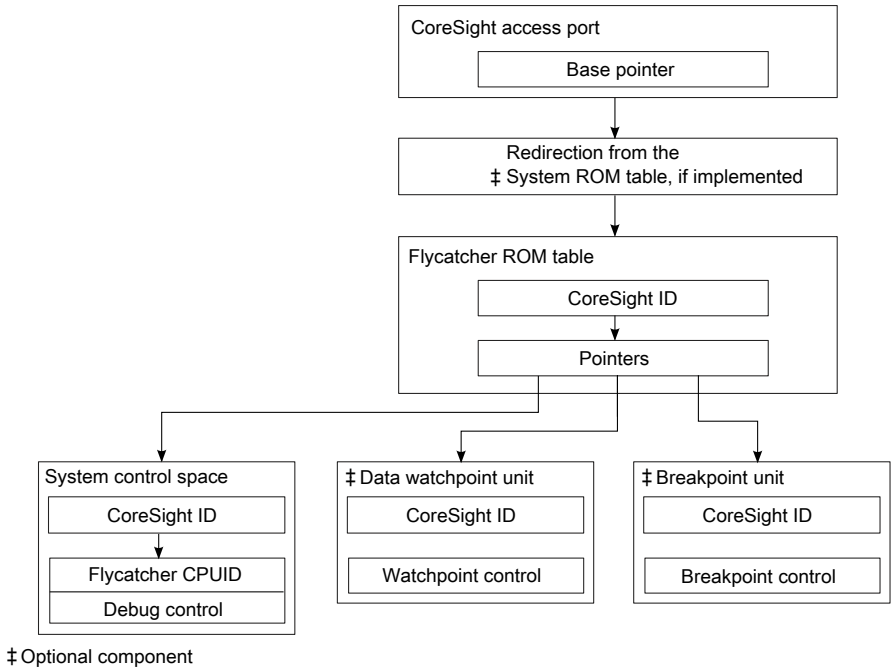

**Figure 14-3. CoreSight discovery process**

## ROM base address: F000_2000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h - Ch | Entry (ENTRY0 - ENTRY3) | 32 | RO | See description. |
| 10h | End of Table Marker Register (TABLEMARK) | 32 | RO | 0000_0000h |
| FCCh | System Access Register (SYSACCESS) | 32 | RO | 0000_0001h |
| FD0h | Peripheral ID Register (PERIPHID4) | 32 | RO | See description. |
| FD4h | Peripheral ID Register (PERIPHID5) | 32 | RO | See description. |
| FD8h | Peripheral ID Register (PERIPHID6) | 32 | RO | See description. |
| FDCh | Peripheral ID Register (PERIPHID7) | 32 | RO | See description. |
| FE0h | Peripheral ID Register (PERIPHID0) | 32 | RO | See description. |
| FE4h | Peripheral ID Register (PERIPHID1) | 32 | RO | See description. |
| FE8h | Peripheral ID Register (PERIPHID2) | 32 | RO | See description. |
| FECh | Peripheral ID Register (PERIPHID3) | 32 | RO | See description. |
| FF0h - FFCh | Component ID Register (COMPID0 - COMPID3) | 32 | RO | See description. |

## 14.3.3.2 Entry (ENTRY0 - ENTRY3)

### 14.3.3.2.1 Offset

For a = 0 to 3:

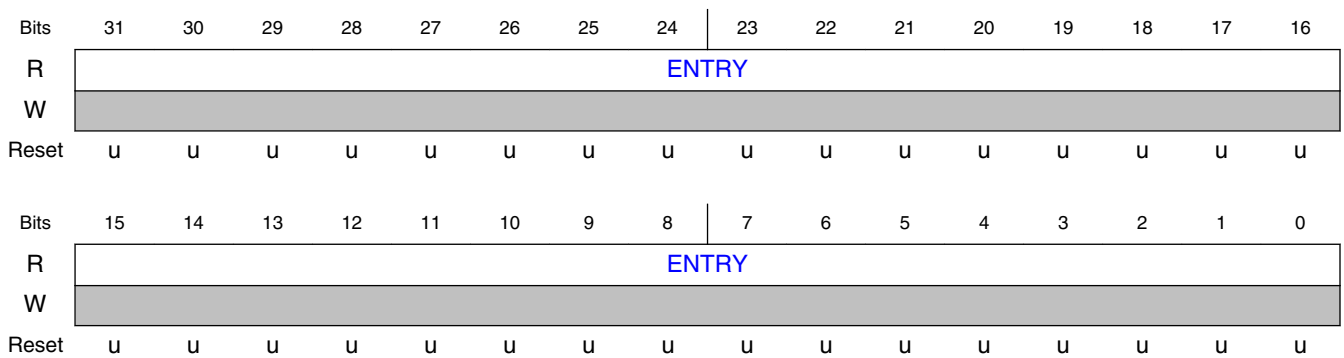
| Register | Offset |
|---|---|
| ENTRYa | 0h + (a × 4h) |

### 14.3.3.2.2 Function

The System ROM Table begins with "n" relative 32-bit addresses, one for each debug component present in the device and terminating with an all-zero value signaling the end of the table at the "n+1"-th value.

It is hardwired to specific values used during the auto-discovery process by an external debug agent.

### 14.3.3.2.3 Diagram



### 14.3.3.2.4 Fields

| Field | Function |
|---|---|
| 31-0<br>ENTRY | ENTRY<br>Entry*n* values are hardwired: Entry 0 (MTB) is hardwired to 0xFFFF_E003, Entry 1 (DWT) to 0xFFFF_F003, Entry 2 (CM0PCTI) to 0x0000_4003, Entry 3 (CM0+ ROM Table) to 0xF00F_D003 |

## 14.3.3.3 End of Table Marker Register (TABLEMARK)

### 14.3.3.3.1 Offset

| Register | Offset |
|---|---|
| TABLEMARK | 10h |

### 14.3.3.3.2 Function

This register indicates end of table marker. It is hardwired to specific values used during the auto-discovery process by an external debug agent.

# Chapter 15
# JTAG Controller (JTAGC)

## 15.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

### 15.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as Register description for more information about the JTAGC registers.

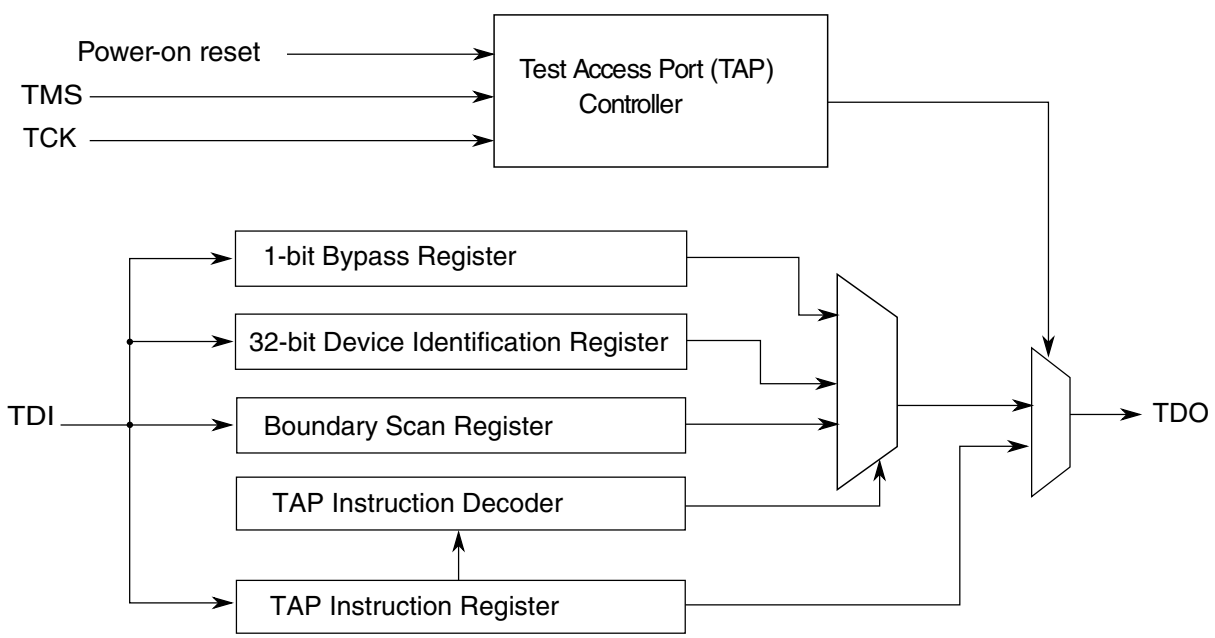

**Figure 15-1. JTAG (IEEE 1149.1) block diagram**

### 15.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to JTAGC block instructions for a list of supported instructions.
- Bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

### 15.1.3 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

#### 15.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

#### 15.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

#### 15.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

## 15.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

**Table 15-1. JTAG signal properties**

| Name | I/O | Function | Reset State |
|---|---|---|---|
| TCK | Input | Test Clock | Weak pulldown |
| TDI | Input | Test Data In | Weak pullup |
| TDO | Output | Test Data Out | High Z[1] |
| TMS | Input | Test Mode Select | Weak pullup |

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

### 15.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

### 15.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 15.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

### 15.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

## 15.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

## 15.3.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

| | 3 | 2 | 1 | 0 |
|---|---|---|---|---|
| R | 0 | 0 | 0 | 1 |
| W | Instruction Code | | | |
| Reset: | 0 | 0 | 0 | 1 |

**Figure 15-2. Instruction register**

## 15.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

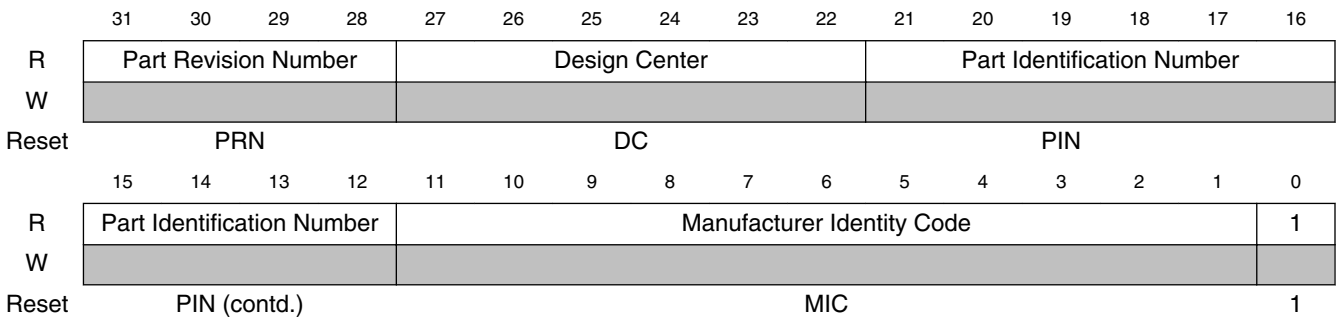
- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

## 15.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is

active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.



The following table describes the device identification register functions.

**Table 15-2. Device identification register field descriptions**

| Field | Description |
|---|---|
| PRN | Part Revision Number. Contains the revision number of the part. Value is cccc. |
| DC | Design Center. Indicates the design center. Value is 0x2C. |
| PIN | Part Identification Number. Contains the part number of the device. Value is 0b0000100000. |
| MIC | Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E. |
| IDCODE ID | IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1. |

### 15.3.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

## 15.4 Functional description

This section explains the JTAGC functional description.

### 15.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

### 15.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

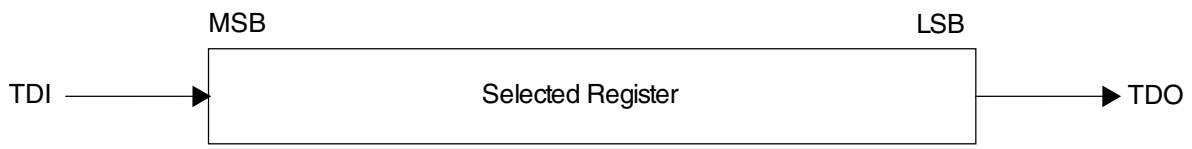


**Figure 15-3. Shifting data through a register**

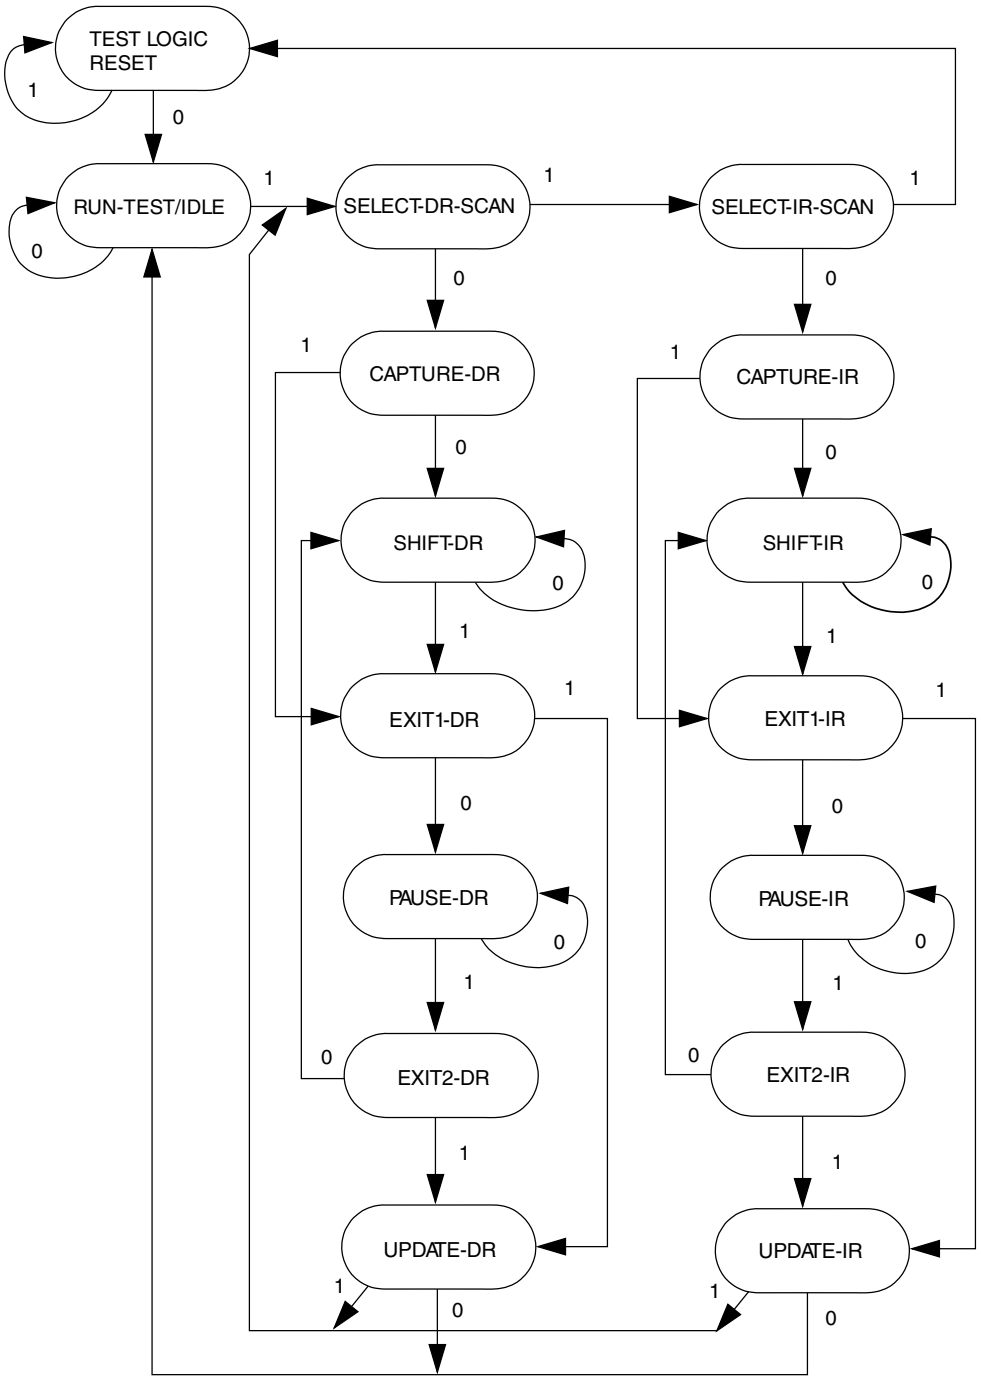
### 15.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 15-4. IEEE 1149.1-2001 TAP controller finite state machine**

## 15.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

### 15.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

## 15.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

**Table 15-3. 4-bit JTAG instructions**

| Instruction | Code[3:0] | Instruction summary |
|---|---|---|
| IDCODE | 0000 | Selects device identification register for shift |
| SAMPLE/PRELOAD | 0010 | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation |
| SAMPLE | 0011 | Selects boundary scan register for shifting and sampling without disturbing functional operation |
| EXTEST | 0100 | Selects boundary scan register and applies preloaded values to output pins.<br>**NOTE:** Execution of this instruction asserts functional reset. |
| Factory debug reserved | 0101 | Intended for factory debug only |
| Factory debug reserved | 0110 | Intended for factory debug only |
| Factory debug reserved | 0111 | Intended for factory debug only |
| ARM JTAG-DP Reserved | 1000 | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information. |
| HIGHZ | 1001 | Selects bypass register and three-states all output pins.<br>**NOTE:** Execution of this instruction asserts functional reset. |
| ARM JTAG-DP Reserved | 1010 | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information. |

*Table continues on the next page...*

**Table 15-3. 4-bit JTAG instructions (continued)**

| Instruction | Code[3:0] | Instruction summary |
|---|---|---|
| ARM JTAG-DP Reserved | 1011 | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information. |
| CLAMP | 1100 | Selects bypass register and applies preloaded values to output pins.<br>**NOTE:** Execution of this instruction asserts functional reset. |
| ARM JTAG-DP Reserved | 1110 | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information. |
| BYPASS | 1111 | Selects bypass register for data operations |

### 15.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

### 15.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

#### 15.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

#### 15.4.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

#### 15.4.4.5 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

#### 15.4.4.6 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

#### 15.4.4.7 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

### 15.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

## 15.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS
2. Load the appropriate instruction for the test or action to be performed

# Chapter 16
# Memory Map

## 16.1 Introduction

This device contains various memories and memory-mapped peripherals which are located in one 32-bit contiguous addressable memory space. This chapter describes the memory and peripheral locations within that memory space.

## 16.2 System memory map

The following table shows the high-level device memory map. This map provides the complete architectural address space definition for the various sections. Based on the physical sizes of the memories and peripherals, the actual address regions used may be smaller.

The system memory map includes aliased address spaces that are intended for specific purposes.

- The region of memory from 0x1000_0000 to 0x1FFF_FFFF is aliased to regions of the External RAM and External Device areas of the system memory. This allows faster execution from these areas because the processor core thinks that they are in the Code area of memory. Additionally, by mapping these regions to the Code space, these devices can be cached in the I/D Caches. The FlexBus controller is the only memory peripheral assigned to this space.

**Table 16-1. System memory map**

| Start Address | Stop Address | Cortex-M4 Map | Cortex-M0+ Map | Access | Cached |
|---|---|---|---|---|---|
| 0x0000_0000 | 0x000F_FFFF | M4 - 1 MB flash (including exception vectors in first 1024 bytes) | M4 - 1 MB flash (including exception vectors in first 1024 bytes) | All Masters[1] | Yes |

1. The CM0+ in the 0x0000_0000 to 0x0000_0FFF will remap to other locations based on boot sources.
2. The Private Peripheral Bus (PPB) is only accessible from the core to which it is attached.

## 16.3 Flash memory map

The flash memory and the flash registers are located at different base addresses as shown in the following figure. The base address for each is specified in System memory map .

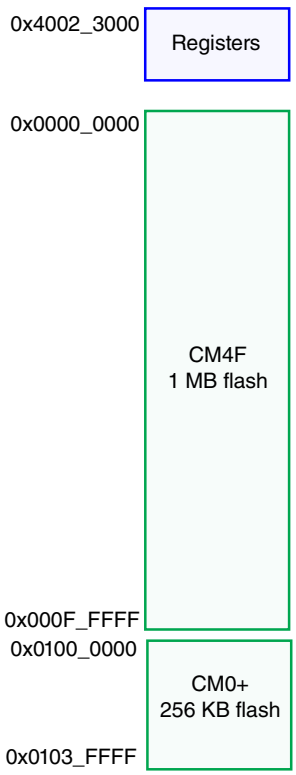

**Figure 16-1. Flash address in Cortex-M4F/M0+ map**

The on-chip Flash includes two portions. One is with 1 MB size mainly for CM4F subsystem beginning at address 0x0000_0000. Another is with 256 KB size mainly for Cortex-M0+ subsystem beginning at address 0x0100_0000.

Both Cortex-M4F/M0+ cores can access the entire amount of flash on the device with one exception – CM0+ cannot access lowest 4 KB region of CM4F flash starting from address 0x0000_0000. Each CPU accesses to the flash associated with the other CPU has lower performance.

Accesses to the flash memory ranges outside the amount of Flash on the device causes the bus cycle to be terminated with an error followed by the appropriate response in the requesting bus master. Read collision events in which flash memory is accessed while a flash memory resource is being manipulated by a flash command also generates a bus error response.

## 16.4 Flash access control introduction

The Flash Access Control (FAC) is a configurable memory protection scheme optimized to allow end users to utilize software libraries while offering programmable restrictions to these libraries. The flash memory is divided into equal size segments that provide protection to proprietary software libraries. The protection of these segments is controlled as the FAC provides a cycle-by-cycle evaluation of the access rights for each transaction routed to the on-chip flash memory. Configurability allows an increasing number of protected segments while supporting two levels of vendors adding their proprietary software to a device.

Flash access control aligns to the three privilege levels supported by ARM Cortex-M family products where the most secure state - supervisor/privileged-secure - aligns to the execute-only and supervisor-only access control. The unsecure state of user-non-secure aligns to no access control states set, and the mid-level state where user-secure aligns to using the access control of execute-only.

Control for this protection scheme is implemented in Program Index NVM locations and is configurable through a Program Index flash command operations. The NVM locations controlling the FAC are affected by Erase All Blocks flash command and debug interface initiated mass erase operations.

## 16.5 SRAM memory map

See the following table for the SRAM memory map. The enabe and disable of each SRAM banks are controlled by SRAMLPR and SRAMDSR in MSMC module.

**Table 16-2. SRAM memory map**

| Start Address | Stop Address | Cortex-M4 Map | Cortex-M0+ Map | SMC0_SRAMLPR SMC0_SRAMDSR | SMC1_SRAMLPR SMC1_SRAMDSR |

## 16.6 Peripheral bridge memory maps

This section covers the peripheral bridges included in this device.

### 16.6.1 ARM Cortex-M0+/RISC-V ZERO-RISCY peripheral bridge memory maps

The peripheral memory map is accessible via one slave port on the crossbar in the 0x4100_0000 – 0x4107_FFFF region. The device implements one peripheral bridge that defines a 512 KB address space.

### 16.6.1.1 ARM Cortex-M0+/RISC-V ZERO-RISCY Peripheral Bridge 1 (AIPS-Lite 1) memory map

## 16.6.2 ARM Cortex-M4RISC-V RI5CY peripheral bridge memory maps

The peripheral memory map is accessible via one slave port on the crossbar in the 0x4000_0000 – 0x4007_FFFF region. The device implements one peripheral bridge that defines a 512 KB address space.

### 16.6.2.1 ARM Cortex M4/RISC-V RI5CY Peripheral Bridge 0 (AIPS-Lite 0) memory map

## 16.7 Private Peripheral Bus (PPB) memory map

The Private Peripheral Bus (PPB) is part of the ARM bus architecture definition and provides access to select processor-local modules. These resources are only accessible from the core; other system masters do not have access to them. The bus is split into an internal Private Peripheral Bus (PPB) and an External Private Peripheral Bus (EPPB). The PPB provides access to tightly coupled ARM system resources such as the Instrumentation Trace Module (ITM), Data Watchpoint and Trace (DWT), Flash Patch Breakpoint (FPB), Memory Protection Unit (MPU), and the Nested Vectored Interrupt Control (NVIC).

The External Private Peripheral Bus (EPPB) is accessed through the Advanced Peripheral Bus (APB) interface. The EPPB is intended for CoreSight™-compatible debug and trace components such as the Trace Port Interface Unit (TPIU) and the Embedded Trace Macrocell (ETM) as well as vendor specific modules. The EPPB has a number of irregular limitations that make it less useful for regular system peripherals.

The following sections detail the Private Peripheral Bus memory maps associated with this device.

### 16.7.1 ARM Cortex-M0+ PPB memory map

The following table shows the memory map for the Cortex M0+ processor in this device.

**Table 16-5. ARM Cortex-M0+ PPB memory map**

| Start | End | Resource |
|---|---|---|
| Internal Private Peripheral Bus | | |
| 0xE000_0000 | 0xE000_DFFF | Reserved |

# Chapter 17
# Flash Memory Module (FTFE)

## 17.1 Chip-specific FTFE information

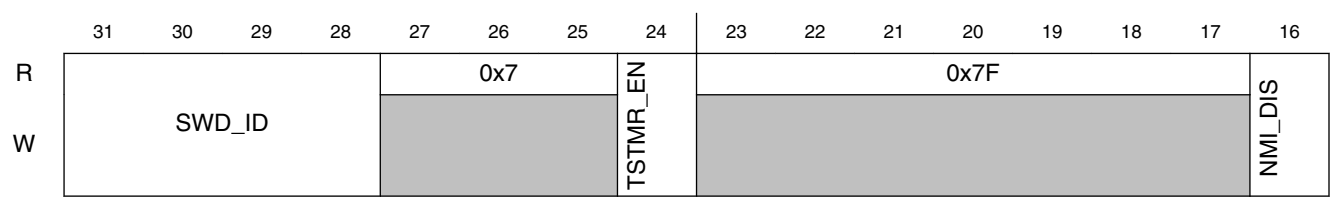
### 17.1.1 Flash Option (FOPT) customization

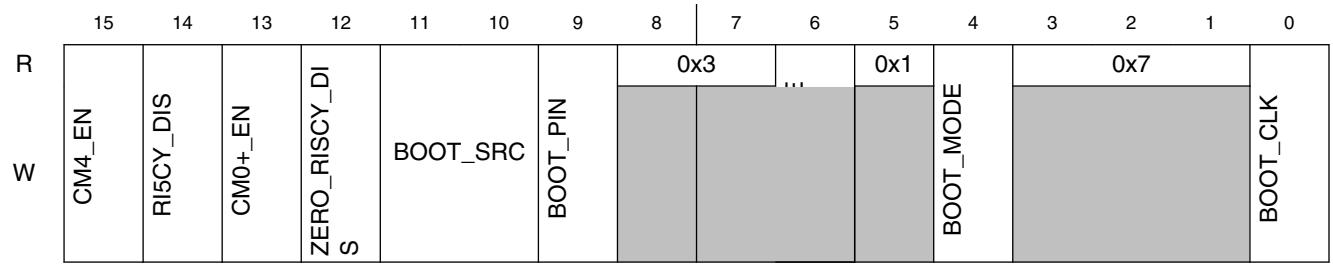
The Flash Option (FOPT) register in the Flash Memory module (FTFE_FOPT) allows the user to customize the operation of the MCU at boot time. The register contains read-only bits that are loaded from the NVM's flash configuration field. The default setting for all values in the FTFE_FOPT register is logic 1 since it is copied from the option byte residing in flash, which has all bits as logic 1 in the flash erased state. To configure for alternate settings, program the appropriate bits in the NVM option byte. The new settings will take effect on subsequent POR and any system reset. For more details on programming the option byte, see the flash memory chapter.

The MCU uses the FTFE_FOPT to configure the device at reset as shown in the following table.

**NOTE**

An FTFE_FOPT value of 0x0000_0000 is invalid and will be ignored. The FOPT register is written to 0xFFFF_FFFF if the contents of the Flash non-volatile option are 0x0000_0000.





## Table 17-3. Flash Option Register Bit Definitions

| Bit Num | Field | Definition |
|---|---|---|
| 31-28 | SWD_ID | **Serial Wire Debug Identification** - The SWD_ID sets the Instance ID of SWD modules that support multidrop. The Instance ID is used to select a specific SWD instance in systems with a single SWD interface port, but multiple devices with SWD interfaces. |
| 27-25 | Reserved | This field is reserved. |
| 24 | TSTMR_EN | **Time Stamp Timer Enable** - The TSTMR_EN bit enables the Time Stamp Timer (TSTMR) when the the Slow-Speed IRC is enabled.<br>• 0 - The TSTMR is disabled and cannot be enabled through any hardware or software operations.<br>• 1 - The TSTMR is enabled and begins counting whenever the Slow-Speed IRC is enabled. |
| 23-17 | Reserved | This field is reserved. |
| 16 | NMI_DIS | **Non-Maskable Interrupt (NMI) Disable** - The NMI_DIS bit disables the NMI signal.<br>• 0 - NMI pin and interrupts are enabled.<br>• 1 - NMI interrupts are always blocked. The associated pin continues to default to NMI pin controls with internal pullup enabled. |
| 15 | CM4_EN | **ARM CM4F core Enable** - The CM4_EN enables CM4F core.<br>• 0 - CM4F core is disabled.<br>• 1 - CM4F core is enabled. |
| 14 | RI5CY_DIS | **RI5CY core Disable** - The RI5CY_DIS bit disables RI5CY core.<br>• 0 - RI5CY core is enabled.<br>• 1 - RI5CY core is disabled. |
| 13 | CM0+_EN | **ARM CM0+ core Enable** - The CM0+_EN enables CM4F core.<br>• 0 - CM0+ core is disabled.<br>• 1 - CM0+ core is enabled. |
| 12 | ZERO_RISCY_DIS | **ZERO_RISCY core Disable** - The ZERO_RISCY_DIS bit disables ZERO_RISCY core.<br>• 0 - ZERO_RISCY core is enabled.<br>• 1 - ZERO_RISCY core is disabled. |
| 11-10 | BOOT_SRC | **Boot Source** - The BOOT_SRC field selects the boot source if the Boot Pin Configuration bit (BOOT_PIN) is set to 1.<br>• 00 - Boot from the internal flash memory.<br>• 01 - Reserved.<br>• 10 - Boot from the Boot ROM, configure communications peripheral(s), and enter boot loader mode. See Boot sequence for more information<br>• 11 - Boot from the Boot ROM, and enter boot loader mode. See Boot sequence for more information. |

*Table continues on the next page...*

**Table 17-3. Flash Option Register Bit Definitions (continued)**

| Bit Num | Field | Definition |
|---|---|---|
| 9 | BOOT_PIN | **Boot Pin Configuration** - The BOOT_PIN bit controls the behavior of the boot pin selection.<br>• 0 - Force Boot from ROM with update if BOOTCFG0 asserted, where BOOTCFG0 is the boot configuration function which is muxed with NMI pin. The RESET_b pin must be enabled when this option is selected.<br>• 1 - Boot source configured by Boot Source (BOOT_SRC) field. |
| 8-7 | Reserved | This field is reserved. |
| 6 | BOOT_CORE | **Boot Core** - The BOOT_CORE bit selects which core will start executing code at the completion of initialization. Additionally, the Non-Maskable Interrupt (NMI) is routed to this core if the NMI_DIS bit is set to 0.<br>• 0 - CPU1 (Cortex-M0+) or/and CPU3 (ZERO-RISCY), which depends on [CM0+_EN] and [ZERO_RISCY_DIS] settings, will start executing code on completion of initialization.<br>• 1 - CPU0 (Cortex-M4) or/and CPU2 (RI5CY), which depends on [CM4_EN] and [RI5CY_DIS] settings,will start executing code on completion of initialization. |
| 5 | Reserved | This field is reserved for future expansion. |
| 4 | BOOT_MODE | **Boot Mode** - The BOOT_MODE bit selects the operational mode that will be entered at the completion of initialization.<br>• 0 - The device will exit initialization in VLPR mode.<br>• 1 - The device will exit initialization in RUN mode. |
| 3-1 | Reserved | This field is reserved. |
| 0 | BOOT_CLK | **Boot Clock** - The BOOT_CLK field controls the setting of the Core Clock Divide Ratio (DIVCORE) field. Depending on the value of the BOOT_MODE bit, this field will be set in either the SCG_RCCR register or the SCG_VCCR register.<br>BOOT_MODE = 1 (Exit initialization in RUN mode.)<br>• 1 - SCG_RCCR[DIVCORE] set to 0000 - Divide-by-1<br>• 0 - SCG_RCCR[DIVCORE] set to 0001 - Divide-by-2<br>BOOT_MODE = 0 (Exit initialization in VLPR mode.)<br>• 1 - SCG_VCCR[DIVCORE] set to 0011 - Divide-by-4<br>• 0 - SCG_VCCR[DIVCORE] set to 0111 - Divide-by-8 |

## 17.2 External signal description

The flash module contains no signals that connect off-chip.

## 17.3 Memory map and registers

This section describes the memory map and registers for the flash module. Data read from unimplemented memory space in the flash module is undefined. Writes to unimplemented or reserved memory space (registers) in the flash module are ignored.

## 17.3.1 IFR descriptions

Primary Program flash block 0 contains two IFR flash memory spaces with restricted access separate from the main flash memory. Each IFR is divided into index fields with unreserved fields accessible using the Read Index command and/or programmable using the Program Index command. Once programmed, the index fields in the erasable IFR can be reprogrammed but only after a successful Erase All Blocks or Erase All Blocks Unsecure command operation which erases the entire flash memory space. There is no mechanism to erase the erasable IFR without erasing the entire flash memory. While each index field actually contains 8 bytes, the maps below indicate how many bytes are used.

### 17.3.1.1 Non-erasable IFR Map

| Record Index | Field Name | Field Size (Bytes) | RDINDEX | PGMINDEX | CCOB Used | Field Description |
|---|---|---|---|---|---|---|
| 0x00 - 0x07 | PGMONCEID | 64 | Yes | Yes | 4 - B | Program Once Identifier |
| 0x08 - 0x0F | | 64 | Yes | Yes | 4 - B | Available |
| 0x10 | VERSIONID | 8 | Yes | No | 4 - B | Version Identifier |
| 0x11 - 0x17 | | 56 | Yes | No | 4 - B | Available |
| 0x18 - 0x1F | | 64 | Yes | No | 4 - B | Available |
| 0x20 - 0x7F | | 768 | | | | Reserved |

#### 17.3.1.3 Flash Configuration Field description

The erasable IFR contains flash configuration field records that store default protection settings (loaded on reset) and security information that allows the MCU to restrict access to the flash module. All fields are programmable using the Program Index command except for the secondary security field (SEC1) which is programmed during a successful Erase All Blocks or Erase All Blocks Unsecure operation. All fields are readable using the Read Index command except for the backdoor comparison key (KEY). The following index fields make up the flash configuration field.

- SEC0 (0x80)
- FSLACC (0x81)
- MEEN (0x82)
- KEYEN (0x83)
- FOPT (0x84)
- FPROTP (0x85)
- FPROTS (0x86)
- SEC1 (0xA0)
- KEY (0xB0)

### 17.3.2 Register descriptions

The flash module contains a set of memory-mapped control and status registers.

**NOTE**

While a command is running (FSTAT[CCIF]=0), register writes are not accepted to any register except FCNFG and FSTAT. The no-write rule is relaxed during the start-up reset sequence, prior to the initial rise of CCIF. During this initialization period the user may write any register. All register writes are also disabled (except for registers FCNFG and FSTAT) whenever an erase suspend request is active (FCNFG[ERSSUSP]=1).

## 17.3.2.1.2 Flash Status Register (FSTAT)

### 17.3.2.1.2.1 Offset

| Register | Offset |
|---|---|
| FSTAT | 0h |

### 17.3.2.1.2.2 Function

The FSTAT register reports the operational status of the flash module.

The CCIF, RDCOLERR, ACCERR, and FPVIOL bits are readable and writable. The MGSTAT0 bit is read only. The unassigned bits read 0 and are not writable.

**NOTE**

When set, the Access Error (ACCERR) and Flash Protection Violation (FPVIOL) bits in this register prevent the launch of any more commands until the flag is cleared (by writing a one to it).

### 17.3.2.1.2.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | CCIF | RDCOLERR | ACCERR | FPVIOL | 0 | | | MGSTAT0 |
| W | W1C | W1C | W1C | W1C | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### 17.3.2.1.2.4 Fields

| Field | Function |
|---|---|
| 7<br>CCIF | Command Complete Interrupt Flag<br>The CCIF flag indicates that a flash command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a flash command, and CCIF stays low until the command completes or a command violation is detected.<br>The CCIF bit is reset to 0 but is set to 1 by the flash module at the end of the reset initialization sequence. Depending on how quickly the read occurs after reset release, the user may or may not see the 0 hardware reset value.<br>0b - Flash command in progress<br>1b - Flash command has completed |
| 6<br>RDCOLERR | Flash Read Collision Error Flag<br>The RDCOLERR error bit indicates that the MCU attempted a read from a flash memory resource that was being manipulated by a flash command (CCIF=0). Any simultaneous access is detected as a collision error by the block arbitration logic. The read data in this case cannot be guaranteed. The RDCOLERR bit is cleared by writing a 1 to it. Writing a 0 to RDCOLERR has no effect.<br>0b - No collision error detected<br>1b - Collision error detected |
| 5<br>ACCERR | Flash Access Error Flag<br>The ACCERR error bit indicates an illegal access has occurred to a flash memory resource caused by a violation of the command write sequence or issuing an illegal flash command. While ACCERR is set, the CCIF flag cannot be cleared to launch a command. The ACCERR bit is cleared by writing a 1 to ACCERR while CCIF is set. Writing a 0 to the ACCERR bit has no effect.<br>0b - No access error detected<br>1b - Access error detected |
| 4<br>FPVIOL | Flash Protection Violation Flag<br>The FPVIOL error bit indicates an attempt was made to program or erase an address in a protected area of program flash memory during a command write sequence. While FPVIOL is set, the CCIF flag cannot be cleared to launch a command. The FPVIOL bit is cleared by writing a 1 to FPVIOL while CCIF is set. Writing a 0 to the FPVIOL bit has no effect.<br>0b - No protection violation detected<br>1b - Protection violation detected |
| 3-1<br>— | Reserved |
| 0<br>MGSTAT0 | Memory Controller Command Completion Status Flag<br>The MGSTAT0 status flag is set if an error is detected during execution of a flash command or during the flash reset sequence. As a status flag, this bit cannot (and need not) be cleared by the user like the other error flags in this register.<br>The value of the MGSTAT0 bit for "command-N" is valid only at the end of the "command-N" execution when CCIF=1 and before the next command has been launched. At some point during the execution of "command-N+1," the previous result is discarded and any previous error is cleared. |

### 17.3.2.1.3 Flash Configuration Register (FCNFG)

#### 17.3.2.1.3.1 Offset

| Register | Offset |
|---|---|
| FCNFG | 1h |

#### 17.3.2.1.3.2 Function

This register provides information on the current functional state of the flash module.

The erase control bits (ERSAREQ and ERSSUSP) have write restrictions. SWAP, PFLSH, and RAMRDY are read-only status bits. The reset values for the SWAP, PFLSH, and RAMRDY bits are determined during the reset sequence.

#### 17.3.2.1.3.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | CCIE | RDCOLLIE | ERSAREQ | ERSSUSP | SWAP | CRCRDY | RAMRDY | 0 |
| W | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |

#### 17.3.2.1.3.4 Fields

| Field | Function |
|---|---|
| 7<br>CCIE | Command Complete Interrupt Enable<br>The CCIE bit controls interrupt generation when a flash command completes.<br>0b - Command complete interrupt disabled<br>1b - Command complete interrupt enabled. An interrupt request is generated whenever the FSTAT[CCIF] flag is set. |
| 6<br>RDCOLLIE | Read Collision Error Interrupt Enable<br>The RDCOLLIE bit controls interrupt generation when a flash read collision error occurs.<br>0b - Read collision error interrupt disabled<br>1b - Read collision error interrupt enabled. An interrupt request is generated whenever a flash read collision error is detected (see the description of FSTAT[RDCOLERR]). |
| 5<br>ERSAREQ | Erase All Request<br>This bit issues a request to the memory controller to execute the Erase All Blocks command and release security. ERSAREQ is not directly writable but is under indirect user control. Refer to the device's Chip Configuration details on how to request this command.<br>The ERSAREQ bit sets when an erase all request is triggered external to the flash module and CCIF is set (no command is currently being executed). ERSAREQ is cleared by the flash module when the operation completes. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 0b - No request or request complete<br>1b - Request to: (1) run the Erase All Blocks command, (2) verify the erased state, (3) program the security byte in the Flash Configuration Field to the unsecure state, and (4) release MCU security by setting the FSEC[SEC] field to the unsecure state. |
| 4<br>ERSSUSP | Erase Suspend<br>The ERSSUSP bit allows the user to suspend (interrupt) the Erase Flash Sector command while it is executing.<br>0b - No suspend requested<br>1b - Suspend the current Erase Flash Sector command execution |
| 3<br>SWAP | Swap<br>The SWAP flag indicates which half of the primary program flash space is located at relative address 0x0000. The state of the SWAP flag is set by the flash module during the reset sequence. See Swap Control command for information on swap management.<br>0b - Program flash 0 block is located at relative address 0x0000<br>1b - Program flash 1 block is located at relative address 0x0000 |
| 2<br>CRCRDY | CRC Ready<br>The CRC Ready flag indicates the programming acceleration RAM is available for CRC operations. See Generate CRC command for more information.<br>0b - Programming acceleration RAM is not available for CRC operations<br>1b - Programming acceleration RAM is available for CRC operations |
| 1<br>RAMRDY | RAM Ready<br>This flag indicates the current status of the programming acceleration RAM.<br>This bit should always be set.<br>0b - Programming acceleration RAM is not available<br>1b - Programming acceleration RAM is available |
| 0<br>— | Reserved |

## 17.3.2.1.4 Flash Security Register (FSEC)

### 17.3.2.1.4.1 Offset

| Register | Offset |
|---|---|
| FSEC | 2h |

### 17.3.2.1.4.2 Function

This read-only register holds all bits associated with the security of the MCU and flash module.

During the reset sequence, the register is loaded with the contents of the flash security byte in the Flash Configuration Field located in program flash memory.

### 17.3.2.1.4.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | KEYEN | | MEEN | | FSLACC | | SEC | |
| W | | | | | | | | |
| Reset | u | u | u | u | u | u | u | u |

### 17.3.2.1.4.4 Fields

| Field | Function |
|---|---|
| 7-6<br>KEYEN | Backdoor Key Security Enable<br>These bits enable and disable backdoor key access to the flash module.<br>00b - Backdoor key access disabled<br>01b - Backdoor key access disabled (preferred KEYEN state to disable backdoor key access)<br>10b - Backdoor key access enabled<br>11b - Backdoor key access disabled |
| 5-4<br>MEEN | Mass Erase Enable Bits<br>Enables and disables mass erase capability of the flash module. The state of the MEEN bits is only relevant when the SEC bits are set to secure. When the SEC field is set to unsecure, the MEEN setting does not matter.<br>00b - Mass erase is enabled<br>01b - Mass erase is enabled<br>10b - Mass erase is disabled<br>11b - Mass erase is enabled |
| 3-2<br>FSLACC | Factory Security Level Access Code<br>These bits enable or disable access to the flash memory contents during returned part failure analysis at NXP. When SEC is secure and FSLACC is denied, access to the program flash contents is denied and any failure analysis performed by NXP factory test must begin with a full erase to unsecure the part.<br>When access is granted (SEC is unsecure, or SEC is secure and FSLACC is granted), NXP factory testing has visibility of the current flash contents. The state of the FSLACC bits is only relevant when the SEC bits are set to secure. When the SEC field is set to unsecure, the FSLACC setting does not matter.<br>00b - Factory access granted<br>01b - Factory access denied<br>10b - Factory access denied<br>11b - Factory access granted |
| 1-0<br>SEC | Flash Security<br>These bits define the security state of the MCU. In the secure state, the MCU limits access to flash module resources. The limitations are defined per device and are detailed in the Chip Configuration details. If the flash module is unsecured using backdoor key access, the SEC bits are forced to 10b.<br>00b - MCU security status is secure<br>01b - MCU security status is secure<br>10b - MCU security status is unsecure (The standard shipping condition of the flash module is unsecure.)<br>11b - MCU security status is secure |

#### 17.3.2.1.5 Flash Common Command Object Registers (FCCOB3 - FCCO B8)

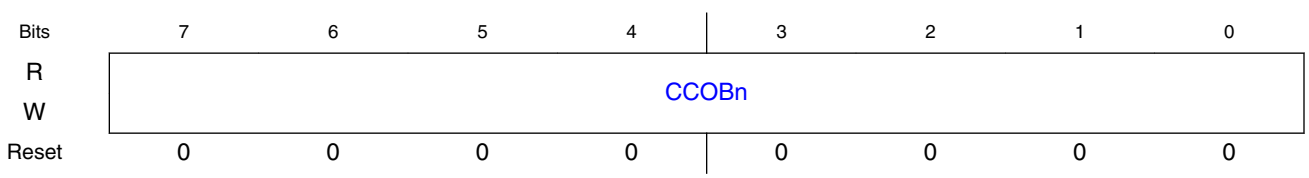
##### 17.3.2.1.5.1 Offset

| Register | Offset |
|---|---|
| FCCOB3 | 4h |
| FCCOB2 | 5h |
| FCCOB1 | 6h |
| FCCOB0 | 7h |
| FCCOB7 | 8h |
| FCCOB6 | 9h |
| FCCOB5 | Ah |
| FCCOB4 | Bh |
| FCCOBB | Ch |
| FCCOBA | Dh |
| FCCOB9 | Eh |
| FCCOB8 | Fh |

##### 17.3.2.1.5.2 Function

The FCCOB register group provides 12 bytes for command codes and parameters. The individual bytes within the set append a 0-B hex identifier to the FCCOB register name: FCCOB0, FCCOB1, ..., FCCOBB.

##### 17.3.2.1.5.3 Diagram



##### 17.3.2.1.5.4 Fields

| Field | Function |
|---|---|
| 7-0<br>CCOBn | CCOBn |

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
The FCCOB register provides a command code and relevant parameters to the memory controller. The individual registers that compose the FCCOB data set can be written in any order, but you must provide all needed values, which vary from command to command. First, set up all required FCCOB fields and then initiate the command's execution by writing a 1 to the FSTAT[CCIF] bit. This clears the CCIF bit, which locks all FCCOB parameter fields and they cannot be changed by the user until the command completes (CCIF returns to 1). No command buffering or queueing is provided; the next command can be loaded only after the current command completes.<br><br>
Some commands return information to the FCCOB registers. Any values returned to FCCOB are available for reading after the FSTAT[CCIF] flag returns to 1 by the memory controller.<br><br>
The following table shows a generic flash command format. The first FCCOB register, FCCOB0, always contains the command code. This 8-bit value defines the command to be executed. The command code is followed by the parameters required for this specific flash command, typically an address and/or data values.<br><br>
NOTE: The command parameter table is written in terms of FCCOB Number (which is equivalent to the byte number). This number is a reference to the FCCOB register name and is not the register address.<br><br>
<table>
<tr><th>FCCOB Number</th><th>Typical Command Parameter Contents [7:0]</th></tr>
<tr><td>0</td><td>FCMD (a code that defines the flash command)</td></tr>
<tr><td>1</td><td>Flash address [23:16]</td></tr>
<tr><td>2</td><td>Flash address [15:8]</td></tr>
<tr><td>3</td><td>Flash address [7:0]</td></tr>
<tr><td>4</td><td>Data Byte 0</td></tr>
<tr><td>5</td><td>Data Byte 1</td></tr>
<tr><td>6</td><td>Data Byte 2</td></tr>
<tr><td>7</td><td>Data Byte 3</td></tr>
<tr><td>8</td><td>Data Byte 4</td></tr>
<tr><td>9</td><td>Data Byte 5</td></tr>
<tr><td>A</td><td>Data Byte 6</td></tr>
<tr><td>B</td><td>Data Byte 7</td></tr>
</table>
<br>
1. Refers to FCCOB register name, not register address<br><br>
FCCOB Endianness and Multi-Byte Access:<br><br>
The FCCOB register group uses a big endian addressing convention. For all command parameter fields larger than 1 byte, the most significant data resides in the lowest FCCOB register number. The FCCOB register group may be read and written as individual bytes, aligned words (2 bytes) or aligned longwords (4 bytes).
</td></tr>
</table>

1. Refers to FCCOB register name, not register address

## 17.3.2.1.6 Flash Option Registers (FOPT3 - FOPT0)

### 17.3.2.1.6.1 Offset

For a = 0 to 3:

| Register | Offset |
|---|---|
| FOPTa | Dh + (a × 1h) |

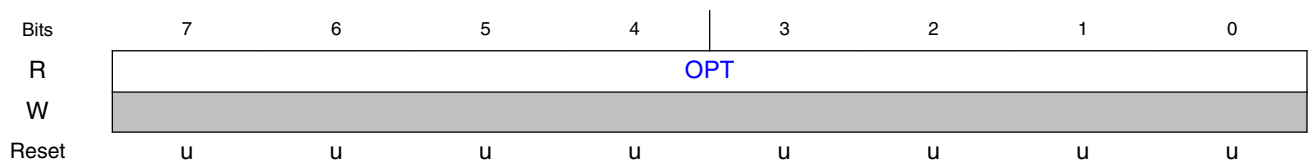
#### 17.3.2.1.6.2 Function

The flash option registers allow the MCU to customize its operations by examining the state of these read-only bits, which are loaded from NVM at reset. The function of the bits is defined in the device's Chip Configuration details.

All bits in these registers are read-only.

During the reset sequence, these registers are loaded from the flash nonvolatile option index in the Flash Configuration Field located in the program flash erasable IFR.

#### 17.3.2.1.6.3 Diagram



#### 17.3.2.1.6.4 Fields

| Field | Function |
|---|---|
| 7-0<br>OPT | Nonvolatile Option<br>These bits are loaded from flash to this register at reset. Refer to the device's Chip Configuration details for the definition and use of these bits. |

### 17.3.2.1.7 Primary Program Flash Protection Registers (FPROTH3 - FPROTL0)

#### 17.3.2.1.7.1 Offset

| Register | Offset |
|---|---|
| FPROTH3 | 18h |
| FPROTH2 | 19h |
| FPROTH1 | 1Ah |
| FPROTH0 | 1Bh |

*Table continues on the next page...*

| Register | Offset |
|---|---|
| FPROTL3 | 1Ch |
| FPROTL2 | 1Dh |
| FPROTL1 | 1Eh |
| FPROTL0 | 1Fh |

#### 17.3.2.1.7.2 Function

The FPROT registers define which primary program flash regions are protected from program and erase operations. Protected flash regions cannot have their content changed; that is, these regions cannot be programmed and cannot be erased by any flash command. Unprotected regions can be changed by program and erase operations.

The eight FPROT registers allow up to 64 protectable regions of equal memory size. The FPROT register bits are mapped to the protectable regions as follows:

- *region_size* = total_program_flash_size / 64
- Starting from the primary program flash base address, Region 0 refers to the first *region_size* bytes, region 1 refers to the next *region_size* bytes, and so on.

In other words:

- region_*n*_start_address = primary_ program_flash_base_address + (n) * *region_size*
- region_*n*_end_address = primary_ program_flash_base_address + ((n+1) * *region_size*) -1

For example, if the total primary program flash size is 1 MByte, the *region_size* is 16 Kbytes. If the lowest primary program flash address is 0x0000_0000, the regions are defined as follows:

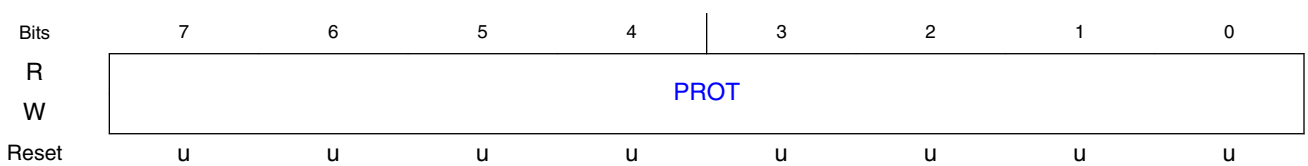
| Region | Start Address | End Address |
|---|---|---|
| 0 | 0x0000_0000 | 0x0000_3FFF |
| 1 | 0x0000_4000 | 0x0000_7FFF |
| 2 | 0x0000_8000 | 0x0000_BFFF |
| 3 | 0x0000_C000 | 0x0000_FFFF |
| . . . | . . . | . . . |
| 63 | 0x000F_C000 | 0x000F_FFFF |

- A '0' in an FPROT[PROT] bit indicates its corresponding flash protection region is protected
- A '1' in an FPROT[PROT] bit indicates its corresponding flash protection region is unprotected

| Primary Program flash protection register | Primary Program flash protection bits | CCOB used (RDINDEX/ PGMINDEX command) |
|---|---|---|
| FPROTH0 | PROT[63:56] | 4 |
| FPROTH1 | PROT[55:48] | 5 |
| FPROTH2 | PROT[47:40] | 6 |
| FPROTH3 | PROT[39:32] | 7 |
| FPROTL0 | PROT[31:24] | 8 |
| FPROTL1 | PROT[23:16] | 9 |
| FPROTL2 | PROT[15:8] | A |
| FPROTL3 | PROT[7:0] | B |

During the reset sequence, the FPROT registers are loaded with the contents of the primary program flash protection index in the Flash Configuration Field located in the program flash erasable IFR. To change the primary program flash protection that is loaded during the reset sequence, the program flash erasable IFR must be erased using the Erase All Blocks or Erase All Blocks Unsecure command. Then, the primary program flash protection index must be programmed using the Program Index command.

### 17.3.2.1.7.3 Diagram



### 17.3.2.1.7.4 Fields

| Field | Function |
|---|---|
| 7-0<br>PROT | Primary Program Flash Region Protect<br>Each primary program flash region can be protected from program and erase operations by setting the associated PROT bit to the protected state.<br>**In NVM Normal mode:** The protection can only be increased, meaning that currently unprotected memory can be protected, but currently protected memory cannot be unprotected. Since unprotected regions are marked with a 1 and protected regions use a 0, only writes changing 1s to 0s are accepted. This 1-to-0 transition check is performed on a bit-by-bit basis. Those FPROT bits with 1-to-0 transitions are accepted while all bits with 0-to-1 transitions are ignored. |

| Field | Function |
|---|---|
| | **Restriction:** The user must never write to any FPROT register while a command is running (CCIF=0) on a primary program flash block.<br>Trying to alter data in any protected area in the primary program flash memory results in a protection violation error and sets the FSTAT[FPVIOL] bit. A full block erase of a primary program flash block is not possible if it contains any protected region. |

#### 17.3.2.1.8 Secondary Program Flash Protection Registers (FPROTSL - FPROTSH)

##### 17.3.2.1.8.1 Offset

| Register | Offset |
|---|---|
| FPROTSL | 24h |
| FPROTSH | 25h |

##### 17.3.2.1.8.2 Function

The FPROTS registers define which secondary program flash regions are protected from program and erase operations. Protected flash regions cannot have their content changed; that is, these regions cannot be programmed and cannot be erased by any flash command. Unprotected regions can be changed by program and erase operations.

The two FPROTS registers allow up to 16 protectable regions of equal memory size. The FPROTS register bits are mapped to the protectable regions as follows:

- *region_size* = total_program_flash_size / 16
- Starting from the secondary program flash base address, Region 0 refers to the first *region_size* bytes, region 1 refers to the next *region_size* bytes, and so on.

In other words:

- region_*n*_start_address = secondary_program_flash_base_address + (n) * *region_size*
- region_*n*_end_address = secondary_program_flash_base_address + ((n+1) * *region_size*) -1

For example, if the total secondary program flash size is 256 KByte, the *region_size* is 16 Kbytes. If the lowest secondary program flash address is 0x0000_0000, the regions are defined as follows:

| Region | Start Address | End Address |
|---|---|---|
| 0 | 0x0000_0000 | 0x0000_3FFF |
| 1 | 0x0000_4000 | 0x0000_7FFF |
| 2 | 0x0000_8000 | 0x0000_BFFF |
| 3 | 0x0000_C000 | 0x0000_FFFF |
| . . . | . . . | . . . |
| 15 | 0x0003_C000 | 0x0003_FFFF |

- A '0' in an FPROTS[PROTS] bit indicates its corresponding flash protection region is protected
- A '1' in an FPROTS[PROTS] bit indicates its corresponding flash protection region is unprotected

| Secondary program flash protection register | Secondary program flash protection bits | CCOB used (RDINDEX/ PGMINDEX command) |
|---|---|---|
| FPROTSH | PROTS[15:8] | A |
| FPROTSL | PROTS[7:0] | B |

During the reset sequence, the FPROTS registers are loaded with the contents of the secondary program flash protection index in the Flash Configuration Field located in the program flash erasable IFR. To change the secondary program flash protection that is loaded during the reset sequence, the program flash erasable IFR must be erased using the Erase All Blocks or Erase All Blocks Unsecure command. Then, the secondary program flash protection index must be programmed using the Program Index command.

| Field | Function |
|---|---|
| 7-0<br>PROTS | Secondary Program Flash Region Protect<br>Each secondary program flash region can be protected from program and erase operations by setting the associated PROTS bit to the protected state. |

| Field | Function |
|---|---|
| | **In NVM Normal mode:** The protection can only be increased, meaning that currently unprotected memory can be protected, but currently protected memory cannot be unprotected. Since unprotected regions are marked with a 1 and protected regions use a 0, only writes changing 1s to 0s are accepted. This 1-to-0 transition check is performed on a bit-by-bit basis. Those FPROTS bits with 1-to-0 transitions are accepted while all bits with 0-to-1 transitions are ignored.<br>**Restriction:** The user must never write to any FPROTS register while a command is running (CCIF=0) on the secondary program flash.<br>Trying to alter data in any protected area in the secondary program flash memory results in a protection violation error and sets the FSTAT[FPVIOL] bit. A full block erase of a secondary program flash block is not possible if it contains any protected region. |

## 17.3.2.1.9 Primary Flash Access Segment Size Register (FACSS)

### 17.3.2.1.9.1 Offset

| Register | Offset |
|---|---|
| FACSS | 2Ch |

### 17.3.2.1.9.2 Function

The primary flash access segment size register determines which bits in the address are used to index into the SACC and XACC bitmaps to get the appropriate permission flags.

All bits in the register are read-only.

The contents of this register are loaded during the reset sequence.

### 17.3.2.1.9.3 Diagram

## 17.3.2.1.13 Primary Execute-only Access Registers (XACCH3 - XACCL0)

### 17.3.2.1.13.1 Offset

| Register | Offset |
|---|---|
| XACCH3 | 30h |
| XACCH2 | 31h |
| XACCH1 | 32h |
| XACCH0 | 33h |
| XACCL3 | 34h |
| XACCL2 | 35h |
| XACCL1 | 36h |
| XACCL0 | 37h |

### 17.3.2.1.13.2 Function

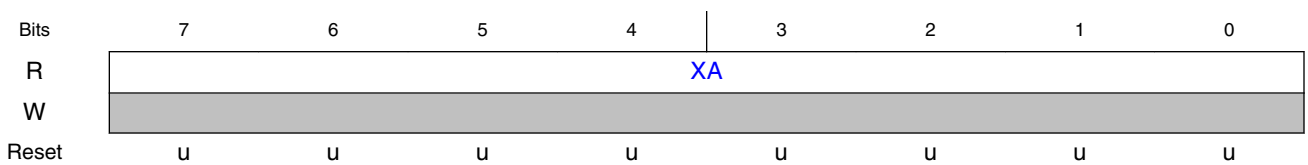
The XACC registers define which primary program flash segments are restricted to data read or execute only or both data and instruction fetches.

The eight XACC registers allow up to 64 restricted segments of equal memory size.

| Primary Execute-only access register | Primary Program flash execute-only access bits |
|---|---|
| XACCH0 | XA[63:56] |
| XACCH1 | XA[55:48] |
| XACCH2 | XA[47:40] |
| XACCH3 | XA[39:32] |
| XACCL0 | XA[31:24] |
| XACCL1 | XA[23:16] |
| XACCL2 | XA[15:8] |
| XACCL3 | XA[7:0] |

During the reset sequence, the XACC registers are loaded with the XACC index located in the program flash erasable IFR. Use the Program Index command to program the primary execute-only access control fields that are loaded during the reset sequence.

### 17.3.2.1.13.3 Diagram



#### 17.3.2.1.13.4 Fields

| Field | Function |
|---|---|
| 7-0<br>XA | Execute-only access control<br>0b - Associated segment is accessible in execute mode only (as an instruction fetch)<br>1b - Associated segment is accessible as data or in execute mode |

### 17.3.2.1.14 Primary Supervisor-only Access Registers (SACCH3 - SACC L0)

#### 17.3.2.1.14.1 Offset

| Register | Offset |
|---|---|
| SACCH3 | 38h |
| SACCH2 | 39h |
| SACCH1 | 3Ah |
| SACCH0 | 3Bh |
| SACCL3 | 3Ch |
| SACCL2 | 3Dh |
| SACCL1 | 3Eh |
| SACCL0 | 3Fh |

#### 17.3.2.1.14.2 Function

The SACC registers define which primary program flash segments are restricted to supervisor only or user and supervisor access.

The eight SACC registers allow up to 64 restricted segments of equal memory size.

| Primary Supervisor-only access register | Primary Program flash supervisor-only access bits |
|---|---|
| SACCH0 | SA[63:56] |
| SACCH1 | SA[55:48] |
| SACCH2 | SA[47:40] |
| SACCH3 | SA[39:32] |
| SACCL0 | SA[31:24] |
| SACCL1 | SA[23:16] |
| SACCL2 | SA[15:8] |
| SACCL3 | SA[7:0] |

During the reset sequence, the SACC registers are loaded with the SACC index located in the program flash erasable IFR. Use the Program Index command to program the primary supervisor access control fields that are loaded during the reset sequence.

#### 17.3.2.1.14.3 Diagram

### 17.3.2.1.15 Secondary Execute-only Access Registers (XACCSL - XACCSH)

#### 17.3.2.1.15.1 Offset

| Register | Offset |
|---|---|
| XACCSL | 44h |
| XACCSH | 45h |

#### 17.3.2.1.15.2 Function

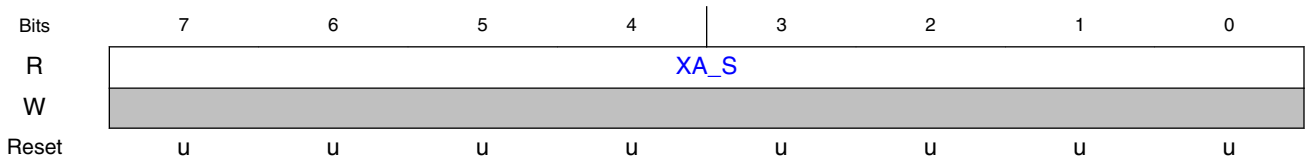
The XACCS registers define which secondary program flash segments are restricted to data read or execute only or both data and instruction fetches.

The two XACCS registers allow up to 16 restricted segments of equal memory size.

| Secondary Execute-only access register | Secondary Program flash execute-only access bits |
|---|---|
| XACCSH | XA_S[15:8] |
| XACCSL | XA_S[7:0] |

During the reset sequence, the XACCS registers are loaded with the XACCS index located in the program flash erasable IFR. Use the Program Index command to program the secondary execute-only access control fields that are loaded during the reset sequence.

#### 17.3.2.1.15.3 Diagram



#### 17.3.2.1.15.4 Fields

| Field | Function |
|---|---|
| 7-0<br>XA_S | Execute-only access control<br>0b - Associated secondary program flash segment is accessible in execute mode only (as an instruction fetch)<br>1b - Associated secondary program flash segment is accessible as data or in execute mode |

### 17.3.2.1.16 Secondary Supervisor-only Access Registers (SACCSL - SACCSH)

#### 17.3.2.1.16.1 Offset

| Register | Offset |
|---|---|
| SACCSL | 4Ch |
| SACCSH | 4Dh |

#### 17.3.2.1.16.2 Function

The SACCS registers define which secondary program flash segments are restricted to supervisor only or user and supervisor access.

The two SACC registers allow up to 16 restricted segments of equal memory size.

| Secondary Supervisor-only access register | Secondary Program flash supervisor-only access bits |
|---|---|
| SACCH | SA_S[15:8] |
| SACCL | SA_S[7:0] |

During the reset sequence, the SACCS registers are loaded with the SACCS index located in the program flash erasable IFR. Use the Program Index command to program the secondary supervisor access control fields that are loaded during the reset sequence.

#### 17.3.2.1.16.3 Diagram

| 1<br>STDBY1 | Standy Mode for Flash Block 1<br>0b - Standby mode not enabled for flash block 1<br>1b - If STDBYDIS is clear, standby mode is enabled for flash block 1 (when SWAP=0/1, flash block 1/0 is the inactive block) |
| 0<br>STDBY0 | Standy Mode for Flash Block 0<br>0b - Standby mode not enabled for flash block 0<br>1b - If STDBYDIS is clear, standby mode is enabled for flash block 0 (when SWAP=0/1, flash block 1/0 is the inactive block) |

## 17.4 Functional description

The following sections describe functional details of the flash module.

### 17.4.1 Primary Program flash memory swap

The user can configure the memory map of the program flash space such that either half of the primary program flash memory can exist at relative address 0x0000. This swap feature enables the lower half of the primary program flash space to be operational while the upper half is being updated for future use.

The Swap Control command handles swapping the two halves of primary program flash memory within the memory map. See Swap Control command for details.

## 17.4.2 Flash Program/Erase Protection

Individual regions within the flash memory can be protected from program and erase operations. Protection is controlled by the following registers:

- FPROT*n* — Eight registers protect 64 regions of the primary program flash memory as shown in the following figure

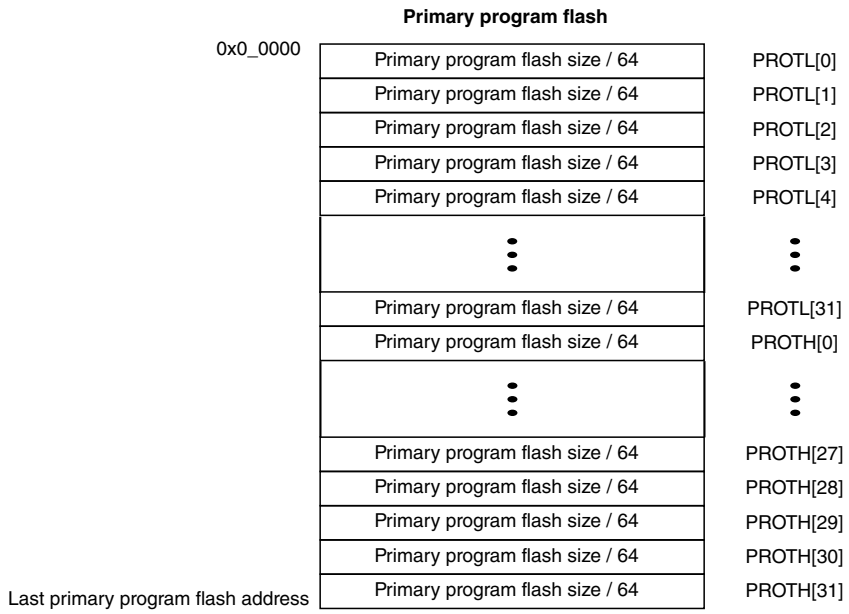

**Figure 17-1. Primary program flash protection**

- FPROTSH/FPROTSL — Two registers protect 16 regions of the secondary program flash memory as shown in the following figure

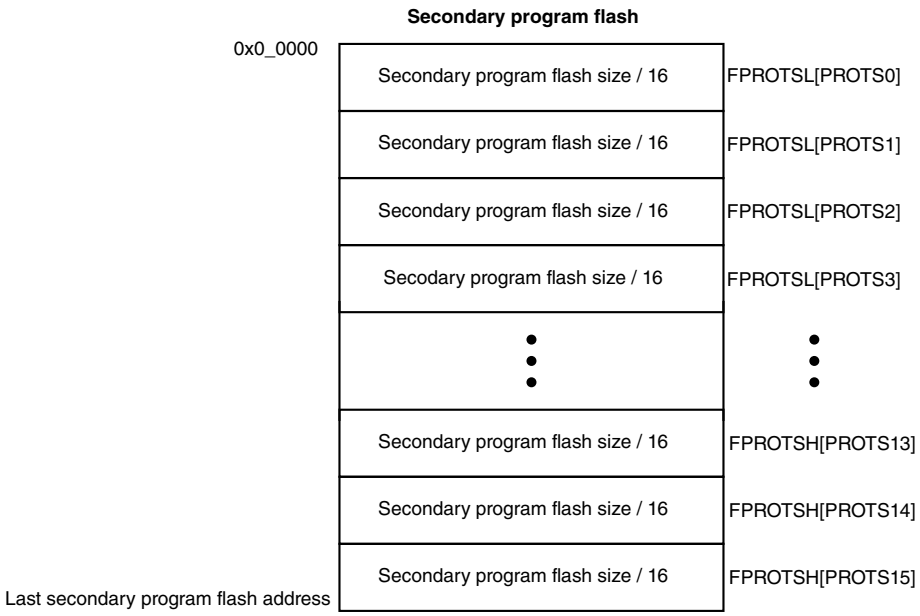

**Figure 17-2. Secondary program flash protection**

**NOTE**

Flash protection features are discussed further in AN4507: Using the Kinetis Security and Flash Protection Features. Some features described in the application note may not be available on this device.

## 17.4.3 Flash Access Protection

Individual segments within the program flash memory can be designated for restricted access. Specific flash commands (Program Check, Program Phrase, Erase Flash Block, Erase Flash Sector) monitor FXACC/FXACCS contents to protect flash memory but the FSACC/FSACCS contents do not impact flash command operation.

See AN5112: Using the Kinetis Flash Execute-Only Access Control Feature for further details.

FXACCH/FXACCL/FSACCH/FSACCL registers control access to 64 segments of the primary program flash memory as shown in the following figure:

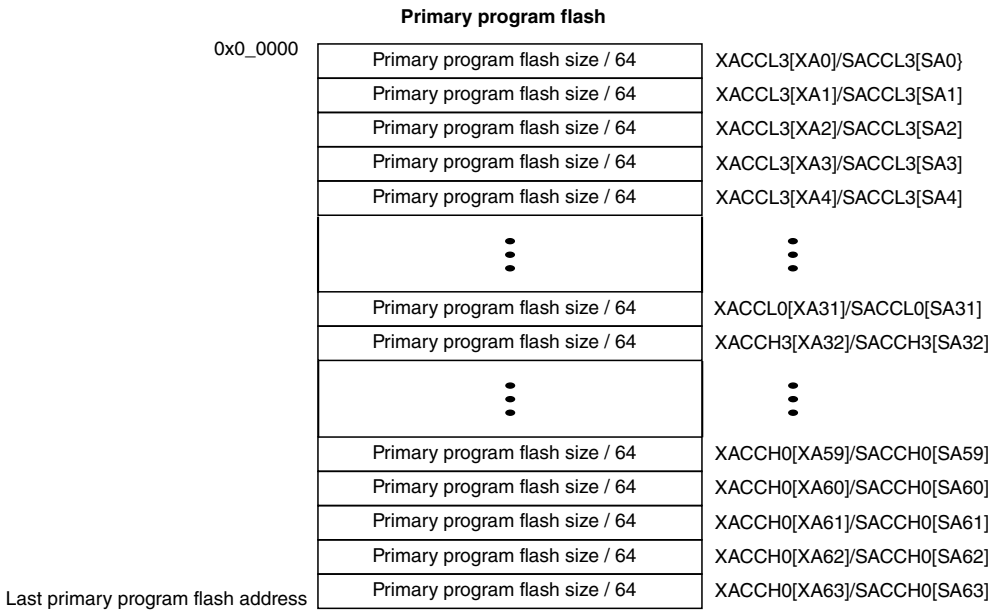

**Figure 17-3. Primary program flash access control**

FXACCSH/FXACCSL/FSACCSH/FSACCSL registers control access to 16 segments of the secondary program flash memory as shown in the following figure:

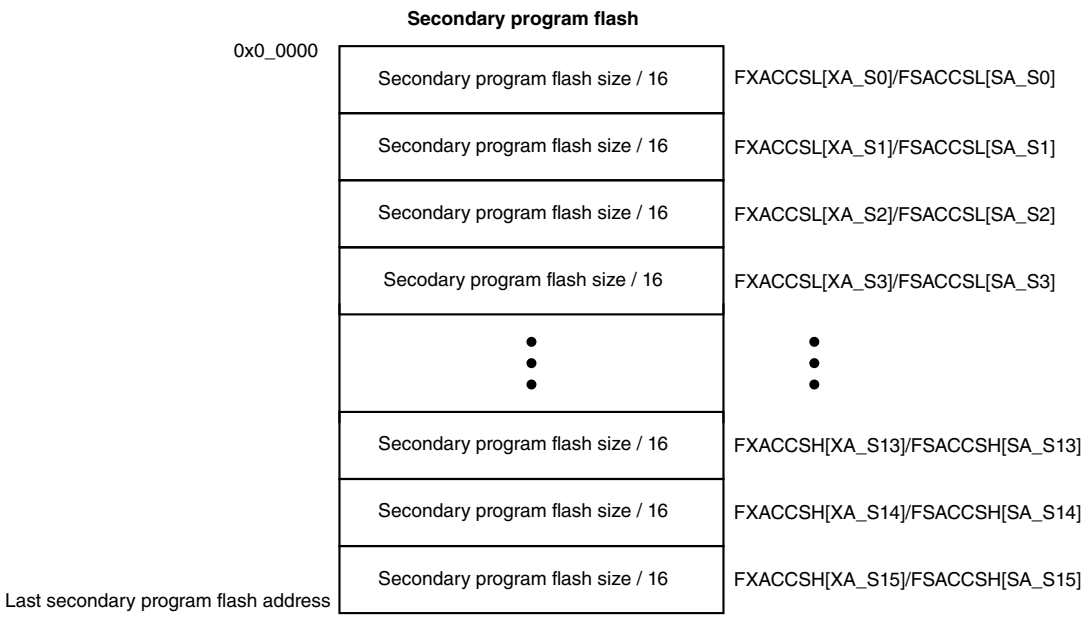

**Figure 17-4. Secondary program flash access control**

## 17.4.4 Interrupts

The flash module can generate interrupt requests to the MCU upon the occurrence of various flash module events. These interrupt events and their associated status and control bits are shown in the following table.

**Table 17-4. Flash Module Interrupt Sources**

| Flash Event | Readable Status Bit | Interrupt Enable Bit |
|---|---|---|
| Flash Command Complete | FSTAT[CCIF] | FCNFG[CCIE] |
| Flash Read Collision Error | FSTAT[RDCOLERR] | FCNFG[RDCOLLIE] |

**Note**

Vector addresses and their relative interrupt priority are determined at the MCU level.

## 17.4.5 Flash Operation in Low-Power Modes

### 17.4.5.1 Wait Mode

When the MCU enters wait mode, the flash module is not affected. The flash module can recover the MCU from wait via the command complete interrupt (see Interrupts).

### 17.4.5.2 Stop Mode

When the MCU requests stop mode, if an flash command is active (CCIF = 0) the command execution completes before the MCU is allowed to enter stop mode.

**CAUTION**

The MCU should never enter stop mode while any flash command is running (CCIF = 0).

**NOTE**

While the MCU is in very-low-power modes (VLPR, VLPW, VLPS), the flash module does not accept flash commands.

## 17.4.6 Flash memory reads and ignored writes

The flash module requires only the flash address to execute a flash memory read. MCU read access is available to all flash memory.

The MCU must not read from the flash memory while commands are running (as evidenced by CCIF=0) on that block. Read data cannot be guaranteed from a block while any command is processing within that block. The block arbitration logic detects any simultaneous access and reports this as a read collision error (see the FSTAT[RDCOLERR] bit).

### 17.4.7 Read while write (RWW)

The following simultaneous accesses are allowed:

- The user may read from one program flash memory block while commands are active in another program flash memory block.

Simultaneous operations are further discussed in Allowed simultaneous flash operations.

### 17.4.8 Flash Program and Erase

All flash functions except read require the user to setup and launch a flash command through a series of peripheral bus writes. The user cannot initiate any more flash commands until notified that the current command has completed. The flash command structure and operation are detailed in Flash Command Operations.

### 17.4.9 Flash Command Operations

Flash command operations are typically used to modify flash memory contents. The next sections describe:

- The command write sequence used to set flash command parameters and launch execution
- A description of all flash commands available

#### 17.4.9.1 Command Write Sequence

Flash commands are specified using a command write sequence illustrated in Figure 17-5. The flash module performs various checks on the command (FCCOB) content and continues with command execution if all requirements are fulfilled.

Before launching a command, the ACCERR and FPVIOL bits in the FSTAT register must be zero and the CCIF flag must read 1 to verify that any previous command has completed. If CCIF is zero, the previous command execution is still active, a new command write sequence cannot be started, and all writes to the FCCOB registers are ignored.

Attempts to launch a flash command in VLP or HSRUN mode will be ignored. Attempts to launch a flash command while the radio is active will also be ignored.

#### 17.4.9.1.1 Load the FCCOB Registers

The user must load the FCCOB registers with all parameters required by the desired flash command. The individual registers that make up the FCCOB data set can be written in any order.

#### 17.4.9.1.2 Launch the Command by Clearing CCIF

Once all relevant command parameters have been loaded, the user launches the command by clearing the FSTAT[CCIF] bit by writing a '1' to it. The CCIF flag remains zero until the flash command completes.

The FSTAT register contains a blocking mechanism, which prevents a new flash command from launching (unable to clear CCIF) if the previous command resulted in an access error (FSTAT[ACCERR]=1) or a protection violation (FSTAT[FPVIOL]=1). In error scenarios, two writes to FSTAT are required to initiate the next command: the first write to clear the error flags, the second write to clear CCIF.

#### 17.4.9.1.3 Command Execution and Error Reporting

The command processing has several steps:

1. The flash reads the command code and performs a series of parameter checks and protection checks, if applicable, which are unique to each command.

   If the parameter check fails, the FSTAT[ACCERR] (access error) flag is set. ACCERR reports invalid instruction codes and out-of bounds addresses. Usually, access errors suggest that the command was not set-up with valid parameters in the FCCOB register group.

   Program and erase commands also check the address to determine if the operation is requested to execute on protected areas. If the protection check fails, the FSTAT[FPVIOL] (protection error) flag is set.

Command processing never proceeds to execution when the parameter or protection step fails. Instead, command processing is terminated after setting the FSTAT[CCIF] bit.

2. If the parameter and protection checks pass, the command proceeds to execution. Run-time errors, such as failure to erase verify, may occur during the execution phase. Run-time errors are reported in the FSTAT[MGSTAT0] bit. A flash command may have access errors, protection errors, and run-time errors, but the run-time errors are not seen until all access and protection errors have been corrected.
3. Command execution results, if applicable, are reported back to the user via the FCCOB and FSTAT registers.
4. The flash module sets the FSTAT[CCIF] bit signifying that the command has completed.

The flow for a generic command write sequence is illustrated in the following figure.

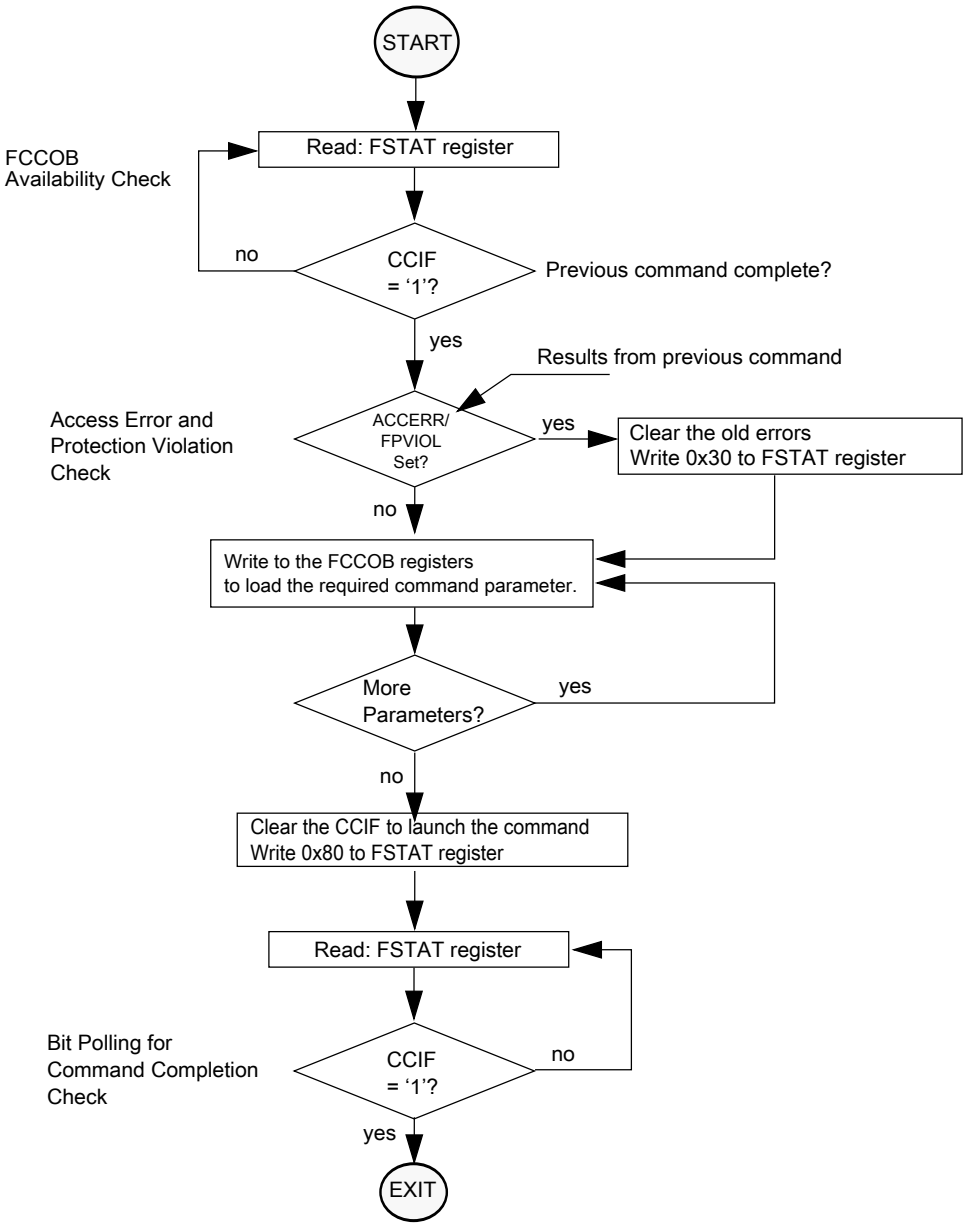

**Figure 17-5. Generic Flash Command Write Sequence Flowchart**

## 17.4.9.2 Flash commands

The following table summarizes the function of all flash commands. If any column is marked with an 'X', the flash command is relevant to that particular memory resource.

| FCMD | Command | Primary Program flash 0 | Primary Program flash 1 | Secondary Program flash 0 | Programming Acceleration RAM | Function |
|---|---|---|---|---|---|---|
| 0x00 | Read 1s Block | × | × | × | | Verify that a program flash block is erased. |
| 0x01 | Read 1s Section | × | × | × | | Verify that a given number of program flash locations from a starting address are erased. |
| 0x02 | Program Check | × | × | × | | Tests previously-programmed phrases at margin read levels. |
| 0x07 | Program Phrase | × | × | × | | Program 8 bytes in a program flash block. |
| 0x08 | Erase Flash Block | × | × | × | | Erase a program flash block. An erase of any flash block is only possible when unprotected. |
| 0x09 | Erase Flash Sector | × | × | × | | Erase all bytes in a program flash sector. |
| 0x0B | Program Section | × | × | × | × | Program data from the Section Program Buffer to a program flash block. |
| 0x0C | Generate CRC | × | × | × | × | Generate CRC signature for selected program flash sectors. |
| 0x40 | Read 1s All Blocks | × | × | × | | Verify that all program flash and the primary program flash erasable IFR are erased then release MCU security. |
| 0x41 | Read Index | IFR | | | | Read 8 bytes of a dedicated 64 byte field in |

*Table continues on the next page...*

| FCMD | Command | Primary Program flash 0 | Primary Program flash 1 | Secondary Program flash 0 | Programming Acceleration RAM | Function |
|---|---|---|---|---|---|---|
| | | | | | | theprimary program flash 0 IFR. |
| 0x43 | Program Index | IFR | | | | One-time program of 8 bytes of a dedicated 64-byte field in theprimary program flash 0 IFR. |
| 0x44 | Erase All Blocks | × | × | × | × | Erase all program flash blocks, theprimary program flash erasable IFR, and the programming acceleration RAM. Then, verify-erase and release MCU security.<br>**NOTE**: An erase is only possible when all memory locations are unprotected. |
| 0x45 | Verify Backdoor Access Key | × | | | | Release MCU security after comparing a set of user-supplied security keys to those stored in the Flash Configuration Field. |
| 0x46 | Swap Control | x | x | | | Handles swap-related activities. |
| 0x49 | Erase All Blocks Unsecure | × | × | × | × | Erase all program flash blocks, theprimary program flash erasable IFR, and the programming acceleration RAM. Then, verify-erase, |

*Table continues on the next page...*

| FCMD | Command | Primary Program flash 0 | Primary Program flash 1 | Secondary Program flash 0 | Programming Acceleration RAM | Function |
|---|---|---|---|---|---|---|
| | | | | | | program the security field to the unsecure state, and release MCU security. An erase occurs even if any flash memory location is protected. |
| 0x4A | Read 1s All Execute-only Segments | x | x | | | Verify that all program flash execute-only (XA and XA_S) segments are erased then release flash access control. |
| 0x4B | Erase All Execute-only Segments | x | x | | | Erase all program flash execute-only (XA and XA_S) segments then release flash access control. |
| 0x81 | Set RAM Function | × | | | × | Switches programming acceleration RAM function between available modes. |

### 17.4.9.3 Allowed simultaneous flash operations

Only the operations marked 'OK' in the following table are permitted to run simultaneously on the program flash memories. Some operations cannot be executed simultaneously because certain hardware resources are shared by the memories.

**Table 17-5. Allowed Simultaneous Memory Operations**

| | | Primary program flash X[1] | | | | Secondary program flash | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | Read | Program Phrase | Erase Flash Sector | Erase Flash Block | Read | Program Phrase | Erase Flash Sector | Erase Flash Block |
| Primary program flash Y[1] | Read | | OK | OK | OK | OK | OK | OK | OK |
| | Program Phrase | OK | | | | OK | | | |
| | Erase Flash Sector | OK | | | | OK | | | |
| | Erase Flash Block | OK | | | | OK | | | |

1. Primary program flash X refers to any of the primary program flash blocks (0, 1) and Primary program Fflash Y refers to any of the primary program flash blocks (0, 1), but not the same block. Thus, it is possible to read from any of the blocks while programming or erasing another.

## 17.4.10 Margin Read Commands

The Read-1s commands (Read 1s All Blocks, Read 1s Block, Read 1s Section, Read 1s All Execute-only Segments) and the Program Check command have a margin choice parameter that allows the user to apply non-standard read reference levels to the program flash array reads performed by these commands. Using the preset 'user' and 'factory' margin levels, these commands perform their associated read operations at tighter tolerances than a 'normal' read. These non-standard read levels are applied only during the command execution. All simple (uncommanded) flash array reads to the MCU always use the standard, un-margined, read reference level.

Only the 'normal' read level should be employed during normal flash usage. The non-standard, 'user' and 'factory' margin levels should be employed only in special cases. They can be used during special diagnostic routines to gain confidence that the device is not suffering from the end-of-life data loss customary of flash memory devices.

Erased ('1') and programmed ('0') bit states can degrade due to elapsed time and data cycling (number of times a bit is erased and re-programmed). The lifetime of the erased states is relative to the last erase operation. The lifetime of the programmed states is measured from the last program time.

The 'user' and 'factory' levels become, in effect, a minimum safety margin; i.e. if the reads pass at the tighter tolerances of the 'user' and 'factory' margins, then the 'normal' reads have at least this much safety margin before they experience data loss.

The 'user' margin is a small delta to the normal read reference level. 'User' margin levels can be employed to check that flash memory contents have adequate margin for normal level read operations. If unexpected read results are encountered when checking flash memory contents at the 'user' margin levels, loss of information might soon occur during 'normal' readout.

The 'factory' margin is a bigger deviation from the norm, a more stringent read criteria that should only be attempted immediately (or very soon) after completion of an erase or program command, early in the cycling life. 'Factory' margin levels can be used to check that flash memory contents have adequate margin for long-term data retention at the normal level setting. If unexpected results are encountered when checking flash memory contents at 'factory' margin levels, the flash memory contents should be erased and reprogrammed.

**CAUTION**

Factory margin levels must only be used during verify of the initial factory programming.

## 17.4.11 Flash command descriptions

This section describes all flash commands that can be launched by a command write sequence. The flash module sets the FSTAT[ACCERR] bit and aborts the command execution if any of the following illegal conditions occur:

- There is an unrecognized command code in the FCCOB FCMD field.
- There is an error in a FCCOB field for the specific commands. Refer to the error handling table provided for each command.

Ensure that the ACCERR and FPVIOL bits in the FSTAT register are cleared prior to starting the command write sequence. As described in Launch the Command by Clearing CCIF, a new command cannot be launched while these error flags are set.

Do not attempt to read a flash block while a flash command is running (CCIF = 0) on that same block. The flash module may return invalid data to the MCU with the collision error flag (FSTAT[RDCOLERR]) set.

When required by the command, address bit 23 selects between primary program flash memory (=0) and secondary program flash memory (=1).

**CAUTION**

Flash data must be in the erased state before being programmed. Cumulative programming of bits (adding more zeros) is not allowed.

### 17.4.11.1 Read 1s Block command

The Read 1s Block command checks to see if an entire flash block has been erased to the specified margin level. The FCCOB flash address bits determine which block is erase-verified.

**Table 17-6. Read 1s Block Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x00 (RD1BLK) |
| 1 | Flash address [23:16] in the flash block to be verified |
| 2 | Flash address [15:8] in the flash block to be verified |
| 3 | Flash address [7:0][1] in the flash block to be verified |
| 4 | Read-1 Margin Choice |

1. Must be 128-bit aligned (Flash address [3:0] = 0000) for primary program flash, 64-bit aligned (Flash address [2:0] = 000) for secondary program flash.

After clearing CCIF to launch the Read 1s Block command, the flash module sets the read margin for 1s according to Table 17-7 and then reads all locations within the selected flash block. If the operation fails to read all 1s (i.e. the flash block is not fully erased), the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Read 1s Block operation completes.

**CAUTION**

The Read 1s Block operation will not react to the early indicator for radio activity. Therefore, the Read 1s Block command must not be launched if there is a concern about inadequate power available to support both radio activity and the Read 1s Block operation.

**Table 17-7. Margin Level Choices for Read 1s Block**

| Read Margin Choice | Margin Level Description |
|---|---|
| 0x00 | Use the 'normal' read level for 1s |
| 0x01 | Apply the 'User' margin to the normal read-1 level |
| 0x02 | Apply the 'Factory' margin to the normal read-1 level |

**Table 17-8. Read 1s Block Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid margin choice is specified | FSTAT[ACCERR] |
| Primary program flash is selected and the address is out of primary program flash range | FSTAT[ACCERR] |
| Secondary program flash is selected and the address is out of secondary program flash range | FSTAT[ACCERR] |
| Flash address is not 128-bit aligned for primary program flash, 64-bit aligned for secondary program flash | FSTAT[ACCERR] |
| Flash block containing the flash address is in standby mode | FSTAT[ACCERR] |
| Read-1s fails | FSTAT[MGSTAT0] |

## 17.4.11.2 Read 1s Section command

The Read 1s Section command checks if a section of flash memory is erased to the specified read margin level. The Read 1s Section command defines the starting address and the number of double-phrases to be verified for primary program flash, phrases for secondary program flash.

**Table 17-9. Read 1s Section Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x01 (RD1SEC) |
| 1 | Flash address [23:16] of the first double-phrase to be verified for primary program flash, phrase for secondary program flash |
| 2 | Flash address [15:8] of the first double-phrase to be verified for primary program flash, phrase for secondary program flash |
| 3 | Flash address [7:0] [1] of the first double-phrase to be verified for primary program flash, phrase for secondary program flash |
| 4 | Number of double-phrases to be verified for primary program flash, phrases for secondary program flash [15:8] |
| 5 | Number of double-phrases to be verified for primary program flash, phrases for secondary program flash [7:0] |
| 6 | Read-1 Margin Choice |

1. Must be 128-bit aligned (Flash address [3:0] = 0000) for primary program flash, 64-bit aligned (Flash address [2:0] = 000) for secondary progra flash .

Upon clearing CCIF to launch the Read 1s Section command, the flash module sets the read margin for 1s according to Table 17-10 and then reads all locations within the specified section of flash memory. If the operation fails to read all 1s (i.e. the flash section is not erased), the FSTAT(MGSTAT0) bit is set. The CCIF flag sets after the Read 1s Section operation completes.

**CAUTION**

The Read 1s Section operation will not react to the early indicator for radio activity. Therefore, the Read 1s Section command must not be launched if there is a concern about inadequate power available to support both radio activity and the Read 1s Section operation if the number of double-phrases for primary program flash, phrases for secondary program flash to be verified is greater than 10,240.

**Table 17-10. Margin Level Choices for Read 1s Section**

| Read Margin Choice | Margin Level Description |
|---|---|
| 0x00 | Use the 'normal' read level for 1s |
| 0x01 | Apply the 'User' margin to the normal read-1 level |
| 0x02 | Apply the 'Factory' margin to the normal read-1 level |

**Table 17-11. Read 1s Section Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid margin code is supplied | FSTAT[ACCERR] |
| An invalid flash address is supplied | FSTAT[ACCERR] |
| Flash address is not 128-bit aligned for primary program flash, 64-bit aligned for secondary program flash | FSTAT[ACCERR] |
| Flash block containing the flash address is in standby mode | FSTAT[ACCERR] |
| The requested section crosses a flash block boundary | FSTAT[ACCERR] |
| The requested number of double-phrases for primary program flash, phrases for secondary program flash is zero | FSTAT[ACCERR] |
| Read-1s fails | FSTAT[MGSTAT0] |

### 17.4.11.3 Program Check command

The Program Check command tests a previously programmed flash longword to see if it reads correctly at the specified margin level.

**Table 17-12. Program Check Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x02 (PGMCHK) |
| 1 | Flash address [23:16] |
| 2 | Flash address [15:8] |
| 3 | Flash address [7:0][1] |
| 4 | Margin Choice |
| 8 | Byte 0 expected data |
| 9 | Byte 1 expected data |
| A | Byte 2 expected data |
| B | Byte 3 expected data |

1. Must be 32-bit aligned (Flash address [1:0] = 00).

Upon clearing CCIF to launch the Program Check command, the flash module sets the read margin for 1s based on the provided margin choice according to Table 17-13. The Program Check operation then reads the specified longword and compares the actual read data to the expected data provided by the FCCOB. If the comparison at margin-1 fails, the MGSTAT0 bit is set. The flash module will then set the read margin for 0s based on the provided margin choice. The Program Check operation will then read the specified longword and compare the actual read data to the expected data provided by the FCCOB. If the comparison at margin-0 fails, the MGSTAT0 bit will be set. The CCIF flag sets after the Program Check operation completes.

The starting address must be 32-bit aligned (the lowest two bits of the byte address must be 00):

- Byte 0 data is expected at the supplied 32-bit aligned address,
- Byte 1 data is expected at byte address specified + 0b01,
- Byte 2 data is expected at byte address specified + 0b10, and
- Byte 3 data is expected at byte address specified + 0b11.

**NOTE**

See the description of margin reads, Margin Read Commands

**Table 17-13. Margin Level Choices for Program Check**

| Read Margin Choice | Margin Level Description |
|---|---|
| 0x01 | Read at 'User' margin-1 and 'User' margin-0 |
| 0x02 | Read at 'Factory' margin-1 and 'Factory' margin-0 |

**Table 17-14. Program Check Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid flash address is supplied | FSTAT[ACCERR] |
| Flash address is not 32-bit aligned | FSTAT[ACCERR] |
| Flash block containing the flash address is in standby mode | FSTAT[ACCERR] |
| An invalid margin choice is supplied | FSTAT[ACCERR] |
| Flash address is located in an XA or XA_S controlled segment and the Erase All Blocks, Erase All Blocks Unsecure, Read 1s All Execute-only Segments, Erase All Execute-only Segments or the Read 1s All Blocks command has not successfully completed since the last reset | FSTAT[FPVIOL] |
| Either of the margin reads does not match the expected data | FSTAT[MGSTAT0] |

### 17.4.11.4 Program Phrase command

The Program Phrase command programs eight previously-erased bytes in the flash memory using an embedded algorithm.

**CAUTION**

A Flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a Flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

**Table 17-15. Program Phrase Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x07 (PGM8) |
| 1 | Flash address [23:16] |
| 2 | Flash address [15:8] |
| 3 | Flash address [7:0][1] |
| 4 | Byte 0 program value |
| 5 | Byte 1 program value |
| 6 | Byte 2 program value |
| 7 | Byte 3 program value |
| 8 | Byte 4 program value |
| 9 | Byte 5 program value |
| A | Byte 6 program value |
| B | Byte 7 program value |

1. Must be 64-bit aligned (Flash address [2:0] = 000)

Upon clearing CCIF to launch the Program Phrase command, the flash module programs the data bytes into the flash memory using the supplied address. The protection status is always checked. If the swap system is enabled, the double-phrase containing the swap indicator address in each half of the primary program flash space is implicitly protected from programming. The targeted flash locations must be currently unprotected (see the description of the FPROT and FPROTS registers) to permit execution of the Program Phrase operation. The programming operation is unidirectional. It can only move NVM bits from the erased state ('1') to the programmed state ('0'). Erased bits that fail to program to the '0' state are flagged as errors in MGSTAT0. The CCIF flag is set after the Program Phrase operation completes.

The starting address must be 64-bit aligned (flash address [2:0] = 000):

- Byte 0 data is written to the starting address ('start'),
- Byte 1 data is programmed to byte address start+0b01,
- Byte 2 data is programmed to byte address start+0b10, and
- Byte 3 data is programmed to byte address start+0b11, etc.

**Table 17-16. Program Phrase Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid flash address is supplied | FSTAT[ACCERR] |
| Flash address is not 64-bit aligned | FSTAT[ACCERR] |
| Flash block containing the flash address is in standby mode | FSTAT[ACCERR] |
| Flash address points to a protected area | FSTAT[FPVIOL] |
| Flash address is located in an XA or XA_S controlled segment and the Erase All Blocks, Erase All Blocks Unsecure, Read 1s All Execute-only Segments, Erase All Execute-only Segments or the Read 1s All Blocks command has not successfully completed since the last reset | FSTAT[FPVIOL] |
| Any errors have been encountered during the verify operation. | FSTAT[MGSTAT0] |

## 17.4.11.5 Erase Flash Block Command

The Erase Flash Block operation erases all addresses in a single flash block.

**Table 17-17. Erase Flash Block Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x08 (ERSBLK) |
| 1 | Flash address [23:16] in the flash block to be erased |
| 2 | Flash address [15:8] in the flash block to be erased |
| 3 | Flash address [7:0][1] in the flash block to be verified |

1. Must be 128-bit aligned (Flash address [3:0] = 0000) for primary program flash, 64-bit aligned (Flash address [2:0] = 000) for secondary program flash.

Upon clearing CCIF to launch the Erase Flash Block command, the flash module erases the main array of the selected flash block and verifies that it is erased. The Erase Flash Block command aborts and sets the FSTAT[FPVIOL] bit if any region within the block is protected (see the description of the program flash protection (FPROT and FPROTS) registers). If the swap system is enabled, the swap indicator address is implicitly protected from block erase unless the swap system is in the UPDATE or UPDATE-ERASED state and the primary program flash block being erased is the non-active block that contains the swap indicator address. If the erase verify fails, the MGSTAT0 bit in FSTAT is set. The CCIF flag sets after the Erase Flash Block operation completes.

**Table 17-18. Erase Flash Block Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| Primary program flash is selected and the address is out of primary program flash range | FSTAT[ACCERR] |
| Secondary program flash is selected and the address is out of secondary program flash range | FSTAT[ACCERR] |
| Flash address is not 128-bit aligned for primary program flash, 64-bit aligned for secondary program flash | FSTAT[ACCERR] |
| Flash block containing the flash address is in standby mode | FSTAT[ACCERR] |
| Any area of the selected flash block is protected | FSTAT[FPVIOL] |
| Flash address is located in an XA or XA_S controlled segment and the Erase All Blocks, Erase All Blocks Unsecure, Read 1s All Execute-only Segments, Erase All Execute-only Segments or the Read 1s All Blocks command has not successfully completed since the last reset | FSTAT[FPVIOL] |
| Any errors have been encountered during the verify operation[1] | FSTAT[MGSTAT0] |

1. User margin read may be run using the Read 1s Block command to verify all bits are erased.

### 17.4.11.5.1 Impact of radio activity on Erase Flash Block operation

The RSIM module provides an early indicator to the flash module that the radio is going active and also indicates when the radio goes inactive. If the radio active indicator is asserted while the Erase Flash Block operation is active, the operation will stall to reduce power consumption before the radio goes active. The Erase Flash Block operation will resume after the radio active indicator negates. FSTAT[CCIF] remains clear during the stall to prevent disruption of the Erase Flash Block operation while the block being erased remains unavailable for read operations.

The following figure shows how the Erase Flash Block operation stalls and resumes based on radio activity.

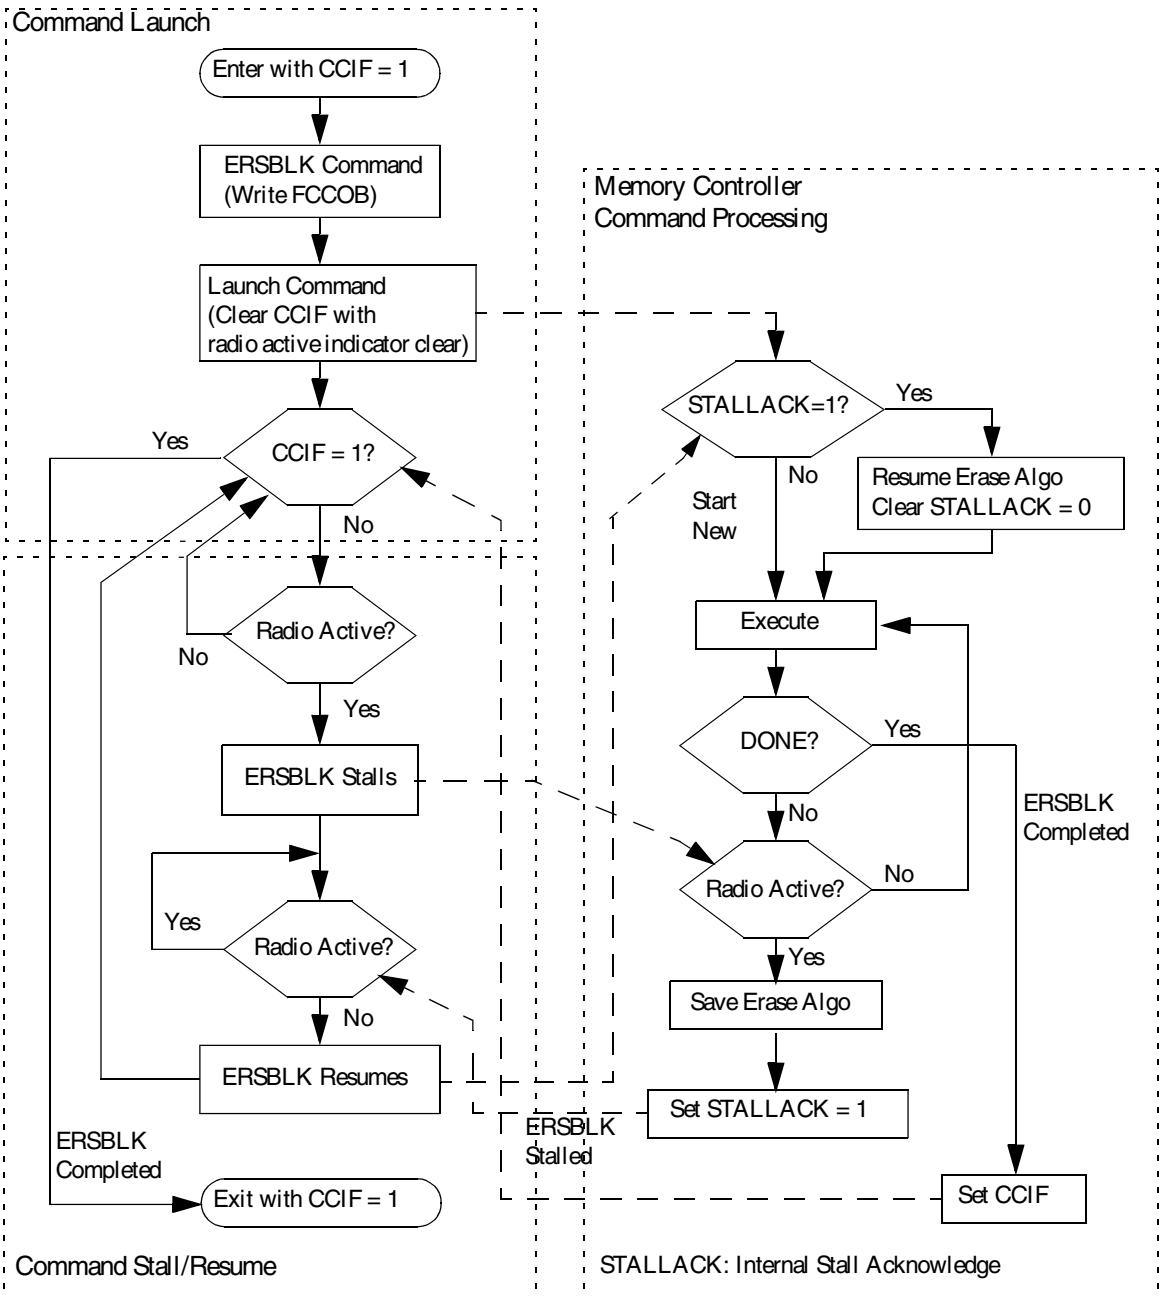

**Figure 17-6. Radio Active Impact on Erase Flash Block Operation**

## 17.4.11.6 Erase Flash Sector command

The Erase Flash Sector operation erases all addresses in a flash sector.

**Table 17-19. Erase Flash Sector Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x09 (ERSSCR) |

*Table continues on the next page...*

**Table 17-19. Erase Flash Sector Command FCCOB Requirements (continued)**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 1 | Flash address [23:16] in the flash sector to be erased |
| 2 | Flash address [15:8] in the flash sector to be erased |
| 3 | Flash address [7:0][1] in the flash block to be verified |

1. Must be 128-bit aligned (Flash address [3:0] = 0000) for primary program flash, 64-bit aligned (Flash address [2:0] = 000) for secondary program flash.

Upon clearing CCIF to launch the Erase Flash Sector command, the flash module erases the selected flash sector and then verifies that it is erased. The Erase Flash Sector command aborts if the selected sector is protected (see the description of the FPROT and FPROTS registers). If the swap system is enabled, the swap indicator address in each primary program flash block is implicitly protected from sector erase unless the swap system is in the UPDATE or UPDATE-ERASED state and the primary program flash sector containing the swap indicator address being erased is in the non-active block. If the erase-verify fails the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Erase Flash Sector operation completes. The Erase Flash Sector command is suspendable (see the FCNFG[ERSSUSP] bit and Suspending an Erase Flash Sector Operation).

**Table 17-20. Erase Flash Sector Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid Flash address is supplied | FSTAT[ACCERR] |
| Flash address is not 128-bit aligned for primary program flash, 64-bit aligned for secondary program flash | FSTAT[ACCERR] |
| Flash block containing the flash address is in standby mode | FSTAT[ACCERR] |
| The selected flash sector is protected | FSTAT[FPVIOL] |
| Flash address is located in an XA or XA_S controlled segment and the Erase All Blocks, Erase All Blocks Unsecure, Read 1s All Execute-only Segments, Erase All Execute-only Segments or the Read 1s All Blocks command has not successfully completed since the last reset | FSTAT[FPVIOL] |
| Any errors have been encountered during the verify operation[1] | FSTAT[MGSTAT0] |

1. User margin read may be run using the Read 1s Section command to verify all bits are erased.

### 17.4.11.6.1 Suspending an Erase Flash Sector Operation

To suspend an Erase Flash Sector operation set the FCNFG[ERSSUSP] bit when CCIF, ACCERR, and FPVIOL are clear and the CCOB command field holds the code for the Erase Flash Sector command. During the Erase Flash Sector operation (see Erase Flash Sector command), the flash module samples the state of the ERSSUSP bit at convenient

points. If the flash module detects that the ERSSUSP bit is set, the Erase Flash Sector operation is suspended and sets CCIF. While ERSSUSP is set, all writes to flash registers are ignored except for writes to the FSTAT FSTDBY, and FCNFG registers.

If an Erase Flash Sector operation effectively completes before the flash module detects that a suspend request has been made, the flash module clears the ERSSUSP bit prior to setting CCIF. When an Erase Flash Sector operation has been successfully suspended, the flash module sets CCIF and leaves the ERSSUSP bit set. While CCIF is set, the ERSSUSP bit can only be cleared to prevent the withdrawal of a suspend request before the flash module has acknowledged it.

Suspending an Erase Flash Sector opeartion has priority over stall due to radio activity.

#### 17.4.11.6.2 Resuming a Suspended Erase Flash Sector Operation

If the ERSSUSP bit is still set when CCIF is cleared to launch the next command, the previous Erase Flash Sector operation resumes. The flash module acknowledges the request to resume a suspended operation by clearing the ERSSUSP bit. A new suspend request can then be made by setting ERSSUSP. A single Erase Flash Sector operation can be suspended and resumed multiple times.

There is a minimum elapsed time limit of 4.3 msec between the request to resume the Erase Flash Sector operation (CCIF is cleared) and the request to suspend the operation again (ERSSUSP is set). This minimum time period is required to ensure that the Erase Flash Sector operation will eventually complete. If the minimum period is continually violated, i.e. the suspend requests come repeatedly and too quickly, no forward progress is made by the Erase Flash Sector algorithm. The resume/suspend sequence runs indefinitely without completing the erase.

#### 17.4.11.6.3 Aborting a Suspended Erase Flash Sector Operation

The user may choose to abort a suspended Erase Flash Sector operation by clearing the ERSSUSP bit prior to clearing CCIF for the next command launch. When a suspended operation is aborted, the flash module starts the new command using the new FCCOB contents.

**Note**

Aborting the erase leaves the bitcells in an indeterminate, partially-erased state. Data in this sector is not reliable until a new erase command fully completes.

The following figure shows how to suspend and resume the Erase Flash Sector operation.

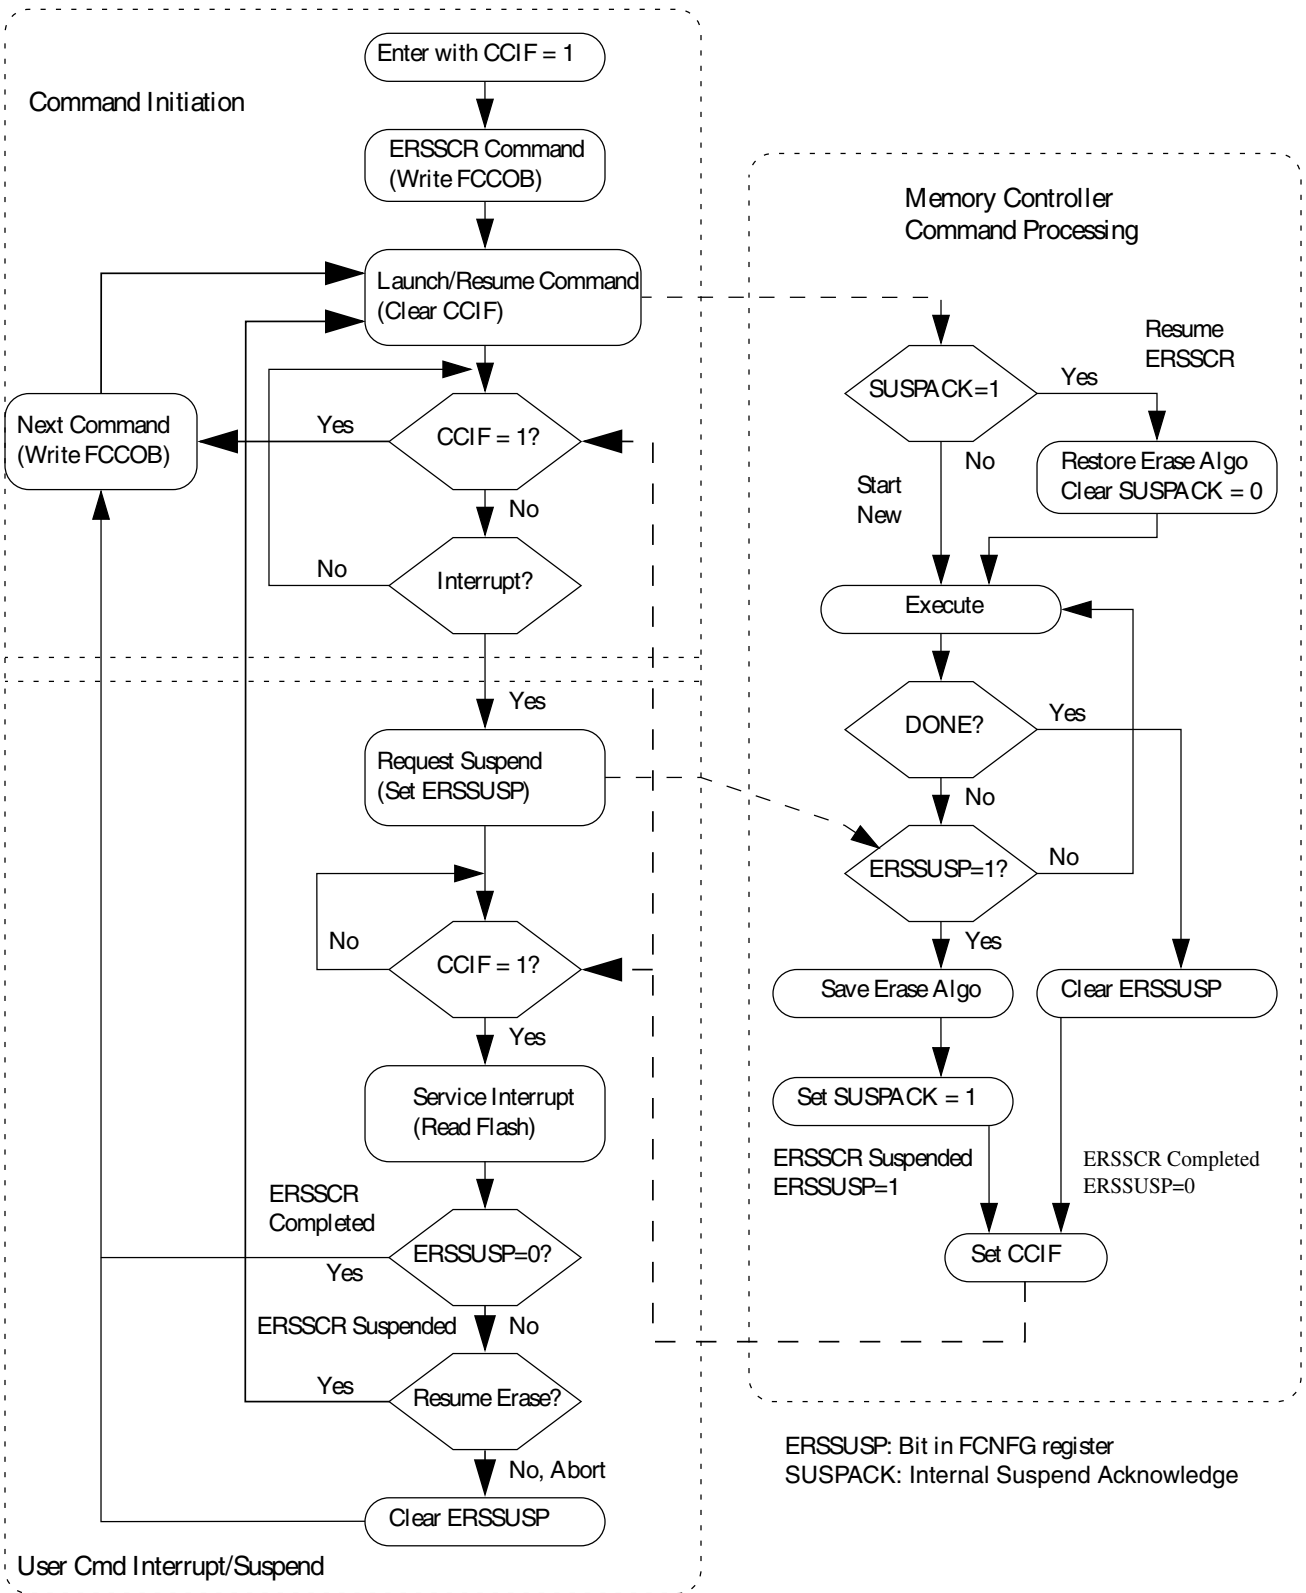

**Figure 17-7. Suspend and Resume of Erase Flash Sector Operation**

#### 17.4.11.6.4 Impact of radio activity on Erase Flash Sector operation

The RSIM module provides an early indicator to the flash module that the radio is going active and also indicates when the radio goes inactive. If the radio active indicator is asserted while the Erase Flash Sector operation is active, the operation will stall to reduce power consumption before the radio goes active. The Erase Flash Sector operation will resume after the radio active indicator negates. FSTAT[CCIF] remains clear during the stall to prevent disruption of the Erase Flash Sector operation while the block containing the sector being erased remains unavailable for read operations.

The following figure shows how the Erase Flash Sector operation stalls and resumes based on radio activity.

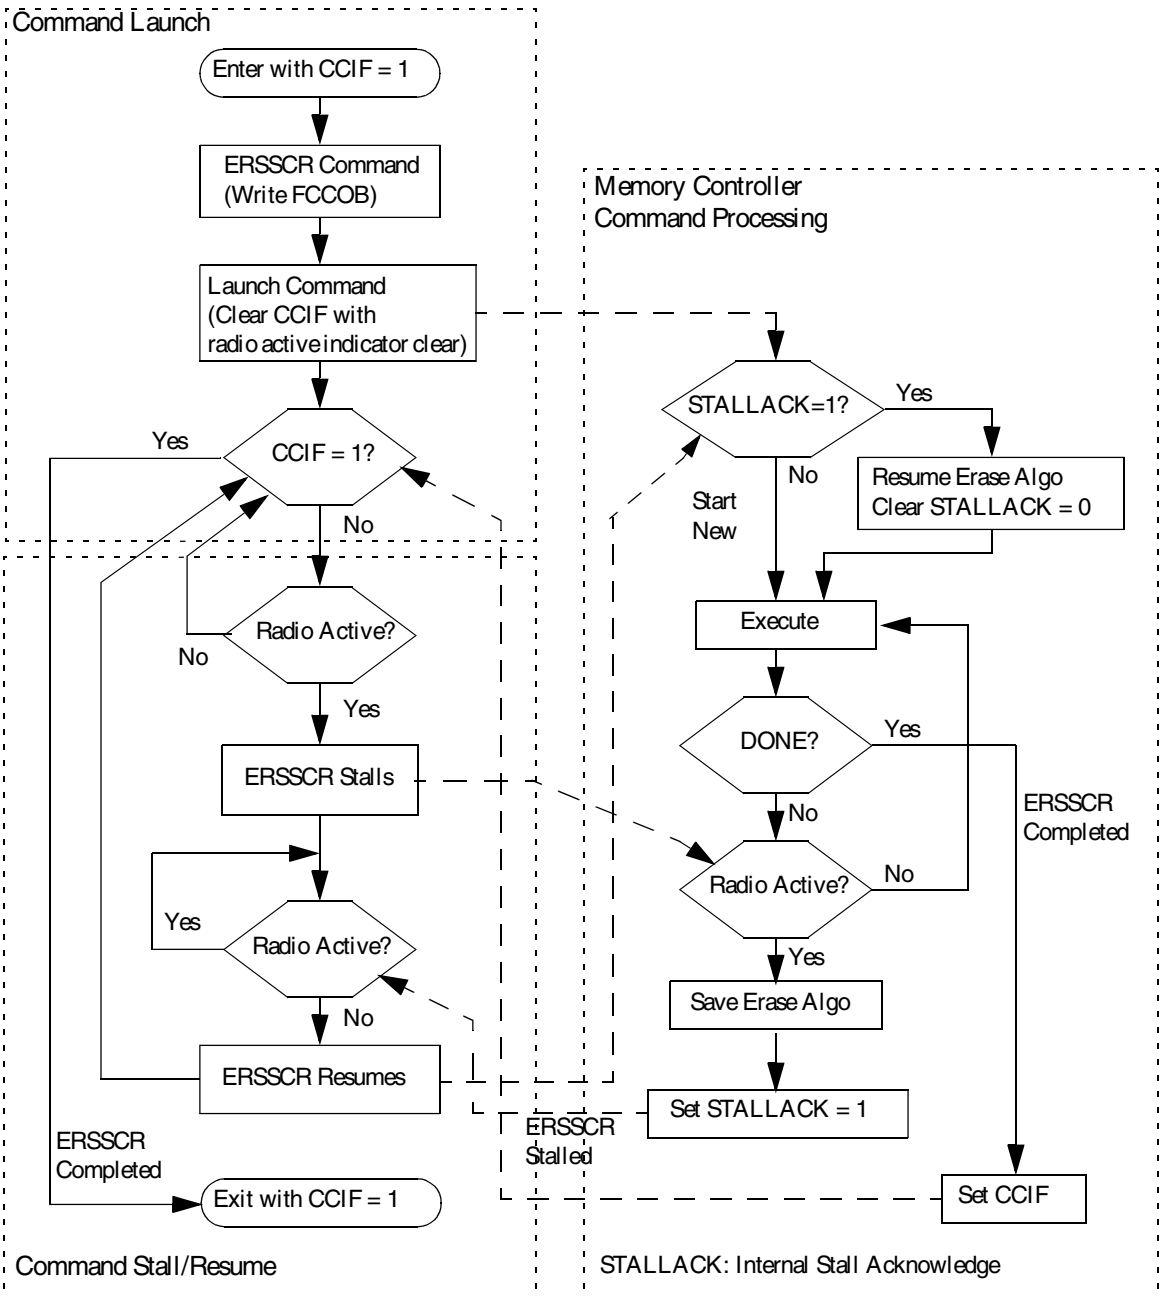

**Figure 17-8. Radio Active Impact on Erase Flash Sector Operation**

## 17.4.11.7 Program Section command

The Program Section operation programs the data found in the section program buffer to previously erased locations in the flash memory using an embedded algorithm. Data is preloaded into the section program buffer (see Flash sector programming).

The section program buffer is limited to the lower quarter of the programming acceleration RAM (relative byte addresses 0x0000-0x03FF - be sure to check your device specific memory map for the location of the programming acceleration RAM). Data written to the remainder of the programming acceleration RAM is ignored and may be overwritten by the flash module during Program Section command execution.

**CAUTION**

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

**Table 17-21. Program Section Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x0B (PGMSEC) |
| 1 | Flash address [23:16] |
| 2 | Flash address [15:8] |
| 3 | Flash address [7:0][1] |
| 4 | Number of double-phrases for primary program flash, phrases for secondary program flash to program [15:8] |
| 5 | Number of double-phrases for primary program flash, phrases for secondary program flash to program [7:0] |

1. Must be 128-bit aligned (Flash address [3:0] = 0000) for primary program flash, 64-bit aligned (Flash address [2:0] = 000) for secondary program flash.

Upon clearing CCIF to launch the Program Section command, the flash module will block access to the programming acceleration RAM and program the data residing in the Section Program Buffer into the flash memory starting at the flash address provided. The starting address must be unprotected (see the description of the FPROT and FPROTS registers) to permit execution of the Program Section operation. If the swap system is enabled, the double-phrase containing the swap indicator address in each half of the primary program flash space is implicitly protected from programming. If the double-phrase containing the swap indicator address is encountered during the Program Section operation, it will be bypassed without setting FPVIOL and the contents will not be programmed. Programming, which is not allowed to cross a flash sector boundary, continues until all requested double-phrases for primary program flash, phrases for secondary program flash have been programmed. After the Program Section operation completes, the CCIF flag sets. The contents of the Section Program Buffer are not changed by the Program Section operation unless the swap system is enabled and the Program Section command is targeting the double-phrase containing the swap indicator in which case that double-phrase is changed to all ones.

**CAUTION**

The Program Section operation will not react to the early indicator for radio activity. Therefore, the Program Section command must not be launched if there is a concern about inadequate power available to support both radio activity and the Program Section operation.

**Table 17-22. Program Section Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid flash address is supplied | FSTAT[ACCERR] |
| Flash address is not 128-bit aligned for primary program flash, 64-bit aligned for secondary program flash | FSTAT[ACCERR] |
| The requested section crosses a flash sector boundary | FSTAT[ACCERR] |
| The requested number of double-phrases for primary program flash, phrases for secondary program flash is zero | FSTAT[ACCERR] |
| The space required to store data for the requested number of double-phrases for primary program flash, phrases for secondary program flash is more than one quarter the size of the programming acceleration RAM | FSTAT[ACCERR] |
| The flash address falls in a protected area | FSTAT[FPVIOL] |
| The requested flash section is located in an XA or XA_S controlled segment and the Erase All Blocks, Erase All Blocks Unsecure, Read 1s All Execute-only Segments, Erase All Execute-only Segments or the Read 1s All Blocks command has not successfully completed since the last reset | FSTAT[FPVIOL] |
| Any errors have been encountered during the verify operation | FSTAT[MGSTAT0] |

#### 17.4.11.7.1 Flash sector programming

The process of programming an entire flash sector using the Program Section command is as follows:

1. If required, execute the Set RAM Function command to make the programming acceleration RAM available and initialize the RAM to all ones.
2. Launch the Erase Flash Sector command to erase the flash sector to be programmed.
3. Beginning with the starting address of the programming acceleration RAM , sequentially write enough data to the RAM to fill an entire flash sector, or as much data is allowed due to RAM size versus flash sector size. This area of the RAM serves as the section program buffer. The section program buffer can be written to while the operation launched in step 2 is executing, i.e. while CCIF = 0.
4. Execute the Program Section command to program the contents of the section program buffer into the selected flash sector.
5. Repeat steps 3 through 4 to complete the entire flash sector, if necessary.
6. To program additional flash sectors, repeat steps 2 through 5.

### 17.4.11.8 Generate CRC command

The Generate CRC command will generate a signature based on the contents of the selected flash sectors using an embedded CRC generator compatible with the Kinetis CRC module using the following fixed parameters:

- WIDTH = 32
- POLYNOMIAL = 0x04C11DB7
- REFIN = True
- REFOUT = True
- XOROUT = 0xFFFF_FFFF

**Table 17-23. Generate CRC Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x0C (CRCGEN) |
| 1 | Flash address in the starting sector [23:16] |
| 2 | Flash address in the starting sector [15:8] |
| 3 | Flash address in the starting sector [7:0][1] |
| 4 | Number of sectors to process |
| 5 | Seed Option:<br>0 - Seed with 0xFFFF_FFFF<br>1 - Seed using the provided optional seed |
| 8 | Optional Seed [31:24] |
| 9 | Optional Seed [23:16] |
| A | Optional Seed [15:8] |
| B | Optional Seed [7:0] |
| Returned values | |
| 8 | CRC signature [31:24] |
| 9 | CRC signature [23:16] |
| A | CRC signature [15:8] |
| B | CRC signature [7:0] |

1. Must be 128-bit aligned (Flash address [3:0] = 0000) for primary program flash and 64-bit aligned (Flash address [2:0] = 000) for secondary program flash.

To allow access to the flash block that the Generate CRC command is executing on, the Set RAM Function command must be run with the 0xCC option resulting in FCNFG[CRCRDY] = 1. If no access to the flash block is required while running the Generate CRC command, the last Set RAM Function command run after reset must not be run with the 0xCC option so that FCNFG[CRCRDY] = 0.

Upon clearing CCIF to launch the Generate CRC command, the flash module will process flash data starting with the first address in the sector containing the flash address provided and will continue until all sectors requested have been processed. No protection checks are made. While the Generate CRC command executes, read access to the flash block containing the selected sector(s) is not blocked, i.e., read collisions are avoided. The CCIF flag sets after the Generate CRC operation completes.

**Table 17-24. Generate CRC Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| An invalid Flash address is supplied | FSTAT[ACCERR] |
| Flash address in not 128-bit aligned for primary program flash and 64-bit aligned for secondary program flash | FSTAT[ACCERR] |
| Flash block containing the flash address is in standby mode | FSTAT[ACCERR] |
| Requested number of sectors is 0 | FSTAT[ACCERR] |
| Requested number of sectors crosses a flash block boundary | FSTAT[ACCERR] |

### 17.4.11.9 Read 1s All Blocks Command

The Read 1s All Blocks command checks if the flash blocks and erasable IFR have been erased to the specified read margin level, if applicable, and releases security if the readout passes, i.e. all data reads as '1'.

**Table 17-25. Read 1s All Blocks Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x40 (RD1ALL) |
| 1 | Read-1 Margin Choice |

Upon clearing CCIF to launch the Read 1s All Blocks command, the flash module:

- sets the read margin for 1s according to Table 17-26,
- checks the contents of the program flash and erasable IFR are in the erased state.

If the flash module confirms that these memory resources are erased, access control is disabled and security is released by setting the FSEC[SEC] field to the unsecure state. If the read fails, i.e. all flash memory resources are not in the fully erased state, the FSTAT[MGSTAT0] bit is set. The CRCRDY and RAMRDY bits are clear during the Read 1s All Blocks operation and are restored at the end of the Read 1s All Blocks operation. The CCIF flag sets after the Read 1s All Blocks operation completes.

**CAUTION**

The Read 1s All Blocks operation will not react to the early indicator for radio activity. Therefore, the Read 1s All Blocks command must not be launched if there is a concern about inadequate power available to support both radio activity and the Read 1s All Blocks operation.

**Table 17-26. Margin Level Choices for Read 1s All Blocks**

| Read Margin Choice | Margin Level Description |
|---|---|
| 0x00 | Use the 'normal' read level for 1s |
| 0x01 | Apply the 'User' margin to the normal read-1 level |
| 0x02 | Apply the 'Factory' margin to the normal read-1 level |

**Table 17-27. Read 1s All Blocks Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid margin choice is specified | FSTAT[ACCERR] |
| Any flash block is in standby mode | FSTAT[ACCERR] |
| Read-1s fails | FSTAT[MGSTAT0] |

## 17.4.11.10 Read Index Command

The Read Index command provides read access to special 8-byte records located in the primary program flash IFR (see Non-erasable IFR Map and Erasable IFR Map).

**Table 17-28. Read Index Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x41 (RDINDEX) |
| 1 | Record index (0x00 - 0x1F / 0x80 - 0xAF) |
| Returned Values | |
| 4 | Record byte 0 value |
| 5 | Record byte 1 value |
| 6 | Record byte 2 value |
| 7 | Record byte 3 value |
| 8 | Record byte 4 value |
| 9 | Record byte 5 value |
| A | Record byte 6 value |
| B | Record byte 7 value |

Upon clearing CCIF to launch the Read Index command, the selected 8-byte record is read from a primary program flash IFR and stored in the FCCOB register. The CCIF flag sets after the Read Index operation completes.

Valid record index values for the Read Index command range from 0x00 to 0x1F and 0x80 to 0xAF unless the record index is reserved. Records with an index between 0x00 - 0x0F and 0x80 - 0x9F are also programmable with restrictions using the Program Index command. Records with an index at or above 0x80 are erasable using the Erase All Blocks or Erase All Blocks Unsecure commands. During execution of the Read Index command, any attempt to read addresses within the primary program flash block containing these records will return invalid data.

**Table 17-29. Read Index Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| Primary Program flash block 0 is in standby mode | FSTAT[ACCERR] |
| An invalid or reserved record index is supplied | FSTAT[ACCERR] |

### 17.4.11.11 Program Index command

The Program Index command enables programming of special 8-byte records located in the primary program flash IFR (see Non-erasable IFR Map and Erasable IFR Map).

**Table 17-30. Program Index Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x43 (PGMINDEX) |
| 1 | Record index (0x00 - 0x0F / 0x80 - 0x9F / 0xB0 - 0xFF) |
| 2 | Not Used |
| 3 | Not Used |
| 4 | Record byte 0 value |
| 5 | Record byte 1 value |
| 6 | Record byte 2 value |
| 7 | Record byte 3 value |
| 8 | Record byte 4 value |
| 9 | Record byte 5 value |
| A | Record byte 6 value |
| B | Record byte 7 value |

Upon clearing CCIF to launch the Program Index command, the operation first verifies that the selected record is erased. If erased, the selected record is programmed using the values provided. The Program Index command also verifies that the programmed values read back correctly. The CCIF flag sets after the Program Index operation completes.

Valid record index values for the Program Index command range from 0x00 to 0x0F, 0x80 to 0x9F, and 0xB0 to 0xFF unless the record index is reserved. Records with an index between 0x00 - 0x0F and 0x80 - 0x9F are also readable with restrictions using the Read Index command. Records with an index at or above 0x80 are erasable using the Erase All Blocks or Erase All Blocks Unsecure commands. During execution of the Program Index command, any attempt to read addresses within the primary program flash block containing these records will return invalid data.

Any attempt to program the SEC0 security record using the Program Index command that does not result in the ACCERR flag being set will first program the SEC1 security record to 0x0000.

**Table 17-31. Program Index Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| Primary Program flash block 0 is in standby mode | FSTAT[ACCERR] |
| An invalid or reserved record index is supplied | FSTAT[ACCERR] |
| The requested record has already been programmed to a non-erased value[1] | FSTAT[ACCERR] |
| Any errors have been encountered during the verify operation | FSTAT[MGSTAT0] |

1. If a record is initially programmed to 0xFFFF_FFFF_FFFF_FFFF, the Program Index command is allowed to execute again on that same record.

## 17.4.11.12 Erase All Blocks Command

The Erase All Blocks operation erases all flash memory including the erasable IFR, initializes the programming acceleration RAM, and releases MCU security.

**Table 17-32. Erase All Blocks Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x44 (ERSALL) |

Upon clearing CCIF to launch the Erase All Blocks command, the flash module erases all flash memory, the erasable IFR space,and the programming acceleration RAM, then verifies that all are erased. If the flash module verifies that all flash memories and the programming acceleration RAM were properly erased, access control is disabled and security is released by setting the FSEC[SEC] field to the unsecure state and the

FCNFG[RAMRDY] bit is set. The Erase All Blocks command aborts if any flash region is protected. The swap indicator address in the primary program flash blocks are not implicitly protected from the erase operation. If the erase-verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Erase All Blocks operation completes.

Access control determined by the contents of the FXACC and FXACCS registers will not block execution of the Erase All Blocks command. The contents of the FXACC, FSACC, FXACCS and FSACCS registers will not be impacted by the execution of the Erase All Blocks command but the associated FXACC, FSACC, FXACCS and FSACCS index fields will be erased. After completion of the Erase All Blocks command, access control is disabled until the next reset of the flash module or the Read 1s All Blocks command is executed and fails (FSTAT[MGSTAT0] is set).

**CAUTION**

The Erase All Blocks operation will not react to the early indicator for radio activity. Therefore, the Erase All Blocks command must not be launched if there is a concern about inadequate power available to support both radio activity and the Erase All Blocks operation.

**Table 17-33. Erase All Blocks Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| Any flash block is in standby mode | FSTAT[ACCERR] |
| Any region of the flash memory is protected | FSTAT[FPVIOL] |
| Any errors have been encountered during the verify operation[1] | FSTAT[MGSTAT0] |

1. User margin read may be run using the Read 1s All Blocks command to verify all bits are erased.

### 17.4.11.12.1 Triggering an erase all external to the flash module

The functionality of the Erase All Blocks/Erase All Blocks Unsecure command is also available in an uncommanded fashion outside of the flash memory. Refer to the device's Chip Configuration details for information on this functionality.

Before invoking the external erase all function, the FCCOB0 register must not contain 0x44 and no flash block can be in standby mode and the flash module cannot be in HSRUN mode. When invoked, the erase all function erases all program flash memory and the program flash erasable IFR space regardless of the state of the FSTAT[ACCERR and FPVIOL] flags or the protection settings or the state of the flash swap system. If the post-erase verify passes, access control determined by the contents of the FXACC and FXACCS registers are disabled and the routine releases security by setting the

FSEC[SEC] field to the unsecure state and the FCNFG[RAMRDY] bit sets. The security field in the Flash Configuration Field is also programmed to the unsecure state. The status of the erase all request is reflected in the FCNFG[ERSAREQ] bit. The FCNFG[ERSAREQ] bit is cleared once the operation completes and the normal FSTAT error reporting, except FPVIOL, is available as described in Erase All Blocks Command/ Erase All Blocks Unsecure Command.

**CAUTION**

Since the swap related fields in the program flash erasable IFR are erased during the Erase All Blocks/Erase All Blocks Unsecure command operation, the swap system becomes uninitialized. The Swap Control command must be run with the initialization code to set the swap indicator address and initialize the swap system.

**CAUTION**

The Erase All Blocks operation will not react to the early indicator for radio activity. Therefore, the Erase All pin must not be asserted if there is a concern about inadequate power available to support both radio activity and the Erase All Blocks operation.

### 17.4.11.13 Verify Backdoor Access Key command

The Verify Backdoor Access Key command only executes if the mode and security conditions are satisfied (see Flash commands by mode). Execution of the Verify Backdoor Access Key command is further qualified by the FSEC[KEYEN] bits. The Verify Backdoor Access Key command releases security if user-supplied keys in the FCCOB match the backdoor keys located in the Flash Configuration Field.

**Table 17-34. Verify Backdoor Access Key Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x45 (VFYKEY) |
| 1-3 | Not Used |
| 4 | Key Byte 0 |
| 5 | Key Byte 1 |
| 6 | Key Byte 2 |
| 7 | Key Byte 3 |
| 8 | Key Byte 4 |
| 9 | Key Byte 5 |

*Table continues on the next page...*

**Table 17-34. Verify Backdoor Access Key Command FCCOB Requirements (continued)**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| A | Key Byte 6 |
| B | Key Byte 7 |

Upon clearing CCIF to launch the Verify Backdoor Access Key command, the flash module checks the FSEC[KEYEN] bits to verify that this command is enabled. If not enabled, the flash module sets the FSTAT[ACCERR] bit and terminates. If the command is enabled, the flash module compares the key provided in FCCOB to the backdoor key located in the Flash Configuration Field. If the backdoor keys match, the FSEC[SEC] field is changed to the unsecure state and security is released. If the backdoor keys do not match, security is not released and all future attempts to execute the Verify Backdoor Access Key command are immediately aborted and the FSTAT[ACCERR] bit is (again) set to 1 until a reset of the flash module occurs. If the entire 8-byte key is all zeros or all ones, the Verify Backdoor Access Key command fails with an access error. The CCIF flag sets after the Verify Backdoor Access Key operation completes.

**NOTE**

*Knowledge of the backdoor access keys supersedes the NXP lockout mechanism provided by the FSLACC bits in the FSEC register. If NXP (or anyone) knows the keys and KEYEN is enabled, they get in.*

**Table 17-35. Verify Backdoor Access Key Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| Primary Program flash block 0 is in standby mode | FSTAT[ACCERR] |
| The supplied key is all-0s or all-1s | FSTAT[ACCERR] |
| An incorrect backdoor key is supplied | FSTAT[ACCERR] |
| Backdoor key access has not been enabled (see the description of the FSEC register) | FSTAT[ACCERR] |
| This command is launched and the backdoor key has mismatched since the last power down reset | FSTAT[ACCERR] |

## 17.4.11.14 Swap Control command

The Swap Control command handles specific activities associated with swapping the two halves of program flash memory within the memory map.

**Table 17-36. Swap Control Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x46 (SWAP) |
| 1 | Flash address [23:16] |
| 2 | Flash address [15:8] |
| 3 | Flash address [7:0][1] |
| 4 | Swap Control Code:<br>• 0x01 - Initialize Swap System<br>• 0x02 - Set Swap in Update State<br>• 0x04 - Set Swap in Complete State<br>• 0x08 - Report Swap Status<br>• 0x10 - Disable Swap System |
| Returned values | |
| 5 | Current Swap Mode:<br>• 0x00 - Uninitialized<br>• 0x01 - Ready<br>• 0x02 - Update<br>• 0x03 - Update-Erased<br>• 0x04 - Complete<br>• 0x05 - Disabled |
| 6 | Current Swap Block Status:<br>0x00 - primary program flash block 0 at 0x0_0000<br>0x01 - primary program flash block 1 at 0x0_0000 |
| 7 | Next Swap Block Status (after any reset):<br>0x00 - primary program flash block 0 at 0x0_0000<br>0x01 - primary program flash block 1 at 0x0_0000 |

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

Upon clearing CCIF to launch the Swap Control command, the flash module will handle swap-related activities based on the Swap Control code provided in FCCOB4 as follows:

- 0x01 (Initialize Swap System to UPDATE-ERASED State) - After verifying that the current swap state is UNINITIALIZED, and that both phrases which will contain the swap indicators (located in each half of the primary program flash memory within the relative double-phrase flash address provided) are erased, and that the flash address provided is in the lower half of the primary program flash memory, the flash address provided (shifted with bits[3:0] removed) will be programmed into the SWAPADDR index field located in the primary program flash erasable IFR. After the swap indicator address has been programmed, the swap enable word (SWAPEN index field) will be programmed to 0x0000. After the swap enable word has been programmed, the swap indicator located in the lower half of the primary program flash memory will be programmed to 0xFF00.
- 0x02 (Progress Swap to UPDATE State) - After verifying that the current swap state is READY and that the aligned flash address provided matches the one stored in the

SWAPADDR index field, the swap indicator located in the currently active primary program flash block will be programmed to 0xFF00.

- 0x04 (Progress Swap to COMPLETE State) - After verifying that the current swap state is UPDATE-ERASED and that the aligned flash address provided matches the one stored in the SWAPADDR index field, the swap indicator located in the currently active primary program flash block will be programmed to 0x0000. Before executing with this Swap Control code, the user must erase the non-active swap indicator using the Erase Flash Block or Erase Flash Sector commands and update the application code or data as needed.
- 0x08 (Report Swap Status) - After verifying that the aligned flash address provided is in the lower half of the primary program flash memory, the status of the swap system will be reported as follows:
  - FCCOB5 (Current Swap State) - indicates the current swap state based on the status of the swap disable word (SWAPDIS index field), swap enable word and the swap indicators. If the MGSTAT0 flag is set after command completion, the swap state returned was not successfully transitioned from and the appropriate swap command code must be attempted again. If the current swap state is UPDATE and the non-active swap indicator is 0xFFFF, the current swap state is changed to UPDATE-ERASED.
  - FCCOB6 (Current Swap Block Status) - indicates which primary program flash block is currently located at relative flash address 0x0_0000.
  - FCCOB7 (Next Swap Block Status) - indicates which primary program flash block will be located at relative flash address 0x0_0000 after the next reset of the flash module.
- 0x10 (Disable Swap System) - After verifying that the current swap state is UNINITIALIZED , the swap disable word is programmed to 0x0000 and the swap system changed to the DISABLED state with primary program flash block 0 located at relative flash address 0x0_0000.

**NOTE**

It is recommended that the user execute the Swap Control command to report swap status (code 0x08) after any reset to determine if issues with the swap system were detected during the swap state determination procedure.

**NOTE**

It is recommended that the user write 0xFF to FCCOB5, FCCOB6, and FCCOB7 since the Swap Control command will not always return the swap state and status fields when an ACCERR is detected.

The CCIF flag sets after the Swap Control operation completes.

The swap indicators are implicitly protected from being programmed during Program Phrase or Program Section command operations and are implicitly unprotected during Swap Control command operations. The swap indicators are implicitly protected from being erased during Erase Flash Block and Erase Flash Sector command operations unless the swap indicator being erased is in the non-active primary program flash block and the swap system is in the UPDATE or UPDATE-ERASED state. The Erase All Blocks or Erase All Blocks Unsecure command or erase-all function can be used to place the swap system in the UNINITIALIZED state.

**Table 17-37. Swap Control Command Error Handling**

| Error Condition | Swap Control Code | Error Bit |
|---|---|---|
| Command not available in current mode/security[1] | All | FSTAT[ACCERR] |
| Flash address is not in the lower half of primary program flash memory | All | FSTAT[ACCERR] |
| Flash address is not 128-bit aligned | All | FSTAT[ACCERR] |
| Any primary program flash block is in standby mode | All | FSTAT[ACCERR] |
| Swap system is in the disabled state | 1, 2, 4, 10 | FSTAT[ACCERR] |
| Flash address does not match the swap indicator address in the IFR | 2, 4 | FSTAT[ACCERR] |
| Swap initialize requested when phrase containing swap indicator (in each half of primary program flash memory) is not in the erased state | 1 | FSTAT[ACCERR] |
| Swap initialize requested when swap system is not in the uninitialized state | 1 | FSTAT[ACCERR] |
| Swap update requested when swap system is not in the ready state | 2 | FSTAT[ACCERR] |
| Swap complete requested when swap system is not in the update-erased state | 4 | FSTAT[ACCERR] |
| Swap disable requested when swap system is not in the uninitialized state | 10 | FSTAT[ACCERR] |
| An undefined swap control code is provided | - | FSTAT[ACCERR] |
| Any errors have been encountered during the swap determination and program-verify operations | 1, 2, 4, 10 | FSTAT[MGSTAT0] |
| Any brownouts were detected during the swap determination procedure | 8 | FSTAT[MGSTAT0] |

1. Returned fields will not be updated, i.e. no swap state or status reporting

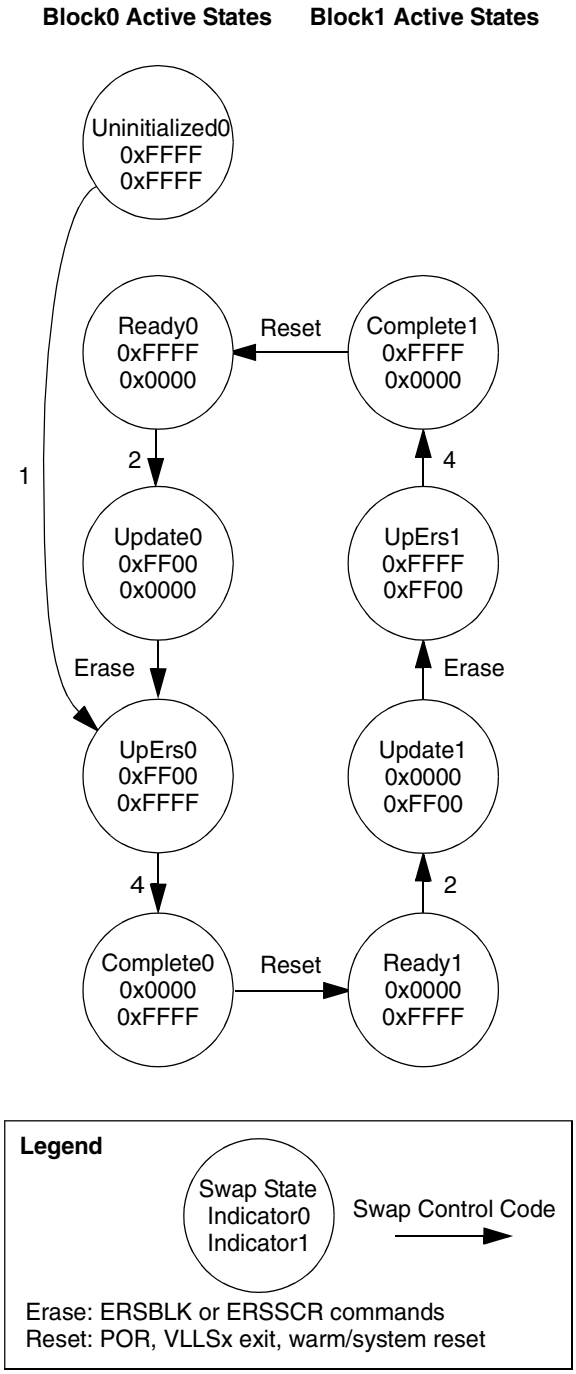

**Figure 17-9. Valid Swap State Sequencing**

## Table 17-38. Swap State Report Mapping

| Case | Swap Disable Word | Swap Enable Field[1] | Swap Indicator 0[1] | Swap Indicator 1[1] | Swap State[2] | State Code | MGSTAT 0 | Active Block |
|---|---|---|---|---|---|---|---|---|
| 1 | 0xFFFF | 0xFFFF | - | - | Uninitialized | 0 | 0 | 0 |
| 2 | 0xFFFF | 0x0000 | 0xFF00 | 0x0000 | Update | 2 | 0 | 0 |
| 3 | 0xFFFF | 0x0000 | 0xFF00- | 0xFFFF | Update-Erased | 3 | 0 | 0 |
| 4 | 0xFFFF | 0x0000 | 0x0000 | 0xFFFF[3] | Complete[4] | 4 | 0 | 0 |
| 5 | 0xFFFF | 0x0000 | 0x0000 | 0xFFFF | Ready[5] | 1 | 0 | 1 |
| 6 | 0xFFFF | 0x0000 | 0x0000 | 0xFF00 | Update | 2 | 0 | 1 |
| 7 | 0xFFFF | 0x0000 | 0xFFFF | 0xFF00 | Update-Erased | 3 | 0 | 1 |
| 8 | 0xFFFF | 0x0000 | 0xFFFF[3] | 0x0000 | Complete[4] | 4 | 0 | 1 |
| 9 | 0xFFFF | 0x0000 | 0xFFFF | 0x0000 | Ready[5] | 1 | 0 | 0 |
| 10 | 0x0000 | - | - | - | Disabled | 5 | 0 | 0 |
| 11 | 0xFFFF | 0xXXXX | - | - | Uninitialized | 0 | 1 | 0 |
| 12 | 0xFFFF | 0x0000 | 0xFFFF | 0xFFFF | Uninitialized | 0 | 1 | 0 |
| 13 | 0xFFFF | 0x0000 | 0xFFXX | 0xFFFF | Ready | 1 | 1 | 0 |
| 14 | 0xFFFF | 0x0000 | 0xFFXX | 0x0000 | Ready | 1 | 1 | 0 |
| 15[6] | 0xFFFF | 0x0000 | 0xXXXX | 0x0000 | Ready | 1 | 1 | 0 |
| 16[6] | 0xFFFF | 0x0000 | 0xFFFF | 0xFFXX | Ready | 1 | 1 | 1 |
| 17 | 0xFFFF | 0x0000 | 0x0000 | 0xFFXX | Ready | 1 | 1 | 1 |
| 18[6] | 0xFFFF | 0x0000 | 0x0000 | 0xXXXX | Ready | 1 | 1 | 1 |
| 19 | 0xFFFF | 0x0000 | 0xFF00 | 0xFFFF[7] | Update | 2 | 1 | 0 |
| 20 | 0xFFFF | 0x0000 | 0xFF00 | 0xXXXX | Update | 2 | 1 | 0 |
| 21 | 0xFFFF | 0x0000 | 0xFF(00) | 0xFFXX | Update | 2 | 1 | 0 |
| 22[6] | 0xFFFF | 0x0000 | 0x0000 | 0x0000 | Update | 2 | 1 | 0 |
| 23[6] | 0xFFFF | 0x0000 | 0xXXXX | 0xXXXX | Update | 2 | 1 | 0 |
| 24 | 0xFFFF | 0x0000 | 0xFFFF[7] | 0xFF00 | Update | 2 | 1 | 1 |
| 25 | 0xFFFF | 0x0000 | 0xXXXX | 0xFF00 | Update | 2 | 1 | 1 |
| 26 | 0xFFFF | 0x0000 | 0xFFXX | 0xFF(00) | Update | 2 | 1 | 1 |
| 27 | 0xFFFF | 0x0000 | 0xXX00 | 0xFFFF | Update-Erased | 3 | 1 | 0 |
| 28 | 0xFFFF | 0x0000 | 0xXXXX | 0xFFFF | Update-Erased | 3 | 1 | 0 |
| 29 | 0xFFFF | 0x0000 | 0xFFFF | 0xXX00 | Update-Erased | 3 | 1 | 1 |
| 30 | 0xFFFF | 0x0000 | 0xFFFF | 0xXXXX | Update-Erased | 3 | 1 | 1 |
| 31 | 0xXXXX | - | - | - | Disabled | 5 | 0 | 0 |

1. 0xXXXX, 0xFFXX, 0xXX00 indicates a non-valid value was read; 0xFF(00) indicates more 0's than other indicator (if same number of 0's, then swap system defaults to block 0 active)
2. Cases 10-29 due to brownout (abort) detected during program or erase steps related to swap
3. Must read 0xFFFF with erase verify level before transition to Complete allowed
4. No reset since successful Swap Complete execution
5. Reset after successful Swap Complete execution
6. Not a valid case
7. Fails to read 0xFFFF at erase verify level

#### 17.4.11.14.1 Swap state determination

During the reset sequence, the state of the swap system is determined by evaluating the IFR Swap Field in the program flash swap IFR and the swap indicators found within the double-phrase containing the relative swap indicator address in each half of the program flash memory.

**Table 17-39. Program Flash Swap IFR Fields**

| Address Range | Size (Bytes) | Field Description |
|---|---|---|
| 0x000 – 0x001 | 2 | Swap Indicator Address |
| 0x002 – 0x003 | 2 | Swap Enable Word |
| 0x004 – 0x009 | 6 | Reserved |
| 0x00A – 0x00B | 2 | Swap Disable Word |
| 0x00C – 0x3FF | 1012 | Reserved |

### 17.4.11.15 Erase All Blocks Unsecure Command

The Erase All Blocks Unsecure operation erases all flash memory including the erasable IFR, initializes the programming acceleration RAM, programs the security related index fields in the Flash Configuration Field to the unsecure state, and releases MCU security.

**Table 17-40. Erase All Blocks Unsecure Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x49 (ERSALLU) |

Upon clearing CCIF to launch the Erase All Blocks Unsecure command, the flash module erases all flash memory, the erasable IFR space,and the programming acceleration RAM, then verifies that all are erased. If the flash module verifies that all flash memories and the programming acceleration RAM were properly erased, access control is disabled and security is released by setting the FSEC[SEC] field to the unsecure state, the security related index fields (see Flash Configuration Field description) are programmed to the unsecure state by the Erase All Blocks Unsecure command, and the FCNFG[RAMRDY] bit is set. The swap indicator address in the primary program flash blocks are not implicitly protected from the erase operation. If the erase or program verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Erase All Blocks Unsecure operation completes.

Access control determined by the contents of the FXACC and FXACCS registers will not block execution of the Erase All Blocks Unsecure command. The contents of the FXACC, FSACC, FXACCS and FSACCS registers will not be impacted by the

execution of the Erase All Blocks Unsecure command but the associated FXACC, FSACC, FXACCS and FSACCS index fields will be erased. After completion of the Erase All Blocks Unsecure command, access control is disabled until the next reset of the flash module or the Read 1s All Blocks command is executed and fails (FSTAT[MGSTAT0] is set).

**CAUTION**

The Erase All Blocks Unsecure operation will not react to the early indicator for radio activity. Therefore, the Erase All Blocks Unsecure command must not be launched if there is a concern about inadequate power available to support both radio activity and the Erase All Blocks Unsecure operation.

**Table 17-41. Erase All Blocks Unsecure Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| Any flash block is in standby mode | FSTAT[ACCERR] |
| Any errors have been encountered during erase or program verify operations | FSTAT[MGSTAT0] |

### 17.4.11.16 Read 1s All Execute-only Segments Command

The Read 1s All Execute-only Segments command checks if the program flash execute-only segments defined by the FXACC and FXACCS registers have been erased to the specified read margin level, if applicable, and releases flash access control if the readout passes, i.e. all data reads as '1'.

**Table 17-42. Read 1s All Execute-only Segments Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x4A (RD1XA) |
| 1 | Read-1 Margin Choice |

Upon clearing CCIF to launch the Read 1s All Execute-only Segments command, the flash memory module:

- sets the read margin for 1s according to Table 17-43,
- verifies the contents of the flash execute-only segments are in the erased state.

If the flash memory module confirms that these segments are erased, flash access control is disabled until the next reset or, after programming any of the execute-only segments, the Read 1s All Execute-only Segments command is executed and fails with the

FSTAT[MGSTAT0] bit set. If the read fails, i.e. all segments are not in the fully erased state, the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Read 1s All Execute-only Segments operation completes.

**CAUTION**

The Read 1s All Execute-only Segments operation will not react to the early indicator for radio activity. Therefore, the Read 1s All Execute-only Segments command must not be launched if there is a concern about inadequate power available to support both radio activity and the Read 1s All Execute-only Segments operation.

**Table 17-43. Margin Level Choices for Read 1s All Execute-only Segments**

| Read Margin Choice | Margin Level Description |
|---|---|
| 0x00 | Use the 'normal' read level for 1s |
| 0x01 | Apply the 'User' margin to the normal read-1 level |
| 0x02 | Apply the 'Factory' margin to the normal read-1 level |

**Table 17-44. Read 1s All Execute-only Segments Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid margin choice is specified | FSTAT[ACCERR] |
| Any program flash block is in standby mode | FSTAT[ACCERR] |
| Read-1s fails | FSTAT[MGSTAT0] |

## 17.4.11.17 Erase All Execute-only Segments Command

The Erase All Execute-only Segments operation erases all program flash execute-only segments defined by the FXACC and FXACCS registers, verifies all segments are erased, and releases flash access control.

**Table 17-45. Erase All Execute-only Segments Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x4B (ERSXA) |

Upon clearing CCIF to launch the Erase All Execute-only Segments command, the flash memory module erases all program flash execute-only segments, then verifies that all segments are erased. If the flash memory module verifies that all segments were properly erased, flash access control is disabled until the next reset or, after programming any of

the execute-only segments, the Read 1s All Execute-only Segments command is executed and fails with the FSTAT[MGSTAT0] bit set. The Erase All Execute-only Segments command aborts if any XA or XA_S controlled segment is protected. If the swap system is enabled, the swap indicator address in each primary program flash block is implicitly protected from erase unless the swap system is in the UPDATE or UPDATE-ERASED state and the flash segment containing the swap indicator address being erased is in the non-active block. If the erase-verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Erase All Execute-only Segments operation completes.

Access control determined by the contents of the FXACC and FXACCS registers will not block execution of the Erase All Execute-only Segments command. The contents of the FXACC and FXACCS registers will not be impacted by the execution of the Erase All Execute-only Segments command.

**CAUTION**

The Erase All Execute-only Segments operation will not react to the early indicator for radio activity. Therefore, the Erase All Execute-only Segments command must not be launched if there is a concern about inadequate power available to support both radio activity and the Erase All Execute-only Segments operation.

**Table 17-46. Erase All Execute-only Segments Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| Any program flash block is in standby mode | FSTAT[ACCERR] |
| Any XA or XA_S controlled segment is protected | FSTAT[FPVIOL] |
| Any errors have been encountered during the verify operation | FSTAT[MGSTAT0] |

## 17.4.11.18 Set RAM Function command

The Set RAM Function command sets the function of the programming acceleration RAM.

**Table 17-47. Set RAM Function Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|---|---|
| 0 | 0x81 (SETRAM) |
| 1 | RAM Function Control Code<br>(see Table 17-48) |

**Table 17-48. Set RAM Function Control**

| RAM Function Control Code | Action |
|---|---|
| 0xCC | Make RAM available for CRC generation:<br>• Clear the FCNFG[RAMRDY] and FCNFG[CRCRDY] flags<br>• Set the FCNFG[CRCRDY] flag<br>• RAM available for Generate CRC command after FSTAT[CCIF] sets |
| 0xFF | Make RAM available for normal use:<br>• Clear the FCNFG[RAMRDY] and FCNFG[CRCRDY] flags<br>• Write a background of ones to all RAM locations<br>• Set the FCNFG[RAMRDY] flag |

Upon clearing CCIF to launch the Set RAM Function command, the CRCRDY and RAMRDY flags are cleared and the programming acceleration RAM is set to function based on the control code entered:

- 0xCC - When making the programming acceleration RAM available for CRC generation, the flash module blocks access to the programming acceleration RAM and sets the FCNFG[CRCRDY] flag. Once the operation has completed, the Generate CRC command can be launched to produce a CRC signature on a flash block while leaving that same flash block accessible for read access. While the CRCRDY flag is set, access to the programming acceleration RAM is blocked until the Set RAM Function command is run with a control code of 0xFF.
- 0xFF - When making the programming acceleration RAM available for normal use, the flash module overwrites the contents of the entire programming acceleration RAM with a background pattern of all ones, and sets the FCNFG[RAMRDY] flag. Normal read and write accesses to the programming acceleration RAM are now available. When large sections of flash memory need to be programmed, e.g. during factory programming, the programming acceleration RAM can be used as the Section Program Buffer for the Program Section command (see Program Section command).

The CCIF flag sets after the Set RAM Function operation completes.

**Table 17-49. Set RAM Function Command Error Handling**

| Error Condition | Error Bit |
|---|---|
| Command not available in current mode/security | FSTAT[ACCERR] |
| Primary Program flash block 0 is in standby mode | FSTAT[ACCERR] |
| Function Control Code is not defined | FSTAT[ACCERR] |

## 17.4.12 Security

The flash module provides security information to the MCU based on contents of the FSEC security register. The MCU then limits access to flash resources as defined in the device's Chip Configuration details. During the reset sequence, the flash module initializes the FSEC register using data read from the security related index fields located in the Flash Configuration Field (see Flash Configuration Field description).

The following fields are available in the FSEC register. Details of the settings are described in the FSEC register description.

**Table 17-50. FSEC fields**

| FSEC field | Description |
|---|---|
| KEYEN | Backdoor Key Access |
| MEEN | Mass Erase Capability |
| FSLACC | Factory Security Level Access |
| SEC | MCU security |

**NOTE**

Flash security features are discussed further in AN4507: Using the Kinetis Security and Flash Protection Features. Some features described in the application note may not be available on this device.

### 17.4.12.1 Changing the Security State

The security state out of reset can be permanently changed by programming the security related index fields located in the flash configuration field. This assumes that you are starting from a mode where the necessary flash erase and program commands are available. If the flash security related index fields are successfully programmed, the new FSEC value takes effect after the next MCU reset.

#### 17.4.12.1.1 Unsecuring the MCU Using Backdoor Key Access

The MCU can be unsecured by using the backdoor key access feature which requires knowledge of the contents of the 8-byte backdoor key value stored in the Flash Configuration Field (see Flash Configuration Field description). If the FSEC[KEYEN] bits are in the enabled state, the Verify Backdoor Access Key command (see Verify Backdoor Access Key command) can be run which allows the user to present prospective keys for comparison to the stored keys. If the keys match, the FSEC[SEC] bits are changed to unsecure the MCU. The entire 8-byte key cannot be all 0s or all 1s, i.e.

0x0000_0000_0000_0000 and 0xFFFF_FFFF_FFFF_FFFF are not accepted by the Verify Backdoor Access Key command as valid comparison values. While the Verify Backdoor Access Key command is active, program flash memory is not available for read access and returns invalid data.

The user code stored in the program flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN bits are in the enabled state, the MCU can be unsecured by the backdoor key access sequence described below:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in Verify Backdoor Access Key command
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the FSEC[SEC] bits are forced to the unsecure state

An illegal key provided to the Verify Backdoor Access Key command prohibits future use of the Verify Backdoor Access Key command. A reset of the MCU is the only method to re-enable the Verify Backdoor Access Key command when a comparison fails.

After the backdoor keys have been correctly matched, the MCU is unsecured by changing the FSEC[SEC] bits. A successful execution of the Verify Backdoor Access Key command changes the security in the FSEC register only. It does not alter the security byte or the keys stored in the Flash Configuration Field (Flash Configuration Field description). After the next reset of the MCU, the security state of the flash module reverts back based on the contents of the security related index fields located in the Flash Configuration Field. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the program flash protection registers.

If the backdoor keys successfully match, the unsecured MCU has full control of the contents of the Flash Configuration Field. The MCU may mass erase the flash memory to erase the IFR containing the Flash Configuration Field and reprogram the flash security fields including the backdoor keys.

## 17.4.13 Reset Sequence

On each system reset the flash module executes a sequence which establishes initial values for the flash block configuration parameters, FPROT, FOPT, FSEC, FXACC, FSACC, FXACCS, FSACCS, and FACNFG registers and the FCNFG[SWAP, CRCRDY, RAMRDY ] bits.

CCIF is cleared throughout the reset sequence. The flash module holds off all CPU access during the reset sequence. Flash reads are possible when the hold is removed. Completion of the reset sequence is marked by setting CCIF which enables flash user commands.

If a reset occurs while any flash command is in progress, that command is immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed. Commands and operations do not automatically resume after exiting reset.

# Chapter 18
# Flash Memory Controller (FMC)

## 18.1 Chip-specific FMC information

### 18.1.1 FMC buffers control

The FMC's buffer are controlled by:

- CM4F: MSCM_OCMDR0
- CM0+: MSCM_OCMDR1

### 18.1.2 Flash Access Control (FAC) Function

The Flash Access Control (FAC) is a configurable memory protection scheme optimized to allow end users to use software libraries while offering programmable restrictions to these libraries. The flash memory is divided into *equal size segments* that provide protection to proprietary software libraries. The protection of these segments is controlled: the FAC provides a cycle-by-cycle evaluation of the access rights for each transaction routed to the on-chip flash memory. Two levels of vendors can add their proprietary software to a device; FAC protection of segments for each level are defined once, using the PGMINDEX command.

Flash access control aligns to the 3 privilege levels supported by ARM Cortex-M family products:

- Most secure state is supervisor/privileged secure: allows execute-only and provides supervisor-only access control.
- Mid-level state is execute-only.
- Unsecure state is where no access control states are set.

Features:

- Lightweight access control logic for on-chip flash memory

- Flash address space divided into (64+16) equal-sized segments (segment size is defined as 16 KB)
- Separate control bits for supervisor-only access and execute-only access per segment
- Access control evaluated on each bus cycle routed to the flash
- Access violation errors terminate the bus cycle and return zeroes for read data
- Programming model allows 2 levels of protected segments

### 18.1.2.1 FAC functional description

The Flash Management Unit (FMU) includes non-volatile configuration information that is retrieved during reset and sent to the platform to control access to the flash array during normal operation.

There are 64-bit XACCP and 64-bit SACCP for primary program flash, 16-bit XACCS and 16-bit SACCS for secondary program flash to support access control features. These NVM locations are summarized in the table below.

**Table 18-1. NVM Locations**

| NVM location | Description | |
|---|---|---|
| NVSACCP | 64-bit location is loaded during reset into the *x*_SACC register to provide access configuration for CM4F. | Segment-wise control for supervisor-only access vs. supervisor and user access |
| NVXACCP | 64-bit location is loaded during reset into the *x*_XACC register to provide access configuration for CM4F. | Segment-wise control for execute-only vs. data and execute |
| NVSACCS | 16-bit location is loaded during reset into the *x*_SACC register to provide access configuration for CM0+. | Segment-wise control for supervisor-only access vs. supervisor and user access |
| NVXACCS | 16-bit location is loaded during reset into the *x*_XACC register to provide access configuration for CM0+. | Segment-wise control for execute-only vs. data and execute |

Each of these NVM locations is programmable through a Program Index command.

The flash is released from reset early while the core continues to be held in reset. The FMU captures the NVM access control information in internal registers. The FMU ANDs the multiple execute-only fields to create a single execute-only field. This execute-only field driven to the platform is static prior to the core being released from reset. The supervisor-only field is handled in the same manner.

The FMU includes the FAC registers that provide control access to the flash address space. During the address phase of every attempted flash transfer, the supervisor access (SA*n*) and execute access (XA*n*) bits are examined to either allow or deny access. If access is denied, then the access is aborted and terminates with a bus error; the read data is also zeroed.

The next table shows segment assignments relative to the flash location.

**Table 18-2. Flash Protection Ranges**

| SA*n* and XA*n* Bit | Protected Segment Address Range | Segment Size (Fraction of total Flash) |
|---|---|---|
| **64 Segment Encodings** | | |
| 0 | 0x0_0000_0000 – (Flash_size/64)-1 | 1/64 |
| 1 | (Flash_size/64) – 2*(Flash_size/64)-1 | 1/64 |
| ..... | | |
| 63 | 62*(Flash_size/64)-1 – 63*(Flash_size/64) | 1/64 |
| **16 Segment Encodings** | | |
| 0 | 0x0_0000_0000 – (Flash_size/16)-1 | 1/16 |
| 1 | (Flash_size/16) – 2*(Flash_size/16)-1 | 1/16 |
| ..... | | |
| 15 | 14*(Flash_size/16)-1 – 15*(Flash_size/16) | 1/16 |

Individual segments within the flash memory can be independently protected from user access and data access. Protection is controlled by the individual bits within the *x*_SACC and *x*_XACC registers, as shown in the next figure.

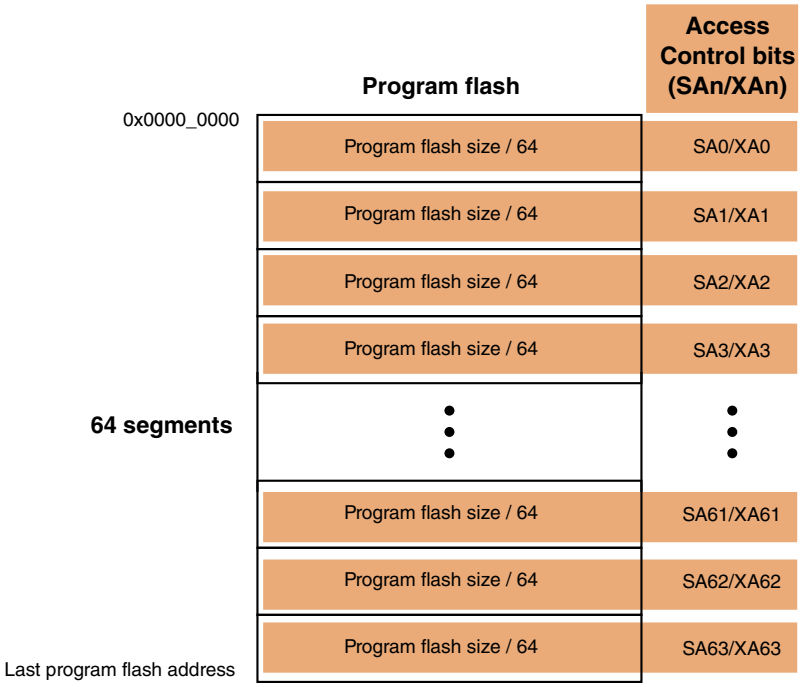

**Figure 18-1. Program flash protection (64 segments)**

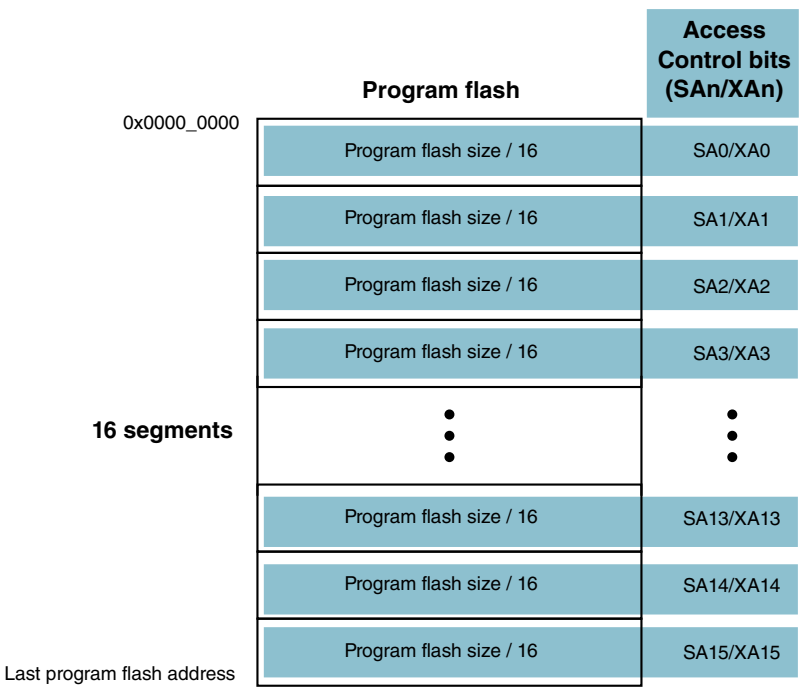

**Figure 18-2. Program flash protection (16 segments)**

#### 18.1.2.1.1 Interface Signals

**Table 18-3. Interface Signals**

| Signal | Width | From | To | Description |
|---|---|---|---|---|
| xacc0 | 64 | FMU | Platform | Direct xacc (execute-only access control) register for CM4F core |
| sacc0 | 64 | FMU | Platform | Direct sacc (supervisor access control) register for CM4F core |
| xacc1 | 16 | FMU | Platform | Direct xacc (execute-only access control) register for CM0+ core |
| sacc1 | 16 | FMU | Platform | Direct sacc (supervisor access control) register for CM0+ core |
| numsg0 | 8 | FMU | Platform | NUMSG bit field - Binary encoded number of segments<br>0x40 for 64 segments<br>0x10 for 16 segments |

#### 18.1.2.1.2 Flash Command Impact

| | |
|---|---|
| **Program Longword/Phrase/ Section** | If the targeted flash location is in an execute-only protected segment, then these program commands are not allowed unless a Read 1s All Blocks command is executed and returns with a pass code (which means the part has been fully erased). After the Read 1s All Blocks command is executed with a pass code returned, then the protected segment is open to program commands. To close off programmability to execute-only spaces once again, the device must be reset or a Read 1s All Blocks command is executed with a fail result. Attempts to program in a protected segment *when not open to program commands* causes a Protection Violation flag. |
| **PGMCHK** | The FMU will not execute the PGMCHK command on a segment that has been configured as execute-only. The Flash Protection Violation flag is set if an attempt is made to execute PGMCHK command on an execute-only address. |
| **Erase Flash Sector** | If the targeted flash sector is in an execute-only protected segment, then the Erase Flash Sector command is not allowed, and sets the Protection Violation flag. The only means of erasing protected space is by an Erase All operation. |
| **ERSALL** | The Erase All Blocks command is not affected by Access Control. An Erase All Blocks command will erase any libraries that have been programmed in any execute-only segment. |
| **SWAP** | A new control has been added to the SWAP command to disable the SWAP feature.<br>The IFR SWAP Field and the SWAP indicator are erased during the Erase All Blocks command operation, resulting in the SWAP system being uninitialized. The SWAP command must be run with the initialization code to set the SWAP indicator address and initialize the SWAP system.<br>After being disabled, SWAP cannot be enabled without doing an Erase All. An Erase All erases preloaded code and libraries in the flash array and resets the SWAP system back to uninitialized. If SWAP is intended to be disabled as part of the access control protection, then the disabled setting must be restored after an Erase All Blocks operation. |
| **ERSXA** | The target regions of the command is controlled by FAC. For ERSXA, if a flash sector is in an execute-only protected segment and it is not protected by flash protection (FPROT), it will be erased. |
| **RD1XA** | The target regions of the command is controlled by FAC. For RD1XA, if a flash sector is in an execute-only protected segment, it will be erase verified. |

#### 18.1.2.1.3 Core Platform Impact

| | |
|---|---|
| **Platform core caches (Flash and LMEM caches)** | If any segment is marked as *execute-only*, then the caches are hidden from the user. The tag is read-only and cannot be written, and the data caches cannot be read or written. Writes to the tag and data arrays are ignored, and reads of the data array return 0's. This will impact debug breakpoints. See the debug section for details. |
| **Debug** | The debugger is a non-processor bus master and cannot step, trace or break in execute-only regions. In supervisor-only mode, the debugger is restricted from changing modes. Debug accesses to any segment of flash space marked as execute-only also terminate with a bus error. |
| **PC-relative addressing** | Restrictions are placed on software for PC relative addressing, because hardware cannot determine if PC relative data references are crossing segment boundaries.<br>• If ifetch is executing in a protected segment, then data references will be allowed.<br>• Hardware cannot track speculative ifetches across boundaries. |
| **Interrupts** | If function calls are used to move into an execute-only segment, then this can be tracked by hardware when typical software controls are used (i.e., saving registers and states before executing new code). |
| **Reset Vector** | In the ARM core, the reset vector fetch is supervisor data, which poses issues if the reset vector is located in a segment marked execute-only. Additional logic has been implemented to allow supervisor data fetches to execute-only spaces, after reset until the first valid instruction fetch. After the first valid instruction fetch, the FAC logic follows normal checks. |

#### 18.1.2.1.4 Software Impact

The hardware cannot see all states of the ARM core and cannot track the software flow, and may require software restrictions to work with the hardware for a robust solution.

- **Any segment marked as execute-only can see all code in the system.** This means that one execute-only segment can read the execute-only code in another segment. Therefore, if we at the factory are sending pre-loaded code to another vendor, then that vendor will have access to our factory code. NDAs and legal agreements might help deal with this issue.
- **For single pre-loads** (for example, if we at the factory are pre-loading for a general purpose (GP) market or if a vendor with a blank part is pre-loading their proprietary code), then both levels of access control must be programmed, to protect the pre-loaded code.
- **If any portion of a protected segment is not used by pre-loaded code**, then it (the portion of a protected segment that is not used by pre-loaded code) should be programmed with NOPs, to prevent additional code from being programmed in that segment by hackers.

#### 18.1.2.1.5 Access Check Evaluation

The flash controller FAC provides a cycle-by-cycle evaluation of the access rights for each data transaction routed to the on-chip flash memory.

The entire flash storage capacity is partitioned into equal sized segments. Two registers include a supervisor-only access control indicator and a execute-only access control indicator for each segment.

The FAC logic performs the required access control evaluation using the reference address and a 2-bit attribute (or "protection" field) as inputs from the bus cycle plus the contents of the programming model registers.

The following code example illustrates C code for FAC evaluation:

```
unsigned long long sacc;  // supervisor-only map
unsigned long long xacc;  // execute-only map
unsigned int seg_size;    // 8-bit segment size
unsigned int fac_error;

fac_evaluation (addr, prot)
  unsigned int addr;  // access address
  unsigned int hprot; // encoded 2-bit "protection" field {supv, data}
{
  unsigned int sacc_flag; // sacc flag for this segment
  unsigned int xacc_flag; // xacc flag for this segment
  unsigned int i;         // segment index

  i         = (addr >> (8 + seg_size & 0x0f)) & 0x3f; // form 6-bit segment index
  sacc_flag = (sacc >> i) & 1;              // extract sacc bit for this segment
  xacc_flag = (xacc >> i) & 1;              // extract xacc bit for this segment

  // create a 4-tuple concatenating the 2-bit protection field + {sacc, xacc} flags

  switch ((hprot & 3) << 2 | (sacc_flag << 1) | xacc_flag) {
  // all these combinations are allowed accesses
    case 0x2: // {user, ifetch} && {supv+user, ifetch-only}
    case 0x3: // {user, ifetch} && {supv+user, ifetch+data}
    case 0x7: // {user, data}   && {supv+user, ifetch+data}
    case 0x8: // {supv, ifetch} && {supv-only, ifetch-only}
    case 0x9: // {supv, ifetch} && {supv-only, ifetch+data}
    case 0xa: // {supv, ifetch} && {supv+user, ifetch-only}
    case 0xb: // {supv, ifetch} && {supv+user, ifetch+data}
    case 0xd: // {supv, data}   && {supv-only, ifetch+data}
    case 0xf: // {supv, data}   && {supv+user, ifetch+data}
      fac_error = 00;
      break;

  // all these combinations are unallowed, that is, errored accesses
    case 0x0: // {user, ifetch} && {supv-only, ifetch-only}
    case 0x1: // {user, ifetch} && {supv-only, ifetch+data}
    case 0x4: // {user, data}   && {supv-only, ifetch-only}
    case 0x5: // {user, data}   && {supv-only, ifetch+data}
    case 0x6: // {user, data}   && {supv+user, ifetch-only}
    case 0xc: // {supv, data}   && {supv-only, ifetch-only}
    case 0xe: // {supv, data}   && {supv+user, ifetch-only}
      fac_error = 1;
      break;

   } // switch()

} // fac_evaluation()
```

## 18.2 Introduction

The Flash Memory Controller (FMC) is a memory interface and acceleration unit, which provides:

- an interface between the device and the nonvolatile memory.
- buffers that can accelerate flash memory transfers.

### 18.2.1 Overview

The Flash Memory Controller manages the interface between the device and the flash memory. The FMC receives status information describing the configuration of the memory and uses this information to ensure a proper interface. The next table shows the supported read/write operations.

| Flash memory type | Read | Write |
|---|---|---|
| Program flash memory | 8-bit, 16-bit, and 32-bit reads | —[1] |

1. A write operation to program flash memory results in a bus error.

- The FMC's input bus can actually operate faster than the flash memory.
- The FMC-to-flash interface has flow control, and can add wait states as needed, for input bus reads that need flash accesses.
- The FMC also contains various configurable buffers that hold recent flash accesses. If an input bus read hits a valid buffer, that access will finish with no wait states.

### 18.2.2 Features

- Interface between the device and the flash memory:
  - The FMC's input bus supports 8-bit, 16-bit, and 32-bit read operations to flash memory.
  - The FMC's flash memory interface fetches a {32, 64, 128, 256}-bit flash page.
  - For input read requests, the FMC fetches a flash page with the desired read data from flash memory.
- Acceleration of data transfer from flash memory to the device:
  - A flash-page-sized buffer that holds the current flash page fetched due to a FMC read request. Subsequent FMC read requests *that hit in the current buffer* return data with no wait states.

- A flash-page-sized prefetch speculation buffer with controls for prefetching on instructions and/or data reads. When prefetching is enabled, idle FMC-to-flash interface cycles are used to fetch the next sequential flash page and hold it in the prefetch buffer. Subsequent FMC read requests *that hit in the speculation buffer* will return data with no wait states.
- Input controls:
  - to disable data type speculation
  - to disable all speculation
  - to invalidate the current and speculation buffers

## 18.3 Modes of operation

The FMC only operates when a bus master accesses the flash memory.

For any device power mode where the flash memory cannot be accessed, the FMC is disabled.

## 18.4 External signal description

The FMC has no external signals.

## 18.5 Functional description

The FMC is a flash interface and acceleration unit, with flexible buffers for user configuration.

- The FMC's input bus can operate faster than the flash memory.
- The FMC-to-flash interface has flow control to add wait states as needed (for input bus reads that need flash accesses).
- The FMC also contains various configurable buffers that hold recent flash accesses. If an input bus read hits a valid buffer, then that access will complete with no wait states.

### 18.5.1 Default configuration

After system reset, the FMC is configured to provide a significant level of buffering for transfers from the flash memory:

- For all banks:

- The current and speculation buffers are cleared by reset.
- Prefetch support for data and instructions is enabled.

## 18.5.2 Configuration options

The default configuration provides a high degree of flash acceleration, however, advanced users may want to customize the FMC buffer configurations, to maximize throughput for their use cases. When reconfiguring the FMC for custom use cases, do not program the FMC's control registers while the flash memory is being accessed. Instead, change the control registers with a routine executing from RAM in supervisor mode.

The FMC's buffering controls allow the tuning of resources to suit specific application requirements. The buffer are each controlled individually. The controls enable buffering and prefetching per access type (instruction fetch or data reference).

As an application example: if both instruction fetches and data references are accessing flash memory, then control is available to send instruction fetches, data references, or both to the single-entry buffer. Likewise, speculation can be enabled or disabled for either type of access.

## 18.5.3 Wait states

Because the core, crossbar switch, and bus masters can be clocked at a higher frequency than the flash clock, flash memory accesses that do not hit in the speculation buffer usually require wait states.

All wait states and synchronization delays are handled automatically by the Flash Memory Controller. No direct user configuration is required (or even allowed) to set up the flash wait states.

## 18.5.4 Speculative reads

The FMC has a single buffer that reads ahead to the next page in the flash memory if there is an idle cycle. Speculative prefetching is programmable for instruction and/or data accesses. Because many code accesses are sequential, using the speculative prefetch buffer improves performance in most cases.

When speculative reads are enabled, the FMC immediately requests the next sequential page address after a read completes. By requesting the next page immediately, speculative reads can help to reduce or even eliminate wait states when accessing sequential code and/or data.

## 18.6 Initialization and application information

The FMC does not require user initialization. Flash acceleration features are enabled by default.

The FMC has no visibility into flash memory erase and program cycles because the Flash Memory module manages them directly. As a result, if an application is executing flash memory commands, the FMC's current buffer and speculation buffer might need to be disabled and/or flushed to prevent the possibility of returning stale data.

# Chapter 19
# Flash security

## 19.1 Introduction

This device implements security based on the mode selected from the flash module. The following sections provide an overview of flash security and details the effects of security on non-flash modules.

## 19.2 Flash Security

The flash module provides security information to the MCU based on the state held by the FTFE_FSEC[SEC] bits. The MCU, in turn, confirms the security request and limits access to flash resources. During reset, the flash module initializes the FSEC register using data read from the security related index fields located in IFR space.

**NOTE**

The security features apply only to external accesses via debug. CPU accesses to the flash are not affected by the status of FSEC.

In the unsecured state all flash commands are available to the programming interfaces (JTAG), as well as user code execution of Flash Controller commands. When the flash is secured (FSEC[SEC] = 00, 01, or 11), programmer interfaces are only allowed to launch mass erase operations and have no access to memory locations.

Further information regarding the flash security options and enabling/disabling flash security is available in the Flash Memory Module.

## 19.3 Security Interactions with other Modules

The flash security settings are used by the SoC to determine what resources are available. The following sections describe the interactions between modules and the flash security settings or the impact that the flash security has on non-flash modules.

### 19.3.1 Security Interactions with Debug

When flash security is active the JTAG port cannot access the memory resources of the MCU. Boundary scan chain operations work, but debugging capabilities are disabled so that the debug port cannot read flash contents.

Although most debug functions are disabled, the debugger can write to the System Reset Request bit and Flash Mass Erase in Progress bit in the MDM-AP Control register to trigger a mass erase (Erase All Blocks Unsecure) command. A mass erase via the debugger is allowed even when some memory locations are protected.

When mass erase is disabled, mass erase via the debugger is blocked.

# Chapter 20
# External Bus Interface (FlexBus)

## 20.1 Chip-specific FlexBus information

### 20.1.1 FlexBus clocking

The system provides a dedicated clock source (SCG CLKOUT) to the FlexBus module's external CLKOUT. The SCG CLKOUT is output from SCG_CLKOUTCNFG mux. In order to be used as FB_CLKOUT, SCG_CLKOUTCFNG[CLKOUTSEL] must be set to 0. And under this configuation, the clock is derived from divider SCG RCCR[DIVEXT] of PLAT_CLK. See Clock Architecture and System Clock Generator (SCG) for more details.

### 20.1.2 FlexBus signal multiplexing

The multiplexing of the FlexBus address and data signals is controlled by the port control module. However, the multiplexing of some of the FlexBus control signals are controlled by the port control and FlexBus modules. The port control module registers control whether the FlexBus or another module signals are available on the external pin, while the FlexBus's CSPMCR register configures which FlexBus signals are available from the modules. The control signals are grouped as illustrated:

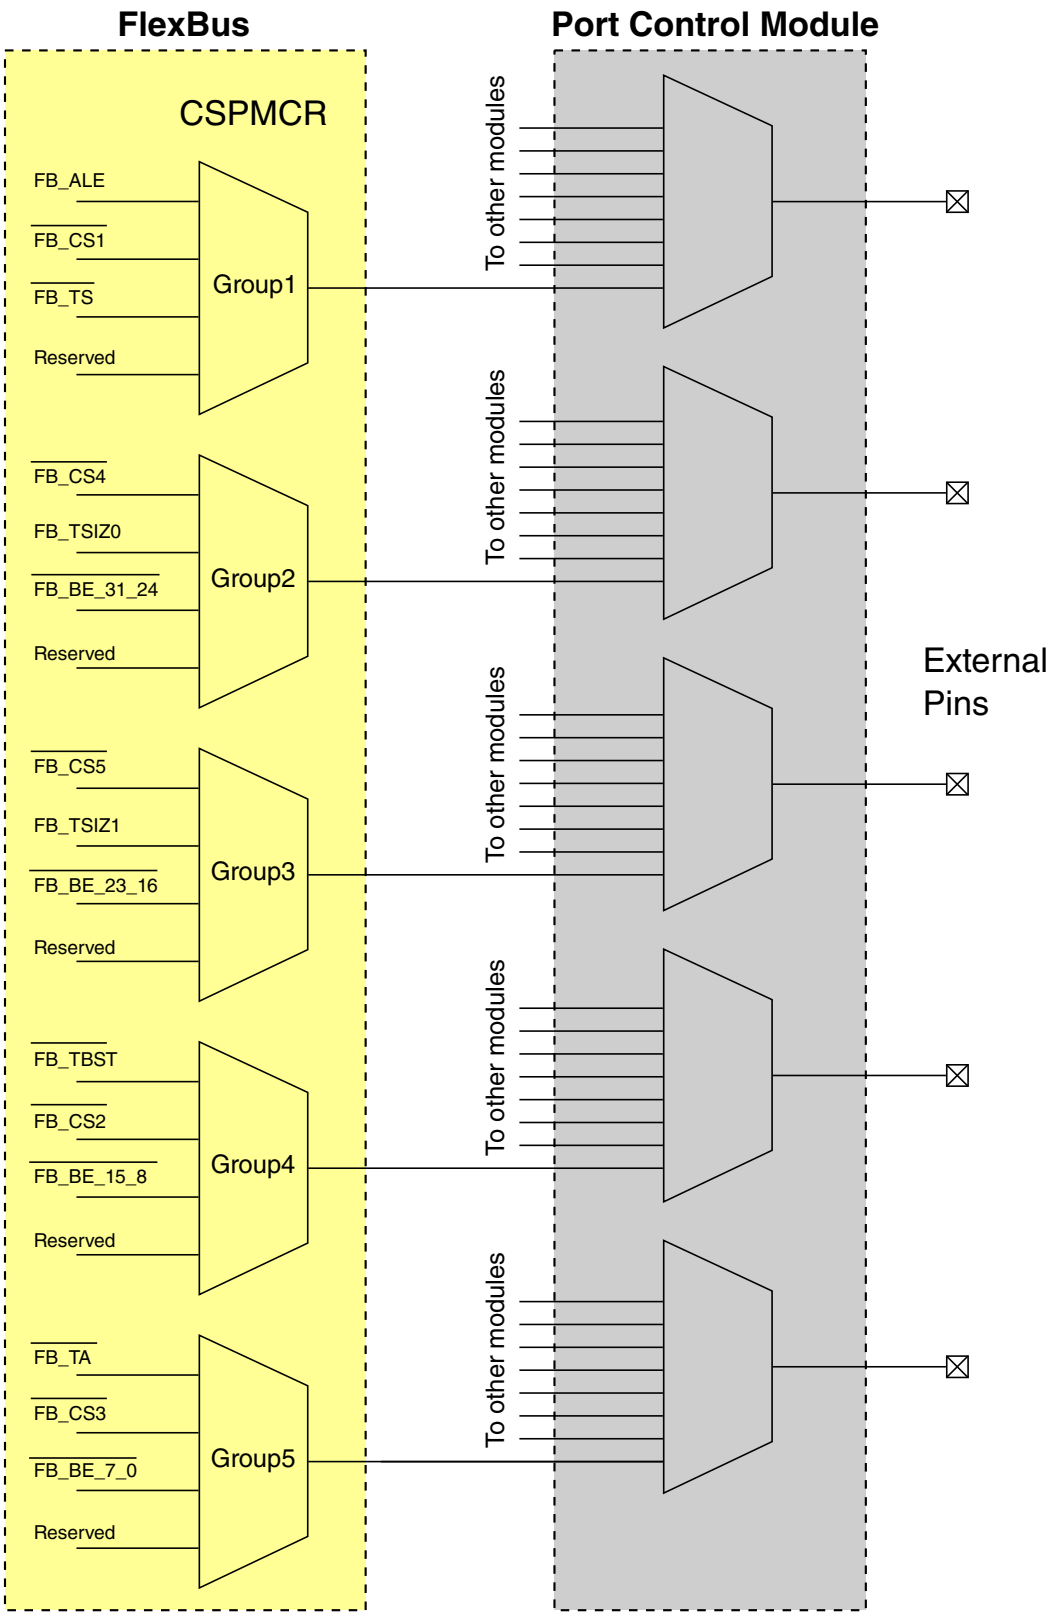

**Figure 20-1. FlexBus control signal multiplexing**

Therefore, use the CSPMCR and port control registers to configure which control signal is available on the external pin. All control signals, except for $\overline{\text{FB_TA}}$, are assigned to the ALT5 function in the port control module. The $\overline{\text{FB_TA}}$ is an input signal, and is assigned to the ALT6 function.

### 20.1.3 FlexBus CSCR0 reset value

On this device the CSCR0 resets to 0x003F_FC00. Configure this register as needed before performing any FlexBus access.

### 20.1.4 FlexBus Security

When security is enabled on the device, FlexBus accesses may be restricted by configuring SIM_CHIPCTRL[FBSL]. See System Integration Module (SIM) for details.

### 20.1.5 FlexBus line transfers

Line transfers are not possible from the ARM Cortex-M4 core. Ignore any references to line transfers in the FlexBus chapter.

## 20.2 Introduction

The FlexBus multifunction external bus interface controller:

- Provides memory expansion and provides connection to external peripherals with a parallel bus
- Provides connections to external peripherals with a parallel bus, and is often used to expand memory
- Can be directly connected to asynchronous or synchronous slave-only devices, using little or no additional circuitry:
  - External ROMs
  - Flash memories
  - Programmable logic devices
  - Other simple target (slave) devices

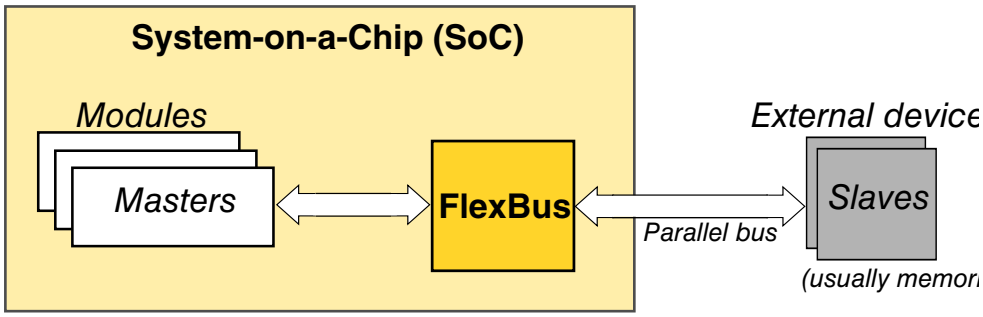

**Figure 20-2. Flexbus module in a System-on-a-Chip (SoC)**

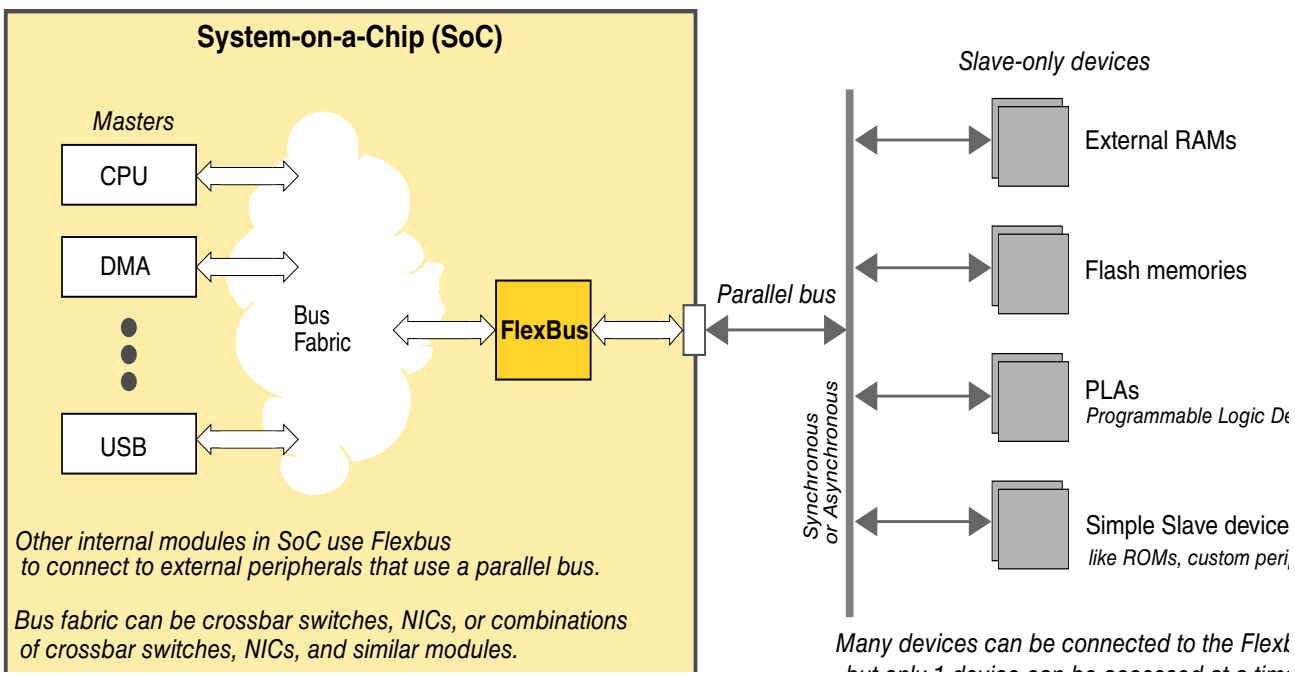

**Figure 20-3. Flexbus module in SoC details**

FlexBus features:

- 6 independent, user-programmable chip-select signals (active low) (FB_CS 5 – FB_CS0)
- 8-bit, 16-bit, and 32-bit transfers
- Programmable burst and burst-inhibited transfers selectable for each chip-select and transfer direction
- Programmable address-setup time with reference to the assertion of a chip-select
- Programmable address-hold time with reference to the deassertion of a chip-select and transfer direction
- Extended transfer start/address latch enable option to assist with glueless connections to synchronous and asynchronous memory devices

## 20.3 Signal descriptions

This table describes the external signals involved in data-transfer operations.

**NOTE**

Not all of the following signals may be available on a particular device. See the Chip Configuration details for information on which signals are available.

**NOTE**

Throughout this document, active low signals are indicated by one of 3 methods:

- "_b" appended to the end of a signal name
- a black line (called an "overbar") over the signal name
- a phrase "active low" next to the signal name

**Table 20-1. FlexBus signal descriptions**

| Signal | I/O | Function |
|---|---|---|
| FB_A31 - FB_A0 (nonmultiplexed address bus) | O | Address Bus<br>When FlexBus is used in a nonmultiplexed configuration, this is the address bus.<br>When FlexBus is used in a multiplexed configuration, this bus is not used. |
| FB_D31 – FB_D0 (nonmultiplexed data bus)<br>FB_AD31 - FB_AD0 (multiplexed address/ data bus) | I/O | When FlexBus is used in a nonmultiplexed configuration, this is the data bus, FB_D.<br>When FlexBus is used in a multiplexed configuration, this is the address and data bus, FB_AD.<br>The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select.<br>The full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0. |
| FB_CS5 – FB_CS0 | O | General Purpose Chip-Selects (active low)—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM]. |
| FB_BE_31_24<br>FB_BE_23_16<br>FB_BE_15_8<br>FB_BE_7_0 | O | Byte Enables (active low)—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only.<br>For external SRAM or flash devices, the active low FB_BE outputs should be connected to individual byte strobe signals. |
| FB_OE_b | O | Output Enable (active low)—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode. |

*Table continues on the next page...*

## Table 20-1. FlexBus signal descriptions (continued)

| Signal | I/O | Function |
|---|---|---|
| FB_R/W_b | O | Read/Write—Indicates whether the current bus operation is a read operation (FB_R/W_b high) or a write operation (FB_R/W_b low). |
| FB_TS_b | O | Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid.<br>An inverted FB_TS_b is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus.<br>FB_TS_b /FB_ALE is asserted for one bus clock cycle.<br>The chip can extend this signal until the first positive clock edge after active low FB_CS asserts. See CSCR[EXTS] and Extended Transfer Start/Address Latch Enable. |
| FB_ALE | O | Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of FB_TS_b). |
| FB_TSIZ1–FB_TSIZ0 | O | Transfer Size—Indicates (along with FB_TBST_b) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports.<br>• 00b = 4 bytes<br>• 01b = 1 byte<br>• 10b = 2 bytes<br>• 11b = 16 bytes (line)<br>For misaligned transfers, FB_TSIZ1–FB_TSIZ0 indicate the size of each transfer. For example, if a 32-bit access through a 32-bit port device occurs at a misaligned offset of 1h, 8 bits are transferred first (FB_TSIZ1–FB_TSIZ0 = 01b), 16 bits are transferred next at offset 2h (FB_TSIZ1–FB_TSIZ0 = 10b), and the final 8 bits are transferred at offset 4h (FB_TSIZ1–FB_TSIZ0 = 01b).<br>For aligned transfers larger than the port size, FB_TSIZ1–FB_TSIZ0 behave as follows:<br>• If bursting is used, FB_TSIZ1–FB_TSIZ0 are driven to the transfer size.<br>• If bursting is inhibited, FB_TSIZ1–FB_TSIZ0 first show the entire transfer size and then show the port size.<br>For burst-inhibited transfers, FB_TSIZ1–FB_TSIZ0 change with each FB_TS_b assertion to reflect the next transfer size.<br>For transfers to port sizes smaller than the transfer size, FB_TSIZ1–FB_TSIZ0 indicate the size of the entire transfer on the first access and the size of the current port transfer on subsequent transfers. For example, for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are 00b for the first transaction and 01b for the next three transactions. If bursting is used for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are driven to 00b for the entire transfer. |
| FB_TBST_b | O | Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size.<br>**Note:** When a burst transfer is in progress (FB_TBST_b = 0b), the transfer size is 16 bytes (FB_TSIZ1–FB_TSIZ0 = 11b), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address. |

*Table continues on the next page...*

**Table 20-1. FlexBus signal descriptions (continued)**

| Signal | I/O | Function |
|---|---|---|
| FB_TA_b | I | Transfer Acknowledge—Indicates that the external data transfer is complete. When FB_TA_b is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When FB_TA_b is asserted during a write transfer, the transfer is terminated.<br><br>If auto-acknowledge is disabled (CSCR[AA] = 0), the external memory or peripheral drives FB_TA_b to terminate the transfer. If auto-acknowledge is enabled (CSCR[AA] = 1), FB_TA_b is generated internally after a specified number of wait states, or the external memory or peripheral may assert external FB_TA_b before the wait-state countdown to terminate the transfer early. The chip deasserts active low FB_CS one cycle after the last FB_TA_b is asserted. During read transfers, the external memory or peripheral must continue to drive data until FB_TA_b is recognized. For write transfers, the chip continues driving data one clock cycle after active low FB_CS is deasserted.<br><br>The number of wait states is determined by CSCR or the external FB_TA_b input. If the external FB_TA_b is used, the external memory or peripheral has complete control of the number of wait states.<br><br>**Note:** External memory or peripherals should assert FB_TA_b only while the active low FB_CS signal to the external memory or peripheral is asserted.<br><br>The CSPMCR register controls muxing of FB_TA_b with other signals. When the CSPMCR register does not allow FB_TA_b control, auto-acknowledge must be used (CSCR[AA] =1'b1); otherwise the bus may hang. |
| FB_CLK | O | FlexBus Clock Output |

## 20.4 Memory Map/Register Definition

The following tables describe the registers and bit meanings for configuring chip-select operation.

The actual number of chip selects available depends upon the device and its pin configuration. If the device does not support certain chip select signals or the pin is not configured for a chip-select function, then that corresponding set of chip-select registers has no effect on an external pin.

### Note

You must set CSMR0[V] before the chip select registers take effect.

A bus error occurs when writing to reserved register locations (for example, when writing to the region between the CS registers and the pin mux). Addresses *base address* + (0x48 - 0x5C) are reserved.

## 20.4.1 FB register descriptions

### 20.4.1.1 FB Memory map

FB base address: 4000_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Chip Select Address Register (CSAR0) | 32 | RW | 0000_0000h |
| 4h | Chip Select Mask Register (CSMR0) | 32 | RW | 0000_0000h |
| 8h | Chip Select Control Register (CSCR0) | 32 | RW | See description. |
| Ch | Chip Select Address Register (CSAR1) | 32 | RW | 0000_0000h |
| 10h | Chip Select Mask Register (CSMR1) | 32 | RW | 0000_0000h |
| 14h | Chip Select Control Register (CSCR1) | 32 | RW | See description. |
| 18h | Chip Select Address Register (CSAR2) | 32 | RW | 0000_0000h |
| 1Ch | Chip Select Mask Register (CSMR2) | 32 | RW | 0000_0000h |
| 20h | Chip Select Control Register (CSCR2) | 32 | RW | See description. |
| 24h | Chip Select Address Register (CSAR3) | 32 | RW | 0000_0000h |
| 28h | Chip Select Mask Register (CSMR3) | 32 | RW | 0000_0000h |
| 2Ch | Chip Select Control Register (CSCR3) | 32 | RW | See description. |
| 30h | Chip Select Address Register (CSAR4) | 32 | RW | 0000_0000h |
| 34h | Chip Select Mask Register (CSMR4) | 32 | RW | 0000_0000h |
| 38h | Chip Select Control Register (CSCR4) | 32 | RW | See description. |
| 3Ch | Chip Select Address Register (CSAR5) | 32 | RW | 0000_0000h |
| 40h | Chip Select Mask Register (CSMR5) | 32 | RW | 0000_0000h |
| 44h | Chip Select Control Register (CSCR5) | 32 | RW | See description. |
| 60h | Chip Select Port Multiplexing Control Register (CSPMCR) | 32 | RW | 0000_0000h |

### 20.4.1.2 Chip Select Address Register (CSAR0 - CSAR5)

#### 20.4.1.2.1 Offset

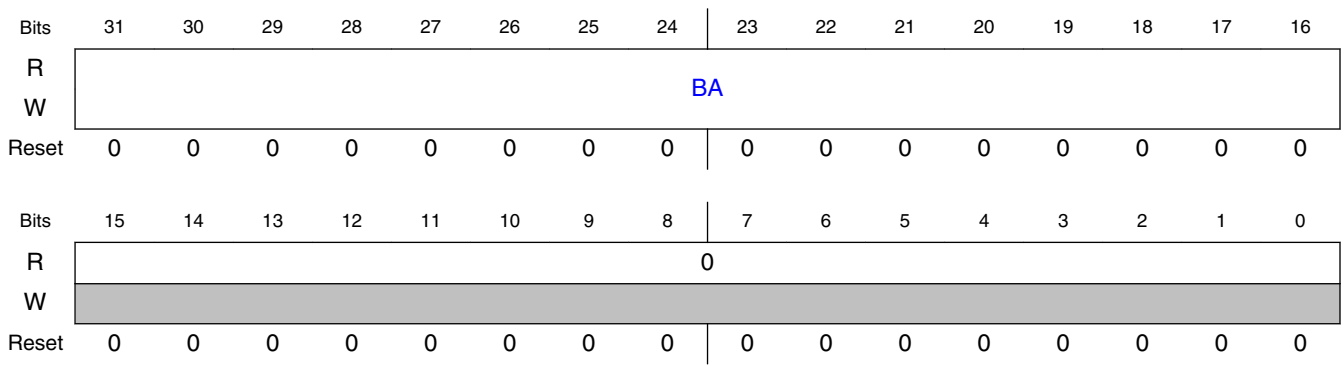
For a = 0 to 5:

| Register | Offset |
|---|---|
| CSARa | 0h + (a × Ch) |

#### 20.4.1.2.2 Function

Specifies the associated chip-select's base address.

#### 20.4.1.2.3 Diagram



#### 20.4.1.2.4 Fields

| Field | Function |
|---|---|
| 31-16<br>BA | Base Address<br>Defines the base address for memory dedicated to the associated chip-select. BA is compared to bits 31–16 on the internal address bus to determine if the associated chip-select's memory is being accessed.<br>**NOTE:** Because the FlexBus module is one of the slaves connected to the crossbar switch, it is only accessible within a certain memory range. See the chip memory map for the applicable FlexBus "expansion" address range for which the chip-selects can be active. Set the CSARn and CSMRn registers appropriately before accessing this region. |
| 15-0<br>— | Reserved |

### 20.4.1.3 Chip Select Mask Register (CSMR0 - CSMR5)

#### 20.4.1.3.1 Offset

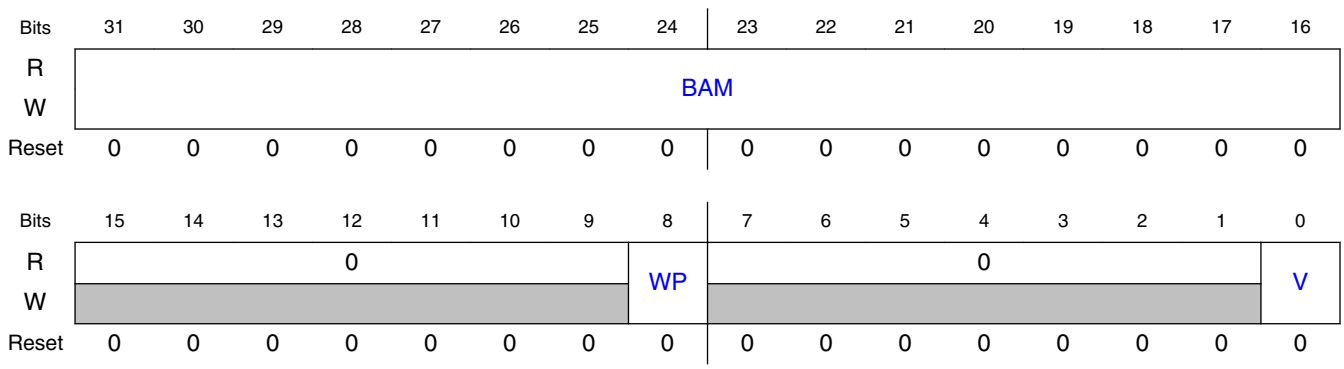
For a = 0 to 5:

| Register | Offset |
|---|---|
| CSMRa | 4h + (a × Ch) |

#### 20.4.1.3.2 Function

Specifies the address mask and allowable access types for the associated chip-select.

#### 20.4.1.3.3 Diagram



#### 20.4.1.3.4 Fields

| Field | Function |
|---|---|
| 31-16<br>BAM | Base Address Mask<br>Defines the associated chip-select's block size by masking address bits.<br>0000000000000000b - The corresponding address bit in CSAR is used in the chip-select decode.<br>0000000000000001b - The corresponding address bit in CSAR is a don't care in the chip-select decode. |
| 15-9<br>— | Reserved |
| 8<br>WP | Write Protect<br>Controls write accesses to the address range in the corresponding CSAR.<br>0b - Write accesses are allowed.<br>1b - Write accesses are not allowed. Attempting to write to the range of addresses for which the WP bit is set results in a bus error termination of the internal cycle and no external cycle. |
| 7-1<br>— | Reserved |
| 0 | Valid |

| Field | Function |
|---|---|
| V | Specifies whether the corresponding CSAR, CSMR, and CSCR contents are valid. Programmed chip-selects do not assert until the V bit is 1b (except for FB_CS0_B, which acts as the global chip-select).<br>**NOTE:** At reset, FB_CS0_B will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed.<br>0b - Chip-select is invalid.<br>1b - Chip-select is valid. |

## 20.4.1.4 Chip Select Control Register (CSCR0 - CSCR5)

### 20.4.1.4.1 Offset

For a = 0 to 5:

| Register | Offset |
|---|---|
| CSCRa | 8h + (a × Ch) |

### 20.4.1.4.2 Function

Controls the auto-acknowledge, address setup and hold times, port size, burst capability, and number of wait states for the associated chip select. FB_CS0_B allows address decoding for an external device to serve as the boot memory before system initialization and configuration are completed.

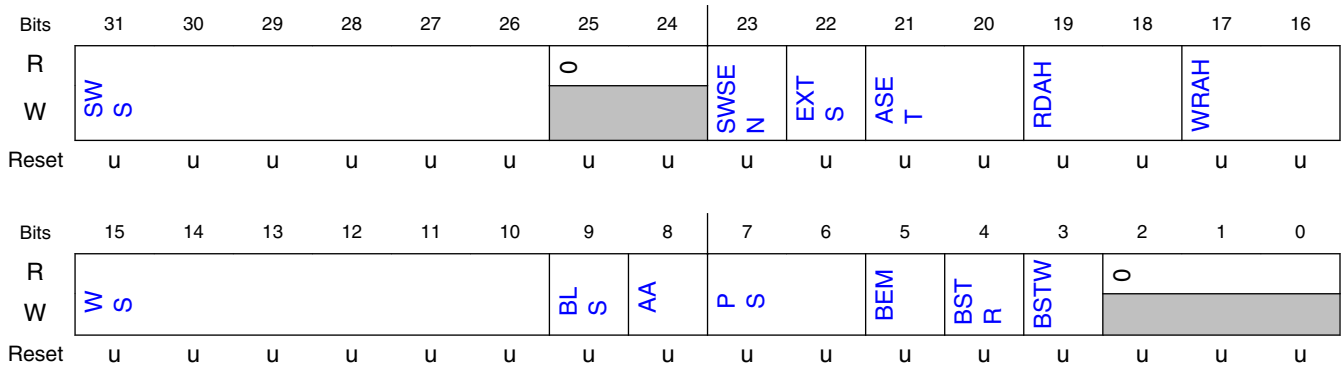
**NOTE**

To support the global chip-select (FB_CS0_B), the CSCR0 reset values differ from the other CSCRs (CSCR1 - CSCR5 all reset to 0). The reset value of CSCR0 is as follows:

- Bits 31 – 24 are 0b
- Bit 23 – 3 are chip-dependent
- Bits 2 – 0 are 0b

See the chip configuration details for your particular chip for information on the exact CSCR0 reset value.

### 20.4.1.4.3 Diagram



### 20.4.1.4.4 Fields

| Field | Function |
|---|---|
| 31-26<br>SWS | Secondary Wait States<br>Used only when the SWSEN bit is 1b. Specifies the number of wait states inserted before an internal transfer acknowledge is generated for a burst transfer (except for the first termination, which is controlled by WS). |
| 25-24<br>— | Reserved |
| 23<br>SWSEN | Secondary Wait State Enable<br>0b - Disabled. A number of wait states (specified by WS) are inserted before an internal transfer acknowledge is generated for all transfers.<br>1b - Enabled. A number of wait states (specified by SWS) are inserted before an internal transfer acknowledge is generated for burst transfer secondary terminations. |
| 22<br>EXTS | EXTS<br>Extended Transfer Start/Extended Address Latch Enable<br>Controls how long FB_TS_B/FB_ALE is asserted.<br>0b - Disabled. FB_TS_B/FB_ALE asserts for one bus clock cycle.<br>1b - Enabled. FB_TS_B/FB_ALE remains asserted until the first positive clock edge after FB_CSn_B asserts. |
| 21-20<br>ASET | Address Setup<br>Controls when the chip-select is asserted with respect to assertion of a valid address and attributes.<br>00b - Assert FB_CSn_B on the first rising clock edge after the address is asserted (default for all but FB_CS0_B).<br>01b - Assert FB_CSn_B on the second rising clock edge after the address is asserted.<br>10b - Assert FB_CSn_B on the third rising clock edge after the address is asserted.<br>11b - Assert FB_CSn_B on the fourth rising clock edge after the address is asserted (default for FB_CS0_B ). |
| 19-18<br>RDAH | Read Address Hold or Deselect<br>Controls the address and attribute hold time after the termination during a read cycle that hits in the associated chip-select's address space. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | **NOTE:** • The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.<br>• The number of cycles the address and attributes are held after FB_CSn_B deassertion depends on the value of the AA bit.<br>00b - When AA is 1b, 1 cycle. When AA is 0b, 0 cycles.<br>01b - When AA is 1b, 2 cycles. When AA is 0b, 1 cycle.<br>10b - When AA is 1b, 3 cycles. When AA is 0b, 2 cycles.<br>11b - When AA is 1b, 4 cycles. When AA is 0b, 3 cycles. |
| 17-16<br>WRAH | Write Address Hold or Deselect<br>Controls the address, data, and attribute hold time after the termination of a write cycle that hits in the associated chip-select's address space.<br>**NOTE:** The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.<br>00b - 1 cycle (default for all but FB_CS0_B)<br>01b - 2 cycles<br>10b - 3 cycles<br>11b - 4 cycles (default for FB_CS0_B) |
| 15-10<br>WS | Wait States<br>Specifies the number of wait states inserted after FlexBus asserts the associated chip-select and before an internal transfer acknowledge is generated (WS = 00h inserts 0 wait states, ..., WS = 3Fh inserts 63 wait states). |
| 9<br>BLS | Byte-Lane Shift<br>Specifies if data on FB_AD appears left-aligned or right-aligned during the data phase of a FlexBus access.<br>0b - Not shifted. Data is left-aligned on FB_AD.<br>1b - Shifted. Data is right-aligned on FB_AD. |
| 8<br>AA | Auto-Acknowledge Enable<br>Asserts the internal transfer acknowledge for accesses specified by the chip-select address.<br>**NOTE:** If AA is 1b for a corresponding FB_CSn_B and the external system asserts an external FB_TA_B before the wait-state countdown asserts the internal FB_TA_B, the cycle is terminated. Burst cycles increment the address bus between each internal termination.<br>**NOTE:** This field must be 1b if CSPMCR disables FB_TA_B.<br>0b - Disabled. No internal transfer acknowledge is asserted and the cycle is terminated externally.<br>1b - Enabled. Internal transfer acknowledge is asserted as specified by WS. |
| 7-6<br>PS | Port Size<br>Specifies the data port width of the associated chip-select, and determines where data is driven during write cycles and where data is sampled during read cycles.<br>00b - 32-bit port size. Valid data is sampled and driven on FB_D[31:0].<br>01b - 8-bit port size. Valid data is sampled and driven on FB_D[31:24] when BLS is 0b, or FB_D[7:0] when BLS is 1b.<br>1xb - 16-bit port size. Valid data is sampled and driven on FB_D[31:16] when BLS is 0b, or FB_D[15:0] when BLS is 1b. |
| 5<br>BEM | Byte-Enable Mode<br>Specifies whether the corresponding FB_BE_B is asserted for read accesses. Certain memories have byte enables that must be asserted during reads and writes. Write 1b to the BEM bit in the relevant CSCR to provide the appropriate mode of byte enable support for these SRAMs.<br>0b - FB_BE_B is asserted for data write only.<br>1b - FB_BE_B is asserted for data read and write accesses. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 4<br>BSTR | Burst-Read Enable<br>Specifies whether burst reads are enabled for memory associated with each chip select.<br>0b - Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a 32-bit read from an 8-bit port is broken into four 8-bit reads.<br>1b - Enabled. Enables data burst reads larger than the specified port size, including 32-bit reads from 8- and 16-bit ports, 16-bit reads from 8-bit ports, and line reads from 8-, 16-, and 32-bit ports. |
| 3<br>BSTW | Burst-Write Enable<br>Specifies whether burst writes are enabled for memory associated with each chip select.<br>0b - Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst writes. For example, a 32-bit write to an 8-bit port takes four byte writes.<br>1b - Enabled. Enables burst write of data larger than the specified port size, including 32-bit writes to 8- and 16-bit ports, 16-bit writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports. |
| 2-0<br>— | Reserved |

## 20.4.1.5 Chip Select Port Multiplexing Control Register (CSPMCR)

### 20.4.1.5.1 Offset

| Register | Offset |
|---|---|
| CSPMCR | 60h |

### 20.4.1.5.2 Function

Controls the multiplexing of the FlexBus signals. Use the CSPMCR register (Chip Select Port Multiplexing Control) and port control registers to configure which control signals are available on the external pins.

The multiplexing of the FlexBus address and data signals is controlled by the port control module. However, the multiplexing of some of the FlexBus control signals are controlled by **both** the FlexBus and port control modules. The FlexBus's CSPMCR register configures which FlexBus signals are available from the FlexBus module, and the port control module registers control whether the FlexBus or other module signals are available on the external pin.

**NOTE**

A bus error occurs when you do any of the following:

- Write to a reserved address
- Write to a reserved field in this register, or
- Access this register using a size other than 32 bits.

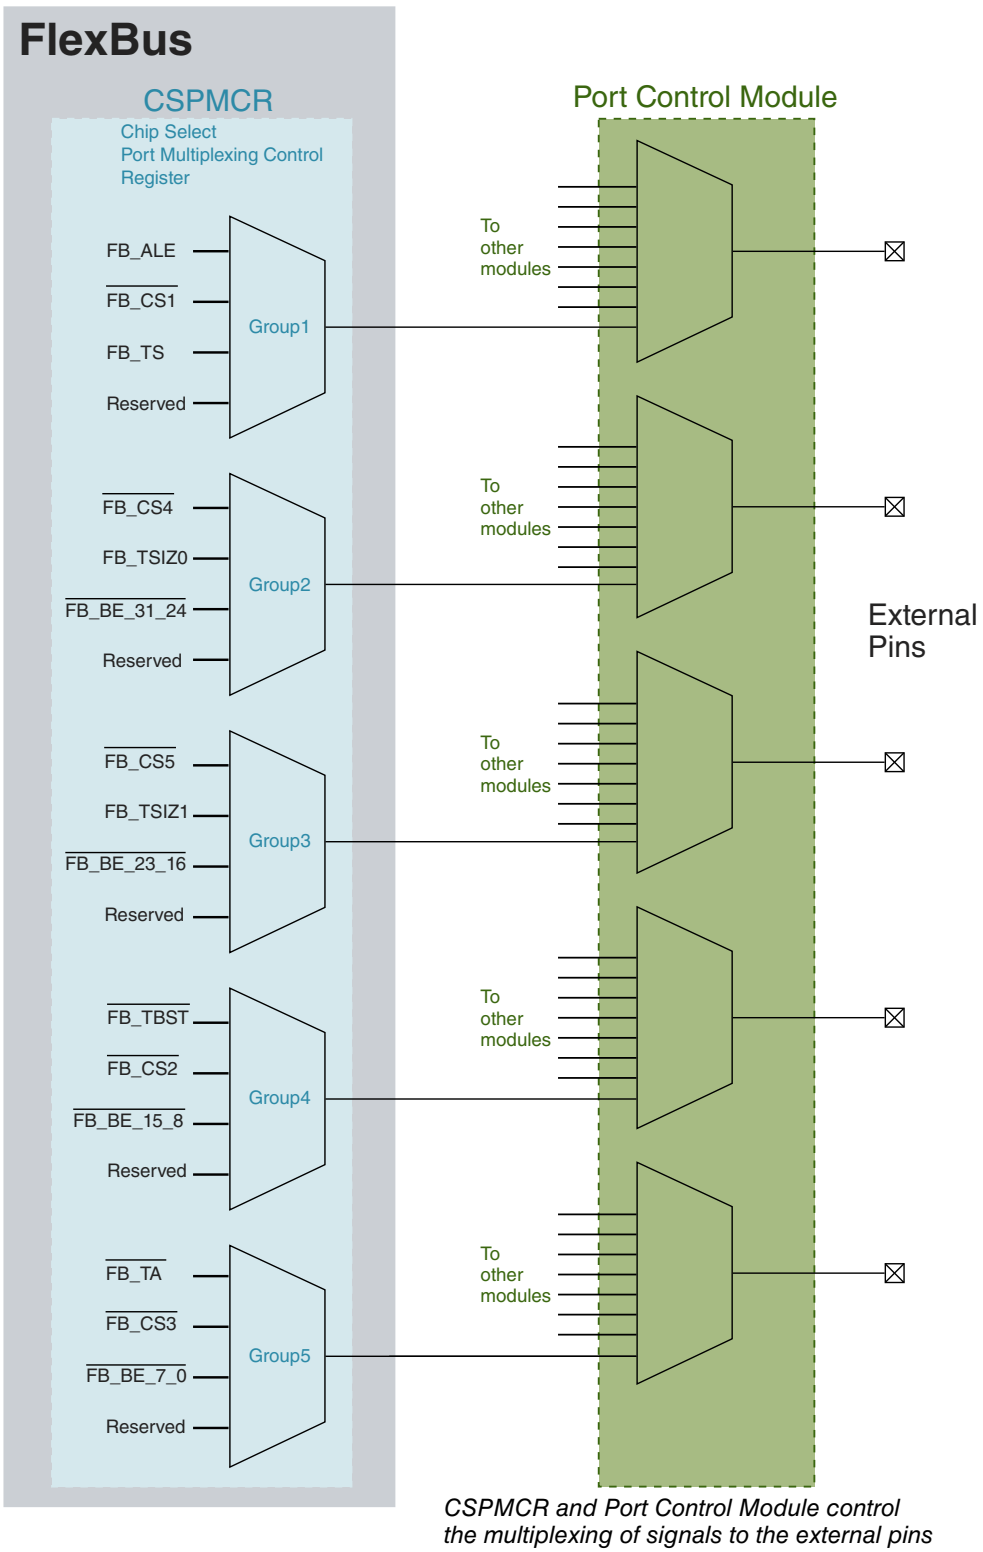


**Figure 20-4. FlexBus and Port Control module**

# 20.5 Functional description

## 20.5.1 Address and data bus configurations

**NOTE**

Address and data line configurations (like 32-bit non-multiplexed address and data busses) require signals to actually be available on the pins of your specific device's package. To make sure that the address and data bus signals are available on a specific device's pins, see your device's signal multiplexing table for that device package.

FlexBus supports:

- **Multiplexed address and data lines:**
  - Multiplexed 32-bit address and 32-bit data
  - Multiplexed 32-bit address and 16-bit data (non-multiplexed 16-bit address and 16-bit data)
  - Multiplexed 32-bit address and 8-bit data (non-multiplexed 24-bit address and 8-bit data)
- **Nonmultiplexed address and data lines:**
  - Non-multiplexed 32-bit address and 32-bit data busses
  - Non-multiplexed 32-bit address and 16-bit data busses
  - Non-multiplexed 32-bit address and 8-bit data busses
- **20-bit addressing:**
  - Up to a 20-bit address (multiplexed) with 16-bit data (write-masking of upper/lower bytes is not supported)
  - Up to a 20-bit address (multiplexed) with 8-bit data
  - Up to a 20-bit address (non-multiplexed) with 8-bit data

## 20.5.2 Address comparison

When a bus cycle is routed to FlexBus, FlexBus compares the transfer address to the base address (see CSAR[BA]) and base address mask (see CSMR[BAM]). This table describes how FlexBus decides to assert a chip-select and complete the bus cycle based on the address comparison.

| When the transfer address | Then FlexBus |
|---|---|
| Matches one address register configuration | Asserts the appropriate chip-select, generating a FlexBus bus cycle as defined in the appropriate CSCR.<br>If CSMR[WP] is set and a write access is performed, FlexBus terminates the internal bus cycle with a bus error, does not assert a chip-select, and does not perform an external bus cycle. |
| Does not match an address register configuration | Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle. |
| Matches more than one address register configuration | Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle. |

### 20.5.3 Address driven on address bus

Regardless of the external memory's or peripheral's address size,

- For multiplexed address and data busses, FlexBus always drives a 32-bit address on the FB_AD bus.
- For nonmultiplexed address and data busses, FlexBus always drives a 24-bit address on the FB_A bus.

### 20.5.4 Connecting address/data lines

The external device must connect its address and data lines as follows:

- Address lines
  - FB_AD from FB_AD0 upward
- Data lines
  - If CSCR[BLS] = 0, FB_AD from FB_AD31 downward
  - If CSCR[BLS] = 1, FB_AD from FB_AD0 upward

### 20.5.5 Bit ordering

No bit ordering is required when connecting address and data lines to the FB_A and FB_D buses. For example, a full 16-bit address/16-bit data device connects its addr15–addr0 to FB_AD16–FB_AD1 and data15–data0 to FB_AD31–FB_AD16. See Data-byte alignment and physical connections for a graphical connection.

### 20.5.6 Global chip-select

After system reset, FB_CS0(active-low) acts as the global (boot) chip-select to support external boot memory accesses before system initialization. Its operation differs from other external chip-select outputs after system reset. After system reset, FB_CS0 is asserted for every external access. No other chip-select can be used until until you write 1b to CSMR0[V]. At this point FB_CS0 functions as programmed. After this, FB_CS5–FB_CS1 can be used as well.

## 20.5.7 Data transfer signals

Data transfers between FlexBus and the external memory or peripheral involve these signals:

- Address/data bus (FB_AD31–FB_AD0 (multiplexed address/data bus)FB_A23–FB_A0, FB_D31–FB_D0 (nonmultiplexed address/data bus))
- Control signals (FB_TS_b/FB_ALE, FB_TA_b, FB_CS_b*n*, FB_OE_b, FB_R/W_b, FB_BE*n*)
- Attribute signals (FB_TBST_b, FB_TSIZ1–FB_TSIZ0)

## 20.5.8 Signal transitions

These signals change on the rising edge of the FlexBus clock (FB_CLK):

- Address
- Write data
- FB_TS_b/FB_ALE
- active low FB_CSn
- All attribute signals

FlexBus latches the read data on the rising edge of the clock.

## 20.5.9 Data-byte alignment and physical connections

The device aligns data transfers in FlexBus byte lanes with the number of lanes depending on the data port width.

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is disabled. For example, an 8-bit memory connects to the single lane

FB_AD31–FB_AD24 (FB_BE_31_24, active low). A 32-bit transfer through this 8-bit port takes 4 transfers, starting with the LSB to the MSB. A 32-bit transfer through a 32-bit port requires one transfer on each 4-byte lane.

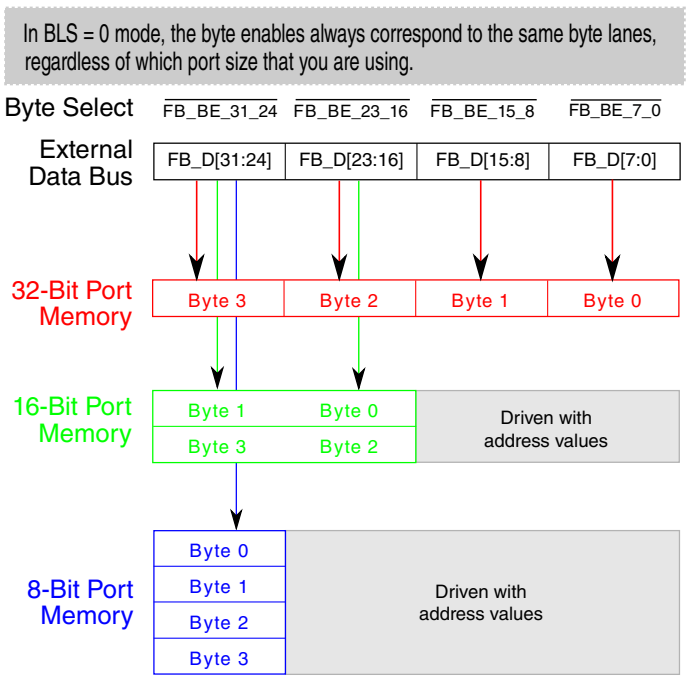

**Figure 20-5. Connections for external memory port sizes (CSCRn[BLS] = 0)**

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is enabled.

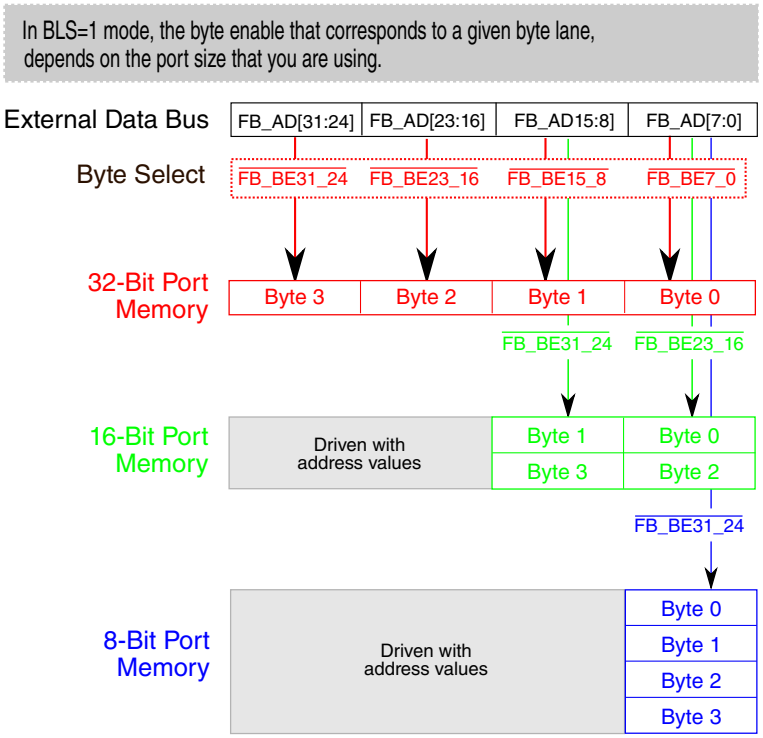

**Figure 20-6. Connections for external memory port sizes (CSCRn[BLS] = 1)**

## 20.5.10 Address/data bus multiplexing

FlexBus supports a single 32-bit wide multiplexed address and data bus (FB_AD31–FB_AD0). FlexBus always drives the full 32-bit address on the first clock of a bus cycle. During the data phase, the FB_AD31– FB_AD0 lines used for data are determined by the programmed port size and BLS setting for the corresponding chip-select. FlexBus continues to drive the address on any FB_AD31– FB_AD0 lines not used for data.

### 20.5.10.1 FlexBus multiplexed operating modes for CSCRn[BLS]=0

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 0b.

| Port size and phase | | FB_AD | | | |
|---|---|---|---|---|---|
| | | 31–24 | 23–16 | 15–8 | 7–0 |
| 32-bit | Address phase | Address | | | |
| | Data phase | Data | | | |
| 16-bit | Address phase | Address | | | |
| | Data phase | Data | | Address | |

*Table continues on the next page...*

| Port size and phase | | FB_AD | | | |
|---|---|---|---|---|---|
| | | 31–24 | 23–16 | 15–8 | 7–0 |
| 8-bit | Address phase | Address | | | |
| | Data phase | Data | Address | | |

## 20.5.10.2 FlexBus multiplexed operating modes for CSCRn[BLS]=1

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 1b.

| Port size and phase | | FB_AD | | | |
|---|---|---|---|---|---|
| | | 31–24 | 23–16 | 15–8 | 7–0 |
| 32-bit | Address phase | Address | | | |
| | Data phase | Data | | | |
| 16-bit | Address phase | Address | | | |
| | Data phase | Address | | Data | |
| 8-bit | Address phase | Address | | | |
| | Data phase | Address | | | Data |

## 20.5.11 Data transfer states

Basic data transfers occur in 4 clocks or states. (See Basic Read Bus Cycle and Basic Write Bus Cycle for examples of basic data transfers.) The FlexBus state machine controls the data-transfer operation. This figure shows the state-transition diagram for basic read and write cycles.

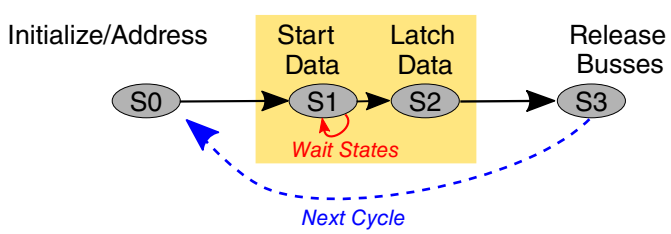

**Figure 20-7. Data transfer state transitions**

| State | | Cycle | Description |
|---|---|---|---|
| Initialize/ address | S0 | All | The read or write cycle is initiated. On the rising clock edge, FlexBus:<br>• Places a valid address on FB_ADn |

*Table continues on the next page...*

| State | | Cycle | Description |
|---|---|---|---|
| | | | • Asserts FB_TS_b/FB_ALE<br>• Drives FB_R/W_b high for a read and low for a write |
| Start data phase | S1 | All | FlexBus:<br>• Negates FB_TS_b/FB_ALE on the rising edge of FB_CLK<br>• Asserts FB_CSn (active low)<br>• Drives the data on FB_AD31– FB_AD*X* for writes<br>• Tristates FB_AD31– FB_AD*X* for reads<br>• Continues to drive the address on FB_AD pins that are unused for data<br><br>• If the external memory or peripheral asserts FB_TA_b, then the process moves to S2.<br>• If FB_TA_b is not asserted internally or externally, then S1 repeats. |
| | | Read | The external memory or peripheral drives the data before the next rising edge of FB_CLK (the rising edge that begins S2) with FB_TA_b asserted. |
| Latch data | S2 | All | • For internal termination, FlexBus negates FB_CSn (active low) and the transfer is complete.<br>• For external termination, the external memory or peripheral negates FB_TA_b, then FlexBus negates FB_CSn (active low) after the rising edge of FB_CLK at the end of S2. |
| | | Read | FlexBus latches the data on the rising clock edge entering S2. The external memory or peripheral can stop driving the data after this edge, or continue to drive the data until the end of S3 or drive the data through any additional address hold cycles. |
| Release busses | S3 | All | FlexBus invalidates the address, data, and FB_R/W_b on the rising edge of FB_CLK at the beginning of S3, terminating the transfer. |

## 20.5.12 FlexBus Timing Examples

**Note**

The timing diagrams in this section use signal names that may not be included on your particular device, so ignore these signals.

**Note**

Throughout this section:

- FB_D[*X*] indicates a 32-, 16-, or 8-bit wide data bus
- FB_A[*Y*] indicates an address bus that can be 32, 24, or 16 bits wide.

### 20.5.12.1 Basic Read Bus Cycle

During a read cycle, the MCU receives data from memory or a peripheral device.

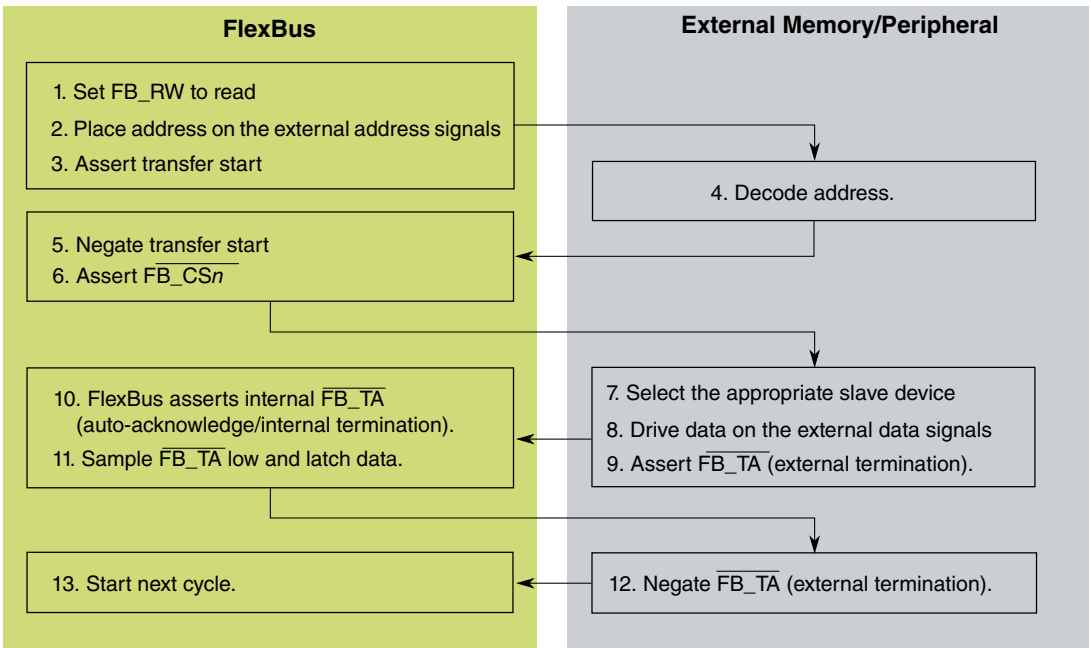

**Figure 20-8. Read Cycle Flowchart**

## Note

FB_TA_b (active low) does not have to be driven by the external device for internally-terminated bus cycles.

## Note

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and another module. At the end of the read bus cycles the address signals are indeterminate.

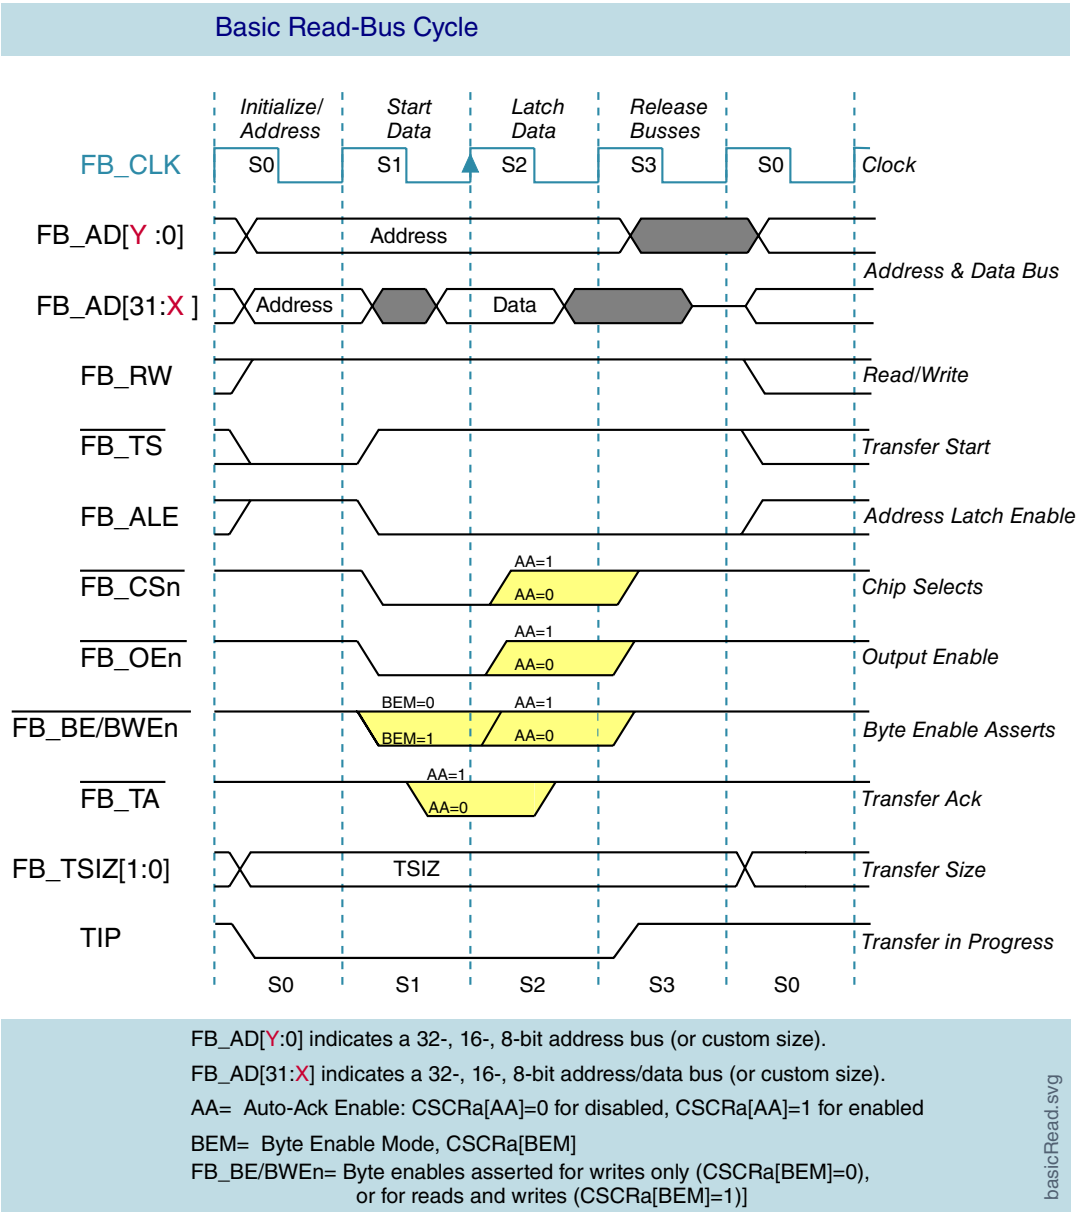

**Figure 20-9. Basic Read Bus Cycle**

## 20.5.12.2 Basic Write Bus Cycle

During a write cycle, the device sends data to memory or to a peripheral device.

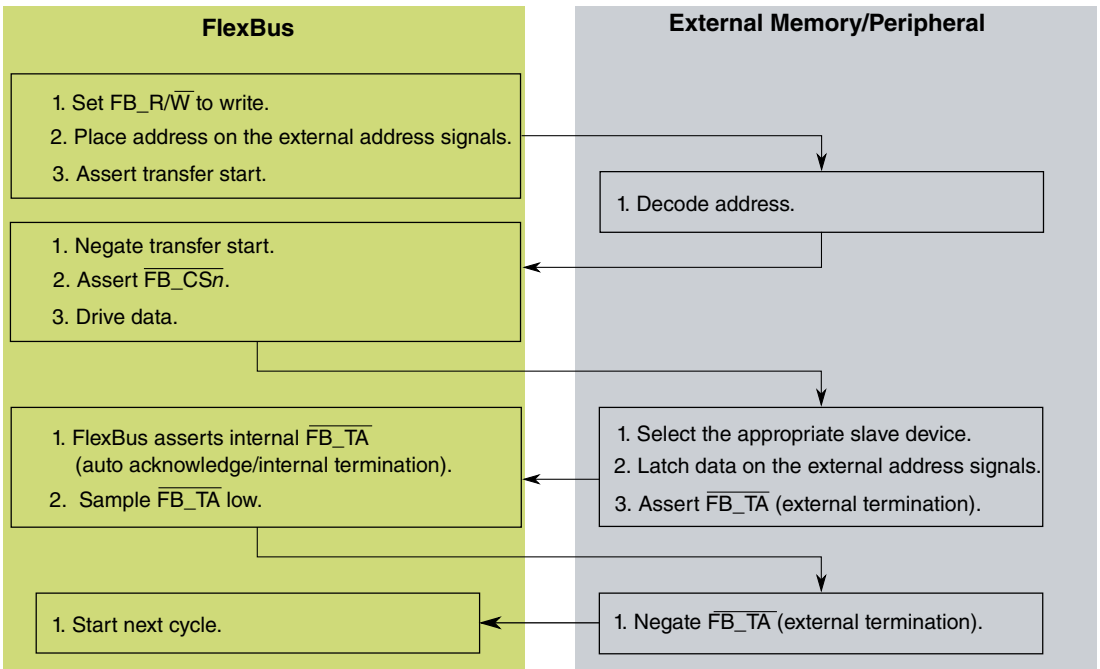

**Figure 20-10. Write Cycle Flowchart**

## Note

The address and data busses are muxed between the FlexBus and another module. At the end of the write bus cycles, the address signals are indeterminate.

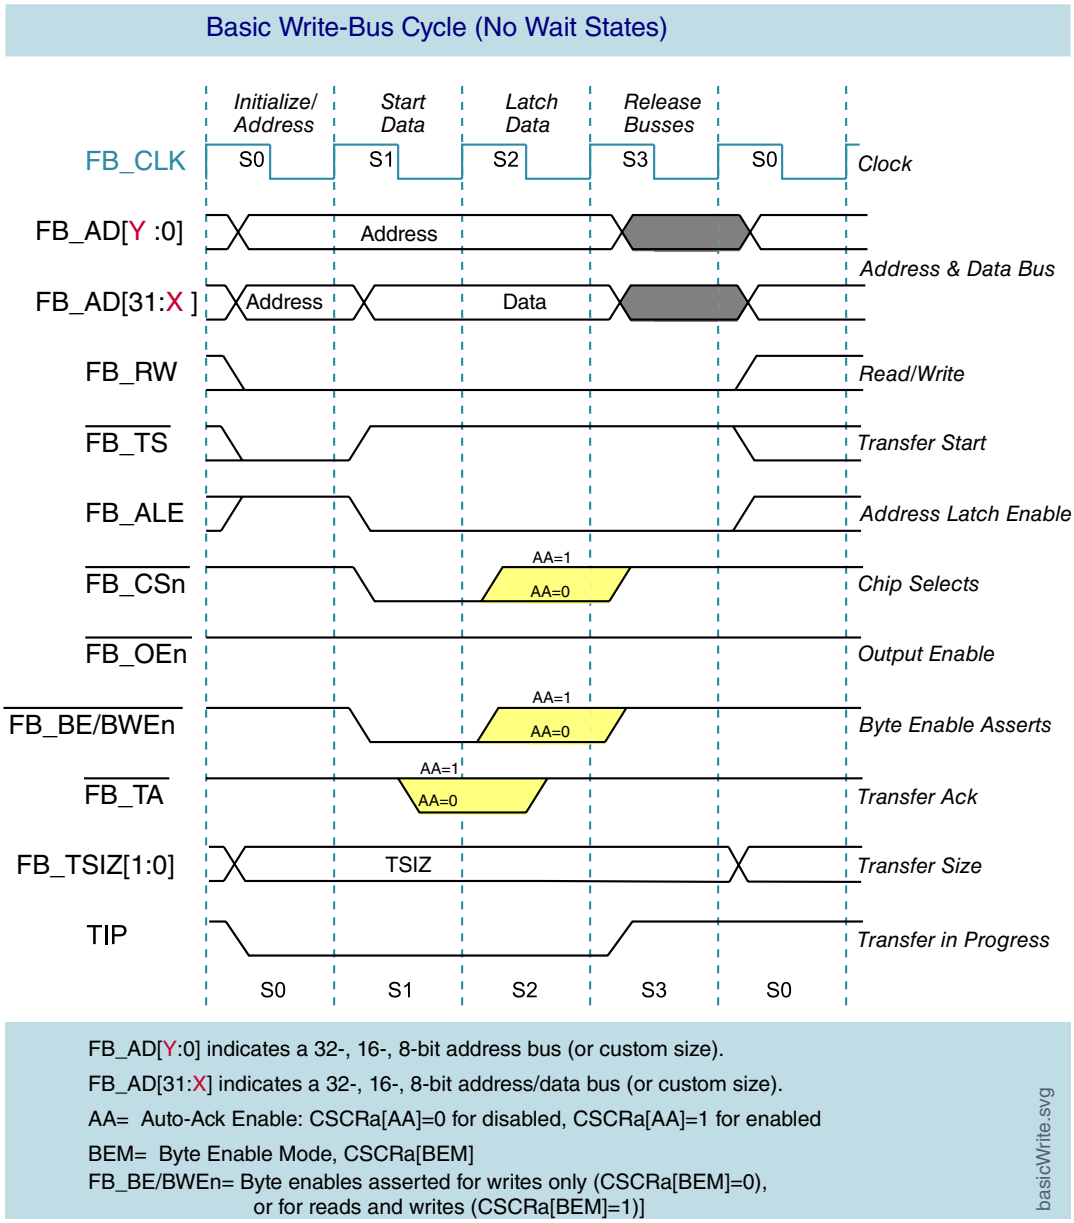

**Figure 20-11. Basic Write Bus Cycle**

## 20.5.12.3 Bus Cycle Sizing

This section shows timing diagrams for various port size scenarios.

**NOTE**

All examples in this "Bus Cycle Sizing" section assume BLS=0.

### 20.5.12.3.1 Bus Cycle Sizing—Byte Transfer, 8-bit Device, No Wait States

The next figure shows the basic byte read transfer to an 8-bit device with no wait states:

- For multiplexed address and data busses, the address is driven on the full FB_AD[31:0] bus in the 1st clock; the device tristates FB_AD[31:24] on the 2nd clock and continues to drive address on FB_AD[23:0] throughout the bus cycle.
- For nonmultiplexed address and data busses, the address is driven on the FB_A[23:8] bus throughout the bus cycle.
- The external device returns the read data on FB_AD[31:24] and may tristate the data line or continue driving the data 1 clock after FB_TA_b (active low) is sampled asserted.

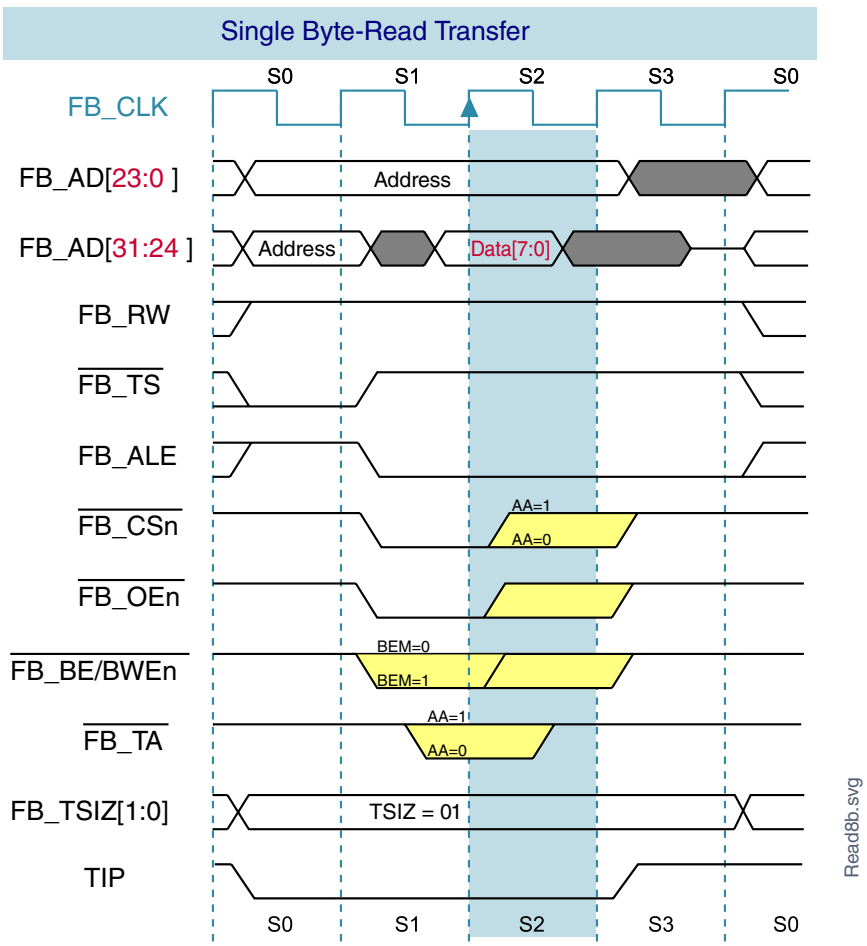

**Figure 20-12. Single Byte-Read Transfer**

The next figure shows the similar configuration for a write transfer. The data is driven from the 2nd clock on FB_AD[31:24].

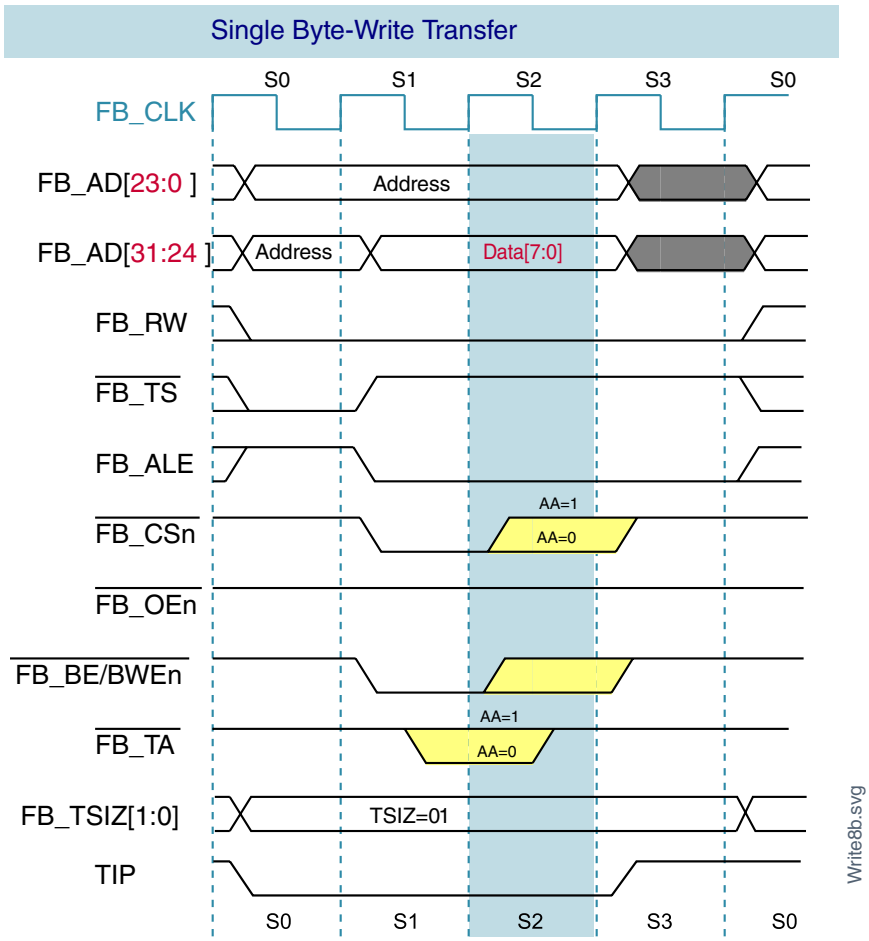

**Figure 20-13. Single Byte-Write Transfer**

### 20.5.12.3.2 Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States

The next figure shows a basic word read transfer to a 16-bit device with no wait states.

- For multiplexed address and data busses, the address is driven on the full FB_AD[31:0] bus in the first clock; the device tristates FB_AD[31:16] on the second clock and continues to drive address on FB_AD[15:0] throughout the bus cycle.
- For nonmultiplexed address and data busses, the address is driven on the FB_A[23] bus throughout the bus cycle.
- The external device returns the read data on FB_AD[31:16] and may tristate the data line or continue driving the data one clock after FB_TA_b (active low) is sampled asserted.

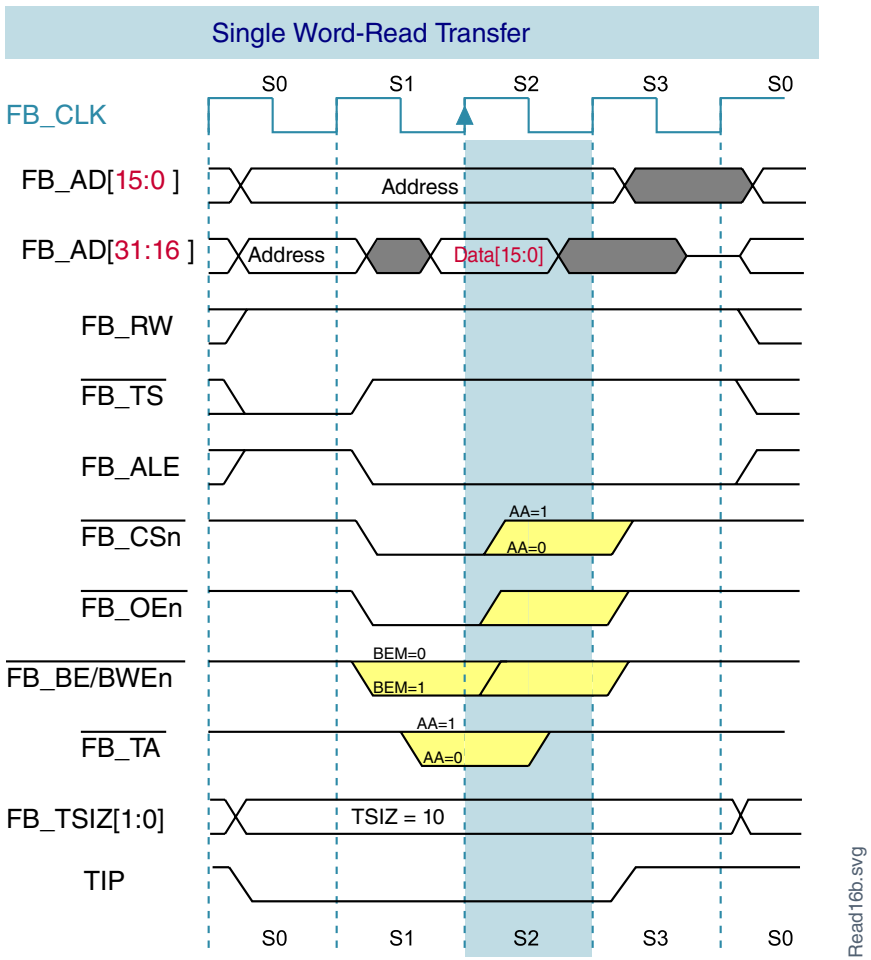

**Figure 20-14. Single Word-Read Transfer**

The next figure shows a basic word write transfer. The data is driven from the second clock on FB_AD[31:16].

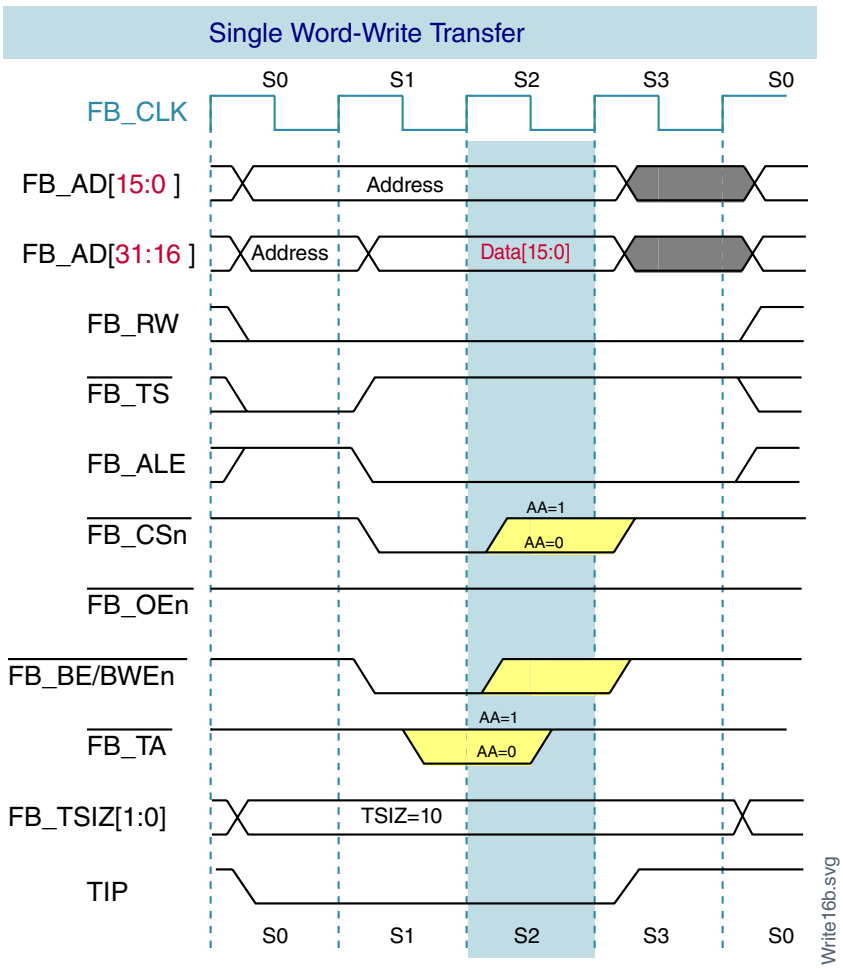

**Figure 20-15. Single Word-Write Transfer**

### 20.5.12.3.3 Bus Cycle Sizing—Longword Transfer, 32-bit Device, No Wait States

The next figure shows a longword read from a 32-bit device.

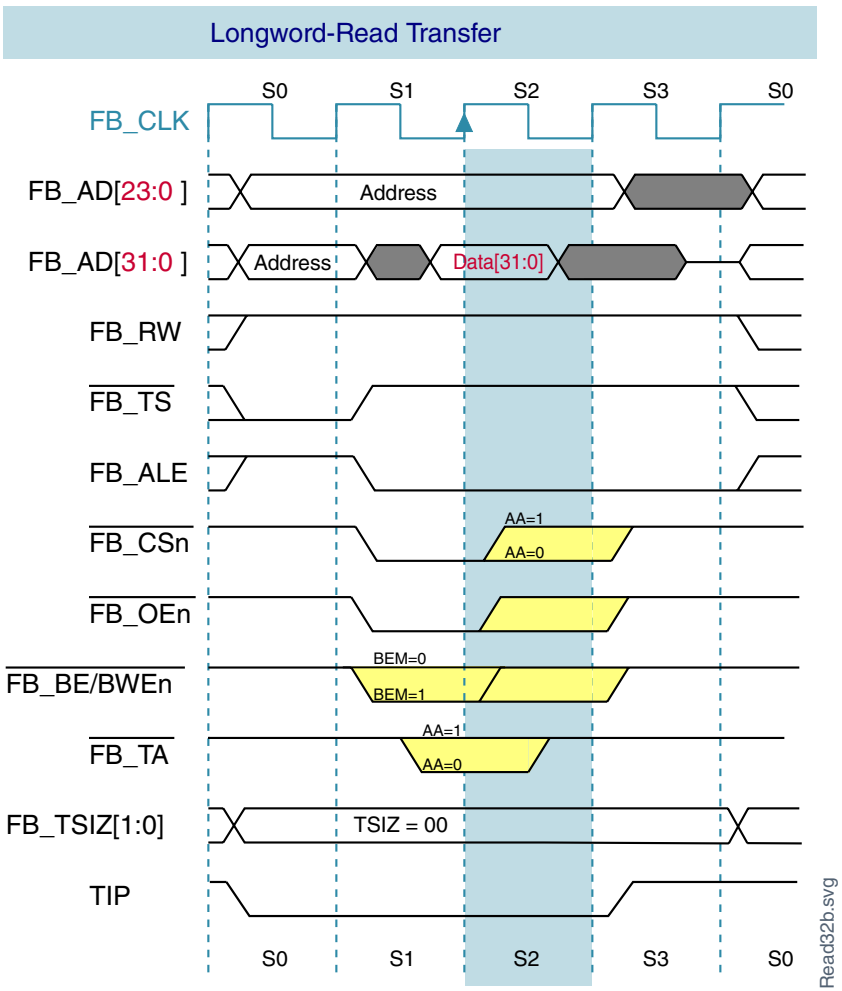

**Figure 20-16. Longword-Read Transfer**

The next figure shows a longword write to a 32-bit device.

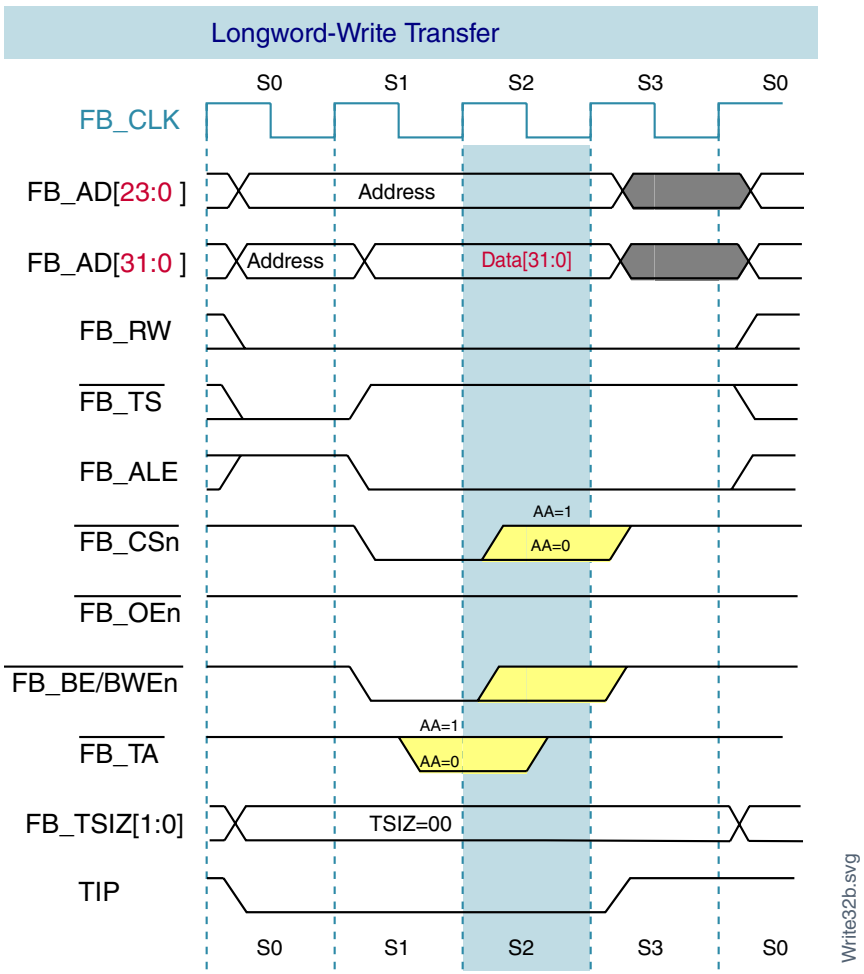

**Figure 20-17. Longword-Write Transfer**

## 20.5.12.4 Timing Variations

The FlexBus module has several features that can change the timing characteristics of a basic read- or write-bus cycle to provide additional address setup, address hold, and time for a device to provide or latch data.

### 20.5.12.4.1 Wait States

Wait states can be inserted before each beat of a transfer by programming the CSCR*n* registers. Wait states can give the peripheral or memory more time to return read data or sample write data.

The following figures show the basic read and write bus cycles (also shown in Basic Read Bus Cycle and Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States) with the default of no wait states respectively.

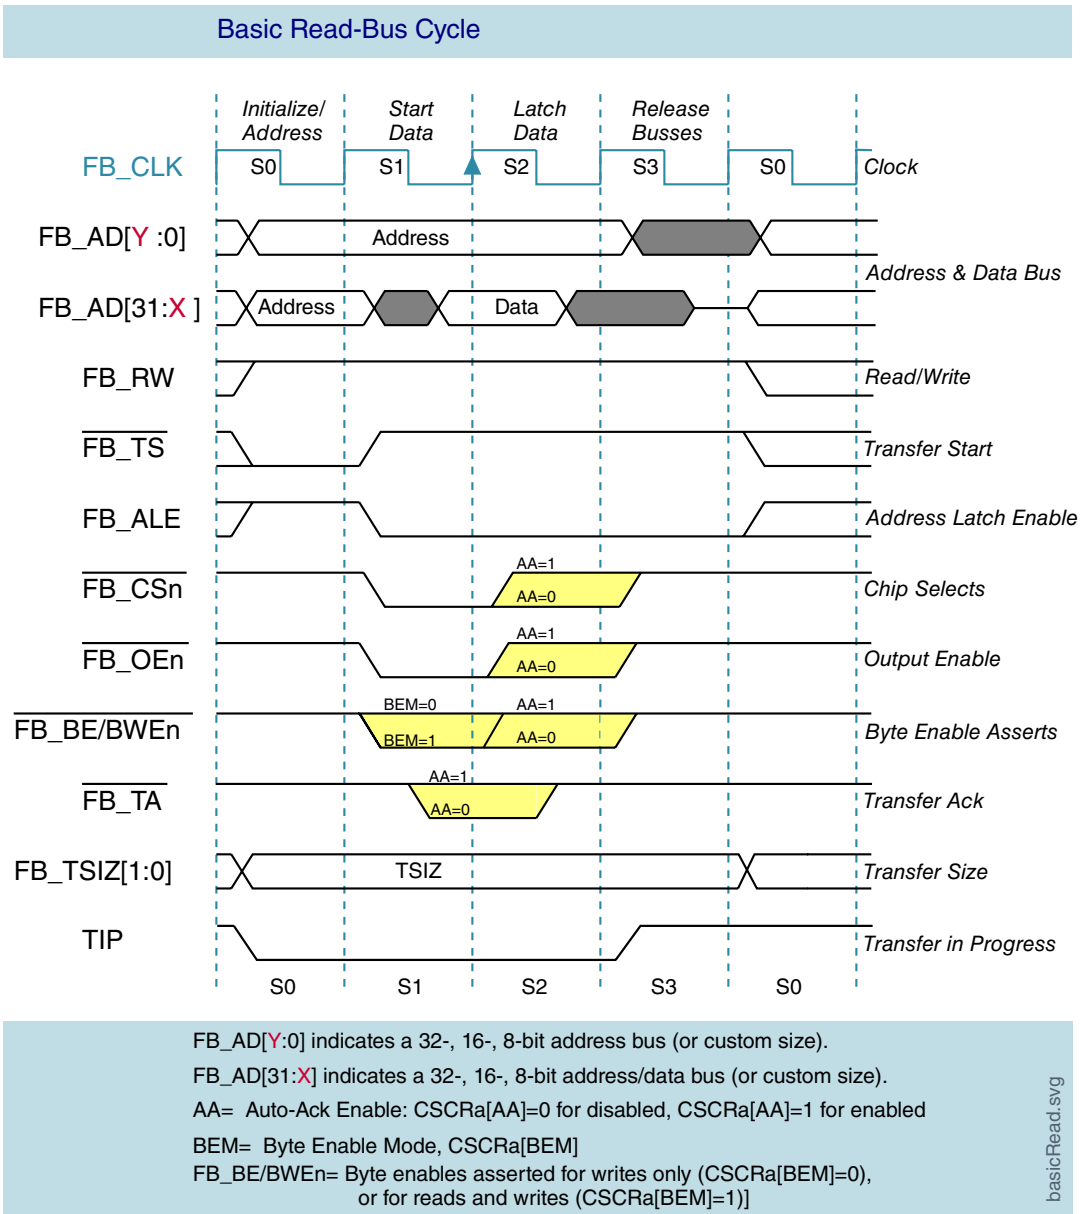

**Figure 20-18. Basic Read-Bus Cycle (No Wait States)**

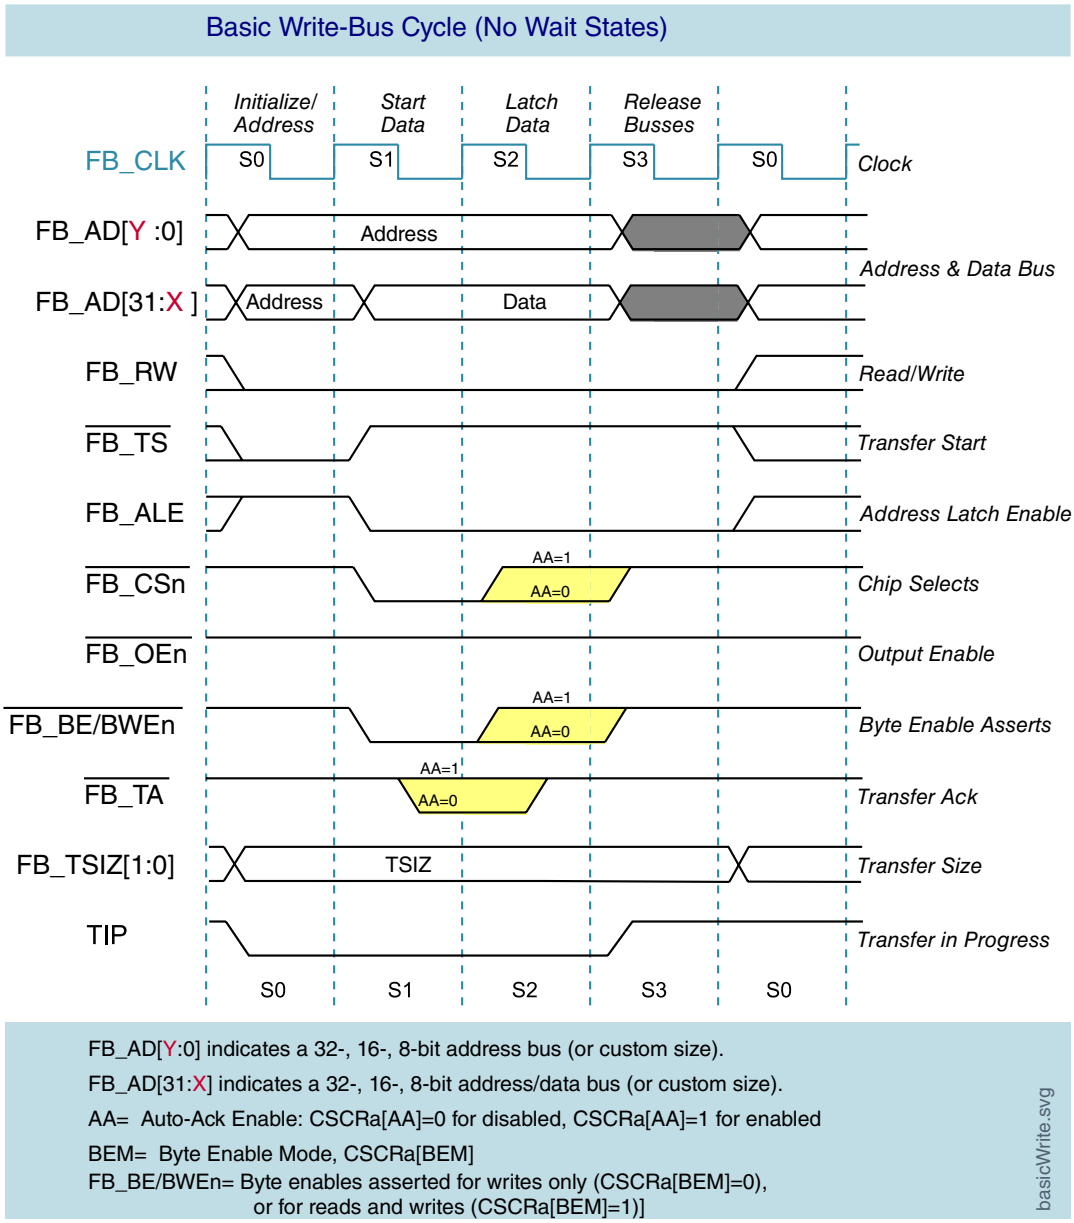

**Figure 20-19. Basic Write-Bus Cycle (No Wait States)**

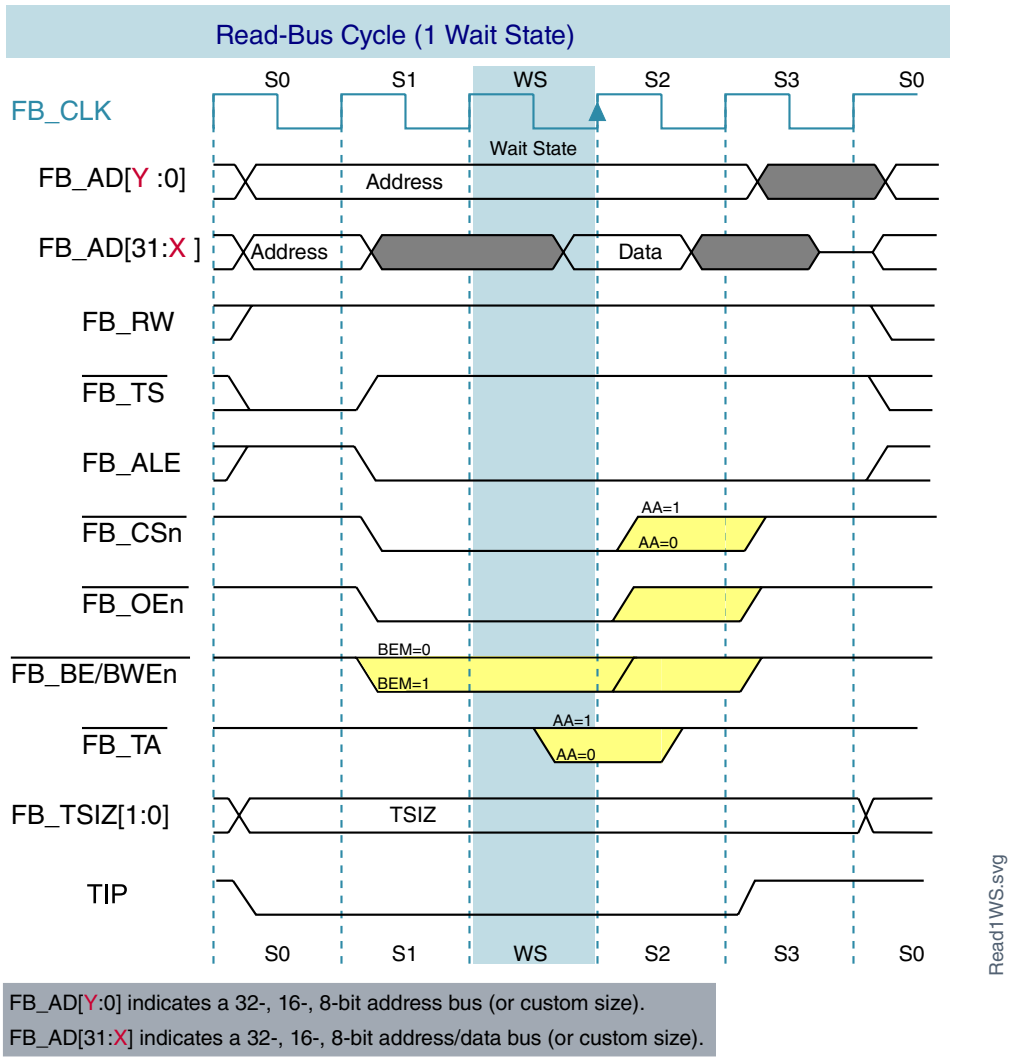
If wait states are used, the S1 state repeats continuously until the chip-select auto-acknowledge unit asserts internal transfer acknowledge or the external FB_TA_b is recognized as asserted. The following figures show a read and write cycle with one wait state respectively.



FB_AD[Y:0] indicates a 32-, 16-, 8-bit address bus (or custom size).
FB_AD[31:X] indicates a 32-, 16-, 8-bit address/data bus (or custom size).

**Figure 20-20. Read-Bus Cycle (One Wait State)**

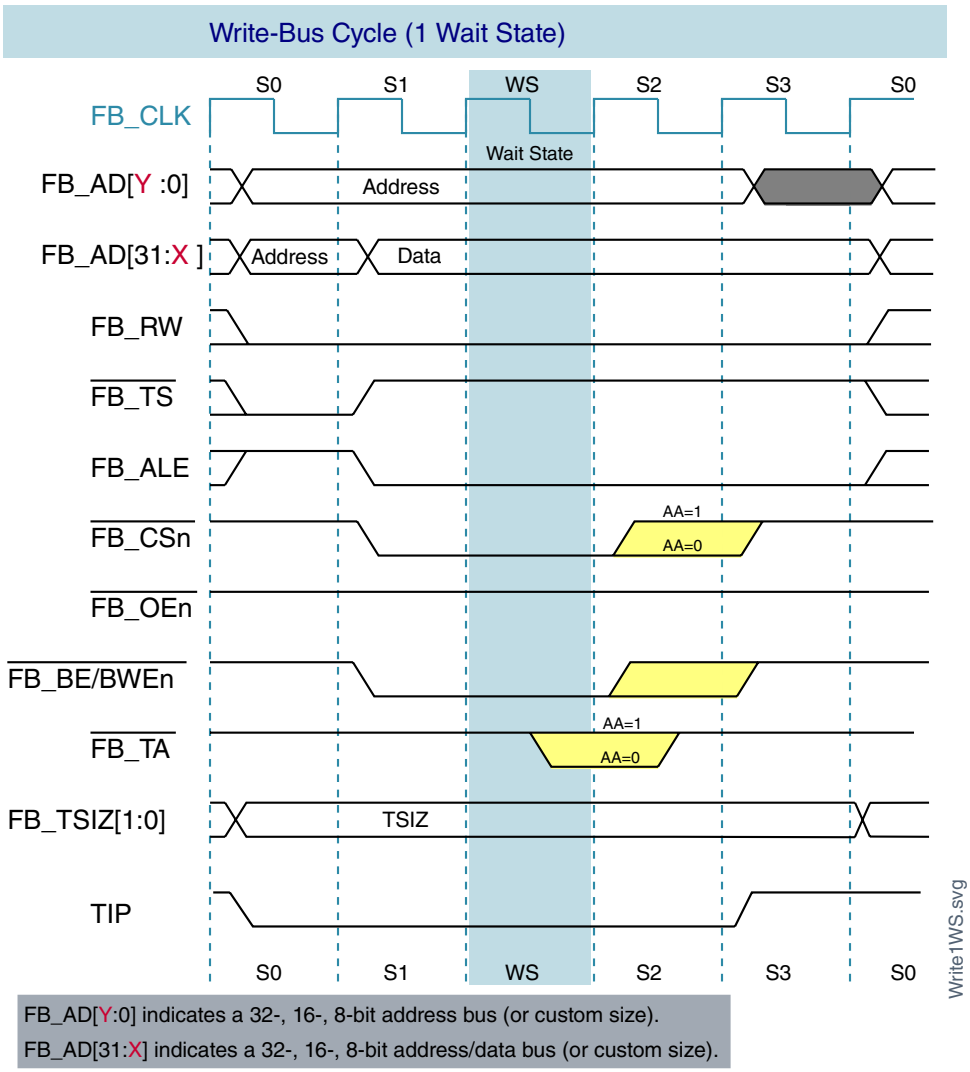


**Figure 20-21. Write-Bus Cycle (One Wait State)**

### 20.5.12.4.2 Address Setup and Hold

The timing of the assertion and negation of the chip selects, byte selects, and output enable can be programmed on a chip-select basis. Each chip-select can be programmed to assert one to four clocks after transfer start/address-latch enable (FB_TS_b/FB_ALE) is asserted. The following figures show read- and write-bus cycles with two clocks of address setup respectively.

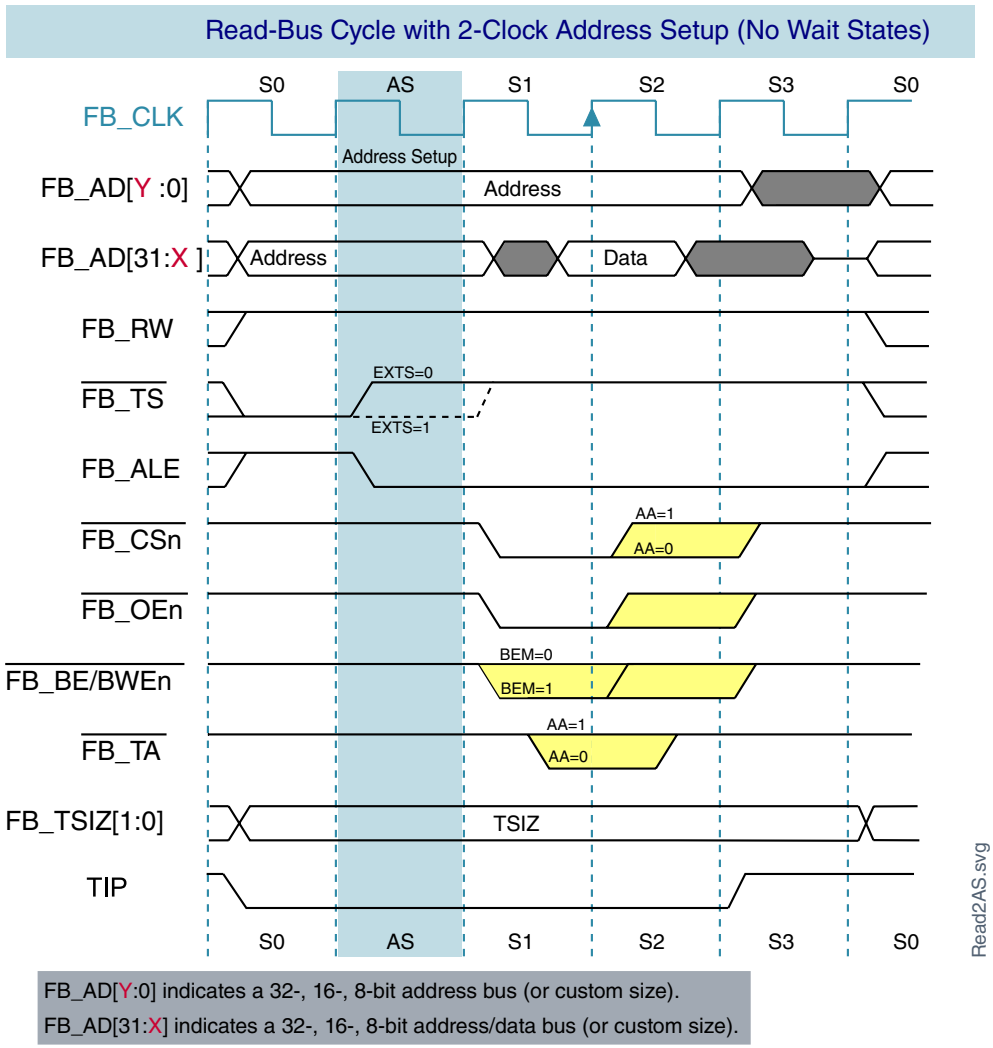

**Figure 20-22. Read-Bus Cycle with Two-Clock Address Setup (No Wait States)**

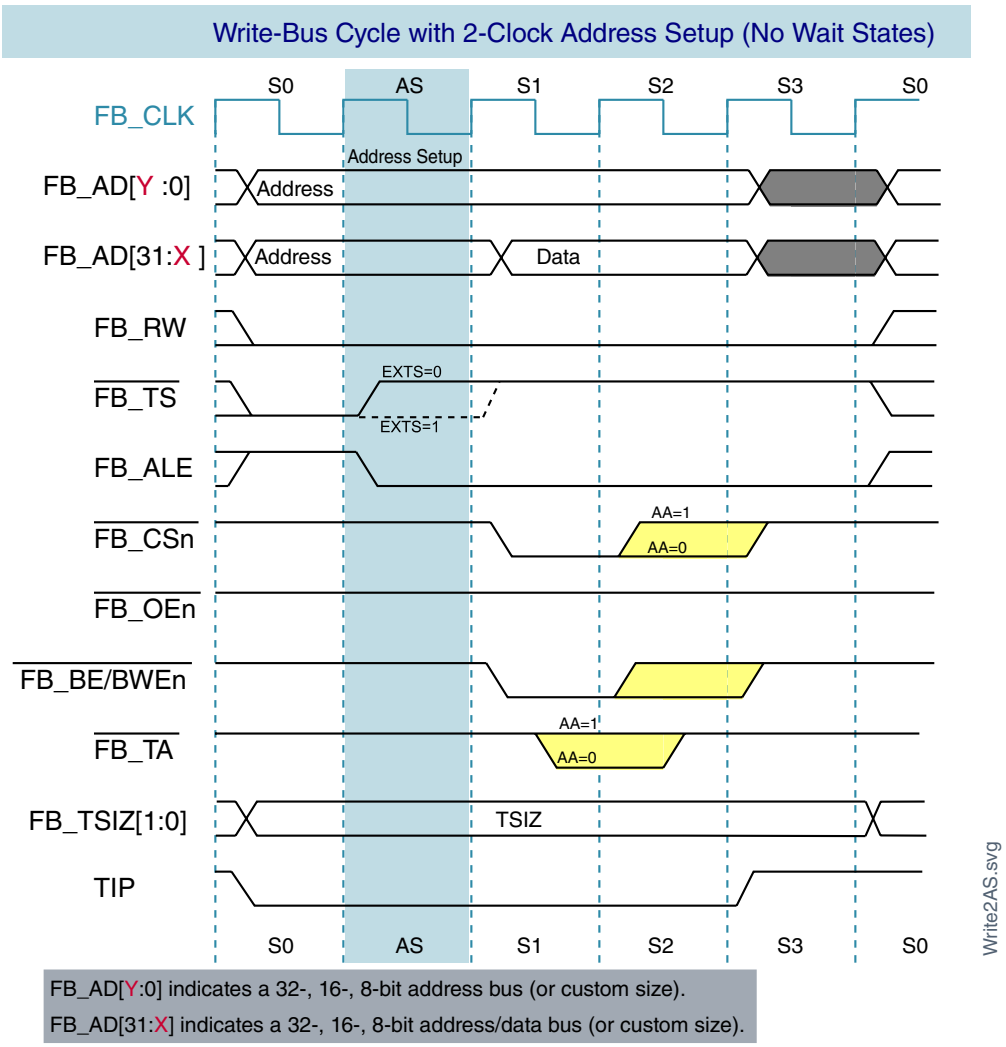

**Figure 20-23. Write-Bus Cycle with Two Clock Address Setup (No Wait States)**

In addition to address setup, a programmable address hold option for each chip select exists. Address and attributes can be held one to four clocks after chip-select, byte-selects, and output-enable negate. The following figures show read and write bus cycles with two clocks of address hold respectively.

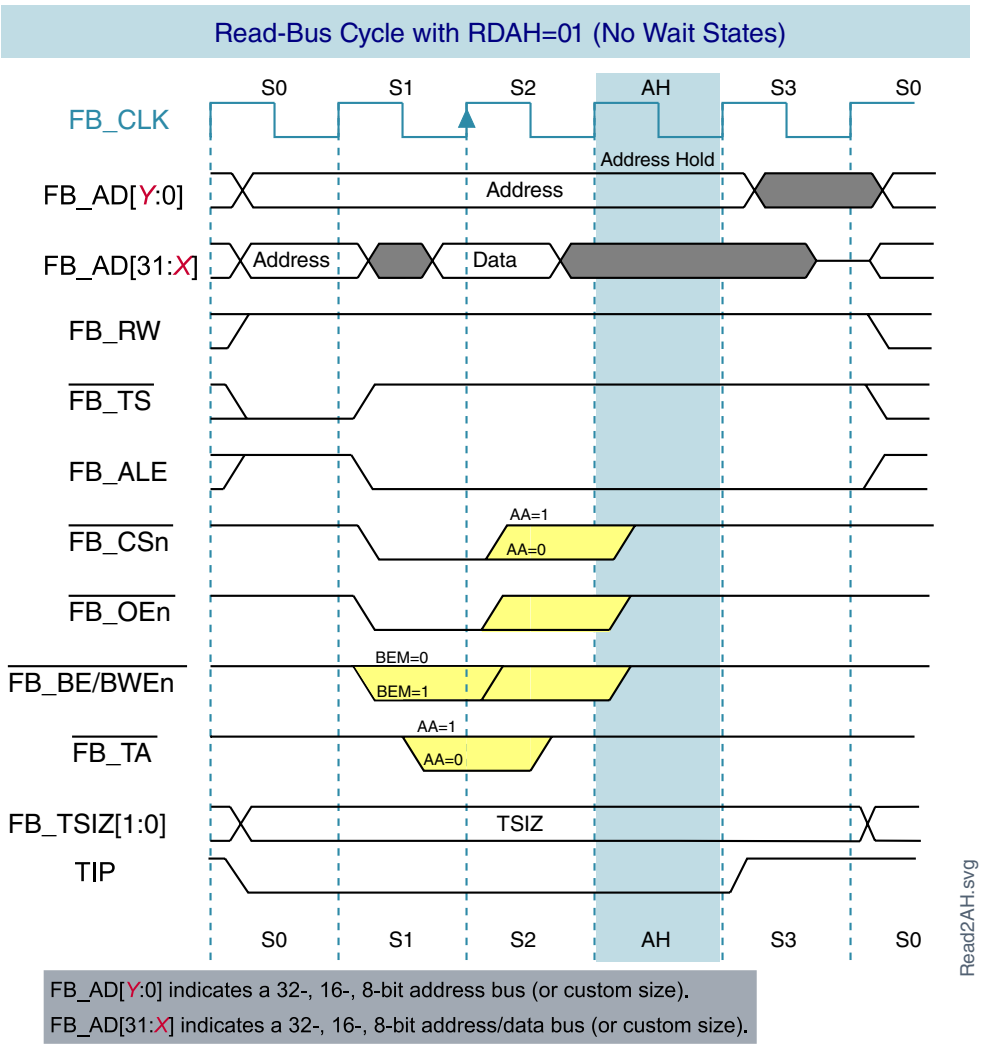

**Figure 20-24. Read Cycle with Two-Clock Address Hold (No Wait States)**

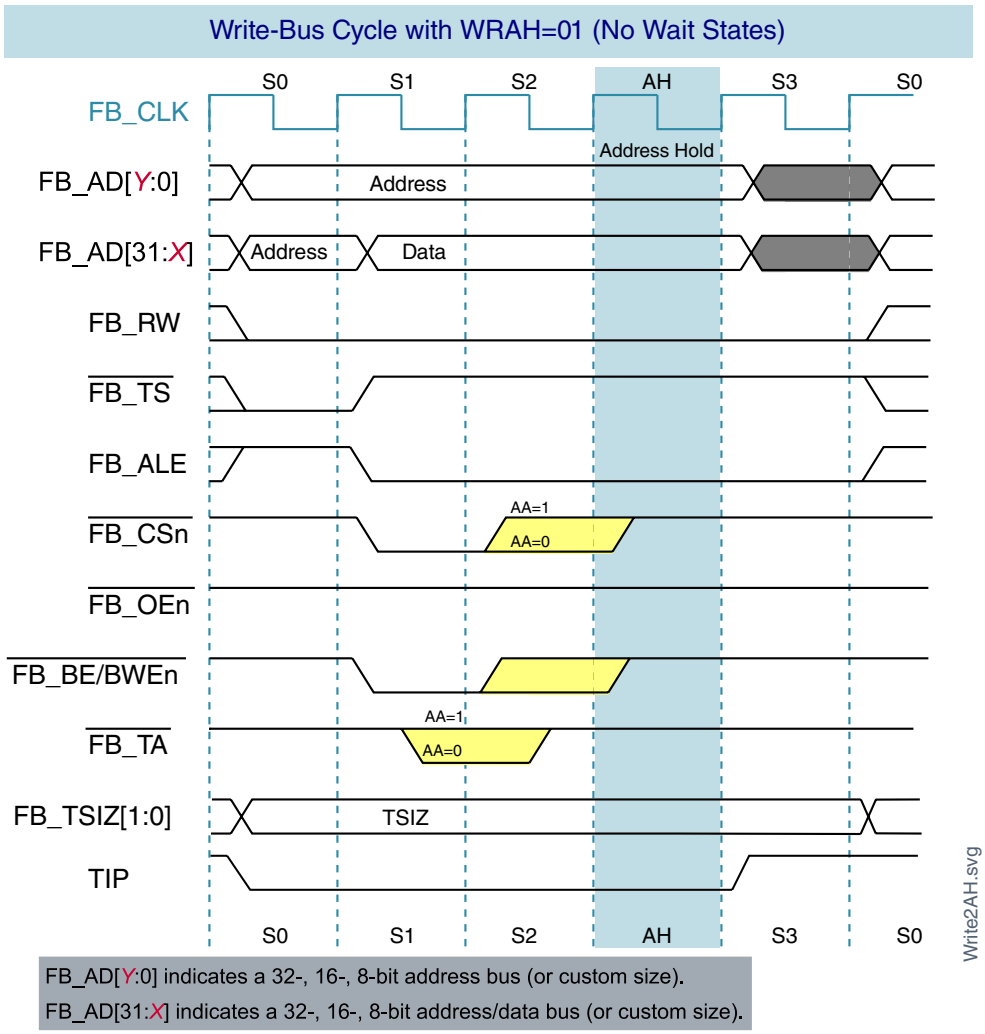

**Figure 20-25. Write Cycle with Two-Clock Address Hold (No Wait States)**

The following figure shows a bus cycle using address setup, wait states, and address hold.

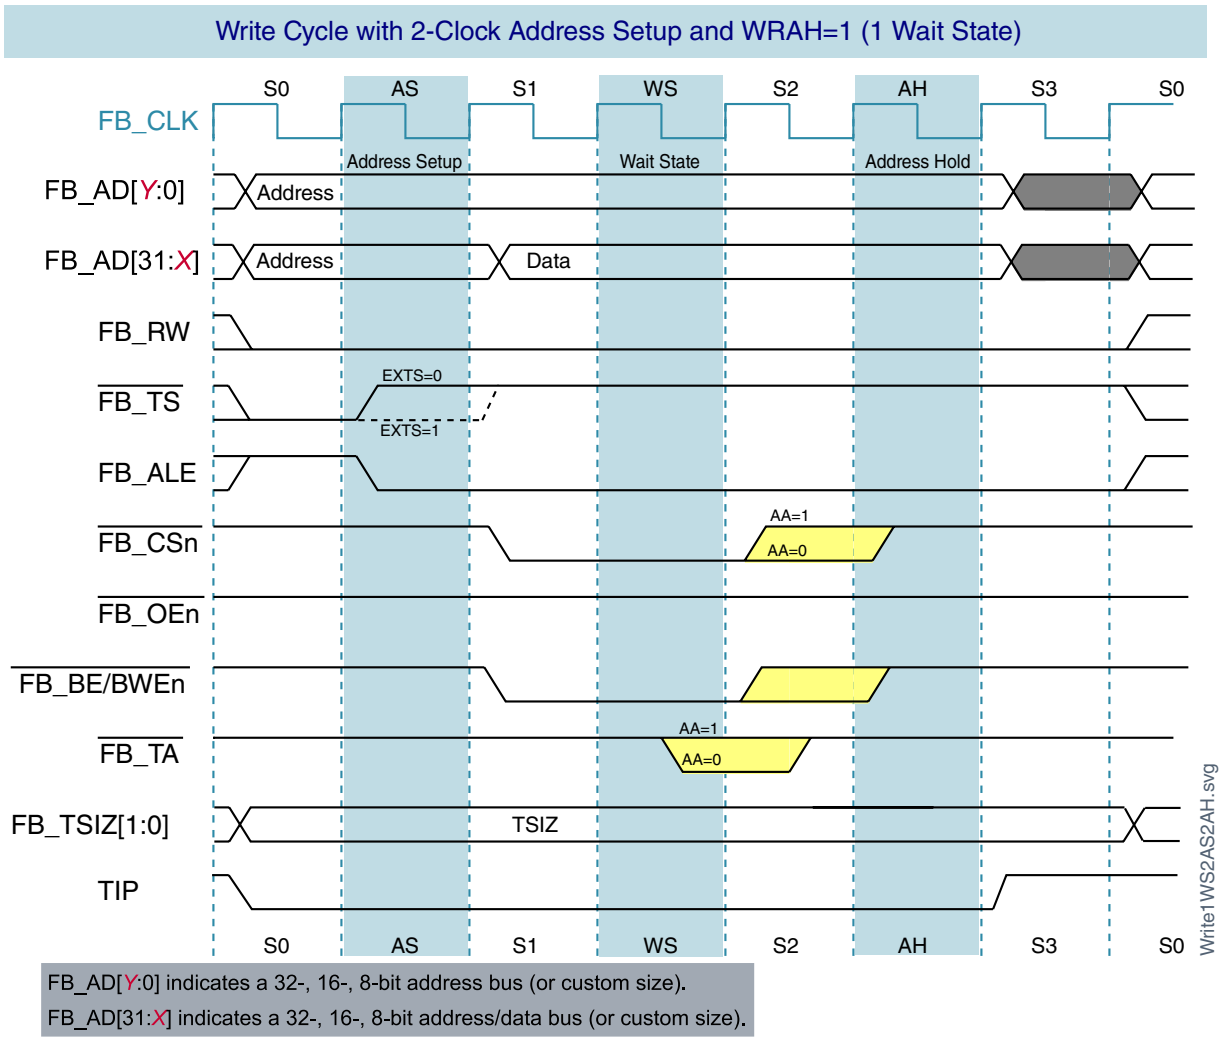

**Figure 20-26. Write Cycle with Two-Clock Address Setup and Two-Clock Hold (One Wait State)**

## 20.5.13 Burst cycles

The chip can be programmed to initiate burst cycles if its transfer size exceeds the port size of the selected destination. The initiation of a burst cycle is encoded on the transfer size pins (FB_TSIZ[1:0]). For burst transfers to smaller port sizes, FB_TSIZ[1:0] indicates the size of the entire transfer. For example, with bursting enabled, a 16-bit transfer to an 8-bit port takes two beats (two byte-sized transfers), for which FB_TSIZ[1:0] equals 10b throughout. A 32-bit transfer to an 8-bit port takes four beats (four byte-sized transfers), for which FB_TSIZ[1:0] equals 00b throughout.

### 20.5.13.1 Enabling and inhibiting burst

The CSCRn registers enable bursting for reads, writes, or both.

Memory spaces can be declared burst-inhibited for reads and writes by writing 0b to the appropriate CSCRn[BSTR] and CSCRn[BSTW] fields.

### 20.5.13.2 Transfer size and port size translation

With bursting disabled, any transfer larger than the port size breaks into multiple individual transfers (e.g. <Addr><Data><Addr+1><Data><Addr+2><Data>). With bursting enabled, any transfer larger than the port size results in a burst cycle of multiple beats (e.g. <Addr><Data><Data><Data>). The following table shows the result of such transfer translations.

| Port size PS[1:0] | Transfer size FB_TSIZ[1:0] | Burst-inhibited: Number of transfers<br>Burst enabled: Number of beats |
|---|---|---|
| 01b (8 bit) | 10b (16 bits) | 2 |
| | 00b (32 bits) | 4 |
| | 11b (16 bytes) | 16 |
| 1Xb (16 bit) | 00b (32 bits) | 2 |
| | 11b (16 bytes) | 8 |
| 00b (32 bit) | 11b (line) | 4 |

The FlexBus can support X-1-1-1 burst cycles to maximize system performance, where X is the primary number of wait states (max 63). Delaying termination of the cycle can add wait states. If internal termination is used, different wait state counters can be used for the first access and the following beats.

### 20.5.13.3 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

The following figure shows a 32-bit read to an 8-bit external chip programmed for burst enable. The transfer results in a 4-beat burst and the data is driven on FB_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

**Note**

- In **non-multiplexed address/data mode:** the address on FB_A increments only during internally-terminated burst

cycles. The first address is driven throughout the entire burst for externally-terminated cycles.

- In **multiplexed address/data mode:** the address is driven on FB_AD only during the first cycle for all terminated cycles. In other words, the lower address lines only increment during internally-terminated burst cycles (assuming that the lower address lines are being driven with the address during the data phase).

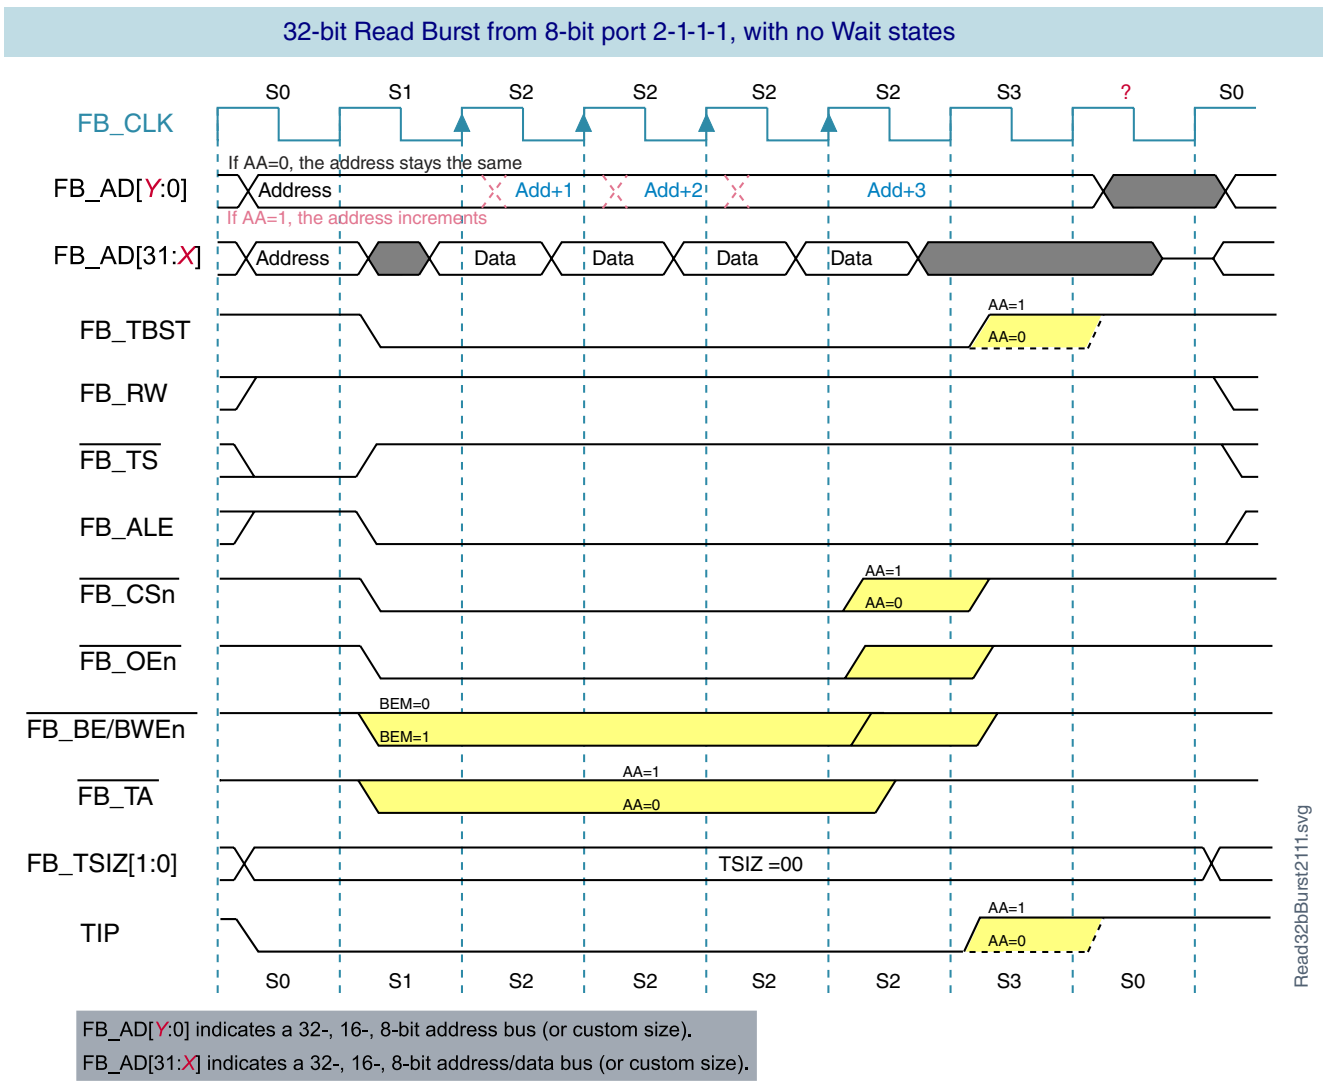

**Figure 20-27. 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)**

### 20.5.13.4 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

The following figure shows a 32-bit write to an 8-bit external chip with burst enabled. The transfer results in a 4-beat burst and the data is driven on FB_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

**Note**

The first beat of any write burst cycle has at least one wait state. If the bus cycle is programmed for zero wait states (CSCRn[WS] = 0b), one wait state is added. Otherwise, the programmed number of wait states are used.

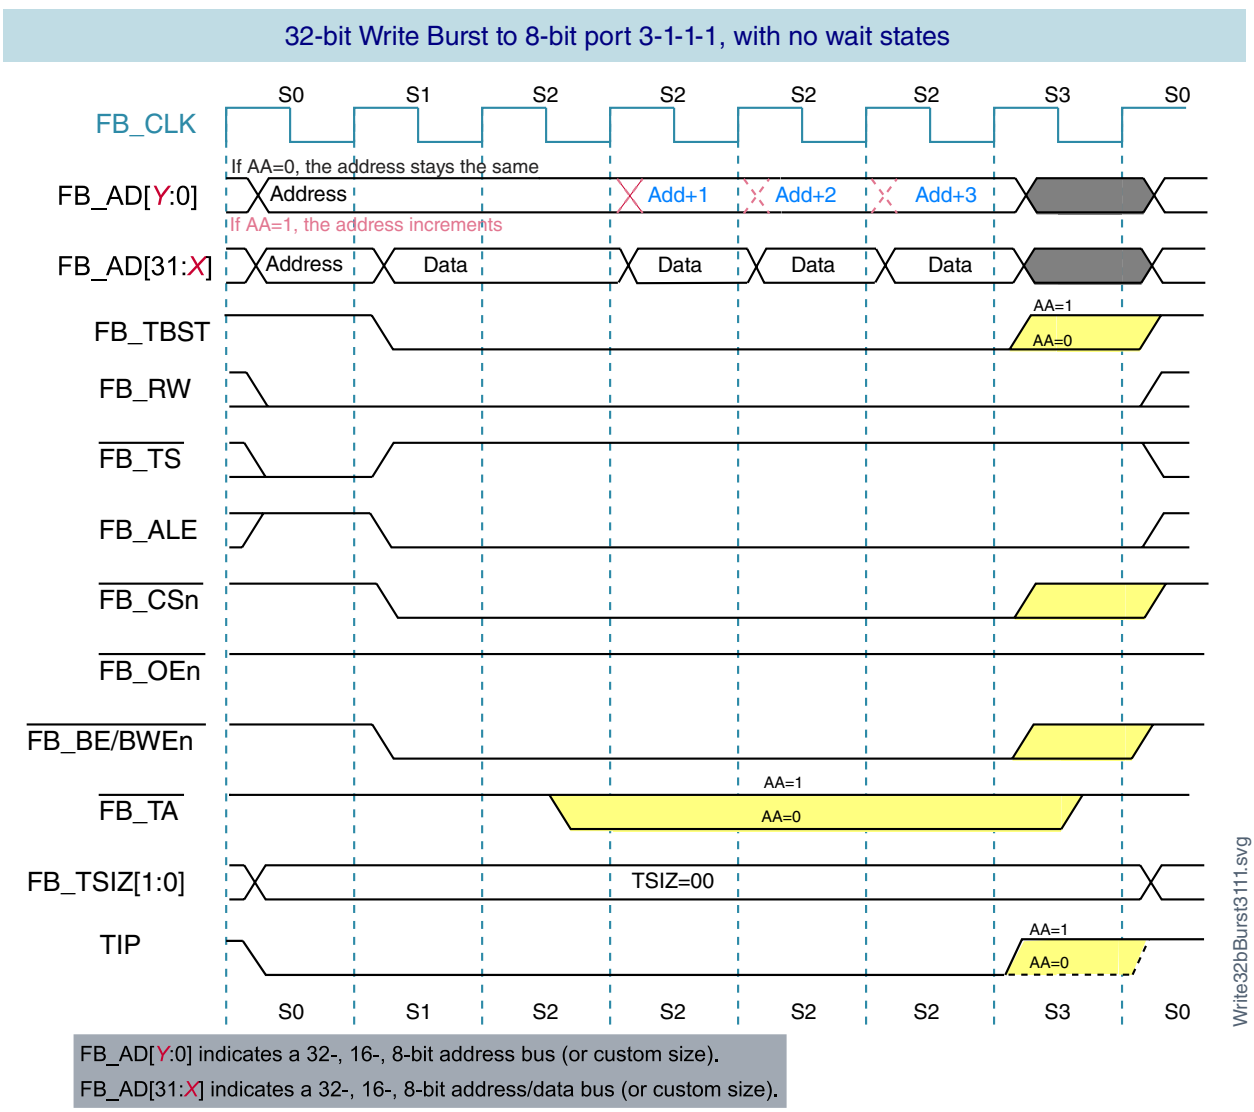

**Figure 20-28. 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)**

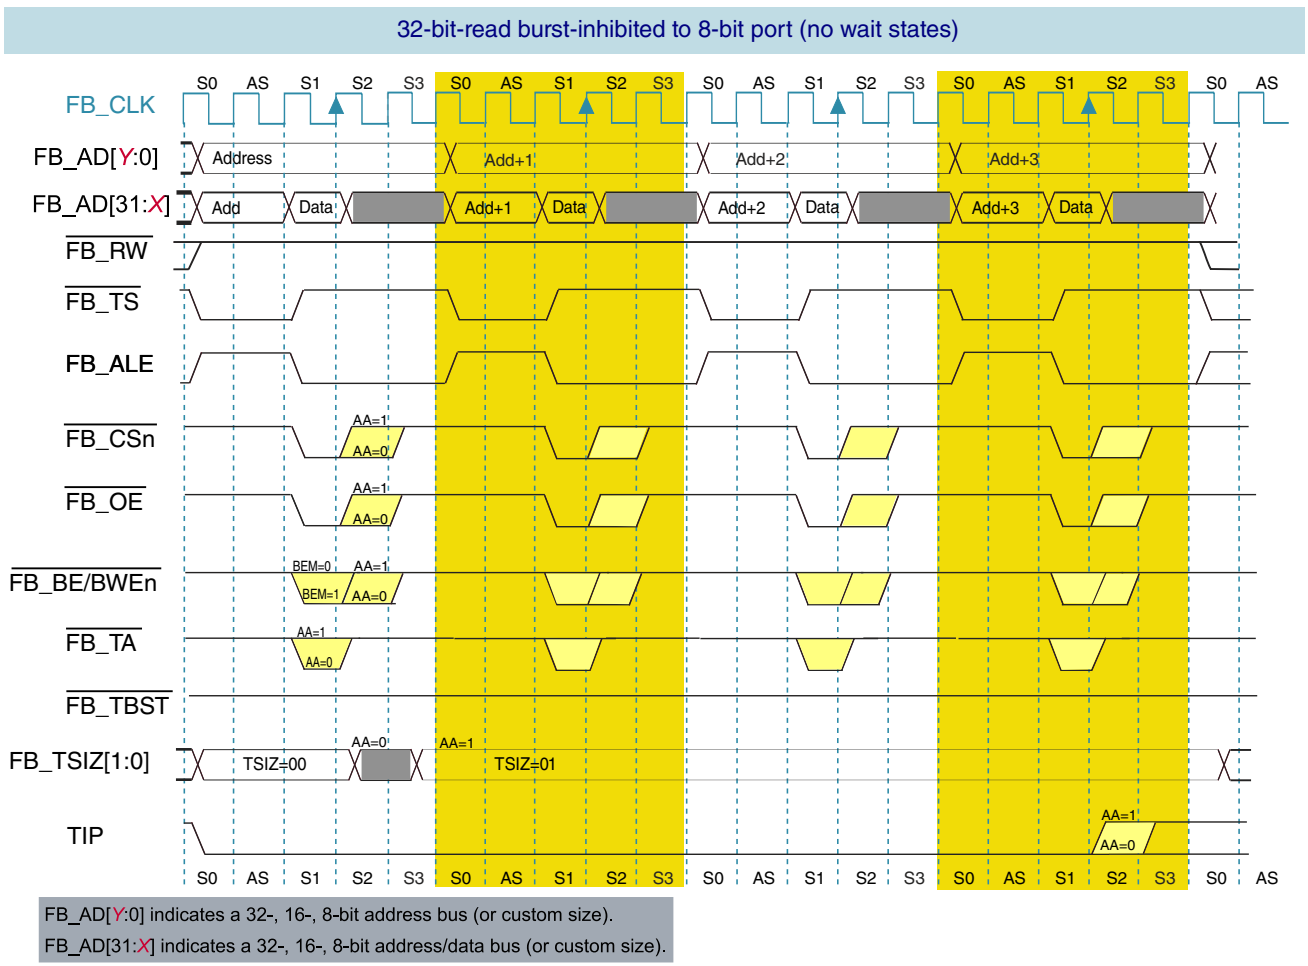
### 20.5.13.5 32-bit-read burst-inhibited from 8-bit port (no wait states)

The following figure shows a 32-bit read from an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

**Note**

There is an extra clock of address setup (AS) for each burst-inhibited transfer between states S0 and S1.



### 20.5.13.6 32-bit-write burst-inhibited to 8-bit port (no wait states)

The following figure shows a 32-bit write to an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

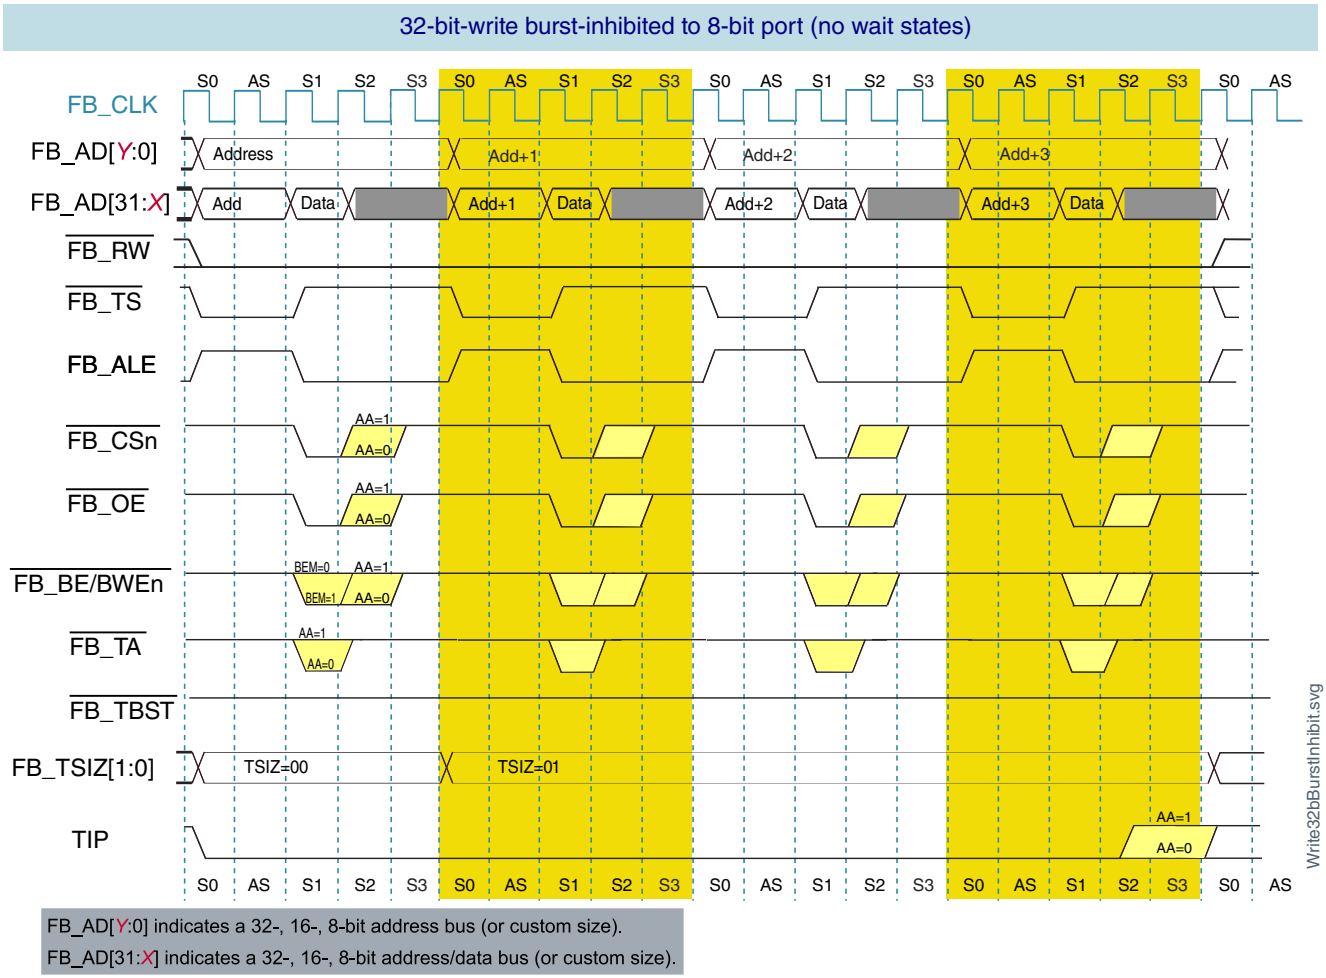


**Figure 20-29. 32-bit-write burst-inhibited to 8-bit port (no wait states)**

## 20.5.13.7 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates another read burst transfer, but in this case a wait state is added between individual beats.

### Note

CSCRn[WS] determines the number of wait states in the first beat. However, for subsequent beats, the CSCRn[WS] (or CSCRn[SWS] if CSCRn[SWSEN] = 1b) determines the number of wait states.

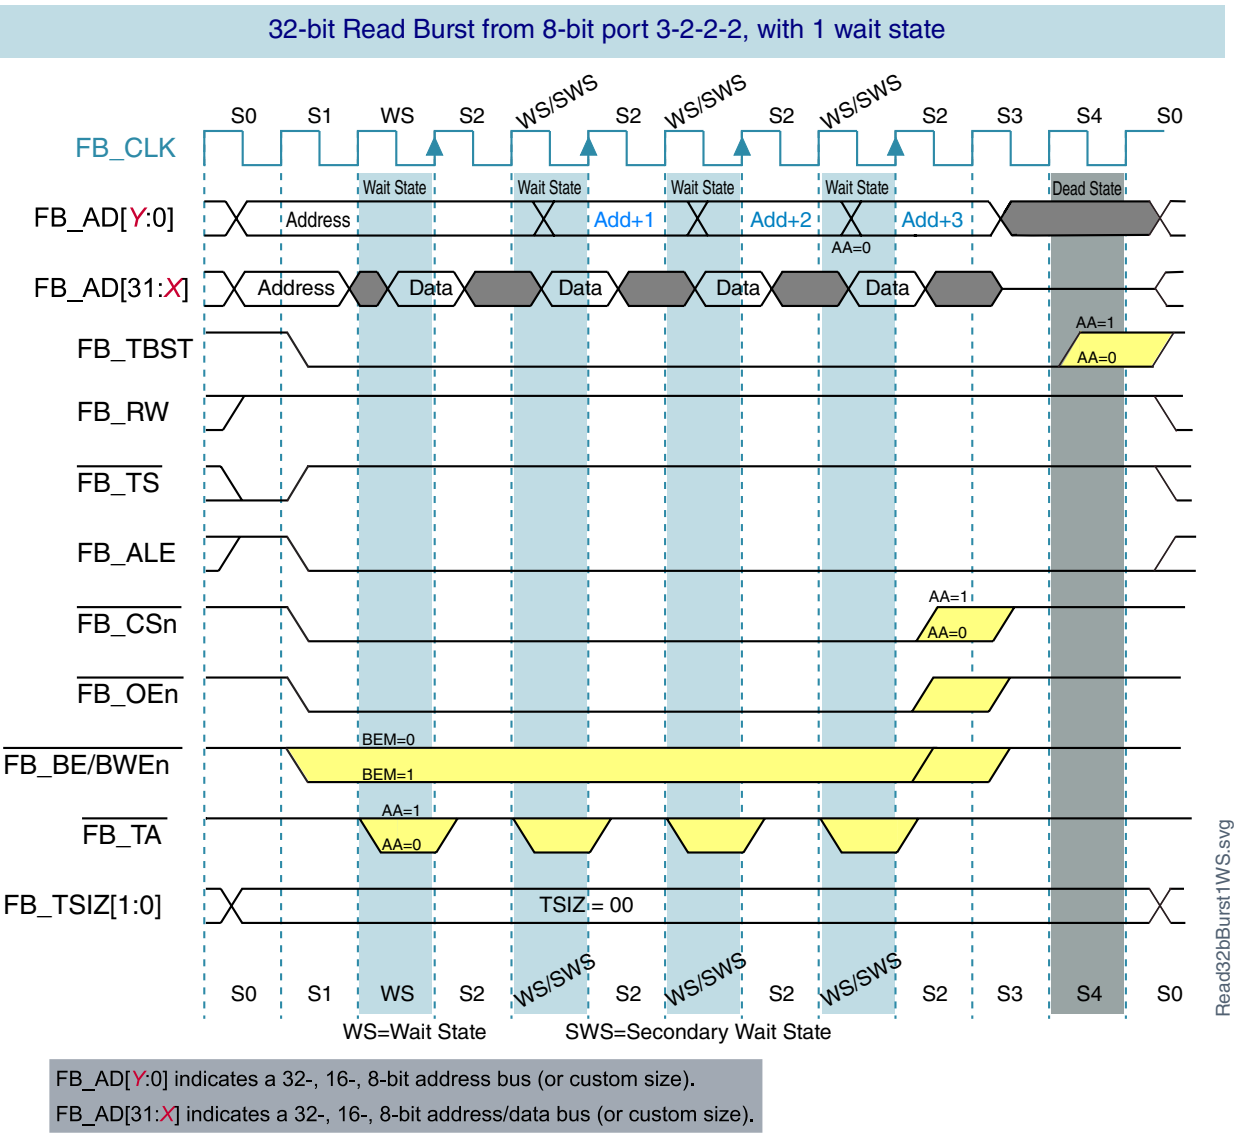

**Figure 20-30. 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)**

## 20.5.13.8 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates a write burst transfer with one wait state.

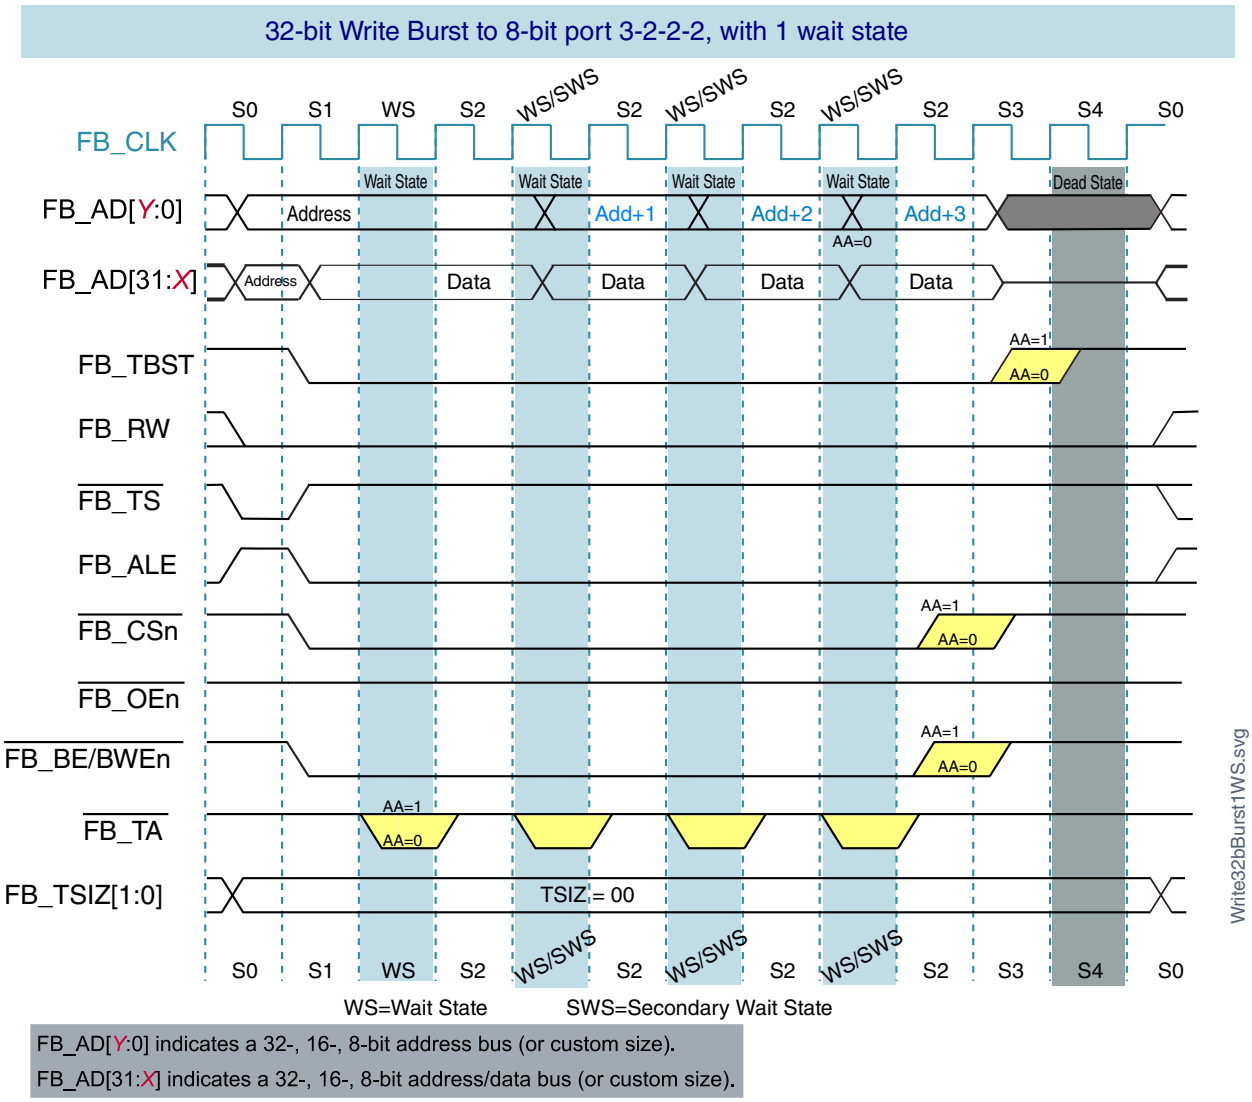

**Figure 20-31. 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)**

## 20.5.13.9 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

If address setup and hold are used, only the first and last beat of the burst cycle are affected. The following figure shows a read cycle with one clock of address setup and address hold.

### Note

- In **non-multiplexed address/data mode:** the address on FB_A increments only during internally-terminated burst cycles (CSCRn[AA] = 1b). The attached device must be able to account for this, or a wait state must be added. The

first address is driven throughout the entire burst for externally-terminated cycles.

- In **multiplexed address/data mode:** the address is driven on FB_AD only during the first cycle for internally- and externally-terminated cycles.

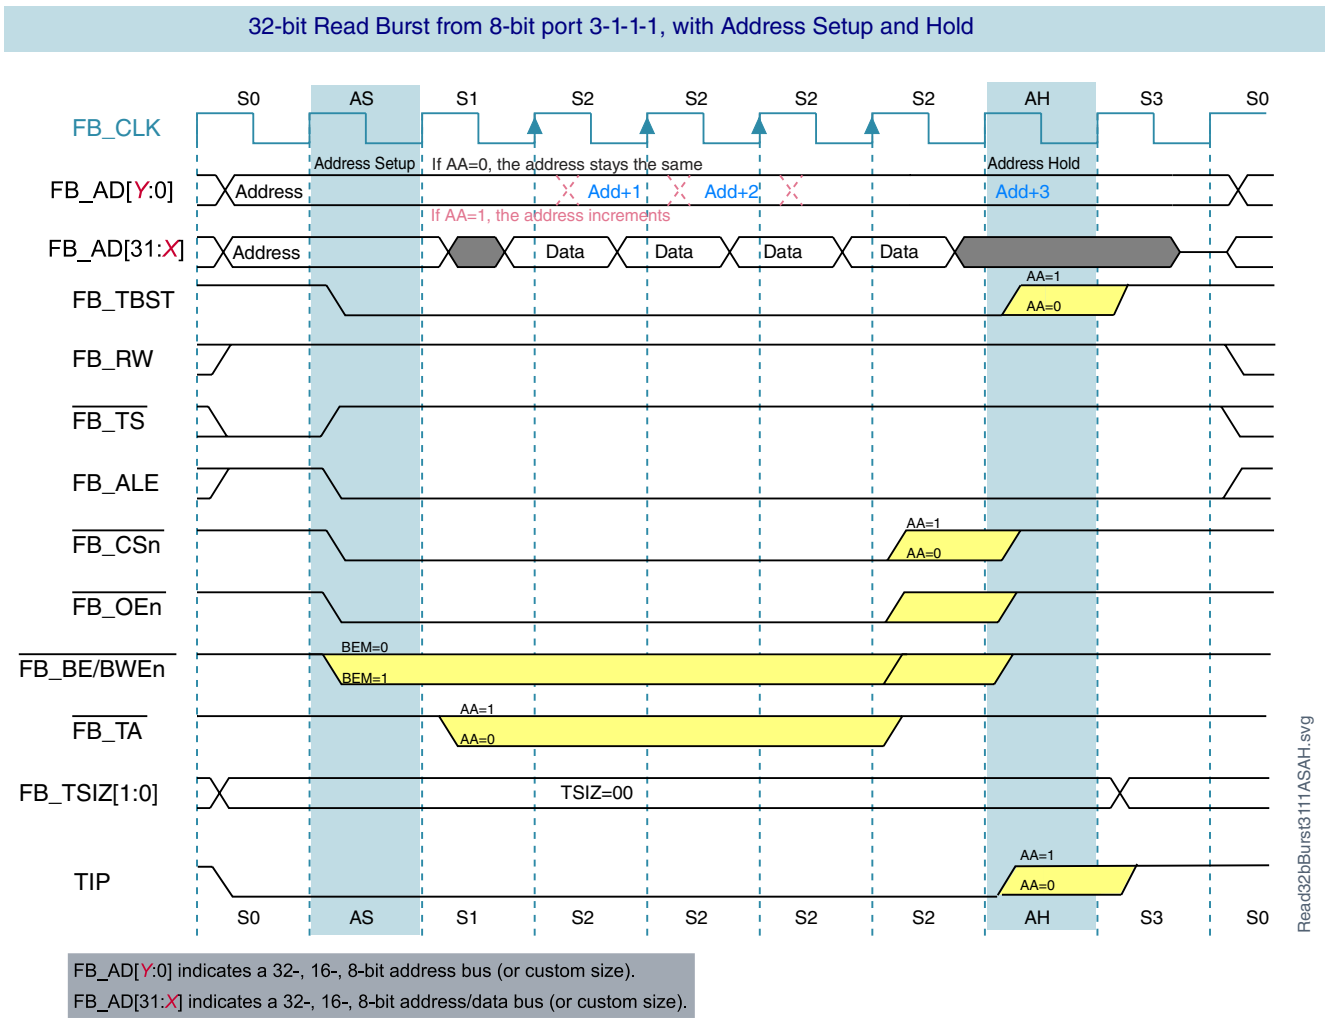

**Figure 20-32. 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)**

## 20.5.13.10 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

The following figure shows a write cycle with one clock of address setup and address hold.

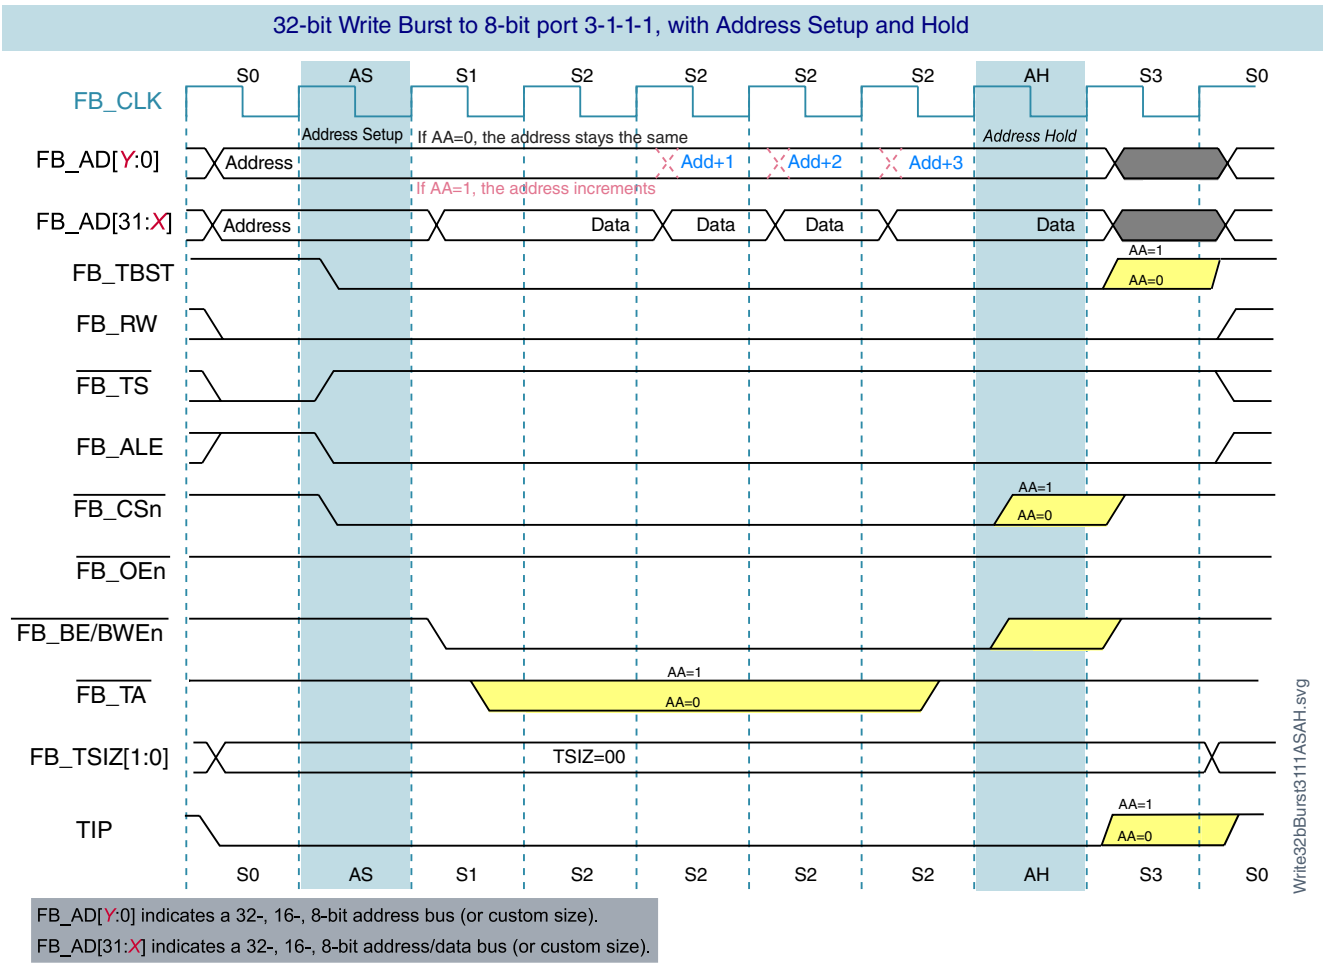

**Figure 20-33. 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)**

## 20.5.14 Misaligned operands

A data operand can reside in memory at any address; however, the transfer requires additional bus cycles if the data operand is misaligned. An operand is misaligned depending on the operand size and address as follows:

- A byte operand is never misaligned (it is aligned at any address)
- A 16-bit operand is misaligned at odd addresses
- A 32-bit operand is misaligned at any address that is not a multiple of four

### 20.5.14.1 Example: Aligned 32-bit transfer to a 32-bit port

This table shows an example of an *32-bit aligned* operand transfer from a longword address (or a byte address) to a 32-bit port. This example assumes CSCR[BLS] = 0.

| Transfer | Description | FB_D | | | | FB_A2–FB_A0 |
|---|---|---|---|---|---|---|
| | | 31–24 | 23–16 | 15–8 | 7–0 | |
| 1 | Byte 0, Byte 1, Byte 2, Byte 3 all transfer at an offset of 0h. | Byte 0 | Byte 1 | Byte 2 | Byte 3 | 001 |

### 20.5.14.2 Example: Misaligned 32-bit transfer to a 32-bit port

This table shows an example of a misaligned 32-bit access from a longword address (or a byte address) to a 32-bit port. This example assumes CSCR[BLS] = 0.

| Transfer | Description | FB_D | | | | FB_A2–FB_A0 |
|---|---|---|---|---|---|---|
| | | 31–24 | 23–16 | 15–8 | 7–0 | |
| 1 | Byte 0 transfers at an offset of 1h. | — | Byte 0 | — | — | 001 |
| 2 | A word (Byte 1 and Byte 2) transfers with an offset of 2h. | — | — | Byte 1 | Byte 2 | 010 |
| 3 | Byte 3 transfers with an offset of 0h and the transfer is complete. | Byte 3 | — | — | — | 100 |

FlexBus transfer sizes are 8, 16, or 32 bits (never 24 bits), which is why it needs to break this example into 3 transfers (8-bit, 16-bit, 8-bit), instead of 2 transfers (8-bit, 24-bit).

### 20.5.14.3 Example: Misaligned 16-bit transfer to a 32-bit port

This table shows an example of a misaligned 16-bit operand transfer from a byte address to a 32-bit port. This example assumes CSCR[BLS] = 0.

| Transfer | Description | FB_D | | | | FB_A2–FB_A0 |
|---|---|---|---|---|---|---|
| | | 31–24 | 23–16 | 15–8 | 7–0 | |
| 1 | Byte 0 transfers at an offset of 3h. | — | — | — | Byte 0 | 001 |
| 2 | Byte 1 transfers with an offset of 0h. | Byte 1 | — | — | — | 100 |

## 20.5.15 Extended Transfer Start/Address Latch Enable

The FB_TS_b/FB_ALE signal indicates that a bus transaction has begun and the address and attributes are valid. By default, the FB_TS_b/FB_ALE signal asserts for a single bus clock cycle. When CSCR*n*[EXTS] is set, the FB_TS_b/FB_ALE signal asserts and remain asserted until the first positive clock edge after FB_CS_b*n* asserts. See the following figure.

**NOTE**

When EXTS is set, CSCR*n*[WS] must be programmed to have at least one primary wait state.

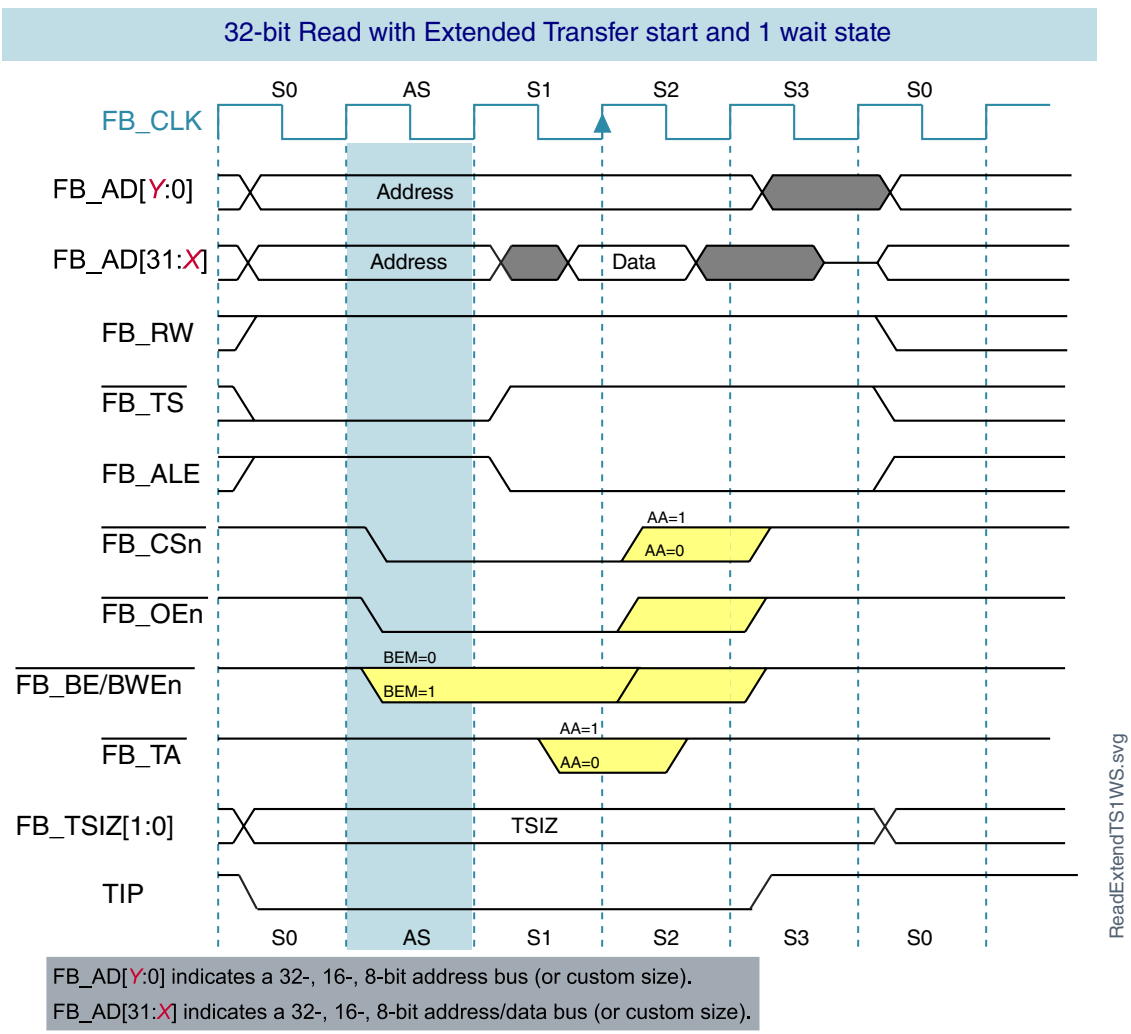

**Figure 20-34. Read-Bus Cycle with CSCR*n*[EXTS] = 1 (One Wait State)**

### 20.5.16 Bus errors

These types of accesses cause a transfer to terminate with a bus error:

- Any access when the clock to the module is disabled
- A write to a write-protected address range
- An access whose address is not in a range covered by a chip-select
- An access whose address is in a range covered by more than one chip-selects
- A write to a reserved address in the memory map
- A write to a reserved field in the CSPMCR
- Any FlexBus accesses when FlexBus is secure

If the auto-acknowledge feature is disabled (CSCR[AA] is 0) for an address that generates an error, then the transfer can be terminated by asserting FB_TA_b. If the processor must manage a bus error differently, then asserting an interrupt to the core along with FB_TA when the bus error occurs can invoke an interrupt handler.

The device can hang if FlexBus is configured for external termination and the CSPMCR is not configured for FB_TA.

## 20.6 Initialization/Application Information

### 20.6.1 Initializing a chip-select

Before using any other chip select, chip select 0 (CS0) should be initialized, to take it out of global chip select mode.

To initialize a chip-select:

1. Write to the associated CSAR.
2. Write to the associated CSCR.
3. Write to the associated CSMR, including writing "1b" to the Valid field (CSMRn[V]).

### 20.6.2 Reconfiguring a chip-select

To reconfigure a previously-used chip-select:

1. Invalidate the chip-select by writing 0b to the associated CSMR's Valid field (CSMRn[V]).
2. Write to the associated CSAR.

3. Write to the associated CSCR.
4. Write to the associated CSMR, including writing "1b" to the Valid field (CSMRn[V]).

# Chapter 21
# AHB Low Power Cache Controller (AHB_LPCAC)

## 21.1 Chip-specific LPCAC information

### 21.1.1 Cache controls

LPCAC is the cache for CM4 or RI5CY core. MCM0_CPCR2 register is used to clear and disable the LPCAC.

## 21.2 Introduction

The AHB Low Power Cache Controller (LPCAC) is a processor-local Level 1 (L1) bus cache (lpcac) controller for use with cores using AMBA-AHB input/output buses. It is optimized for minimum RunIDD (dynamic power).

### 21.2.1 Overview

The LPCAC has a 32-bit datapath AMBA-AHB input bus and a 32-bit datapath AMBA-AHB output bus. Internally, LPCAC decodes a cacheable region (with the cache region writethrough).

Any input AHB accesses with addresses that:

- hit the cache region, use a portion of the attached RAM as a cache; cache misses use the AHB output bus to fetch the miss data.
- miss the cache region, go to the AHB output bus.

## 21.3 Signal descriptions

The LPCAC has no external signals.

## 21.4 Memory map and Input Control description

### 21.4.1 Memory regions

The LPCAC decodes cacheable address regions.

- The cache memory region may be composed of one or more disjoint memory regions and the total size may be larger than the cache storage.

Any address not in the cacheable memory regions is in the pass-through memory region. All accesses to the pass-through memory regions are non-cacheable. For all access to the cacheable memory regions, the accesses is cacheable if the attributes of the access indicate it can be cached, else it is non-cacheable.

See the System Memory Map for cache memory range information.

### 21.4.2 Input controls

The LPCAC does not have a module-resident programming model. An external block supplies the needed LPCAC control inputs.

**Table 21-1. Control inputs for LPCAC**

| Function | Control input | Description |
|---|---|---|
| clear lpcac | clr_lpcac | One cycle active-high pulse clears the lpcac. |
| disable lpcac | dis_lpcac | • 0 = lpcac enabled (reset configuration)<br>• 1 = lpcac disabled, all cacheable accesses pass from LPCAC input to output bus |
| ignore CACHE_MAP | mode_ctl_hprot | • 0 = use LPCAC Memory Regions to determine if a access to a given address may be cached. Then, if the attributes of the access indicate it can be cached, the access is cached.<br>• 1 = Use only the attributes of the access to indicate it can be cached. |

## 21.5 Functional description

This section provides further information on the LPCAC operation.

The LPCAC is cleared and enabled by a reset.

The LPCAC examines every valid AHB input access. If the access hits the cache memory region and the cache is enabled, the access goes to the cache portion of the LPCAC. If the access does not go to the cache, the access is passed directly to the AHB output bus.

The LPCAC cache has a 4 word (128-bit) cache line size:

- Byte, half-word, or word read cache misses do an aligned 4 word-size cache miss read to the LPCAC AHB output bus then load the needed data in the cache. The cache miss uses a 4 beat, 32-bit per beat, wrapped burst bus access to fetch the cache miss data.
- Read cache hits return the desired read data from the cache.
- Byte, half-word, or word write cache misses do the desired write operation only to the LPCAC AHB output bus (writethrough mode has a no cache allocation on write miss policy).
- Byte, half-word, or word write cache hits do the desired write operation to the cache and to the LPCAC AHB output bus.

### 21.5.1 Cache Functional description

The LPCAC cache is an 8-way, 2-set-associative write-through design. It supports total cache capacities of 4 KB for a 32-bit wide cache miss datapath.

#### 21.5.1.1 Cache controls

The cache control inputs are as follows:

- clr_lpcac: clear lpcac
- dis_lpcac: disable lpcac
- mode_ctl_hprot: ignore LPCAC Memory Regions

See Input controls for more information.

# Chapter 22
# AHB Low Power Local Memory Controller (AHB_LPLMEM)

## 22.1 Chip-specific LPLMEM information

### 22.1.1 Cache controls

LPLMEM is the cache for CM0+ or ZERO-RISCY core. MCM1_CPCR2 register is used to clear and disable the LPLMEM.

## 22.2 Introduction

The AHB Low Power Local Memory (LPLMEM) Controller is a processor-local Level 1 (L1) bus cache (bcache) controller for use with cores using AMBA-AHB input/output buses. It is optimized for minimum RunIDD (dynamic power).

### 22.2.1 Overview

The LPLMEM has a 32-bit datapath AMBA-AHB input bus and a 32-bit datapath AMBA-AHB output bus. Internally, LPLMEM decodes a cacheable region (with the cache region writethrough).

Any input AHB accesses with addresses that

- hit the cache region, use a portion of the attached RAM as a cache; cache misses use the AHB output bus to fetch the miss data.
- miss the cache region, go to the AHB output bus.

There are also a small number of control inputs (cache enable and cache clear control).

## 22.3 Signal descriptions

The LPLMEM has no external signals.

## 22.4 Memory map and Input Control description

### 22.4.1 Memory regions

The LPLMEM decodes cacheable address regions.

- The cache memory region may be composed of one or more disjoint memory regions and the total size may be larger than the cache storage.

Any address not in the cacheable memory regions is in the pass-through memory region.

### 22.4.2 Input controls

The LPLMEM does not have a module-resident programming model. An external block supplies the needed LPLMEM control inputs.

**Table 22-1. Control inputs for LPLMEM**

| Function | Control input | Description |
|---|---|---|
| clear bcache | clr_bcache | One cycle active-high pulse clears the bcache. |
| disable bcache | dis_bcache | • 0 = bcache enabled (reset configuration)<br>• 1 = bcache disabled, all cacheable accesses pass from LPLMEM input to output bus |

## 22.5 Functional description

This section provides further information on the LPLMEM operation.

The LPLMEM is cleared and enabled by a reset.

The LPLMEM examines every valid AHB input access. If the access hits the cache memory region and the cache is enabled, the access goes to the cache portion of the LPLMEM. If the access does not go to the cache, the access is passed directly to the AHB output bus.

The LPLMEM cache has a word (32-bit) cache line size:

- Byte, half-word, or word read cache misses do an aligned word-size cache miss read to the LPLMEM AHB output bus then load the needed data in the cache.
- Read cache hits return the desired read data from the cache.
- Byte, half-word, or word write cache misses do the desired write operation only to the LPLMEM AHB output bus (writethrough mode has a no cache allocation on write miss policy).
- Byte, half-word, or word write cache hits do the desired write operation to the cache and to the LPLMEM AHB output bus.

## 22.5.1 Cache Functional description

The LPLMEM cache is an 8-way, 2-set-associative write-through design. It supports total cache capacities of 4 KB for a 32-bit wide cache miss datapath.

### 22.5.1.1 Cache controls

There are 2 cache control inputs:

- clr_bcache: clear bcache
- dis_bcache: disable bcache

# Chapter 23
# Signal Multiplexing and Signal Descriptions

## 23.1 Signal Multiplexing Introduction

To optimize functionality in small packages, pins have several functions available via signal multiplexing. This chapter illustrates which of this device's signals are multiplexed on which external pin.

The Port Control block controls which signal is present on the external pin. Reference that chapter to find which register controls the operation of a specific pin.

## 23.2 Clock gating

The clock to the port control module can be gated on and off using the SCGC5[PORTx] bits in the SIM module. These bits are cleared after any reset, which disables the clock to the corresponding module to conserve power. Prior to initializing the corresponding module, set SCGC5[PORTx] in the SIM module to enable the clock. Before turning off the clock, make sure to disable the module. For more details, refer to the clock distribution chapter.

## 23.4 Module Signal Description Tables

The following sections correlate the chip-level signal name with the signal name used in the module's chapter. They also briefly describe the signal function and direction.

### 23.4.1 Core Modules

**Table 23-2. JTAG ARM Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| JTAG_TMS | TMS | Test Mode Select | Input |
| JTAG_TCLK | TCK | Test Clock | Input |
| JTAG_TDI | TDI | Test Data In | Input |
| JTAG_TDO | TDO | Test Data Out | Output |

**Table 23-3. RISC-V core JTAG Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| RV_JTAG_TMS | TMS | Test Mode Select | Input |
| RV_JTAG_TCLK | TCK | Test Clock | Input |
| RV_JTAG_TDI | TDI | Test Data In | Input |
| RV_JTAG_TDO | TDO | Test Data Out | Output |

**Table 23-4. SWD Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| SWD_DIO | SWD_DIO | Serial Wire Data Input/Output. The SWD_DIO pin is used by an external debug tool for communication and device control. This pin is pulled up internally. | Input / Output |
| SWD_CLK | SWD_CLK | Serial Wire Clock. This pin is the clock for debug logic when in the Serial Wire Debug mode. This pin is pulled down internally. | Input |
| SWD_SWO | SWD_SWO | Trace output over a single pin | Output |

**Table 23-5. TPIU Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| TRACE_CLKOUT | TRACECLK | Trace clock output from the ARM CoreSight debug block | O |
| TRACE_D[3:2] | TRACEDATA | Trace output data from the ARM CoreSight debug block used for 5-pin interface | O |
| TRACE_D[1:0] | TRACEDATA | Trace output data from the ARM CoreSight debug block used for both 5-pin and 3-pin interfaces | O |

## 23.4.2 System Modules

**Table 23-6. System Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| NMI_b | — | Non-maskable interrupt<br>**NOTE:** Driving the $\overline{\text{NMI}}$ signal low forces a non-maskable interrupt, if the $\overline{\text{NMI}}$ function is selected on the corresponding pin. | I |
| RESET_b | — | Reset bi-directional signal | I/O |
| VDD_CORE | — | MCU power | I |
| VDDIO1 | — | I/O rings power | I |
| VDDIO2 | — | I/O rings power | I |

*Table continues on the next page...*

**Table 23-6. System Signal Descriptions (continued)**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| VDD_RF | — | Radio power supply | I |
| VSS | — | MCU ground | I |
| VSSA | — | Analog ground | I |

**Table 23-7. EWM Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| EWM_IN | EWM_in | EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low. | I |
| EWM_OUT_b | $\overline{\text{EWM_out}}$ | EWM reset out signal | O |

**Table 23-8. LLWU0 Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LLWU_Pn (n=[31:0] | LLWU_Pn (n=[31:0] | External Pin Wakeup inputs | I |

## 23.4.3 Memories and Memory Interfaces

**Table 23-9. FlexBus Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| FB_CLKOUT | FB_CLK | FlexBus Clock Output | O |
| FB_A[23:16] | FB_A[23:16] | This is the address and data bus | I/O |
| FB_AD[31:0] | FB_ADn | This is the address and data bus, FB_AD.<br>The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select.<br>The full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0. | I/O |
| FB_CSn_b (n=[5:0]) | $\overline{\text{FB_CS}}$n (n=[5:0]) | General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM]. | O |

*Table continues on the next page...*

**Table 23-9. FlexBus Signal Descriptions (continued)**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| FB_BE31_24_b<br>FB_BE23_16_b<br>FB_BE15_8_b<br>FB_BE7_0_b | FB_BE_31_24,<br>FB_BE_23_16,<br>FB_BE_15_8,<br>FB_BE_7_0 | Byte Enables—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only.<br>For external SRAM or flash devices, the FB_BE outputs should be connected to individual byte strobe signals. | O |
| FB_OE_b | FB_OE | Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode. | O |
| FB_RW_b | FB_RW | Read/Write—Indicates whether the current bus operation is a read operation (FB_R/W high) or a write operation (FB_R/W low). | O |
| FB_TS_b | FB_TS | Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid. | O |
| FB_ALE | FB_ALE | Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of FB_TS). | O |
| FB_TSIZn (n=[1:0]) | FB_TSIZn (n=[1:0]) | Transfer Size—Indicates (along with FB_TBST) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports. | O |
| FB_TA_b | FB_TA | Transfer Acknowledge—Indicates that the external data transfer is complete. When FB_TA is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When FB_TA is asserted during a write transfer, the transfer is terminated. | I |
| FB_TBST_b | FB_TBST | Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size. | O |

## 23.4.4 Clock Modules

**Table 23-10. RTC OSC Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| EXTAL32 | EXTAL32 | 32.768 kHz oscillator input | I |
| XTAL32 | XTAL32 | 32.768 kHz oscillator output | O |

**Table 23-11. Radio OSC Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| XTAL_RF | RF XTAL | 26 or 32 MHz oscillator output | O |
| EXTAL_RF | RF EXTAL | 26 or 32 MHz oscillator input | I |

*Table continues on the next page...*

**Table 23-11. Radio OSC Signal Descriptions (continued)**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| RF0_EXT_OSC_EN | RF_EXT_OSC_EN | Internal request to turn on an External Osc for use by the internal Radio, this can also be a request from the SoC if it is using the RF Osc as it's clock. | O |
| RF0_RFOSC_EN | RF_INT_OSC_EN | External request to turn on the Radio's internal RF Osc. The Osc will be present on the XTAL_OUT pin if the RF Osc XTAL_OUT buffer is enabled by writing the Radio XTAL_OUT_BUF_EN bit in the RSIM ANA_TEST register. | I |
| RF_CLKOUT | XTAL_OUT | 26 MHz/32 MHz reference clock output | O |

## 23.4.5 Communication Interfaces

**Table 23-12. EMVSIM Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| EMVSIM0_CLK | EMVSIM_SCLK | Card Clock. Clock to Smart Card. | O |
| EMVSIM0_RST | EMVSIM_SRST | Card Reset. Reset signal to Smart Card | O |
| EMVSIM0_VCCEN | EMVSIM_VCC_EN | Card Power Enable. This signal controls the power to Smart Card | O |
| EMVSIM0_IO | EMVSIM_IO | Card Data Line. Bi-directional data line. | I/O |
| EMVSIM0_PD | EMVSIM_PD | Card Presence Detect. Signal indicating presence or removal of card | I |

**Table 23-13. USB FS Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| USB0_DM | usb_dm | USB D- analog data signal on the USB bus. | I/O |
| USB0_DP | usb_dp | USB D+ analog data signal on the USB bus. | I/O |
| USB_SOF_OUT | — | USB start of frame signal. Can be used to make the USB start of frame available for external synchronization. | O |
| USB0_VSS | — | $V_{SS}$ for USB0 | — |

**Table 23-14. USB VREG Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| VOUT33 | reg33_out | Regulator output voltage | O |
| VREGIN | vreg_in1 | Unregulated power supply | I |

## Table 23-15. LPSPI0 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| SPI0_SCK | SCK | Serial clock. Input in slave mode, output in master mode. | I/O |
| SPI0_PCS0 | PCS[0] | Peripheral Chip Select. Input in slave mode, output in master mode. | I/O |
| SPI0_PCS1 | PCS[1] | Peripheral Chip Select or Host Request. Host Request pin is selected when HREN=1 and HRSEL=0. Input in either slave mode or when used as Host Request, output in master mode. | I/O |
| SPI0_PCS2 | PCS[2] | Peripheral Chip Select or data pin 2 during quad-data transfers. Input in slave mode, output in master mode, input in quad-data receive transfers, output in quad-data transmit transfers. | I/O |
| SPI0_PCS3 | PCS[3] | Peripheral Chip Select or data pin 3 during quad-data transfers. Input in slave mode, output in master mode, input in quad-data receive transfers, output in quad-data transmit transfers. | I/O |
| SPI0_SOUT | SOUT | Serial Data Output. Can be configured as serial data input signal. Used as data pin 0 in quad-data and dual-data transfers. | I/O |
| SPI0_SIN | SIN | Serial Data Input. Can be configured as serial data output signal. Used as data pin 1 in quad-data and dual-data transfers. | I/O |

## Table 23-16. LPSPI1 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| SPI1_SCK | SCK | Serial clock. Input in slave mode, output in master mode. | I/O |
| SPI1_PCS0 | PCS[0] | Peripheral Chip Select. Input in slave mode, output in master mode. | I/O |
| SPI1_PCS1 | PCS[1] | Peripheral Chip Select or Host Request. Host Request pin is selected when HREN=1 and HRSEL=0. Input in either slave mode or when used as Host Request, output in master mode. | I/O |
| SPI1_PCS2 | PCS[2] | Peripheral Chip Select or data pin 2 during quad-data transfers. Input in slave mode, output in master mode, input in quad-data receive transfers, output in quad-data transmit transfers. | I/O |
| SPI1_PCS3 | PCS[3] | Peripheral Chip Select or data pin 3 during quad-data transfers. Input in slave mode, output in master mode, input in quad-data receive transfers, output in quad-data transmit transfers. | I/O |
| SPI1_SOUT | SOUT | Serial Data Output. Can be configured as serial data input signal. Used as data pin 0 in quad-data and dual-data transfers. | I/O |
| SPI1_SIN | SIN | Serial Data Input. Can be configured as serial data output signal. Used as data pin 1 in quad-data and dual-data transfers. | I/O |

## Table 23-17. LPSPI2 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| SPI2_SCK | SCK | Serial clock. Input in slave mode, output in master mode. | I/O |
| SPI2_PCS0 | PCS[0] | Peripheral Chip Select. Input in slave mode, output in master mode. | I/O |

*Table continues on the next page...*

## Table 23-17. LPSPI2 Signal Descriptions (continued)

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| SPI2_PCS1 | PCS[1] | Peripheral Chip Select or Host Request. Host Request pin is selected when HREN=1 and HRSEL=0. Input in either slave mode or when used as Host Request, output in master mode. | I/O |
| SPI2_PCS2 | PCS[2] | Peripheral Chip Select or data pin 2 during quad-data transfers. Input in slave mode, output in master mode, input in quad-data receive transfers, output in quad-data transmit transfers. | I/O |
| SPI2_PCS3 | PCS[3] | Peripheral Chip Select or data pin 3 during quad-data transfers. Input in slave mode, output in master mode, input in quad-data receive transfers, output in quad-data transmit transfers. | I/O |
| SPI2_SOUT | SOUT | Serial Data Output. Can be configured as serial data input signal. Used as data pin 0 in quad-data and dual-data transfers. | I/O |
| SPI2_SIN | SIN | Serial Data Input. Can be configured as serial data output signal. Used as data pin 1 in quad-data and dual-data transfers. | I/O |

## Table 23-18. LPSPI3 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| SPI3_SCK | SCK | Serial clock. Input in slave mode, output in master mode. | I/O |
| SPI3_PCS0 | PCS[0] | Peripheral Chip Select. Input in slave mode, output in master mode. | I/O |
| SPI3_PCS1 | PCS[1] | Peripheral Chip Select or Host Request. Host Request pin is selected when HREN=1 and HRSEL=0. Input in either slave mode or when used as Host Request, output in master mode. | I/O |
| SPI3_PCS2 | PCS[2] | Peripheral Chip Select or data pin 2 during quad-data transfers. Input in slave mode, output in master mode, input in quad-data receive transfers, output in quad-data transmit transfers. | I/O |
| SPI3_PCS3 | PCS[3] | Peripheral Chip Select or data pin 3 during quad-data transfers. Input in slave mode, output in master mode, input in quad-data receive transfers, output in quad-data transmit transfers. | I/O |
| SPI3_SOUT | SOUT | Serial Data Output. Can be configured as serial data input signal. Used as data pin 0 in quad-data and dual-data transfers. | I/O |
| SPI3_SIN | SIN | Serial Data Input. Can be configured as serial data output signal. Used as data pin 1 in quad-data and dual-data transfers. | I/O |

## Table 23-19. LPI2C0 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| I2C0_SCL | SCL | LPI2C clock line. In 4-wire mode, this is the SCL input pin. | I/O |
| I2C0_SDA | SDA | LPI2C data line. In 4-wire mode, this is the SDA input pin. | I/O |
| LPI2C0_HREQ | HREQ | Host request, can initiate an LPI2C master transfer if asserted and the I2C bus is idle. | I |

*Table continues on the next page...*

## Table 23-19. LPI2C0 Signal Descriptions (continued)

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPI2C0_SCLS | SCLS | Secondary I2C clock line. In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, this the LPI2C slave SCL pin. | I/O |
| LPI2C0_SDAS | SDAS | Secondary I2C data line. In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, this the LPI2C slave SDA pin. | I/O |

## Table 23-20. LPI2C1 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| I2C1_SCL | SCL | LPI2C clock line. In 4-wire mode, this is the SCL input pin. | I/O |
| I2C1_SDA | SDA | LPI2C data line. In 4-wire mode, this is the SDA input pin. | I/O |
| LPI2C1_HREQ | HREQ | Host request, can initiate an LPI2C master transfer if asserted and the I2C bus is idle. | I |
| LPI2C1_SCLS | SCLS | Secondary I2C clock line. In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, this the LPI2C slave SCL pin. | I/O |
| LPI2C1_SDAS | SDAS | Secondary I2C data line. In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, this the LPI2C slave SDA pin. | I/O |

## Table 23-21. LPI2C2 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| I2C2_SCL | SCL | LPI2C clock line. In 4-wire mode, this is the SCL input pin. | I/O |
| I2C2_SDA | SDA | LPI2C data line. In 4-wire mode, this is the SDA input pin. | I/O |
| LPI2C2_HREQ | HREQ | Host request, can initiate an LPI2C master transfer if asserted and the I2C bus is idle. | I |
| LPI2C2_SCLS | SCLS | Secondary I2C clock line. In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, this the LPI2C slave SCL pin. | I/O |
| LPI2C2_SDAS | SDAS | Secondary I2C data line. In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, this the LPI2C slave SDA pin. | I/O |

## Table 23-22. LPI2C3 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| I2C3_SCL | SCL | LPI2C clock line. In 4-wire mode, this is the SCL input pin. | I/O |
| I2C3_SDA | SDA | LPI2C data line. In 4-wire mode, this is the SDA input pin. | I/O |

*Table continues on the next page...*

## Table 23-22. LPI2C3 Signal Descriptions (continued)

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPI2C3_HREQ | HREQ | Host request, can initiate an LPI2C master transfer if asserted and the I2C bus is idle. | I |
| LPI2C3_SCLS | SCLS | Secondary I2C clock line. In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, this the LPI2C slave SCL pin. | I/O |
| LPI2C3_SDAS | SDAS | Secondary I2C data line. In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, this the LPI2C slave SDA pin. | I/O |

## Table 23-23. LPUART0 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPUART0_CTS | CTS | Clear to Send. | I |
| LPUART0_RTS | RTS | Request to send. | O |
| LPUART0_TX | TXD | Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data. | I/O |
| LPUART0_RX | RXD | Receive data. | I |

## Table 23-24. LPUART1 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPUART1_CTS | CTS | Clear to Send. | I |
| LPUART1_RTS | RTS | Request to send. | O |
| LPUART1_TX | TXD | Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data. | I/O |
| LPUART1_RX | RXD | Receive data. | I |

## Table 23-25. LPUART2 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPUART2_CTS | CTS | Clear to Send. | I |
| LPUART2_RTS | RTS | Request to send. | O |
| LPUART2_TX | TXD | Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data. | I/O |
| LPUART2_RX | RXD | Receive data. | I |

## Table 23-26. LPUART3 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPUART3_CTS | CTS | Clear to Send. | I |
| LPUART3_RTS | RTS | Request to send. | O |
| LPUART3_TX | TXD | Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data. | I/O |
| LPUART3_RX | RXD | Receive data. | I |

## Table 23-27. SDHC Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| SDHC0_DCLK | CLK | Clock for MMC/SD/SDIO card | O |
| SDHC0_CMD | CMD | CMD line connect to card | I/O |
| SDHC0_D0 | DAT0 | DAT0 line in all modes. Also used to detect busy state | I/O |
| SDHC0_D1 | DAT1 | DAT1 line in 4/8-bit mode.Also used to detect interrupt in 1/4-bit mode | I/O |
| SDHC0_D2 | DAT2 | DAT2 line or Read Wait in 4-bit mode. Read Wait in 1-bit mode | I/O |
| SDHC0_D3 | DAT3 | DAT3 line in 4/8-bit mode or configured as card detection pin. May be configured as card detection pin in 1-bit mode | I/O |
| SDHC0_D4 | DAT4 | DAT4 line in 8-bit mode. Not used in other modes | I/O |
| SDHC0_D5 | DAT5 | DAT5 line in 8-bit mode. Not used in other modes | I/O |
| SDHC0_D6 | DAT6 | DAT6 line in 8-bit mode. Not used in other modes | I/O |
| SDHC0_D7 | DATA7 | DAT7 line in 8-bit mode.Not used in other modes | I/O |

## Table 23-28. $I^2S0$ Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| I2S0_TX_BCLK | SAI_TX_BCLK | Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated. | I/O |
| I2S0_TX_FS | SAI_TX_SYNC | Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated. | I/O |
| I2S0_TX_Dn n=[1:0] | SAI_TX_DATA[1:0] | Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word. | O |
| I2S0_RX_BCLK | SAI_RX_BCLK | Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated. | I/O |
| I2S0_RX_FS | SAI_RX_SYNC | Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated. | I/O |

*Table continues on the next page...*

**Table 23-28. I²S0 Signal Descriptions (continued)**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| I2S0_RX_Dn | SAI_RX_DATA[1:0] | Receive Data. The receive data is sampled synchronously by the bit clock. | I |
| I2S0_MCLK | MCLK_EN | Audio Master Clock. | I |

**Table 23-29. FlexIO Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| FXIO0_Dn (n=[31:0] | FXIO_Dn (n=[31:0] | Bidirectional FlexIO Shifter and Timer pin inputs/outputs | I/O |

## 23.4.6 Analog

**Table 23-30. LPADC0 Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPADC0_SE[23:0] | CHnA (n=[23:0] | A-side Analog Channel Inputs | I |
| VDDA | VDDA | Analog Power Supply | I |
| VSSA | VSSA | Analog Ground | I |

**Table 23-31. LPCMP0 Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPCMP0_IN[5:0] | IN[5:0] | Analog voltage inputs | I |
| LPCMP0_OUT | CMPO | Comparator output | O |

**Table 23-32. LPCMP1 Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPCMP1_IN[5:0] | IN[5:0] | Analog voltage inputs | I |
| LPCMP1_OUT | CMPO | Comparator output | O |

**Table 23-33. LPDAC0 Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| DAC0_OUT | — | DAC output | O |

### Table 23-34. VREF Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| VREF_OUT | VREF_OUT | Internally-generated Voltage Reference output | O |

## 23.4.7 Human-Machine Interfaces (HMI)

### Table 23-35. GPIO Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| PTA[31:0][1] | PORTA31–PORTA0 | General-purpose input/output | I/O |
| PTB[31:0][1] | PORTB31–PORTB0 | General-purpose input/output | I/O |
| PTC[31:0][1] | PORTC31–PORTC0 | General-purpose input/output | I/O |
| PTD[31:0][1] | PORTD31–PORTD0 | General-purpose input/output | I/O |
| PTE[31:0][1] | PORTE31–PORTE0 | General-purpose input/output | I/O |

1. The available GPIO pins depends on the specific package. See the signal multiplexing section for which exact GPIO signals are available.

## 23.4.8 Timer Modules

### Table 23-36. LPTMR0 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPTMR0_ALT[3:1] | LPTMR_ALTn,n=[3:1] | Pulse Counter Input - The LPTMR can select one of the input pins to be used in Pulse Counter mode. | I |

### Table 23-37. LPTMR1 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPTMR1_ALT[3:1] | LPTMR_ALTn,n=[3:1] | Pulse Counter Input - The LPTMR can select one of the input pins to be used in Pulse Counter mode. | I |

### Table 23-38. LPTMR2 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| LPTMR2_ALT[3:1] | LPTMR_ALTn,n=[3:1] | Pulse Counter Input - The LPTMR can select one of the input pins to be used in Pulse Counter mode. | I |

## Table 23-39. TPM0 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| TPM0_CH[5:0] | TPM_CHn (n=[5:0]) | TPM channel. A TPM channel pin is configured as output when configured in an output compare or PWM mode and the TPM counter is enabled, otherwise the TPM channel pin is an input. | I/O |
| TPM0_CLKIN | TPM_EXTCLK | External clock. TPM external clock can be selected to increment the counter on every rising edge synchronized to the counter clock. | I |

## Table 23-40. TPM1 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| TPM1_CH[1:0] | TPM_CHn (n=[1:0]) | TPM channel. A TPM channel pin is configured as output when configured in an output compare or PWM mode and the TPM counter is enabled, otherwise the TPM channel pin is an input. | I/O |
| TPM1_CLKIN | TPM_EXTCLK | External clock. TPM external clock can be selected to increment the counter on every rising edge synchronized to the counter clock. | I |

## Table 23-41. TPM2 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| TPM2_CH[5:0] | TPM_CHn (n=[5:0]) | TPM channel. A TPM channel pin is configured as output when configured in an output compare or PWM mode and the TPM counter is enabled, otherwise the TPM channel pin is an input. | I/O |
| TPM2_CLKIN | TPM_EXTCLK | External clock. TPM external clock can be selected to increment the counter on every rising edge synchronized to the counter clock. | I |

## Table 23-42. TPM3 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| TPM3_CH[1:0] | TPM_CHn (n=[1:0]) | TPM channel. A TPM channel pin is configured as output when configured in an output compare or PWM mode and the TPM counter is enabled, otherwise the TPM channel pin is an input. | I/O |
| TPM3_CLKIN | TPM_EXTCLK | External clock. TPM external clock can be selected to increment the counter on every rising edge synchronized to the counter clock. | I |

## Table 23-43. TPM0 Signal Descriptions

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| EXTAL32 | EXTAL32 | 32.768 kHz oscillator input | I |
| XTAL32 | XTAL32 | 32.768 kHz oscillator output | O |
| RTC_CLKOUT | RTC_CLKOUT | Prescaler square-wave output or 32kHz crystal clock | O |
| RTC_WAKEUP_b | $\overline{\text{RTC_WAKEUP}}$ | Active low wakeup for external device | O |

## 23.4.9 Security Modules

**Table 23-44. Tamper Detect Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|---|---|---|---|
| TAMPER[3:0] [1] | RTC_TAMPER[3:0] | Tamper pin input | I |

1. The TAMPER signals have dedicated pins and are not included in the JTAG boundary scan. TAMPER0 is an exception because it is priority muxed with the RTC_WAKEUP_b function. If TAMPER0 is enabled as either an input or output, the RTC_WAKEUP_b function is disabled. The RTC_WAKEUP_b pin can be configured to assert on a Tamper Detect, if the RTC enables the DryIce tamper detect interrupt.

# Chapter 24
# Port Control and Interrupts (PORT)

## 24.1 Introduction

### 24.1.1 Overview

The Port Control and Interrupt (PORT) module provides support for port control, and external interrupt functions.

Most functions can be configured independently for each pin in the 32-bit port and affect the pin regardless of its pin muxing state.

There is one instance of the PORT module for each port. Not all pins within each port are implemented on a specific device.

### 24.1.2 Features

The PORT module has the following features:

- Pin interrupt on selected pins
  - Interrupt flag and enable registers for each pin
  - Support for edge sensitive (rising, falling, both) or level sensitive (low, high) configured per pin
  - Support for interrupt or DMA request configured per pin
  - Asynchronous wake-up in low-power modes
  - Pin interrupt is functional in all digital pin muxing modes
  - Peripheral trigger output (active high, low) configured per pin
- Port control
  - Individual pull control fields with pullup, pulldown, and pull-disable support
  - Individual slew rate field supporting fast and slow slew rates
  - Individual input passive filter field supporting enable and disable of the individual input passive filter on selected pins

- Individual open drain field supporting enable and disable of the individual open drain output
- Individual mux control field supporting analog or pin disabled, GPIO, and up to 6 chip-specific digital functions
- Pad configuration fields are functional in all digital pin muxing modes

### 24.1.3 Modes of operation

#### 24.1.3.1 Run mode

In Run mode, the PORT operates normally.

#### 24.1.3.2 Wait mode

In Wait mode, PORT continues to operate normally and may be configured to exit the Low-Power mode if an enabled interrupt is detected. DMA requests are still generated during the Wait mode, but do not cause an exit from the Low-Power mode.

#### 24.1.3.3 Stop mode

In Stop mode, the PORT can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

In Stop mode, the PORT configuration is static.

#### 24.1.3.4 Debug mode

In Debug mode, PORT operates normally.

## 24.2 External signal description

The table found here describes the PORT external signal.

**Table 24-1. Signal properties**

| Name | Function | I/O | Reset | Pull |
|---|---|---|---|---|
| PORTx[31:0] | External interrupt | I/O | 0 | - |

**NOTE**

Not all pins within each port are implemented on each device.

### 24.2.1 Detailed signal description

The table found here contains the detailed signal description for the PORT interface.

**Table 24-2. PORT interface—detailed signal description**

| Signal | I/O | Description | |
|---|---|---|---|
| PORTx[31:0] | I/O | External interrupt. | |
| | | State meaning | Asserted—pin is logic 1.<br>Negated—pin is logic 0. |
| | | Timing | Assertion—may occur at any time and can assert asynchronously to the system clock.<br>Negation—may occur at any time and can assert asynchronously to the system clock. |

## 24.3 Memory map and register definition

Any read or write access to the PORT memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states.

### 24.3.1 PORTA register descriptions

#### 24.3.1.1 PORTA Memory map

PORTA base address: 4004_6000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Pin Control Register 0 (PCR0) | 32 | RW | 0000_0703h |
| 4h | Pin Control Register 1 (PCR1) | 32 | RW | 0000_0702h |
| 8h - 10h | Pin Control Register a (PCR2 - PCR4) | 32 | RW | 0000_0703h |
| 24h | Pin Control Register 9 (PCR9) | 32 | RW | 0000_0000h |
| 28h | Pin Control Register 10 (PCR10) | 32 | RW | 0000_0000h |

*Table continues on the next page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 38h | Pin Control Register 14 (PCR14) | 32 | RW | 0000_0000h |
| 3Ch | Pin Control Register 15 (PCR15) | 32 | RW | 0000_0000h |
| 44h | Pin Control Register 17 (PCR17) | 32 | RW | 0000_0000h |
| 48h | Pin Control Register 18 (PCR18) | 32 | RW | 0000_0000h |
| 4Ch | Pin Control Register 19 (PCR19) | 32 | RW | 0000_0000h |
| 50h | Pin Control Register 20 (PCR20) | 32 | RW | 0000_0000h |
| 54h | Pin Control Register 21 (PCR21) | 32 | RW | 0000_0000h |
| 58h | Pin Control Register 22 (PCR22) | 32 | RW | 0000_0000h |
| 5Ch | Pin Control Register 23 (PCR23) | 32 | RW | 0000_0000h |
| 60h | Pin Control Register 24 (PCR24) | 32 | RW | 0000_0000h |
| 64h | Pin Control Register 25 (PCR25) | 32 | RW | 0000_0000h |
| 68h | Pin Control Register 26 (PCR26) | 32 | RW | 0000_0000h |
| 6Ch | Pin Control Register 27 (PCR27) | 32 | RW | 0000_0000h |
| 70h | Pin Control Register 28 (PCR28) | 32 | RW | 0000_0000h |
| 78h | Pin Control Register 30 (PCR30) | 32 | RW | 0000_0000h |
| 7Ch | Pin Control Register 31 (PCR31) | 32 | RW | 0000_0000h |
| 80h | Global Pin Control Low Register (GPCLR) | 32 | WORZ | 0000_0000h |
| 84h | Global Pin Control High Register (GPCHR) | 32 | WORZ | 0000_0000h |
| 88h | Global Interrupt Control Low Register (GICLR) | 32 | WORZ | 0000_0000h |
| 8Ch | Global Interrupt Control High Register (GICHR) | 32 | WORZ | 0000_0000h |
| A0h | Interrupt Status Flag Register (ISFR) | 32 | W1C | 0000_0000h |

## 24.3.1.2 Pin Control Register 0 (PCR0)

### 24.3.1.2.1 Offset

| Register | Offset |
|---|---|
| PCR0 | 0h |

### 24.3.1.2.2 Function

**NOTE**

See the Signal Multiplexing and Pin Assignment chapter for the reset values for the pins on this device.

See the Chip specific PORT information section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

### 24.3.1.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 24.3.1.3 Pin Control Register 1 (PCR1)

### 24.3.1.3.1 Offset

| Register | Offset |
|---|---|
| PCR1 | 4h |

### 24.3.1.3.2 Function

**NOTE**

See the Signal Multiplexing and Pin Assignment chapter for the reset values for the pins on this device.

See the Chip specific PORT information section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

## 24.3.2.2 Pin Control Register a (PCR0 - PCR31)

### 24.3.2.2.1 Offset

For a = 0 to 31:

| Register | Offset |
|---|---|
| PCRa | 0h + (a × 4h) |

### 24.3.2.2.2 Function

**NOTE**

See the Signal Multiplexing and Pin Assignment chapter for the reset values for the pins on this device.

See the Chip specific PORT information section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

### 24.3.2.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Field | Function |
|---|---|
| 31-0<br>ISF | Interrupt Status Flag<br>Each bit in the field indicates the detection of the configured interrupt of the same number as the field.<br>0b - Configured interrupt is not detected.<br>1b - Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared. |

## 24.3.3 PORTC register descriptions

### 24.3.3.1 PORTC Memory map

PORTC base address: 4004_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h - 4h | Pin Control Register a (PCR0 - PCR1) | 32 | RW | 0000_0000h |
| 1Ch - 30h | Pin Control Register a (PCR7 - PCR12) | 32 | RW | 0000_0000h |
| 68h - 78h | Pin Control Register a (PCR26 - PCR30) | 32 | RW | 0000_0000h |
| 80h | Global Pin Control Low Register (GPCLR) | 32 | WORZ | 0000_0000h |
| 84h | Global Pin Control High Register (GPCHR) | 32 | WORZ | 0000_0000h |
| 88h | Global Interrupt Control Low Register (GICLR) | 32 | WORZ | 0000_0000h |

*Table continues on the next page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 8Ch | Global Interrupt Control High Register (GICHR) | 32 | WORZ | 0000_0000h |
| A0h | Interrupt Status Flag Register (ISFR) | 32 | W1C | 0000_0000h |

## 24.3.3.2 Pin Control Register a (PCR0 - PCR1)

### 24.3.3.2.1 Offset

For a = 0 to 1:

| Register | Offset |
|---|---|
| PCRa | 0h + (a × 4h) |

### 24.3.3.2.2 Function

**NOTE**

See the Signal Multiplexing and Pin Assignment chapter for the reset values for the pins on this device.

See the Chip specific PORT information section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

### 24.3.3.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 24.3.3.8.4 Fields

| Field | Function |
|---|---|
| 31-16 | Global Interrupt Write Data |
| GIWD | Write value that is written to upper 16-bits of the Pin Control Registers that are selected by GIWE. |
| 15-0 | Global Interrupt Write Enable |
| GIWE | Selects which upper 16-bits of Pin Control Registers (31 through 16) update with the value in GIWD.<br>0b - Corresponding upper 16-bits of Pin Control Register is not updated with the value in GIWD.<br>1b - Corresponding upper 16-bits of Pin Register is updated with the value in GIWD. |

## 24.3.3.9 Interrupt Status Flag Register (ISFR)

### 24.3.3.9.1 Offset

| Register | Offset |
|---|---|
| ISFR | A0h |

### 24.3.3.9.2 Function

The pin interrupt configuration is valid in all digital pin muxing modes. The Interrupt Status Flag for each pin is also visible in the corresponding Pin Control Register, and each flag can be cleared in either location.

#### 24.3.3.9.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 24.3.4.2 Pin Control Register a (PCR0 - PCR7)

### 24.3.4.2.1 Offset

For a = 0 to 7:

| Register | Offset |
|---|---|
| PCRa | 0h + (a × 4h) |

### 24.3.4.2.2 Function

**NOTE**

See the Signal Multiplexing and Pin Assignment chapter for the reset values for the pins on this device.

See the Chip specific PORT information section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

### 24.3.4.2.3 Diagram

### 24.3.4.8.4 Fields

| Field | Function |
|---|---|
| 31-0 | Interrupt Status Flag |
| ISF | Each bit in the field indicates the detection of the configured interrupt of the same number as the field.<br><br>0b - Configured interrupt is not detected.<br>1b - Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared. |

## 24.3.4.9 Digital Filter Enable Register (DFER)

### 24.3.4.9.1 Offset

| Register | Offset |
|---|---|
| DFER | C0h |

### 24.3.4.9.2 Function

The digital filter configuration is valid in all digital pin muxing modes.

### 24.3.4.9.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 24.3.4.9.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DFE | Digital Filter Enable<br>The digital filter configuration is valid in all digital pin muxing modes. The output of each digital filter is reset to zero at system reset and whenever the digital filter is disabled. Each bit in the field enables the digital filter of the same number as the field.<br>0b - Digital filter is disabled on the corresponding pin and output of the digital filter is reset to zero.<br>1b - Digital filter is enabled on the corresponding pin, if the pin is configured as a digital input. |

## 24.3.4.10 Digital Filter Clock Register (DFCR)

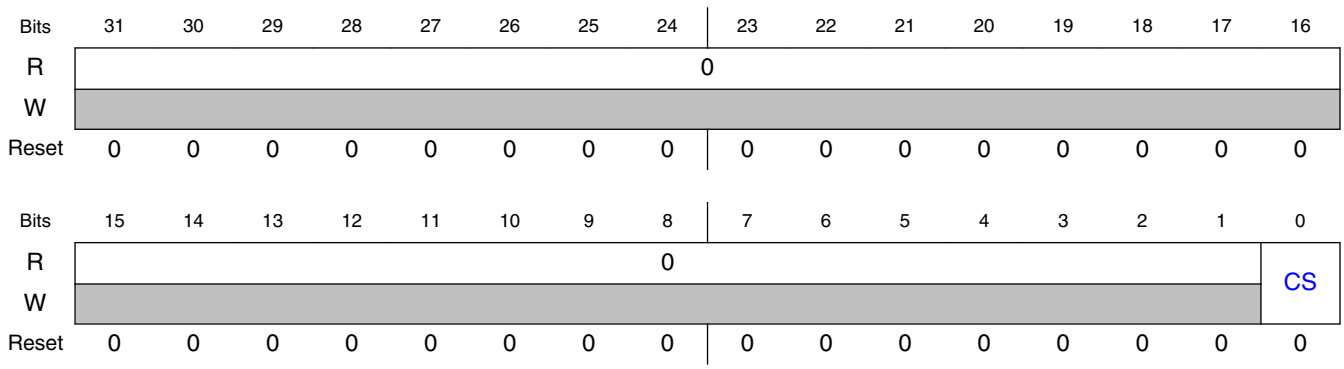
### 24.3.4.10.1 Offset

| Register | Offset |
|---|---|
| DFCR | C4h |

### 24.3.4.10.2 Function

The digital filter configuration is valid in all digital pin muxing modes.

### 24.3.4.10.3 Diagram



### 24.3.4.10.4 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>CS | Clock Source<br>The digital filter configuration is valid in all digital pin muxing modes. Configures the clock source for the digital input filters. Changing the filter clock source must be done only when all digital filters are disabled.<br>0b - Digital filters are clocked by the bus clock.<br>1b - Digital filters are clocked by the 8 clock. |

## 24.3.4.11 Digital Filter Width Register (DFWR)

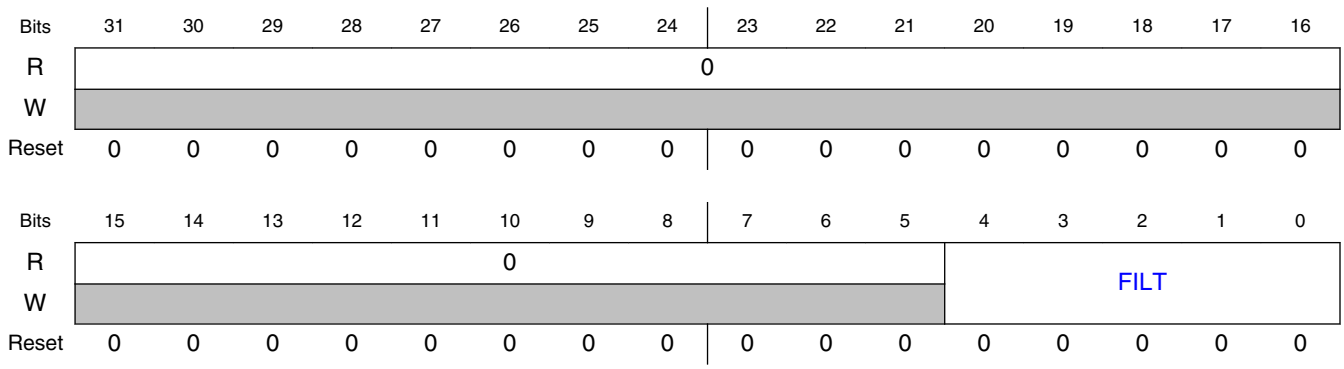
#### 24.3.4.11.1 Offset

| Register | Offset |
|---|---|
| DFWR | C8h |

#### 24.3.4.11.2 Function

The digital filter configuration is valid in all digital pin muxing modes.

#### 24.3.4.11.3 Diagram



#### 24.3.4.11.4 Fields

| Field | Function |
|---|---|
| 31-5<br>— | Reserved |
| 4-0<br>FILT | Filter Length<br>The digital filter configuration is valid in all digital pin muxing modes. Configures the maximum size of the glitches, in clock cycles, that the digital filter absorbs for the enabled digital filters. Glitches that are longer than this register setting will pass through the digital filter, and glitches that are equal to or less than this register setting are filtered. Changing the filter length must be done only after all filters are disabled. |

## 24.3.5 PORTE register descriptions

### 24.3.5.1 PORTE Memory map

PORTE base address: 4103_7000h

### 24.3.5.2 Pin Control Register a (PCR0 - PCR9)

#### 24.3.5.2.1 Offset

For a = 0 to 9:

| Register | Offset |
|---|---|
| PCRa | 0h + (a × 4h) |

#### 24.3.5.2.2 Function

**NOTE**

See the Signal Multiplexing and Pin Assignment chapter for the reset values for the pins on this device.

See the Chip specific PORT information section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

#### 24.3.5.2.3 Diagram

### 24.3.5.9.4 Fields

| Field | Function |
|---|---|
| 31-0<br>ISF | Interrupt Status Flag<br>Each bit in the field indicates the detection of the configured interrupt of the same number as the field.<br>0b - Configured interrupt is not detected.<br>1b - Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared. |

## 24.4 Functional description

### 24.4.1 Pin control

Each port pin has a corresponding Pin Control register, PORT_PCRn, associated with it. The Pin Control register configures the following functions for each pin within the 32-bit port.

- Pullup or pulldown enable
- Slew rate configuration
- Open drain enable
- Passive input filter enable on selected pins
- Software configuration lock
- Pin Muxing mode

The functions apply across all digital pin muxing modes and individual peripherals do not override the configuration in the Pin Control register. For example, if an $I^2C$ function is enabled on a pin, that does not override the pullup or open drain configuration for that pin.

When the Pin Muxing mode is configured for analog or is disabled, all the digital functions on that pin are disabled. This includes the pullup and pulldown enables, output buffer enable, input buffer enable, and passive filter enable.

The LK bit (bit 15 of Pin Control Register PCR*n*) allows the configuration for each pin to be locked until the next system reset. When locked, writes to the lower half of that pin control register are ignored, although a bus error is not generated on an attempted write to a locked register.

The configuration of each Pin Control register is retained when the PORT module is disabled.

Whenever a pin is configured in any digital pin muxing mode, the input buffer for that pin is enabled allowing the pin state to be read via the corresponding GPIO Port Data Input Register (GPIO_PDIR) or allowing a pin interrupt or DMA request to be generated. If a pin is ever floating when its input buffer is enabled, then this can cause an increase in power consumption and must be avoided. A pin can be floating due to an input pin that is not connected or an output pin that has tri-stated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) will ensure a pin does not float when its input buffer is enabled; note that the internal pull resistor is automatically disabled whenever the output buffer is enabled allowing the Pull Enable bit to remain set. Configuring the Pin Muxing mode to disabled or analog will disable the pin's input buffer and results in the lowest power consumption.

## 24.4.2 Global pin control

The two global pin control registers allow a single register write to update the lower 16-bits of the Pin Control Register for up to 16 pins, all with the same value. Registers that are locked cannot be written using the global pin control registers.

The global pin control registers are designed to enable software to quickly configure multiple pins within the same port with the same peripheral function.

The global pin control registers are write-only registers, that always read as 0.

### 24.4.3 Global interrupt control

The two global interrupt control registers allow a single register write to update the upper 16-bits of the Pin Control Register for up to 16 pins, all with the same value.

The global interrupt control registers are designed to enable software to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read as 0.

### 24.4.4 External interrupts

The external interrupt capability of the PORT module is available in all digital pin muxing modes provided the PORT module is enabled.

Each pin can be individually configured for any of the following external interrupt modes:

- Interrupt disabled, default out of reset
- Rising edge flag (for software polling)
- Falling edge flag (for software polling)
- Rising and falling edge flag (for software polling)
- Active high level peripheral trigger (status flag disabled)
- Active low level peripheral trigger (status flag disabled)
- Active high level sensitive interrupt
- Active low level sensitive interrupt
- Rising edge sensitive interrupt
- Falling edge sensitive interrupt
- Rising and falling edge sensitive interrupt
- Rising edge sensitive DMA request
- Falling edge sensitive DMA request
- Rising and falling edge sensitive DMA request

The interrupt status flag is set when the configured edge or level is detected on the pin . When not in Stop mode, the input is first synchronized to the bus clock to detect the configured level or edge transition.

The PORT module generates a single pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that port. The interrupt negates after the interrupt status flags for all enabled interrupts have been cleared by writing a logic 1 to the ISF flag in either the PORT_ISFR or PORT_PCRn registers.

The PORT module generates a single DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that port. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

During Stop mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

The PORT module generates a single peripheral trigger output that asserts if any pin configured for active high trigger is logic one, or any pin triggered for active low trigger is logic zero. The peripheral trigger output asynchronously updates from the value on the configured pins.

# Chapter 25
# General-Purpose Input/Output (GPIO)

## 25.1 Chip-specific GPIO information

### 25.1.1 GPIO signals

See Pin properties for GPIO signal properties.

## 25.2 Introduction

The general-purpose input and output (GPIO) module communicates to the processor core via a zero wait state interface (IOPORT) for maximum pin performance.The general-purpose input and output (GPIO) module is also accessible via the peripheral bus. The GPIO registers support 8-bit, 16-bit or 32-bit accesses.

The GPIO data direction and output data registers control the direction and output data of each pin when the pin is configured for the GPIO function. The GPIO input data register displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt module for that pin is enabled.

Efficient bit manipulation of the general-purpose outputs is supported through the addition of set, clear, and toggle write-only registers for each port output data register.

### 25.2.1 Features

Features of the GPIO module include:

- Port Data Input register visible in all digital pin-multiplexing modes
- Port Data Output register with corresponding set/clear/toggle registers

- Port Data Direction register
- Zero wait state access to GPIO registers through IOPORT

**NOTE**

The GPIO module is clocked by system clock.

## 25.2.2 Modes of operation

The following table depicts different modes of operation and the behavior of the GPIO module in these modes.

**Table 25-1. Modes of operation**

| Modes of operation | Description |
|---|---|
| Run | The GPIO module operates normally. |
| Wait | The GPIO module operates normally. |
| Stop | The GPIO module is disabled. |
| Debug | The GPIO module operates normally. |

## 25.2.3 GPIO signal descriptions

**Table 25-2. GPIO signal descriptions**

| GPIO signal descriptions | Description | I/O |
|---|---|---|
| PORTA31–PORTA0 | General-purpose input/output | I/O |
| PORTB31–PORTB0 | General-purpose input/output | I/O |
| PORTC31–PORTC0 | General-purpose input/output | I/O |
| PORTD31–PORTD0 | General-purpose input/output | I/O |
| PORTE31–PORTE0 | General-purpose input/output | I/O |

**NOTE**

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

### 25.2.3.1 Detailed signal description

**Table 25-3. GPIO interface-detailed signal descriptions**

| Signal | I/O | Description |
|---|---|---|
| PORTA31–PORTA0 | I/O | General-purpose input/output |

*Table continues on the next page...*

**Table 25-3. GPIO interface-detailed signal descriptions (continued)**

| Signal | I/O | Description | |
|---|---|---|---|
| PORTB31–PORTB0<br>PORTC31–PORTC0<br>PORTD31–PORTD0<br>PORTE31–PORTE0 | | State meaning | Asserted: The pin is logic 1.<br>Deasserted: The pin is logic 0. |
| | | Timing | Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.<br>Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. |

**NOTE**

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

## 25.3 Memory map and register definition

The registers for each GPIO port occupy 64-byte of the memory map. Any read or write access to the GPIO slot outside this space results in a bus error.

**NOTE**

For simplicity, each GPIO port's registers appear with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. Refer to the chip-specific GPIO information to see the exact control bits for each port.

### 25.3.1 GPIO register descriptions

### 25.3.1.1 GPIO Memory map

GPIOA base address: 4802_0000h

GPIOB base address: 4802_0040h

GPIOC base address: 4802_0080h

GPIOD base address: 4802_00C0h

GPIOE base address: 4100_F000h

|---|---|
| 31-0<br>PDD | Port Data Direction<br>Configures individual port pins for input or output.<br>0b - Pin is configured as general-purpose input, for the GPIO function.<br>1b - Pin is configured as general-purpose output, for the GPIO function. |

## 25.4 FGPIO memory map and register definition

The GPIO registers are also aliased to the IOPORT interface on the Cortex-M0+ from address 0xF800_0000.

Accesses via the IOPORT interface occur in parallel with any instruction fetches and will therefore complete in a single cycle. This aliased Fast GPIO memory map is called FGPIO.

Any read or write access to the FGPIO memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states, except error accesses which complete with one wait state.

**NOTE**

For simplicity, each FGPIO port's registers appear with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. Refer to the Chip Configuration chapter to see the exact control bits for the non-identical port instance.

## 25.4.1 FGPIOE register descriptions

### 25.4.1.1 FGPIOE Memory map

FGPIOE base address: F800_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Port Data Output Register (PDOR) | 32 | RW | 0000_0000h |
| 4h | Port Set Output Register (PSOR) | 32 | WORZ | 0000_0000h |
| 8h | Port Clear Output Register (PCOR) | 32 | WORZ | 0000_0000h |
| Ch | Port Toggle Output Register (PTOR) | 32 | WORZ | 0000_0000h |
| 10h | Port Data Input Register (PDIR) | 32 | RO | 0000_0000h |
| 14h | Port Data Direction Register (PDDR) | 32 | RW | 0000_0000h |

### 25.4.1.2 Port Data Output Register (PDOR)

#### 25.4.1.2.1 Offset

| Register | Offset |
|---|---|
| PDOR | 0h |

#### 25.4.1.2.2 Function

This register configures the logic levels that are driven on each general-purpose output pin.

**NOTE**

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

#### 25.4.1.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Field | Function |
|---|---|
| 31-0<br>PDD | Port Data Direction<br>Configures individual port pins for input or output.<br>0b - Pin is configured as general-purpose input, for the GPIO function.<br>1b - Pin is configured as general-purpose output, for the GPIO function. |

## 25.5 Functional description

### 25.5.1 General-purpose input

The logic state of each pin is available via the Port Data Input registers, provided the pin is configured for a digital function and the corresponding Port Control and Interrupt module is enabled.

The input pin synchronizers are shared with the Port Control and Interrupt module, so that if the corresponding Port Control and Interrupt module is disabled, then synchronizers are also disabled. This reduces power consumption when a port is not required for general-purpose input functionality.

### 25.5.2 General-purpose output

The logic state of each pin can be controlled via the port data output registers and port data direction registers, provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input/output.

| If | Then |
|---|---|
| A pin is configured for the GPIO function and the corresponding port data direction register bit is clear. | The pin is configured as an input. |
| A pin is configured for the GPIO function and the corresponding port data direction register bit is set. | The pin is configured as an output and and the logic state of the pin is equal to the corresponding port data output register. |

To facilitate efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers exist to allow one or more outputs within one port to be set, cleared, or toggled from a single register write.

The corresponding Port Control and Interrupt module does not need to be enabled to update the state of the port data direction registers and port data output registers including the set/clear/toggle registers.

### 25.5.3 IOPORT

The GPIO registers are also aliased to the IOPORT interface on the Cortex-M0+ from address 0xF800_0000. Accesses via the IOPORT interface occur in parallel with any instruction fetches and will therefore complete in a single cycle. If another bus master attempts to access the GPIO registers on the same cycle as an IOPORT access, then the DMA access will stall until any IOPORT accesses have completed.

# Chapter 26
# Reset and Boot

## 26.1 Introduction

The following reset sources exist in this MCU:

**Table 26-1. Reset sources**

| Reset Type | Description |
|---|---|
| Voltage resets | • System Power-On Reset (POR)<br>• System High-Voltage Detect (HVD)<br>• System Low-Voltage Detect (LVD)<br>• Battery Power-On Reset (VBATPOR) |
| External resets | • External pin reset (RESET_b)<br>• Low Leakage Wake-Up (LLWU) |
| Internal resets | • Watchdog (WDOG)<br>• Loss-of-Clock (LOC)<br>• Software (SW)<br>• Stop mode ACKnowledge ERRor (SACKERR)<br>• Lockup (LOCKUP)<br>• MDM-AP system reset request |
| Debug reset | • JTAG IR commands<br>• Resetting the debug sub-system |

Each system reset source has a corresponding bit in the System Reset Status (MSMC_SRS) register. This information can be used to take appropriate action when coming out of a reset. See the Multi System Mode Controller (MSMC) section for detailed information.

The microcontroller has 4 CPUs: Core0 (CM4F), Core1 (CM0+), Core2 (RI5CY), and Core3 (ZERO_RISCY).

- Resets initiated externally from the Cores (like External Global System resets) force a reset to all Cores.
- On exit from any reset, the boot core defined by the FTFE_FOPT[BOOT_CORE], FTFE_FOPT[CM4_EN], FTFE_FOPT[RI5CY_DIS], FTFE_FOPT[CM0+_EN] and FTFE_FOPT[ZERO_RISCY_DIS] is enabled and starts to execute. All other cores

are hold in reset until they are enabled by software. By default, the Cortex M4 is the boot core.

The microcontroller can exit and reset in functional mode where the Core is executing code (default) or the Core is in a debug halted state. There are several boot options that can be configured. See the Boot section for more information.

## 26.2 Reset

Asserting a reset to the device, a core, or a peripheral provides a way to start processing from a known set of initial conditions. On de-assertion of a system level reset source, the on-chip regulator is in full regulation and system clock generation is from an internal source. When the device exits reset, the boot core performs the following actions:

- ARM cores: Reads the initial Stack Pointer (SP) from vector-table at offset 0x0000_0000
- ARM cores: Reads the initial Program Counter (PC) from vector-table at offset 0x0000_0004
- ARM cores: Sets the Link Register (LR) to 0xFFFF_FFFF

After a system level reset, the on-chip peripherals are disabled, the non-analog I/O pins return to their default disabled configuration, and the analog I/O pins return to their default analog function configuration.

On the assertion of a system level reset, the debug pins return to their default enabled configuration as:

- JTAG_TCK/SWD_CLK with pull-down (PD) enabled
- JTAG_TMS with pull-up (PU) enabled
- JTAG_TDI/SWD_DIO with pull-up (PU) enabled
- JTAG_TDO with pull-up (PU) and pull-down (PD) disbaled

Some modules that cause resets can be configured to cause interrupts instead. Consult the individual peripheral chapters for more information.

### 26.2.1 Voltage monitor reset sources

To ensure predictable operation of the device, the supply voltages must remain in their specified ranges during execution. Because this is not possible during power-up and power-down, the device implements multiple voltage monitors to detect when the supply is below an acceptable level. When this occurs, the voltage monitor asserts a reset to halt execution and ensure that unexpected events do not occur.

#### 26.2.1.1 System Power-On Reset (POR)

The POR voltage monitor is used to ensure that the voltage applied to the system is high enough for other analog modules such as the bias circuits and low voltage monitors to operate correctly. When voltage is initially applied to the device or when the supply voltage drops below the Power-On Reset re-arm voltage ($V_{POR}$), the POR monitor asserts POR to the device.

The POR will reset everything in the device that is not in the battery voltage ($V_{BAT}$) domain. The POR field in the System Reset Status register (MSMC_SRS[POR]) is set following a POR.

#### 26.2.1.2 High-voltage detect (HVD)

The chip includes a system to guard against high-voltage conditions. See:

- High-voltage detect (HVD) system
- HVD reset operation
- HVD interrupt operation

#### 26.2.1.3 Low-Voltage Detect (LVD)

The LVD voltage monitor, which including VDDIO1 and CORE_VDD voltage monitor, is used to ensure that the core voltage is high enough for the digital logic and memories to operate correctly. When voltage is initially applied to the device, the POR voltage monitor will hold the LVD voltage monitor in reset until the voltage is high enough. The LVD monitor will continue to hold the device in reset until the core voltage has risen above the default LVD Low threshold ($V_{LVDL}$).

The VDDIO1 LVD monitor can be configured to generate a reset when the voltage drops below the VLVDL threshold. The voltage threshold at which the reset will assert is user programmable. This ensures that the device will halt operation and remain in reset while the core voltage is not within the desired range. The LVD Low threshold ($V_{LVDL}$) can be configured by programming the LVDV field of the Low Voltage Detect Status and Control 1 register (SPM_LVDSC1).

The CORE_VDD LVD monitor is enabled in the RUN and WAIT modes. The CORE_VDD LVD monitor can be configured to be enabled or disabled in STOP, VLPR, VLPW, VLPS, LLS, and VLLS modes. Additionally, the CORE_VDD LVD monitor can be configured not to generate resets by writing a 0 to the SPM_LVDSC1[COREVDD_LVDRE] field.

The LVD will reset everything in the device that is not in the battery voltage ($V_{BAT}$) domain except the Low-Power Timers (LPTMR), the contents of the System Register File (SYSREG), portions of the System Power Manager (SPM), and the debug sub-systems. The LVD field in the System Reset Status register (SRS[LVD] of MSMC) is set following a LVD reset.

#### 26.2.1.4 Battery Power-On Reset (VBATPOR)

The VBATPOR voltage monitor is used to ensure that the voltage applied to the battery domain is high enough for the $V_{BAT}$ modules to operate correctly. When voltage is initially applied to the $V_{BAT}$ domain or when the voltage drops below an acceptable level, the VBATPOR monitor asserts a POR to the $V_{BAT}$ domain.

### 26.2.2 External system reset sources

External system resets are provided so that the device can be reset or awakened from very low power states. This allows the user to start the device at the correct time from a known state. The external system resets available in this device are described in the following sections.

#### 26.2.2.1 External pin reset (RESET_b)

The RESET_b is a dedicated pin on this device. This pin is open drain and has an internal pull-up. Asserting RESET_b wakes the device from any mode.

##### 26.2.2.1.1 RESET_b filter functionality

The RESET_b pin filter supports filtering from both the 1kHz LPO clock and the bus clock. The LPOFEN, FILTEN and FILTCFG fields of the Reset Pin Control (MSMC_RPC) register controls this functionality. For detailed information on these features, please refer to the Multi System Mode Controller (MSMC) chapter. The filters are asynchronously reset by the system POR. The reset value for each filter assumes the RESET_b pin is negated.

For all stop modes where LPO clock is still active (STOP, VLPS, LLS, and VLLS), the only filtering option is the LPO-based digital filter. The filtering logic either switches to bypass operation or has continued filtering operation depending on the filtering mode selected. When entering VLLS0, the RESET_b pin filter is disabled and bypassed.

The LPO filter has a fixed filter value of 3. Due to a synchronizer on the input data, there is also an associated latency of 2 cycles. As a result, 5 cycles are required to complete a transition from low-to-high or high-to-low.

#### 26.2.2.1.2 RESET_b output functionality

For all reset sources except a VLLS Wakeup that does not occur via the RESET_b pin, the RESET_b pin is driven low by the MCU for at least 128 bus clock cycles and until flash initialization has completed.

After flash initialization has completed, the RESET_b pin is released, and the internal Chip Reset negates after the RESET_b pin is pulled high. Keeping the RESET_b pin asserted externally delays the negation of the internal Chip Reset.

### 26.2.2.2 Low Leakage Wake-Up (LLWU)

The LLWU module provides the means for a number of external pins and a number of internal peripherals to wake the device from low leakage power modes, LLS and VLLS. It also allows for asynchronous DMA operation to wake-up from LLS when transfers to or from certain peripherals complete.

The LLWU can enable the external input pin and filter detection in all power modes (not only LLS/VLLS). In LLS_mode, only the RESET_b pin can generate a system reset through the LLWU. In VLLS modes, all enabled inputs to the LLWU can generate a system reset. After a system reset, the LLWU retains the flags indicating the input source of the last wakeup until the user clears them. The WAKEUP field in the System Reset Status register (MSMC_SRS[WAKEUP]) is set following a LLWU reset.

## 26.2.3 Internal system reset sources

Internal system resets are provided so that the device can be reset when certain erroneous conditions are detected. This allows the device to reset a portion of the device or the entire device to recover from the erroneous conditions. The internal system resets available in this device are described in the following sections.

#### 26.2.3.1 Watchdog (WDOG) timer

The WDOG monitors the operation of the system by receiving periodic communication from the software. This communication is generally known as servicing or refreshing the Watchdog. If this periodic servicing does not occur, then the Watchdog issues a system reset.

The WDOG will reset everything in the device that is not in the battery voltage ($V_{BAT}$) domain except the Low-Power Timers (LPTMR), the contents of the System Register File (SYSREG), System Power Manager (SPM), and the debug sub-systems. The WDOG field in the System Reset Status register (MSMC_SRS[WDOG]) is set following a WDOG reset.

In multi-core devices, the WDOG can be configured to generate an interrupt to the boot core in the device rather than assert an interrupt. This allows the boot core to run an Interrupt Service Routine (ISR) and make a determination on how to handle the WDOG interrupt. The boot core could decide to reset the core domain that generated the WDOG interrupt through MUA/B_CCR[RSTH] or reset the entire device.

#### 26.2.3.2 Loss-of-Clock (LOC)

The System Clock Generator (SCG) module contains a clock monitor with reset and interrupt request capability for external clocks. The LOC indicates a reset has been caused by a loss of external clock. The SCG clock monitor must be enabled for a loss of clock to be detected. For details on enabling the clock monitor, please refer to the SCG chapter.

**NOTE**

To prevent unexpected reset events, all clock monitors must be disabled before entering any low-power modes, including VLPR and VLPW.

#### 26.2.3.3 Software (SW)

During execution, if the software detects erroneous operation, the software can initiate a reset to restart the device from a known state. The software can write the SYSRESETREQ field in the Nested Vectored Interrupt Controller - Application Interrupt and Reset Control Register (NVIC_AIRCR) to force a SW reset to the core. (See ARM's NVIC documentation for the full description of the register fields, especially the VECTKEY field requirements.)

The SW SYSRESETREQ request will reset all of the major components of the core except for the debug sub-systems. The SW field in the System Reset Status register (MSMC_SRS[SW]) is set following a SW reset.

In multi-core devices, the SW can be configured to generate an interrupt to the master core in the device rather than assert an interrupt. This allows the master core to run an Interrupt Service Routine (ISR) and make a determination on how to handle the SW interrupt. The master core could decide to reset the core domain that generated the SW interrupt or reset the entire device.

The SW system reset will reset everything in the device that is not in the battery voltage ($V_{BAT}$) domain except the Low-Power Timers (LPTMR), the contents of the System Register File (SYSREG), portions of the System Power Manager (SPM), and the debug sub-systems. The PIN and SW fields in the System Reset Status (MSMC_SRS) register are set following a SW system reset.

#### 26.2.3.4 Stop mode ACKnowledge ERRor (SACKERR)

The SACKERR reset is generated if a core attempts to enter STOP mode or Compute Operation and one or more of the modules in the core's domain fails to acknowledge Stop mode within 1025 cycles of the 1 kHz LPO clock.

A module might not acknowledge the entry to STOP mode if an error condition occurs. The error can be caused by a failure of an external clock input to a module.

The SACKERR condition will reset everything in the device that is not in the battery voltage (VBAT) domain except the Low-Power Timers (LPTMR), the contents of the System Register File (SYSREG), portions of the System Power Manager (SPM), and the debug sub-systems. The SACKERR field in the System Reset Status register (MSMC_SRS[SACKERR]) is set following a SACKERR reset.

#### 26.2.3.5 Lockup (LOCKUP)

The assertion of the LOCKUP condition gives an immediate indication of seriously errant kernel software. This is the result of the core being locked, because of an unrecoverable exception, following the activation of the processor's built-in system state protection hardware.

In multi-core devices, the LOCKUP can be configured to generate an interrupt to the master core in the device rather than assert an interrupt. This allows the master core to run an Interrupt Service Routine (ISR) and make a determination on how to handle the LOCKUP interrupt. The master core could decide to reset the core domain that generated the LOCKUP interrupt or reset the entire device.

#### 26.2.3.6 MDM-AP system reset request

To initiate a system reset, set the System Reset Request field in the MDM-AP control register. This is the primary method for resets via the debug interfaces. The system reset is held until this field is cleared.

To hold the core in reset as the rest of the chip comes out of system reset, set the Core Hold Reset field in the MDM-AP control register.

### 26.2.4 Debug resets

The following sections detail the debug resets available on the device.

#### 26.2.4.1 JTAG Instruction Register (IR) commands

Some JTAG IR commands will assert reset to the system. This is required to ensure proper behavior in the JTAG TAP modes. This reset acts the same as a pin reset to the system. For more information on the JTAG IR commands, please refer to the JTAG chapter.

#### 26.2.4.2 Resetting the debug sub-system

Use the CDBGRSTREQ bit within the SWJ-DP CTRL/STAT register to reset the debug modules. However, as explained below, using the CDBGRSTREQ bit does not reset all debug-related registers.

CDBGRSTREQ resets the debug-related registers within the following modules:

- SWJ-DP
- AHB-AP
- ETM
- TPIU
- MDM-AP (MDM control and status registers)

CDBGRSTREQ does not reset the debug-related registers within the following modules:

- CM0+ core
- CM4F core
- BPU
- FPB
- DWT
- ITM
- NVIC
- Crossbar bus switch[1]
- AHB-AP[1]
- Private peripheral bus[1]

## 26.3 Boot

This section describes the boot sources, boot options, and boot sequence.

The various boot options apply to the Boot Core, which is the Core on exit from reset. By default, Core0 is the Boot Core and Core1, Core2, and Core 3 are disabled. If the user sets the appropriate bits in the boot options field, Core1 or/and Core3 will be enabled as the boot core, and Core0 or/and Core2 will be disabled on exit from reset.

Some configuration information such as clock trim values stored in factory programmed flash locations is autoloaded.

### 26.3.1 Boot sources

Based on the source selections in the Flash Option (FOPT) register, the device will boot from the internal Flash or the internal Boot ROM. If the device boots from the Boot ROM, the device executes in boot loader mode.

### 26.3.2 Flash Option (FOPT) customization

The Flash Option (FOPT) register in the Flash Memory module (FTFE_FOPT) allows the user to customize the operation of the MCU at boot time. The register contains read-only bits that are loaded from the NVM's flash configuration field. The default setting for all values in the FTFE_FOPT register is logic 1 since it is copied from the option byte

1. CDBGRSTREQ does not affect AHB resources so that debug resources on the private peripheral bus are available during System Reset.

residing in flash, which has all bits as logic 1 in the flash erased state. To configure for alternate settings, program the appropriate bits in the NVM option byte. The new settings will take effect on subsequent POR and any system reset. For more details on programming the option byte, see the flash memory chapter.

The MCU uses the FTFE_FOPT to configure the device at reset as shown in the following table.

**NOTE**

An FTFE_FOPT value of 0x0000_0000 is invalid and will be ignored. The FOPT register is written to 0xFFFF_FFFF if the contents of the Flash non-volatile option are 0x0000_0000.

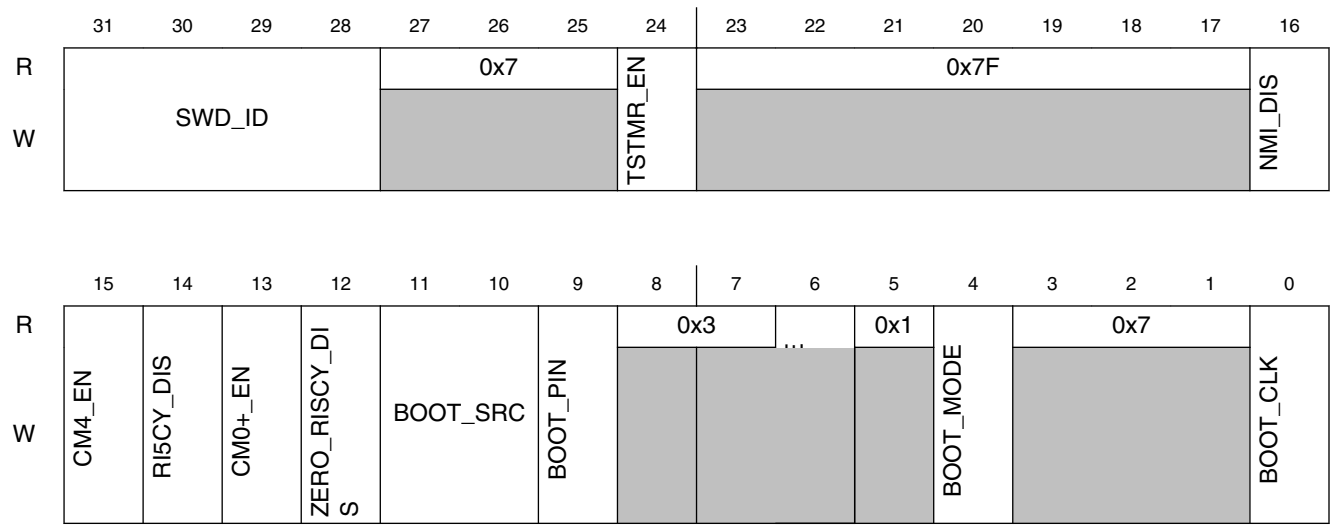

**Table 26-4. Flash Option Register Bit Definitions**

| Bit Num | Field | Definition |
|---|---|---|
| 31-28 | SWD_ID | **Serial Wire Debug Identification** - The SWD_ID sets the Instance ID of SWD modules that support multidrop. The Instance ID is used to select a specific SWD instance in systems with a single SWD interface port, but multiple devices with SWD interfaces. |
| 27-25 | Reserved | This field is reserved. |
| 24 | TSTMR_EN | **Time Stamp Timer Enable** - The TSTMR_EN bit enables the Time Stamp Timer (TSTMR) when the the Slow-Speed IRC is enabled.<br>• 0 - The TSTMR is disabled and cannot be enabled through any hardware or software operations.<br>• 1 - The TSTMR is enabled and begins counting whenever the Slow-Speed IRC is enabled. |
| 23-17 | Reserved | This field is reserved. |
| 16 | NMI_DIS | **Non-Maskable Interrupt (NMI) Disable** - The NMI_DIS bit disables the NMI signal. |

*Table continues on the next page...*

## Table 26-4. Flash Option Register Bit Definitions (continued)

| Bit Num | Field | Definition |
|---|---|---|
| | | • 0 - NMI pin and interrupts are enabled.<br>• 1 - NMI interrupts are always blocked. The associated pin continues to default to NMI pin controls with internal pullup enabled. |
| 15 | CM4_EN | **ARM CM4F core Enable** - The CM4_EN enables CM4F core.<br>• 0 - CM4F core is disabled.<br>• 1 - CM4F core is enabled. |
| 14 | RI5CY_DIS | **RI5CY core Disable** - The RI5CY_DIS bit disables RI5CY core.<br>• 0 - RI5CY core is enabled.<br>• 1 - RI5CY core is disabled. |
| 13 | CM0+_EN | **ARM CM0+ core Enable** - The CM0+_EN enables CM4F core.<br>• 0 - CM0+ core is disabled.<br>• 1 - CM0+ core is enabled. |
| 12 | ZERO_RISCY_DIS | **ZERO_RISCY core Disable** - The ZERO_RISCY_DIS bit disables ZERO_RISCY core.<br>• 0 - ZERO_RISCY core is enabled.<br>• 1 - ZERO_RISCY core is disabled. |
| 11-10 | BOOT_SRC | **Boot Source** - The BOOT_SRC field selects the boot source if the Boot Pin Configuration bit (BOOT_PIN) is set to 1.<br>• 00 - Boot from the internal flash memory.<br>• 01 - Reserved.<br>• 10 - Boot from the Boot ROM, configure communications peripheral(s), and enter boot loader mode. See Boot sequence for more information<br>• 11 - Boot from the Boot ROM, and enter boot loader mode. See Boot sequence for more information. |
| 9 | BOOT_PIN | **Boot Pin Configuration** - The BOOT_PIN bit controls the behavior of the boot pin selection.<br>• 0 - Force Boot from ROM with update if BOOTCFG0 asserted, where BOOTCFG0 is the boot configuration function which is muxed with NMI pin. The RESET_b pin must be enabled when this option is selected.<br>• 1 - Boot source configured by Boot Source (BOOT_SRC) field. |
| 8-7 | Reserved | This field is reserved. |
| 6 | BOOT_CORE | **Boot Core** - The BOOT_CORE bit selects which core will start executing code at the completion of initialization. Additionally, the Non-Maskable Interrupt (NMI) is routed to this core if the NMI_DIS bit is set to 0.<br>• 0 - CPU1 (Cortex-M0+) or/and CPU3 (ZERO-RISCY), which depends on [CM0+_EN] and [ZERO_RISCY_DIS] settings, will start executing code on completion of initialization.<br>• 1 - CPU0 (Cortex-M4) or/and CPU2 (RI5CY), which depends on [CM4_EN] and [RI5CY_DIS] settings,will start executing code on completion of initialization. |
| 5 | Reserved | This field is reserved for future expansion. |
| 4 | BOOT_MODE | **Boot Mode** - The BOOT_MODE bit selects the operational mode that will be entered at the completion of initialization.<br>• 0 - The device will exit initialization in VLPR mode.<br>• 1 - The device will exit initialization in RUN mode. |
| 3-1 | Reserved | This field is reserved. |
| 0 | BOOT_CLK | **Boot Clock** - The BOOT_CLK field controls the setting of the Core Clock Divide Ratio (DIVCORE) field. Depending on the value of the BOOT_MODE bit, this field will be set in either the SCG_RCCR register or the SCG_VCCR register.<br>BOOT_MODE = 1 (Exit initialization in RUN mode.) |

**Table 26-4. Flash Option Register Bit Definitions**

| Bit Num | Field | Definition |
|---|---|---|
| | | • 1 - SCG_RCCR[DIVCORE] set to 0000 - Divide-by-1<br>• 0 - SCG_RCCR[DIVCORE] set to 0001 - Divide-by-2<br><br>BOOT_MODE = 0 (Exit initialization in VLPR mode.)<br>• 1 - SCG_VCCR[DIVCORE] set to 0011 - Divide-by-4<br>• 0 - SCG_VCCR[DIVCORE] set to 0111 - Divide-by-8 |

## 26.3.3 Boot sequence

At power up, the on-chip POR voltage monitor holds the device in a POR state until the input supply exceeds the POR threshold, VPOR. The system continues to be held in this static state until the internal supplies have reached a safe operating voltage as determined by the LVD. The Multi System Mode Controller (MSMC) logic then completes a sequence of operations to exit reset.

1. The MSMC continues to assert reset to the internal logic, the RESET_b pin is driven low, and the SCG is enabled in its default clocking mode, (FIRC clock source selected).
2. The SCG enables the required clocks (system clock, flash clock, and any bus clocks).
3. The MSMC de-asserts reset to the Flash Memory Controller (FMC) while still asserting reset to the rest of the internal logic and driving the RESET_b pin low.
4. The FMC then configures the flash and reads the flash option byte. The data is stored in the Flash Memory Module (FTFE) in the Flash Option (FTFE_FOPT) register.
5. The flash option configurations from the FTFE_FOPT register are applied to the system to adjust the clock frequency, the clock divider, and other associated functions.
6. The FMC then reads the core option byte. The data is stored in the FTFE in the Core Option (FTFE_FOPT) register.
7. The core option configurations from the FTFE_FOPT register are applied to the system to select which core will be used as the boot core and which one remains power gated.
8. When flash initialization completes, the MSMC stops driving the RESET_b pin low. If RESET_b continues to be asserted (an indication of a slow rise time on the RESET_b pin or an external device driving the pin low), the device continues to be held in reset. Once the RESET_b pin is detected high, the boot core clock is enabled and the device is released from reset.
9. When the device exits reset, the boot core sets up the stack, program counter (PC), and link register (LR). The processor reads the start SP (SP_main) from vector-table

offset 0. The core reads the start PC from vector-table offset 4. LR is set to 0xFFFF_FFFF. The next sequence of events depends on the FTFE_FOPT[BOOT_PIN] and FTFE_FOPT[BOOT_SRC].

- If FTFE_FOPT[BOOT_PIN] = 0:
  - If NMI=0, boot from ROM
  - If NMI=1, boot option base on FTFE_FOPT[BOOT_SRC]
- If FTFE_FOPT[BOOT_PIN] = 1, boot option base on FTFE_FOPT[BOOT_SRC]

FTFE_FOPT[BOOTSRC]:

- If FTFE_FOPT[BOOT_SRC] == 00, boot from flash
- If FTFE_FOPT[BOOT_SRC] == 11/10, boot from ROM
- If FTFE_FOPT[BOOT_SRC] == 01, reserved

**NOTE**

If the NMFI function is not required, either for an interrupt or wake up source, it is recommended that the NMI function be disabled by setting the FTFE_FOPT[NMI_DIS].

Subsequent system resets follow this same reset flow.

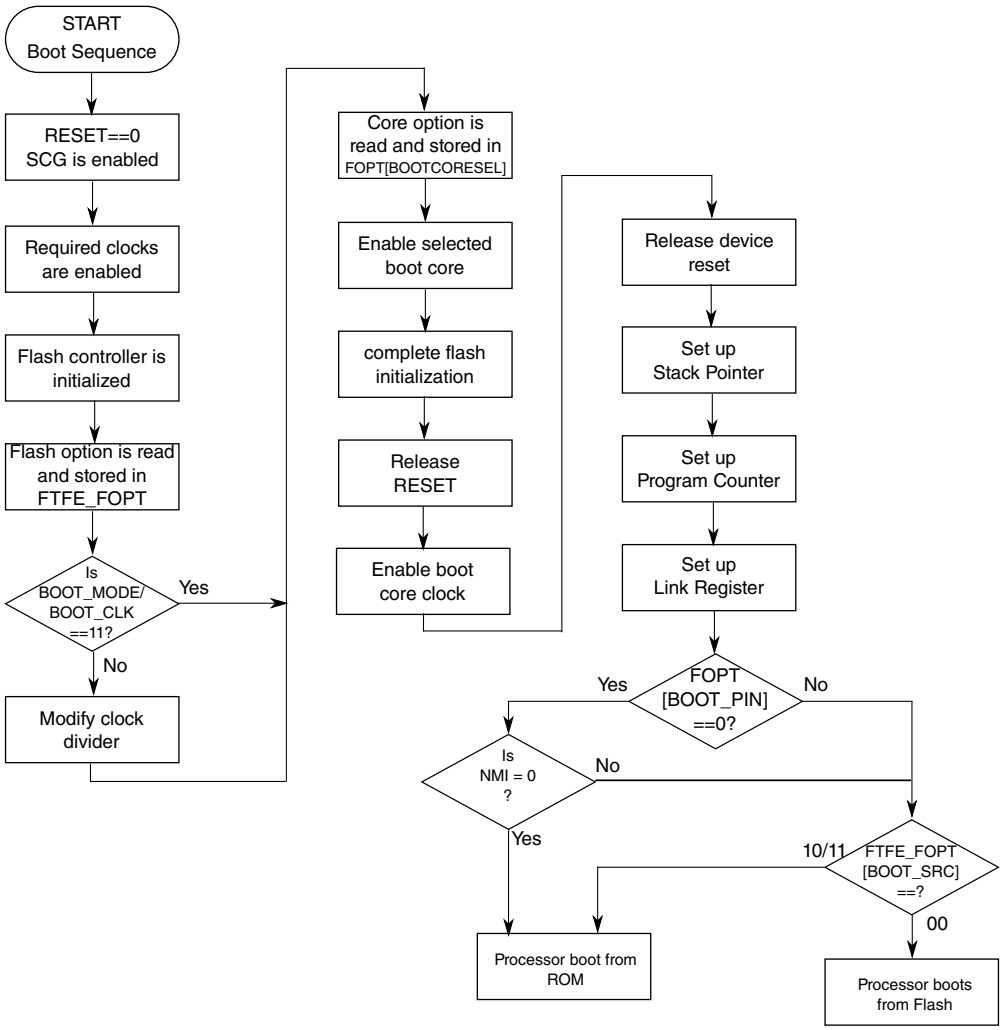

**Figure 26-1. Boot Sequence**

# Chapter 27
# Kinetis ROM Bootloader

## 27.1 Chip-specific information

This chapter is for ARM core only.

### 27.1.1 Also see the Kinetis Bootloader Reference Manual

This chapter describes only part of the information for your device's specific ROM Bootloader. For more detailed information and explanations of how the ROM Bootloader works, see the Kinetis Bootloader v2.0.0 Reference Manual, which can be found on https://www.nxp.com.

### 27.1.2 Kinetis bootloader peripheral pinmux

This device has various peripherals (LPUART, LPI2C, LPSPI , USB) supported by the Kinetis ROM Bootloader. To use an interface for bootloader communications, the peripheral must be enabled in the BCA, as shown in The Kinetis Bootloader Configuration Area (BCA). If the BCA is invalid (such as all 0xFF bytes), then all peripherals will be enabled by default. The next table shows the pads used by the Kinetis ROM Bootloader.

**Table 27-1. Kinetis Bootloader Peripheral Pinmux**

| Peripheral | Instance | Alt Mode | Pins |
|---|---|---|---|
| LPUART | 0 | 3 | PTC7, LPUART0_RX |
| | | | PTC8, LPUART0_TX |
| I2C | 0 | 4 | PTC10, LPI2C0_SCL |
| | | | PTC9, LPI2C0_SDA |
| SPI | 0 | 2 | PTC12, LPSPI0_PCS0 |
| | | | PTC8, LPSPI0_SCK |

*Table continues on the next page...*

**Table 27-1. Kinetis Bootloader Peripheral Pinmux (continued)**

| Peripheral | Instance | Alt Mode | Pins |
|---|---|---|---|
| | | | PTC11, LPSPI0_SIN |
| | | | PTC9, LPSPI0_SOUT |
| USB | 0 | 0 | USB0_DP |
| | | | USB0_DM |

### 27.1.3 Bootloader Memory Access

While executing, the Kinetis Bootloader uses the following address ranges in ROM and RAM memory:

- 0x0880_0000 – 0x0880_BFFF (Boot ROM, 48 KB)
- 0x0800_0000 – 0x0800_FFFF (Cortex M4 ITCM SRAM, 64 KB)

## 27.2 Introduction

The Kinetis bootloader is the program residing in the on-chip read-only memory (ROM) of a Kinetis microcontroller device. There is hardware logic in place at boot time that either starts execution of an embedded image available on the internal flash memory, or starts the execution of the Kinetis Bootloader from on-chip ROM.

The Kinetis Bootloader's main task is to provision the internal flash memory with an embedded firmware image during manufacturing, or at any time during the life of the Kinetis device. The Kinetis Bootloader does the provisioning by acting as a slave device, and listening to various peripheral ports where a master can start communication.

For the Kinetis device, the Kinetis Bootloader can interface with USB, LPI2C, LPSPI, and LPUART peripherals in slave mode and respond to the commands sent by a master (or host) communicating on one of those ports. The host/master can be a firmware-download application running on a PC or an embedded host communicating with the Kinetis Bootloader. Regardless of the host/master (PC or embedded host), the Kinetis Bootloader always uses a command protocol to communicate with that host/master. Commands are provided to write to memory (internal flash or RAM), erase flash, and get/set bootloader options and property values. The host application can query the set of available commands.

On start-up, the bootloader reads optional configuration parameters from a fixed area on flash called the bootloader configuration area (BCA). These parameters can be modified by the write memory command or by downloaded flash image. BCA parameters include configuration data such as enabled peripherals, peripheral-specific settings, etc.

This chapter describes Kinetis Bootloader features, functionality, command structure and which peripherals are supported.

Features supported by the Kinetis Bootloader in Kinetis ROM:

- Supports USB, LPI2C, LPSPI, and LPUART peripheral interfaces
- Automatic detection of the active peripheral
- Ability to disable any peripheral
- LPUART peripheral implements autobaud
- Common packet-based protocol for all peripherals
- Packet error detection and retransmission
- Flash-resident configuration options
- Fully supports internal flash security, including ability to mass erase or unlock security via the backdoor key
- Protection of RAM used by the bootloader while it is running
- Provides command to read properties of the device, such as flash and RAM size
- Multiple options for executing the bootloader either at system start-up or under application control at runtime
- Supports internal flash
- Supports encrypted image download
- Supports application image authentication
- ROM boots from either M4 (Default) or M0+ by configuring to FOPT IFR (record Index 0x84)

**Table 27-2. Commands supported by the Kinetis Bootloader in ROM**

| Command | Description | When flash security is enabled, then this command is |
|---|---|---|
| Call | Runs user application code and returns control to bootloader | Not supported |
| Execute | Run user application code that never returns control to the bootloader | Not supported |
| FillMemory | Fill a range of bytes in flash with a word pattern | Not supported |
| FlashEraseAll | Erase the entire flash array | Not supported |
| FlashEraseRegion | Erase a range of sectors in flash | Not supported |
| WriteMemory | Write data to memory | Not supported |
| ReadMemory | Read data from memory | Not supported |
| FlashProgramOnce | Writes data provided in a command packet to a specified range of bytes in the program once field | Not supported |

*Table continues on the next page...*

**Table 27-2. Commands supported by the Kinetis Bootloader in ROM (continued)**

| Command | Description | When flash security is enabled, then this command is |
|---|---|---|
| FlashReadOnce | Returns the contents of the program once field by given index and byte count | Not supported |
| FlashReadResource | Returns the contents of the IFR field or Flash Version ID, by given offset, byte count and option | Not supported |
| ReliableUpdate | Copy backup application from address to main application region, or swap flash using an indicator address | Not supported |
| | | |
| FlashSecurityDisable | Attempt to unlock flash security using the backdoor key | Supported |
| GetProperty | Get the current value of a property | Supported |
| ReceiveSbFile | Receive an SB file (which is generated by the `elftosb` tool) | Supported if the SB file is encrypted. See the SB File Decryption Support section for more details. |
| Reset | Reset the chip | Supported |
| SetProperty | Attempt to modify a writable property | Supported |
| FlashEraseAllUnsecure | Erase the entire flash array, including protected sectors | Supported |

## 27.3 Functional Description

The following sub-sections describe the Kinetis Bootloader in ROM functionality.

### 27.3.1 The Kinetis Bootloader Configuration Area (BCA)

The Kinetis Bootloader reads data from the Bootloader Configuration Area (BCA) to configure various features of the bootloader. The BCA resides in flash memory at offset 0x3C0 when device boots from CM4, otherwise the BCA location is 0x010003C0 when device boots from CM0+, and provides all of the parameters needed to configure the Kinetis Bootloader operation. For uninitialized flash, the Kinetis Bootloader uses a predefined default configuration. A host application can use the Kinetis Bootloader to program the BCA for use during subsequent initializations of the bootloader.

**Table 27-3. Configuration Fields for the Kinetis Bootloader**

| Offset | Size (bytes) | Configuration Field | Description |
|---|---|---|---|
| 0x00 - 0x03 | 4 | tag | Magic number to verify bootloader configuration is valid. Must be set to 'kcfg'. |

*Table continues on the next page...*

## Table 27-3. Configuration Fields for the Kinetis Bootloader (continued)

| Offset | Size (bytes) | Configuration Field | Description |
|---|---|---|---|
| 0x04 - 0x07 | 4 | crcStartAddress | Start address for application image CRC check. To generate the CRC, refer to the CRC chapter. If the bits are all set then Kinetis bootloader by default will not perform any CRC check. |
| 0x08 - 0x0B | 4 | crcByteCount | Byte count for application image CRC check. If the bits are all set then Kinetis bootloader by default will not perform any CRC check. |
| 0x0C - 0x0F | 4 | crcExpectedValue | Expected CRC value for application CRC check. If the bits are all set then Kinetis bootloader by default will not perform any CRC check. |
| 0x10 | 1 | enabledPeripherals | Bitfield of peripherals to enable.<br>bit 0 LPUART<br>bit 1 LPI2C<br>bit 2 LPSPI<br>bit 4 USB<br>Kinetis bootloader will enable the peripheral if corresponding bit is set to 1. |
| 0x11 | 1 | i2cSlaveAddress | If not 0xFF, used as the 7-bit I2C slave address. If 0xFF, defaults to 0x10 for I2C slave address |
| 0x12 - 0x13 | 2 | peripheralDetectionTimeout | Timeout in milliseconds for active peripheral detection. If 0xFFFF, defaults to 5 seconds. |
| 0x14 - 0x15 | 2 | usbVid | Sets the USB Vendor ID reported by the device during enumeration. If 0xFFFF, it defaults to 0x15A2. |
| 0x16 - 0x17 | 2 | usbPid | Sets the USB Product ID reported by the device during enumeration. |
| 0x18 - 0x1B | 4 | usbStringsPointer | Sets the USB Strings reported by the device during enumeration. Default string values are described in the USB peripheral section. |
| 0x1C | 1 | Reserved | - |
| 0x1D | 1 | Reserved | - |
| 0x1F | 1 | Reserved | - |
| 0x20 | 4 | Reserved | - |
| 0x24 - 0x27 | 8 | Reserved | - |
| 0x29 - 0x2F | 7 | Reserved | - |
| 0x28 | 1 | Reserved | - |
| 0x30 | 4 | Reserved | - |
| 0x34 | 12 | Reserved | - |

**NOTE**

The flash sector containing the BCA should not be located in the execute-only region, because the Kinetis bootloader cannot read an execute-only region.

The first configuration field 'tag' is a tag value or magic number. The tag value must be set to 'kcfg' for the bootloader configuration data to be recognized as valid. If tag-field verification fails, then the Kinetis Bootloader assumes that the flash is not initialized and uses a predefined default configuration. The tag value is treated as a character string, so bytes 0-3 must be set as shown in the table.

**Table 27-4. tag Configuration Field**

| Offset | tag Byte Value |
|---|---|
| 0 | 'k' (0x6B) |
| 1 | 'c' (0x63) |
| 2 | 'f' (0x66) |
| 3 | 'g' (0x67) |

## 27.3.2 Start-up Process

Any of the following conditions will force the hardware to start the Kinetis Bootloader:

- FOPT [11] is set to 1. This forces the ROM to run out of reset.
- The BOOTCFG0 pin is asserted. The pin must be configured as BOOTCFG0 by setting the BOOTPIN_OPT bit of FOPT to 0.
- A user applications running on flash or RAM calls into the Kinetis Bootloader entry point address in ROM, to start Kinetis Bootloader execution.

The FOPT[BOOT_SRC] determines the boot source. The FOPT register is located in flash erasable IFR field at index 0x84 in the flash IFR memory array. For a complete list of options, see the Boot options section in the Reset and Boot chapter. If FOPT [11] is set to 1, then the device will boot to ROM out of reset. Flash memory defaults to all 1s when erased, so a blank chip will automatically boot to ROM.

The BOOTCFG0 pin is shared with the NMI pin, with NMI being the default usage. Regardless of whether the NMI pin is enabled or not, the NMI functionality is disabled if the ROM is executed out of reset, for as long as the ROM is running.

When the ROM is executed out of reset, vector fetches from the CPU are redirected to the ROM's vector table in ROM memory at offset 0x0880_0000. This ensures that any exceptions will be handled by the ROM.

After the Kinetis Bootloader has started, the following procedure starts bootloader operations:

1. The FOPT[BOOT_CORE] determines which core is currently booting from ROM.
2. The MSMC_MR[BOOTCFG] bit is set, so that the device will reboot back into the ROM if/when the device is reset.
3. Initializes the bootloader's .data and .bss sections.
4. Reads bootloader configuration data from flash at address 0x3C0 or 0x010003C0. The configuration data is only used if the tag field is set to the expected 'kcfg' value. If the tag is incorrect, then the configuration values are set to default, as if the data was all 0xFF bytes.
5. Enabled peripherals are initialized.
6. After coming out of reset, the ROM bootloader initializes all peripherals, looks to see if a valid application is in flash, then auto-detects any peripheral activities within a peripheral detect timeout period.

   ```
   #define BL_DEFAULT_PERIPHERAL_DETECT_TIMEOUT 5000   // 5s
   ```

   Before the BL_DEFAULT_PERIPHERAL_DETECT_TIMEOUT expires and even if a valid application exists in flash, the ROM bootloader still runs the automatic peripheral detection. After the BL_DEFAULT_PERIPHERAL_DETECT_TIMEOUT time period expires:
   - If no active peripherals are detected but there is a valid application in flash, then the ROM bootloader jumps to the application.
   - If no active peripherals are detected and there is no valid application in flash, then the ROM bootloader continues to auto-detect peripherals activities, until the hit time (BL_DEFAULT_POWERDOWN_TIMEOUT) expires; after that, the ROM bootloader puts the chip into vlls1 mode (enter_vlls1();).

   ```
   #define BL_DEFAULT_POWERDOWN_TIMEOUT 600000 //10mins)
   ```

**NOTE**

The flash sector containing the vector table should not be located in the execute-only region, because the Kinetis bootloader cannot read the PC and SP addresses in an execute-only region.

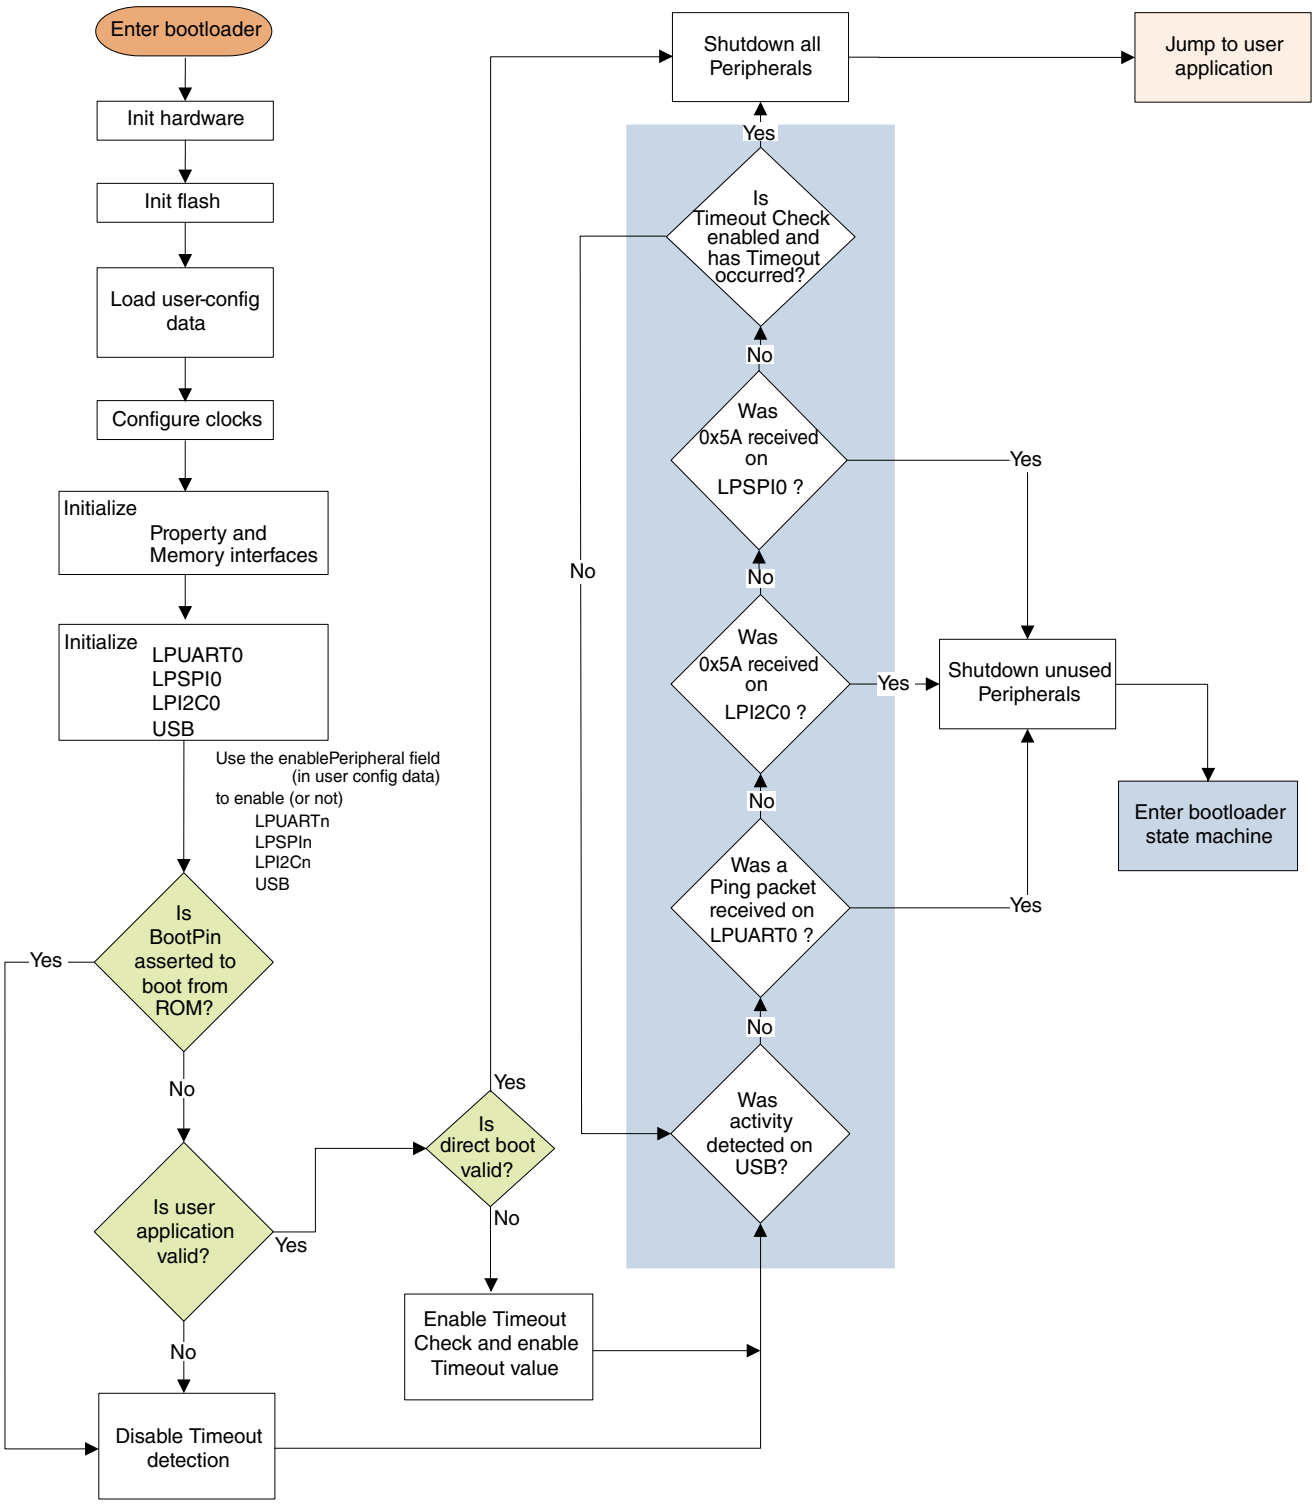

**Figure 27-1. Kinetis Bootloader Start-up Flowchart**

### 27.3.3 Bootloader Entry Point / API Tree

To run the Kinetis Bootloader, a user application simply calls the runBootloader function. To get the address of the entry point, the user application reads the word containing the pointer to the bootloader API tree at offset 0x1C of the bootloader's vector table. The vector table is placed at the base of the bootloader's address range, which for the ROM is 0x0880_0000; the API tree pointer is at address 0x0880_001C.

The bootloader API tree is a structure that contains pointers to other structures, which have the function and data addresses for the bootloader. The bootloader entry point is always the 1st word of the API tree.

```
typedef struct BootloaderTree
{
    void (*runBootloader)(void *arg);            //!< Function to start the bootloader
executing.
    standard_version_t version;                  //!< Bootloader version number.
    const char *copyright;                       //!< Copyright string.
    const bootloader_context_t *runtimeContext;  //!< Pointer to the bootloader's runtime
context.
    const flash_driver_interface_t *flashDriver; //!< Flash driver API.
    const aes_driver_interface_t *aesDriver;     //!< AES driver API.
    const kb_interface_t *kbApi;                 //!< Bootloader API.
} bootloader_tree_t;
```

The prototype of the entry point is:

```
void run_bootloader(void * arg);
```

The `arg` parameter is currently unused, and is intended for future expansion (for example, passing options to the bootloader). To ensure future compatibility, a value of NULL should be passed for `arg`.

***Example:*** code to get the entry pointer address from the ROM and start the bootloader.

**NOTE**

This entry must be called in supervisor (privileged) mode.

```
// Variables

uint32_t runBootloaderAddress;

void (*runBootloader)(void * arg);

// Read the function address from the ROM API tree.

runBootloaderAddress = **(uint32_t **)(0x0880001c);

runBootloader = (void (*)(void * arg))runBootloaderAddress;

// Start the bootloader.

runBootloader(NULL);
```

### 27.3.4 Bootloader Protocol

This section explains the general protocol for the packet transfers between the host and the Kinetis Bootloader. The description includes the transfer of packets for different transactions, such as commands with no data phase and commands with incoming or outgoing data phase. The next section describes various packet types used in a transaction.

Each command sent from the host is replied to with a response command.

Commands may include an optional data phase:

- If the data phase is **incoming** (from host to bootloader ), then the data phase is part of the **original command**.
- If the data phase is **outgoing** (from bootloader to host), then the data phase is part of the **response command**.

**NOTE**

In all protocols (described in the next subsections), the Ack sent in response to a Command or Data packet can arrive at any time *before, during, or after* the Command/Data packet has processed.

#### 27.3.4.1 Command with no data phase

The protocol for a command with no data phase contains:

- Command packet (from host)
- Generic response command packet (to host)

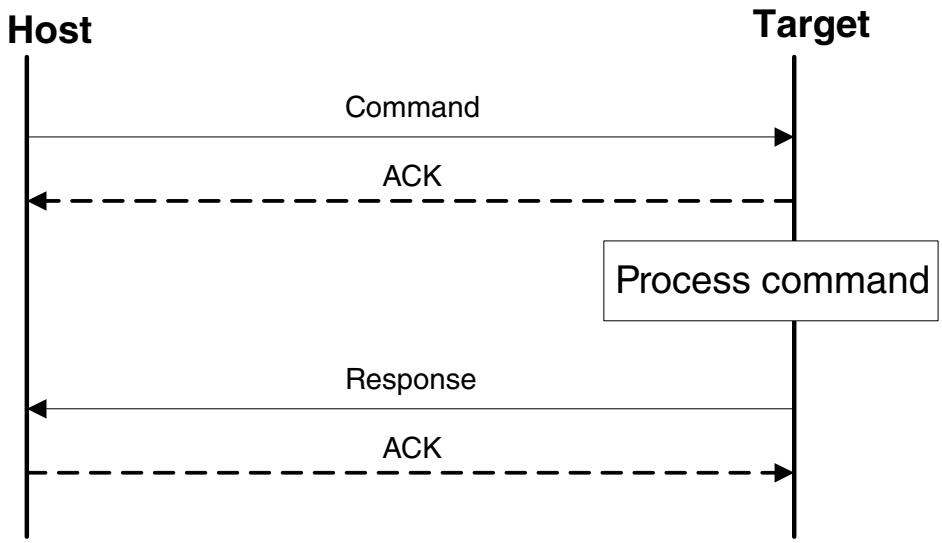

**Figure 27-2. Command with No Data Phase**

### 27.3.4.2 Command with incoming data phase

The protocol for a command with an incoming data phase contains:

- Command packet (from host)
- Generic response command packet (to host)
- Incoming data packets (from host)
- Generic response command packet (to host)

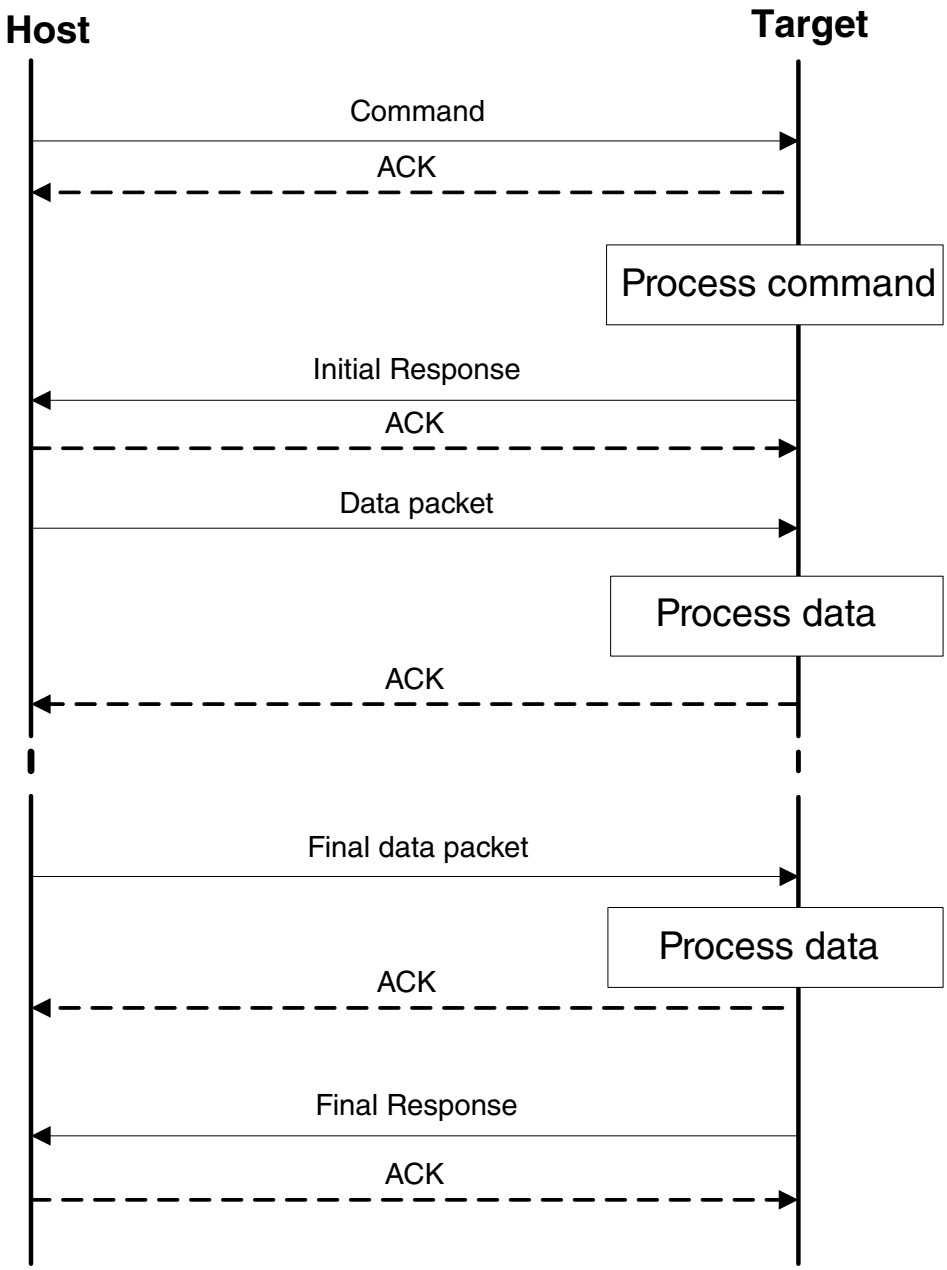

**Figure 27-3. Command with incoming data phase**

## NOTE

- The host may not send any further packets while it (the host) is waiting for the response to a command.
- If the Generic Response packet prior to the start of the data phase does not have a status of kStatus_Success, then the data phase is aborted.
- Data phases may be aborted by the receiving side by sending the final Generic Response early with a status of

kStatus_AbortDataPhase. The host may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet *sent after the data phase* includes the status for the entire operation.

#### 27.3.4.3 Command with outgoing data phase

The protocol for a command with an outgoing data phase contains:
- Command packet (from host)
- ReadMemory Response command packet (to host) (kCommandFlag_HasDataPhase set)
- Outgoing data packets (to host)
- Generic response command packet (to host)

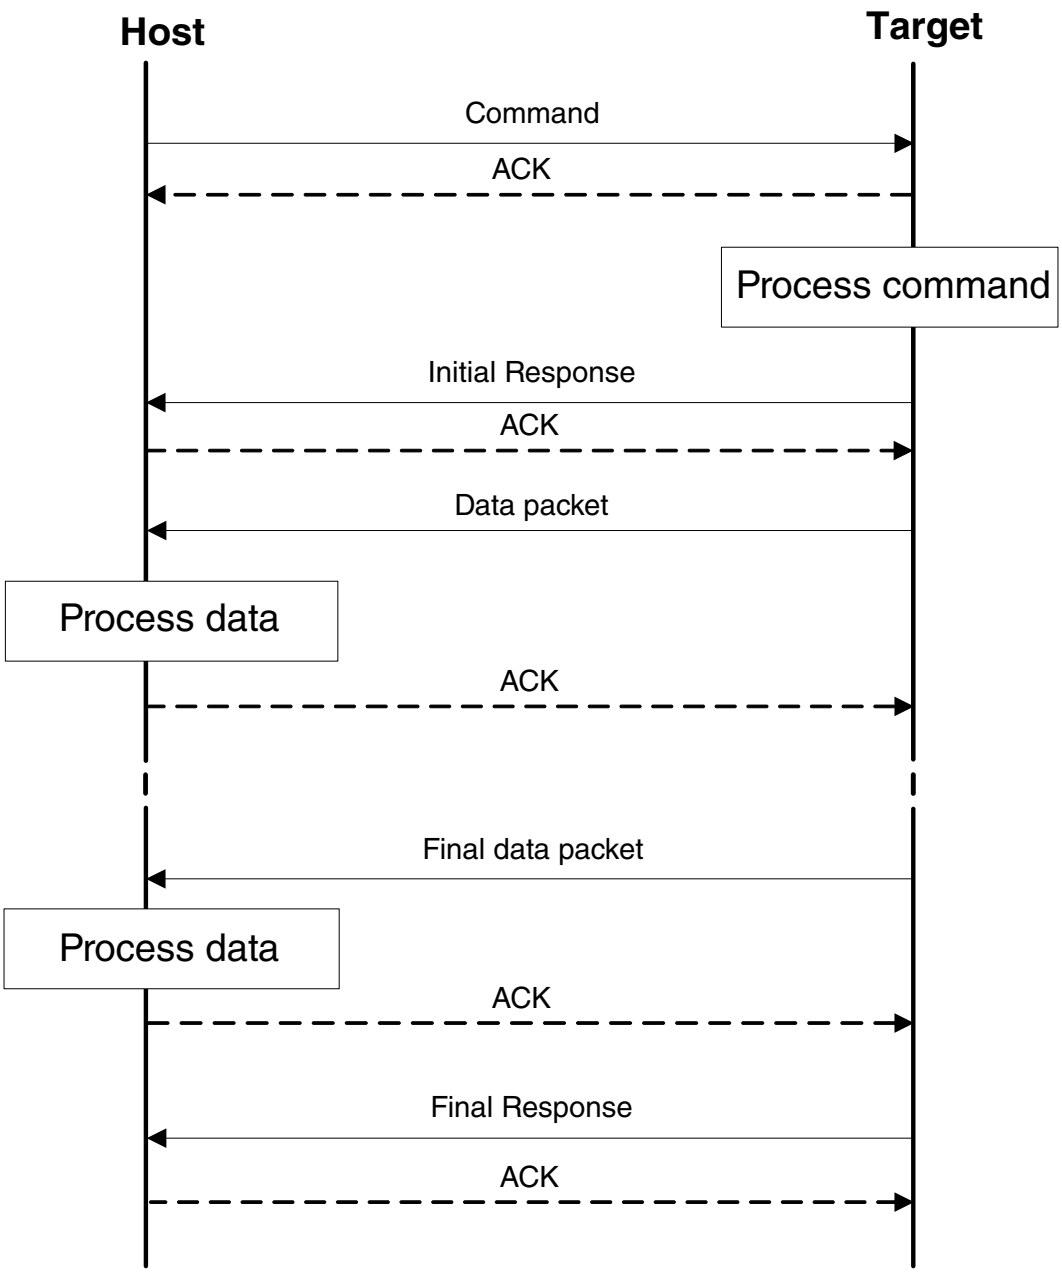

**Figure 27-4. Command with outgoing data phase**

## NOTE

- For the outgoing data phase sequence above, the data phase is really considered part of the response command.
- The host may not send any further packets while it (the host) is waiting for the response to a command.
- If the ReadMemory Response command packet prior to the start of the data phase does not contain the kCommandFlag_HasDataPhase flag, then the data phase is aborted.

- Data phases may be aborted by the host sending the final Generic Response early with a status of kStatus_AbortDataPhase. The sending side may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet *sent after the data phase* includes the status for the entire operation.

## 27.3.5 Bootloader Packet Types

The Kinetis Bootloader device works in slave mode. All data communication is initiated by a host, which is either a PC or an embedded host . The Kinetis Bootloader device is the target, which receives a command or data packet. All data communication between host and target is packetized.

**NOTE**

The term "target" refers to the "Kinetis Bootloader device."

There are 6 types of packets used in the device:

- Ping packet
- Ping Response packet
- Framing packet
- Command packet
- Data packet
- Response packet

All fields in the packets are in little-endian byte order.

### 27.3.5.1 Ping packet

The Ping packet is the first packet sent from a host to the target (Kinetis Bootloader), to establish a connection on a selected peripheral. For a LPUART peripheral, the Ping packet is used to determine the baudrate. A Ping packet must be sent before any other communications. In response to a Ping packet, the target sends a Ping Response packet.

**Table 27-5. Ping Packet Format**

| Byte # | Value | Name |
|---|---|---|
| 0 | 0x5A | start byte |
| 1 | 0xA6 | ping |

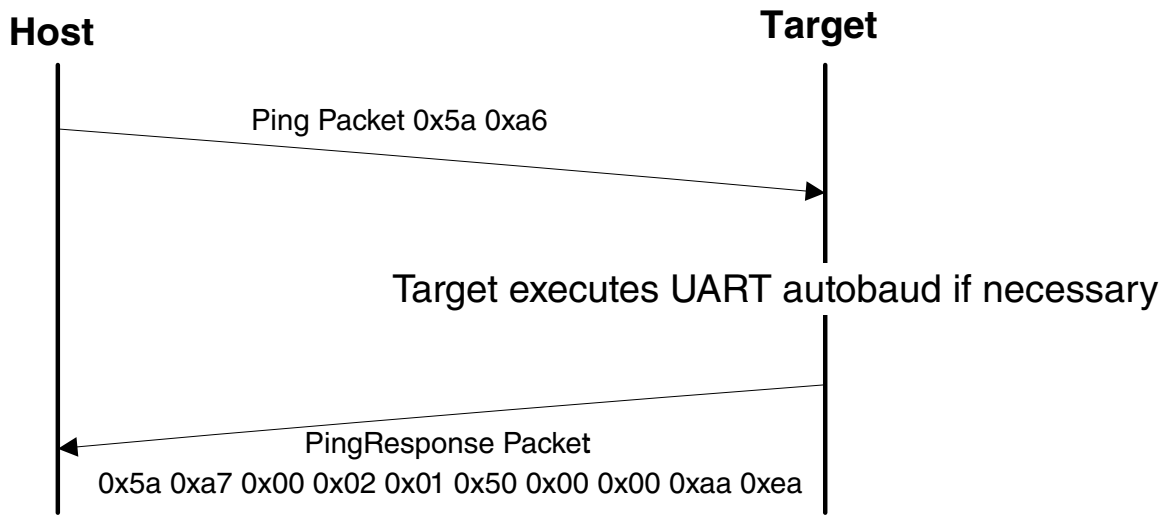

**Figure 27-5. Ping Packet Protocol Sequence**

### 27.3.5.2 Ping Response Packet

The target (Kinetis Bootloader) sends a Ping Response packet back to the host after receiving a Ping packet. If communication is over a LPUART peripheral, the target uses the incoming Ping packet to determine the baud rate before replying with the Ping Response packet. Once the Ping Response packet is received by the host, the connection is established, and the host starts sending commands to the target (Kinetis Bootloader).

**Table 27-6. Ping Response Packet Format**

| Byte # | Value | Parameter |
|---|---|---|
| 0 | 0x5A | start byte |
| 1 | 0xA7 | Ping response code |
| 2 | | Protocol bugfix |
| 3 | | Protocol minor |
| 4 | | Protocol major |
| 5 | | Protocol name = 'P' (0x50) |
| 6 | | Options low |
| 7 | | Options high |
| 8 | | CRC16 low |
| 9 | | CRC16 high |

### 27.3.5.3 Framing Packet

The framing packet is used for flow control and error detection, and it (the framing packet) wraps command and data packets as well.

The framing packet described in this section is used for serial peripherals including LPUART, LPI2C and LPSPI. The USB HID peripheral does not use framing packets. Instead, the packetization inherent in the USB protocol itself is used. Please refer to the USB peripheral section for details.

**Table 27-7. Framing Packet Format**

| Byte # | Value | Parameter | |
|---|---|---|---|
| 0 | 0x5A | start byte | |
| 1 | | packetType | |
| 2 | | length_low | Length is a 16-bit field that specifies the entire command or data packet size in bytes. |
| 3 | | length_high | |
| 4 | | crc16_low | This is a 16-bit field. The CRC16 value covers entire framing packet, including the start byte and command or data packets, but does not include the CRC bytes. See the CRC16 algorithm after this table. |
| 5 | | crc16_high | |
| 6 . . .n | | Command or Data packet payload | |

A special framing packet that contains only a start byte and a packet type is used for synchronization between the host and target.

**Table 27-8. Special Framing Packet Format**

| Byte # | Value | Parameter |
|---|---|---|
| 0 | 0x5A | start byte |
| 1 | 0xA*n* | packetType |

The Packet Type field specifies the type of the packet from one of the defined types (below):

**Table 27-9. packetType Field**

| packetType | Name | Description |
|---|---|---|
| 0xA1 | kFramingPacketType_Ack | The previous packet was received successfully; the sending of more packets is allowed. |
| 0xA2 | kFramingPacketType_Nak | The previous packet was corrupted and must be re-sent. |
| 0xA3 | kFramingPacketType_AckAbort | Data phase is being aborted. |
| 0xA4 | kFramingPacketType_Command | The framing packet contains a command packet payload. |
| 0xA5 | kFramingPacketType_Data | The framing packet contains a data packet payload. |

*Table continues on the next page...*

**Table 27-9. packetType Field (continued)**

| packetType | Name | Description |
|---|---|---|
| 0xA6 | kFramingPacketType_Ping | Sent to verify the other side is alive. Also used for UART autobaud. |
| 0xA7 | kFramingPacketType_PingResponse | A response to Ping; contains the framing protocol version number and options. |

## CRC16 algorithm:

```
uint16_t crc16_update(const uint8_t * src, uint32_t lengthInBytes)
{
    uint32_t crc = 0;
    uint32_t j;
    for (j=0; j < lengthInBytes; ++j)
    {
        uint32_t i;
        uint32_t byte = src[j];
        crc ^= byte << 8;
        for (i = 0; i < 8; ++i)
        {
            uint32_t temp = crc << 1;
            if (crc & 0x8000)
            {
                temp ^= 0x1021;
            }
            crc = temp;
        }
    }
    return crc;
}
```

### 27.3.5.4 Command packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.

**Table 27-10. Command Packet Format**

| Command Packet Format (32 bytes) | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| Command Header (4 bytes) | | | | 28 bytes for Parameters (Max 7 parameters) | | | | | | |
| Tag | Flags | Rsvd | Param Count | Param1 (32-bit) | Param2 (32-bit) | Param3 (32-bit) | Param4 (32-bit) | Param5 (32-bit) | Param6 (32-bit) | Param7 (32-bit) |
| byte 0 | byte 1 | byte 2 | byte 3 | | | | | | | |

**Table 27-11. Command Header Format**

| Byte # | Command Header Field | |
|---|---|---|
| 0 | Command or Response tag | The command header is 4 bytes long, with these fields. |
| 1 | Flags | |
| 2 | Reserved. Should be 0x00. | |
| 3 | ParameterCount | |

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only 7 parameters can fit into the command packet.

Command packets are also used by the target to send responses back to the host. As mentioned earlier, command packets and data packets are embedded into framing packets for all of the transfers.

**Table 27-12. Commands that are supported**

| Command | Name |
|---|---|
| 0x01 | FlashEraseAll |
| 0x02 | FlashEraseRegion |
| 0x03 | ReadMemory |
| 0x04 | WriteMemory |
| 0x05 | FillMemory |
| 0x06 | FlashSecurityDisable |
| 0x07 | GetProperty |
| 0x08 | ReceiveSBFile |
| 0x09 | Execute |
| 0x0A | Call |
| 0x0B | Reset |
| 0x0C | SetProperty |
| 0x0D | FlashEraseAllUnsecure |

*Table continues on the next page...*

**Table 27-12. Commands that are supported (continued)**

| Command | Name |
|---|---|
| 0x0E | FlashProgramOnce |
| 0x0F | FlashReadOnce |
| 0x10 | FlashReadResource |
| 0x11 | Reserved |
| 0x12 | ReliableUpdate |

**Table 27-13. Responses that are supported**

| Response | Name |
|---|---|
| 0xA0 | GenericResponse |
| 0xA3 | ReadMemoryResponse (used for sending responses to ReadMemory command only) |
| 0xA7 | GetPropertyResponse (used for sending responses to GetProperty command only) |
| 0xAF | FlashReadOnceResponse (used for sending responses to FlashReadOnce command only) |
| 0xB0 | FlashReadResourceResponse (used for sending responses to FlashReadResource command only) |

**Flags:** Each command packet contains a Flag byte. Only bit 0 of the flag byte is used. If bit 0 of the flag byte is set to 1, then data packets will follow in the command sequence. The number of bytes that will be transferred in the data phase is determined by a command-specific parameter in the parameters array.

**ParameterCount:** The number of parameters included in the command packet.

**Parameters:** The parameters are word-length (32 bits). With the default maximum packet size of 32 bytes, a command packet can contain up to 7 parameters.

### 27.3.5.5 Data packet

The data packet carries just the data, either host sending data to target, or target sending data to host. The data transfer direction is determined by the last command sent from the host. The data packet is also wrapped within a framing packet, to ensure the correct packet data is received.

The contents of a data packet are simply the data itself. There are no other fields, so that the most data per packet can be transferred. Framing packets are responsible for ensuring that the correct packet data is received.

### 27.3.5.6 Response packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses include:

- GenericResponse
- GetPropertyResponse
- ReadMemoryResponse
- FlashReadOnceResponse
- FlashReadResourceResponse

**GenericResponse:** After the Kinetis Bootloader has processed a command, the bootloader will send a generic response with status and command tag information to the host. The generic response is the last packet in the command protocol sequence. The generic response packet contains the framing packet data and the command packet data (with generic response tag = 0xA0) and a list of parameters (defined in the next section). The parameter count field in the header is always set to 2, for status code and command tag parameters.

**Table 27-14. GenericResponse Parameters**

| Byte # | Parameter | Descripton |
|---|---|---|
| 0 - 3 | Status code | The Status codes are errors encountered during the execution of a command by the target (Kinetis Bootloader). If a command succeeds, then a kStatus_Success code is returned. Table 27-99, Kinetis Bootloader Status Error Codes, lists the status codes returned to the host by the Kinetis Bootloader for ROM. |
| 4 - 7 | Command tag | The Command tag parameter identifies the response to the command sent by the host. |

**GetPropertyResponse:** The GetPropertyResponse packet is sent by the target in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a GetPropertyResponse tag value (0xA7).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

**Table 27-15. GetPropertyResponse Parameters**

| Byte # | Value | Parameter |
|---|---|---|
| 0 - 3 | | Status code |
| 4 - 7 | | Property value |

*Table continues on the next page...*

**Table 27-15. GetPropertyResponse Parameters (continued)**

| Byte # | Value | Parameter |
|---|---|---|
| . . . | | . . . |
| | | Can be up to maximum 6 property values, limited to the size of the 32-bit command packet and property type. |

**ReadMemoryResponse:** The ReadMemoryResponse packet is sent by the target in response to the host sending a ReadMemory command. The ReadMemoryResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a ReadMemoryResponse tag value (0xA3), the flags field set to kCommandFlag_HasDataPhase (1).

The parameter count set to 2 for the status code and the data byte count parameters shown below.

**Table 27-16. ReadMemoryResponse Parameters**

| Byte # | Parameter | Descripton |
|---|---|---|
| 0 - 3 | Status code | The status of the associated Read Memory command. |
| 4 - 7 | Data byte count | The number of bytes sent in the data phase. |

**FlashReadOnceResponse:**The FlashReadOnceResponse packet is sent by the target in response to the host sending a FlashReadOnce command. The FlashReadOnceResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a FlashReadOnceResponse tag value (0xAF), and the flags field set to 0. The parameter count is set to 2 plus *the number of words* requested to be read in the FlashReadOnceCommand.

**Table 27-17. FlashReadOnceResponse Parameters**

| Byte # | Value | Parameter |
|---|---|---|
| 0 – 3 | | Status Code |
| 4 – 7 | | Byte count to read |
| … | | … |
| | | Can be up to 20 bytes of requested read data. |

The FlashReadResourceResponse packet is sent by the target in response to the host sending a FlashReadResource command. The FlashReadResourceResponse packet contains the framing packet data and command packet data, with the command/response tag set to a FlashReadResourceResponse tag value (0xB0), and the flags field set to kCommandFlag_HasDataPhase (1).

**Table 27-18. FlashReadResourceResponse Parameters**

| Byte # | Value | Parameter |
|---|---|---|
| 0 – 3 | | Status Code |
| 4 – 7 | | Data byte count |

## 27.3.6 Bootloader Command API

All Kinetis Bootloader command APIs follow the command packet format that is wrapped by the framing packet, as explained in previous sections.

- For a list of commands supported by the Kinetis Bootloader in ROM, see Table 27-2, Commands supported.
- For a list of status codes returned by the Kinetis Bootloader in ROM, see Table 27-99, Kinetis Bootloader Status Error Codes.

**NOTE**

All the examples in this section depict byte traffic on serial peripherals that use framing packets. USB HID transactions use the USB HID report packets instead of the serial framing packets shown in this section. Please refer to the HID reports section for details of the USB HID packet structure.

### 27.3.6.1 ReliableUpdate command

The ReliableUpdate command performs the reliable update operation.

- **For a software implementation:** the backup application address is the parameter that is required for the ReliableUpdate command. If the *backup address* is set to 0, then the bootloader uses the *predefined address*.
- **For a hardware implementation:** the swap indicator address is the parameter that is required for the ReliableUpdate command.

- If the flash swap system is **uninitialized**, then the swap indicator address can be arbitrarily specified.
- If the flash swap system is **initialized**, then the swap indicator must be aligned with the swap system.

**Table 27-19. Parameters for ReliableUpdate command**

| Byte number | Command |
|---|---|
| 0 - 3 | • **For a software implementation:** the value is the backup application address.<br>• **For a hardware implementation:** the value is the swap indicator address. |

**Response:** The target returns a GenericResponse packet with a status code either set to kStatus_Success upon a successful execution of the command, or set to an appropriate error status code.

### 27.3.6.2 Call command

The Call command will execute a function that is written in memory at the address sent in the command. The address needs to be a valid memory location residing in accessible flash (internal or external) or in RAM. The command supports the passing of one 32-bit argument. Although the command supports a stack address, at this time the call will still take place using the current stack pointer. After execution of the function, a 32-bit return value will be returned in the generic response message.

**Table 27-20. Parameters for Call Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Call address |
| 4 - 7 | Argument word |
| 8 - 11 | Stack pointer |

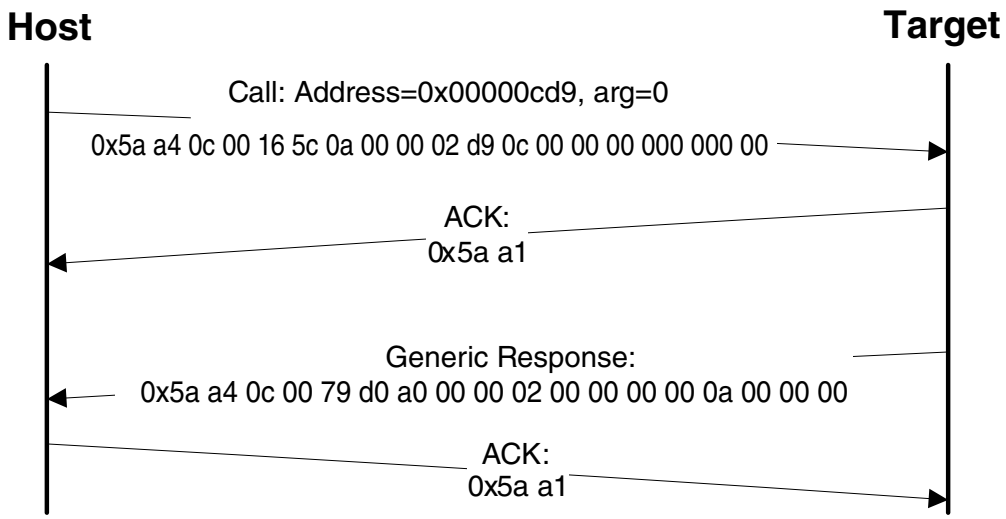

**Figure 27-6. Protocol Sequence for Call Command**

**Response:** The target (Kinetis Bootloader) will return a GenericResponse packet with a status code either set to the return value of the function called or set to kStatus_InvalidArgument (105).

### 27.3.6.3 ReceiveSBFile command

The ReceiveSBFile command (ReceiveSbFile) will start the transfer of an SB file to the target. The command only specifies the size in bytes of the SB file that will be sent in the data phase. The SB file will be processed as it is received by the Bootloader .

**Table 27-21. Parameters for ReceiveSBFile Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Byte count |

**Data Phase:** The Receive SB file command has a data phase; the host will send data packets until the number of bytes of data specified in the byteCount parameter of the Receive SB File command are received by the target.

**Response:** The target (Bootloader) will return a GenericResponse packet with a status code set to the kStatus_Success upon successful execution of the command, or set to an appropriate error code.

### 27.3.6.4 Execute command

The execute command results in the bootloader setting the program counter to the code at the provided jump address, R0 to the provided argument, and a Stack pointer to the provided stack pointer address. Prior to the jump, the system is returned to the reset state.

The Jump address, function argument pointer, and stack pointer are the parameters required for the Execute command.

**Table 27-22. Parameters for Execute Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Jump address |
| 4 - 7 | Argument word |
| 8 - 11 | Stack pointer address |

The Execute command has no data phase.

**Response:** Before executing the Execute command, the target (Kinetis Bootloader) will validate the parameters and return a GenericResponse packet with a status code either set to kStatus_Success or an appropriate error status code.

### 27.3.6.5 Reset command

The Reset command will result in bootloader resetting the chip.

The Reset command requires no parameters.

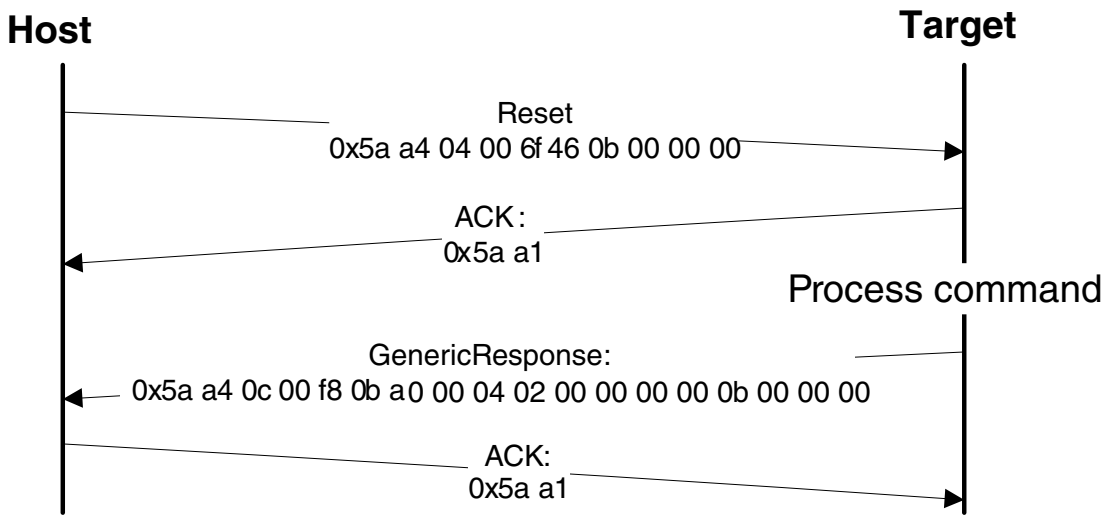

**Figure 27-7. Protocol Sequence for Reset Command**

**Table 27-23. Reset Command Packet Format (Example)**

| Reset | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x04 0x00 |
| | crc16 | 0x6F 0x46 |
| Command packet | commandTag | 0x0B - reset |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x00 |

The Reset command has no data phase.

**Response:** The target (Kinetis Bootloader) will return a GenericResponse packet with status code set to kStatus_Success, before resetting the chip.

## 27.3.6.6 GetProperty command

The GetProperty command is used to query the bootloader about various properties and settings. Each supported property has a unique 32-bit tag associated with it. The tag occupies the first parameter of the command packet. The target returns a GetPropertyResponse packet with the property values for the property identified with the tag in the GetProperty command.

Properties are the defined units of data that can be accessed with the GetProperty or SetProperty commands. Properties may be read-only or read-write. All read-write properties are 32-bit integers, so they can easily be carried in a command parameter.

For a list of properties and their associated 32-bit property tags supported by the Kinetis Bootloader in ROM, see Table 27-82.

The 32-bit property tag is the only parameter required for GetProperty command.

**Table 27-24. Parameters for GetProperty Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Property tag |

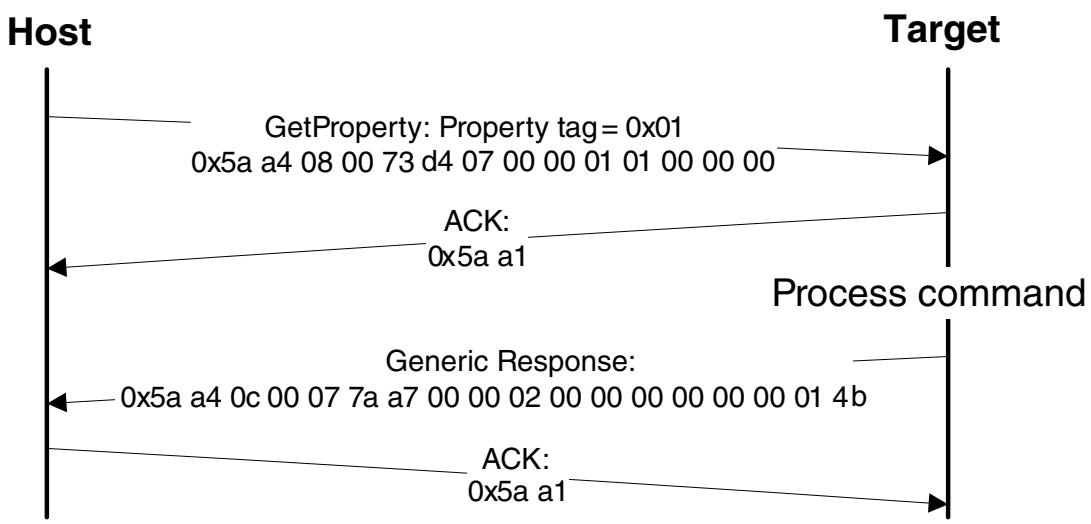

**Figure 27-8. Protocol Sequence for GetProperty Command**

**Table 27-25. GetProperty Command Packet Format (Example)**

| GetProperty | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x08 0x00 |
| | crc16 | 0x73 0xD4 |
| Command packet | commandTag | 0x07 – GetProperty |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x01 |
| | propertyTag | 0x00000001 - CurrentVersion |

The GetProperty command has no data phase.

**Response:** In response to a GetProperty command, the target will send a GetPropertyResponse packet with the response tag set to 0xA7. The parameter count indicates the number of parameters sent for the property values, with the first parameter showing status code 0, followed by the property value(s). The next table shows an example of a GetPropertyResponse packet.

**Table 27-26. GetProperty Response Packet Format (Example)**

| GetPropertyResponse | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x0c 0x00 (12 bytes) |
| | crc16 | 0x07 0x7a |
| Command packet | responseTag | 0xA7 |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x02 |
| | status | 0x00000000 |
| | propertyValue | 0x0000014b - CurrentVersion |

### 27.3.6.7 SetProperty command

The SetProperty command is used to change or alter the values of the properties or options in the Kinetis Bootloader ROM. However, the SetProperty command can only change the value of properties that are writable—see Table 27-82, Properties used by Get/SetProperty Commands. If you try to set a value for a read-only property, then the Kinetis Bootloader will return an error.

The property tag and the new value to set are the 2 parameters required for the SetProperty command.

**Table 27-27. Parameters for SetProperty Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Property tag |
| 4 - 7 | Property value |

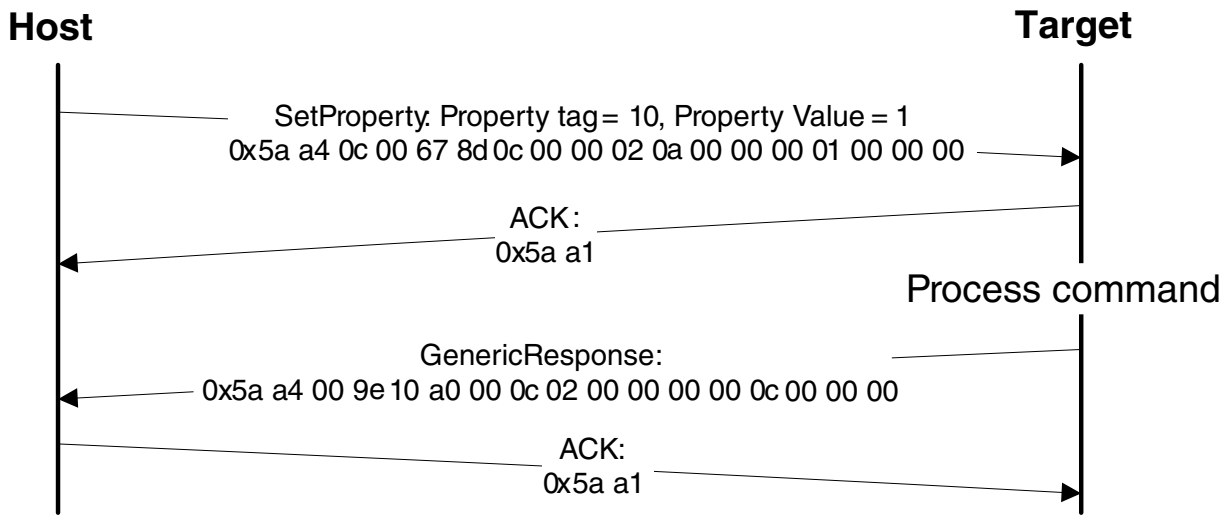

**Figure 27-9. Protocol Sequence for SetProperty Command**

**Table 27-28. SetProperty Command Packet Format (Example)**

| SetProperty | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x0C 0x00 |
| | crc16 | 0x67 0x8D |
| Command packet | commandTag | 0x0C – SetProperty with property tag 10 |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x02 |
| | propertyTag | 0x0000000A - VerifyWrites |
| | propertyValue | 0x00000001 |

The SetProperty command has no data phase.

**Response:** The target (Kinetis Bootloader) will return a GenericResponse packet with one of following status codes:

**Table 27-29. SetProperty Response Status Codes**

| Status Code |
|---|
| kStatus_Success |
| kStatus_ReadOnly |
| kStatus_UnknownProperty |
| kStatus_InvalidArgument |

### 27.3.6.8 FlashEraseAll command

The FlashEraseAll command performs an erase of the entire flash memory. If any flash regions are protected, then the FlashEraseAll command will fail and return an error status code. Executing the FlashEraseAll command will release flash security if it (flash security) was enabled, by setting the FTFE_FSEC register. However, the FSEC field of the flash configuration field is erased, so unless it is reprogrammed, the flash security will be re-enabled after the next system reset. The Command tag for FlashEraseAll command is 0x01 set in the commandTag field of the command packet.

The FlashEraseAll command requires no parameters.

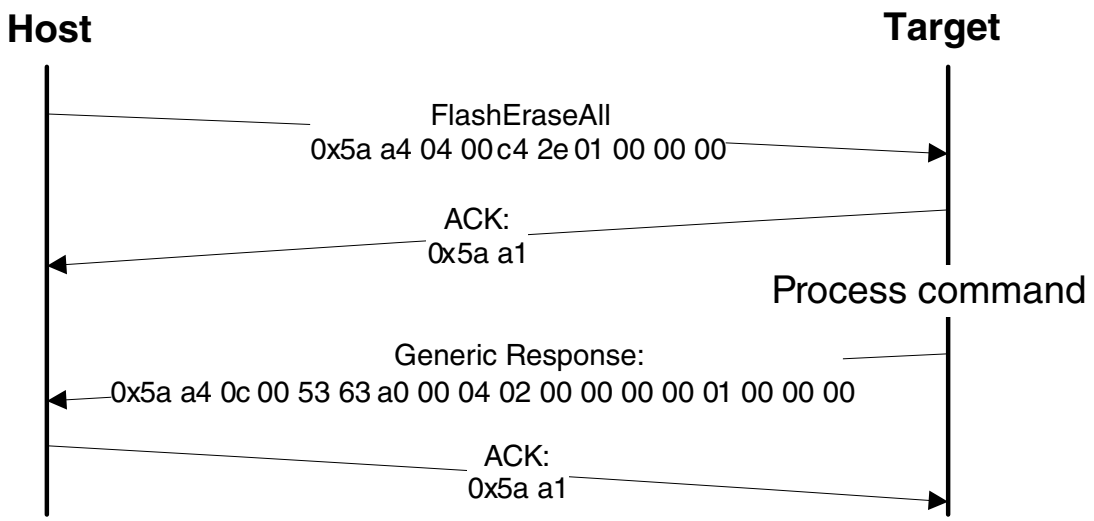

**Figure 27-10. Protocol Sequence for FlashEraseAll Command**

**Table 27-30. FlashEraseAll Command Packet Format (Example)**

| FlashEraseAll | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x04 0x00 |
| | crc16 | 0xC4 0x2E |
| Command packet | commandTag | 0x01 - FlashEraseAll |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x00 |
| | MemoryID | • If MemoryID = 0x00h, then internal flash.<br>• If MemoryID = 0x01h, then QSPI0 memory. |

The FlashEraseAll command has no data phase.

**Response:** The target (Kinetis Bootloader ) will return a GenericResponse packet with status code either set to kStatus_Success for successful execution of the command, or set to an appropriate error status code.

### 27.3.6.9 FlashEraseRegion command

The FlashEraseRegion command performs an erase of one or more sectors of the flash memory or a specified range of flash within the connected SPI flash devices.

The start address and number of bytes are the 2 parameters required for the FlashEraseRegion command. The start and byte count parameters must be , or the FlashEraseRegion command will fail and return kStatus_FlashAlignmentError (0x101). If the region specified does not fit in the flash memory space, the FlashEraseRegion command will fail and return kStatus_FlashAddressError (0x102). If any part of the region specified is protected, the FlashEraseRegion command will fail and return kStatus_MemoryRangeInvalid (0x10200).

**Table 27-31. Parameters for FlashEraseRegion Command**

| Byte # | Parameter |
|---|---|
| 0 - 3 | Start address |
| 4 - 7 | Byte count |

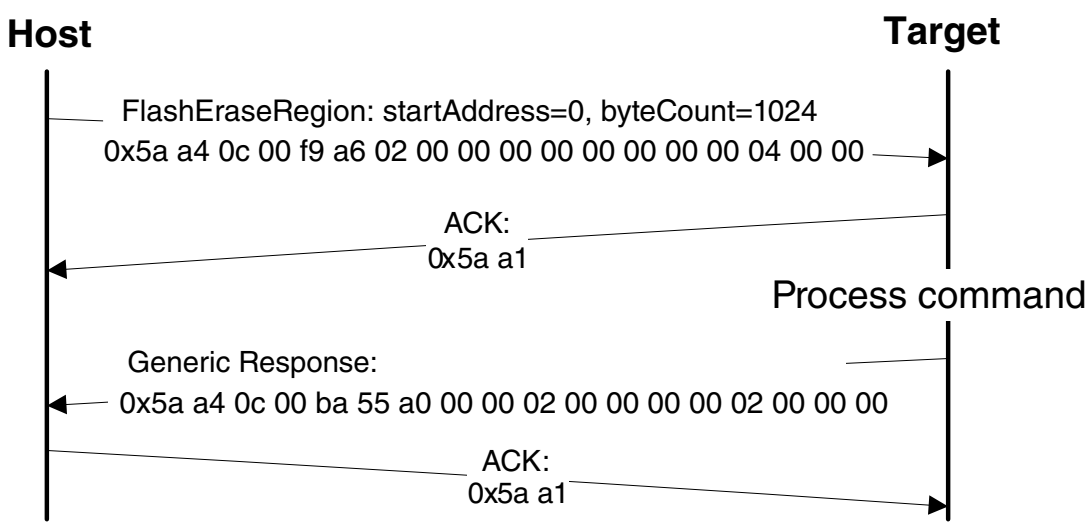

**Figure 27-11. Protocol Sequence for FlashEraseRegion Command**

**Table 27-32. FlashEraseRegion Command Packet Format (Example)**

| FlashEraseRegion | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x0C 0x00 |
| | crc16 | 0xF9 0x A6 |
| Command packet | commandTag | 0x02, kCommandTag_FlashEraseRegion |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x02 |
| | startAddress | 0x00 0x00 0x00 0x00 (0x0000_0000) |
| | byte count | 0x00 0x04 0x00 0x00 (0x400) |

The FlashEraseRegion command has no data phase.

**Response:** The target (Kinetis Bootloader ) will return a GenericResponse packet with one of following error status codes.

**Table 27-33. FlashEraseRegion Response Status Codes**

| Status Code |
|---|
| kStatus_Success (0x0) |
| kStatus_MemoryRangeInvalid (0x10200) |
| kStatus_FlashAlignmentError (0x101) |
| kStatus_FlashAddressError (0x102) |
| kStatus_FlashAccessError (0x103) |
| kStatus_FlashProtectionViolation (0x104) |
| kStatus_FlashCommandFailure (0x105) |

## 27.3.6.10 FlashEraseAllUnsecure command

The FlashEraseAllUnsecure command performs a mass erase of the flash memory, including protected sectors. Flash security is immediately disabled if it (flash security) was enabled, and the FSEC byte in the flash configuration field at address 0x40C is programmed to 0xFE. However, if the mass erase enable option in the FSEC field is disabled, then the FlashEraseAllUnsecure command will fail.

The FlashEraseAllUnsecure command requires no parameters.

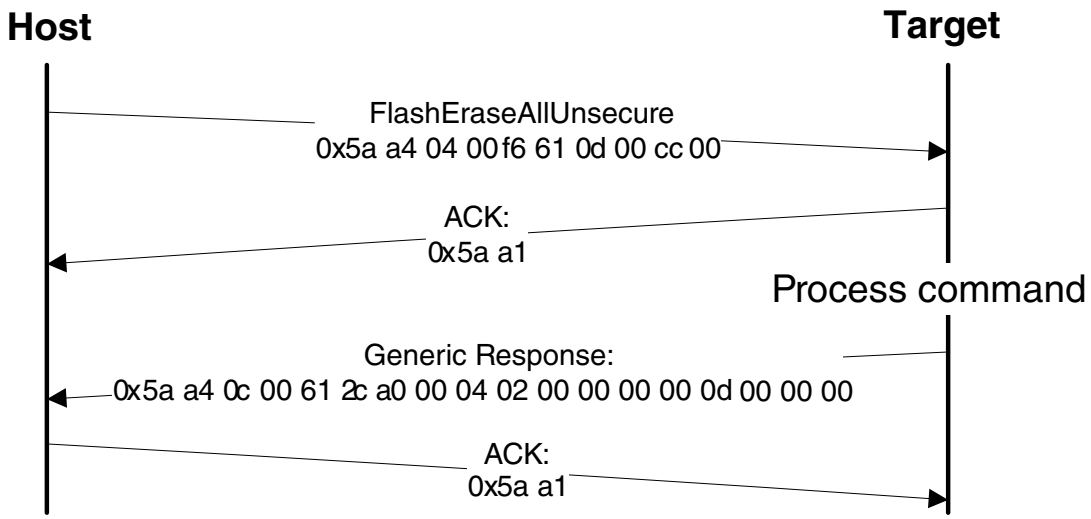

**Figure 27-12. Protocol Sequence for FlashEraseAll Command**

**Table 27-34. FlashEraseAllUnsecure Command Packet Format (Example)**

| FlashEraseAllUnsecure | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x04 0x00 |
| | crc16 | 0xF6 0x61 |
| Command packet | commandTag | 0x0D - FlashEraseAllUnsecure |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x00 |

The FlashEraseAllUnsecure command has no data phase.

**Response:** The target (Kinetis Bootloader) will return a GenericResponse packet with status code either set to kStatus_Success for successful execution of the command, or set to an appropriate error status code.

### 27.3.6.11 FlashProgramOnce command

The FlashProgramOnce command writes data (that is provided in a command packet) to a specified range of bytes in the program once field. Special care must be taken when writing to the program once field.

- The program once field only supports programming once, so any attempted to reprogram a program once field will get an error response.
- Writing to the program once field requires the byte count to be 4-byte aligned or 8-byte aligned.

The FlashProgramOnce command uses 3 parameters: index, byteCount, data.

**Table 27-35. Parameters for FlashProgramOnce Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Index of program once field |
| 4 - 7 | Byte count (must be evenly divisible by 4) |
| 8 - 11 | Data |
| 12 - 16 | Data |

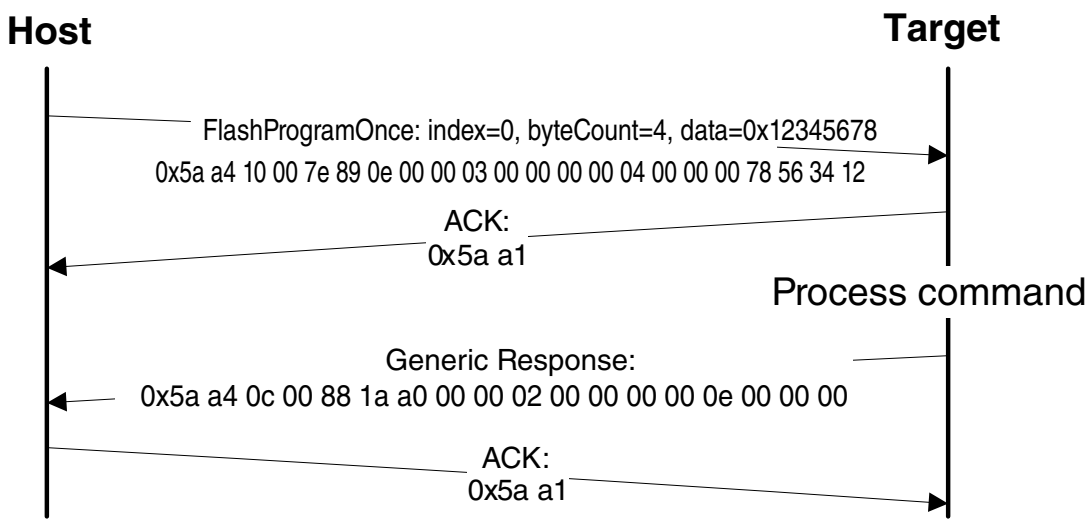

**Figure 27-13. Protocol Sequence for FlashProgramOnce Command**

**Table 27-36. FlashProgramOnce Command Packet Format (Example)**

| FlashProgramOnce | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x10 0x00 |
| | crc16 | 0x7E4 0x89 |
| Command packet | commandTag | 0x0E – FlashProgramOnce |
| | flags | 0 |
| | reserved | 0 |
| | parameterCount | 3 |
| | index | 0x0000_0000 |

*Table continues on the next page...*

**Table 27-36. FlashProgramOnce Command Packet Format (Example) (continued)**

| FlashProgramOnce | Parameter | Value |
|---|---|---|
| | byteCount | 0x0000_0004 |
| | data | 0x1234_5678 |

**Response:** upon successful execution of the command, the target (Kinetis Bootloader) will return a GenericResponse packet with a status code set to kStatus_Success, or to an appropriate error status code.

## 27.3.6.12 FlashReadOnce command

The FlashReadOnce command returns the contents of the program once field by given index and byte count. The FlashReadOnce command uses 2 parameters: index and byteCount.

**Table 27-37. Parameters for FlashReadOnce Command**

| Byte # | Parameter | Description |
|---|---|---|
| 0 - 3 | index | Index of the program once field (to read from) |
| 4 - 7 | byteCount | Number of bytes to read and return to the caller |

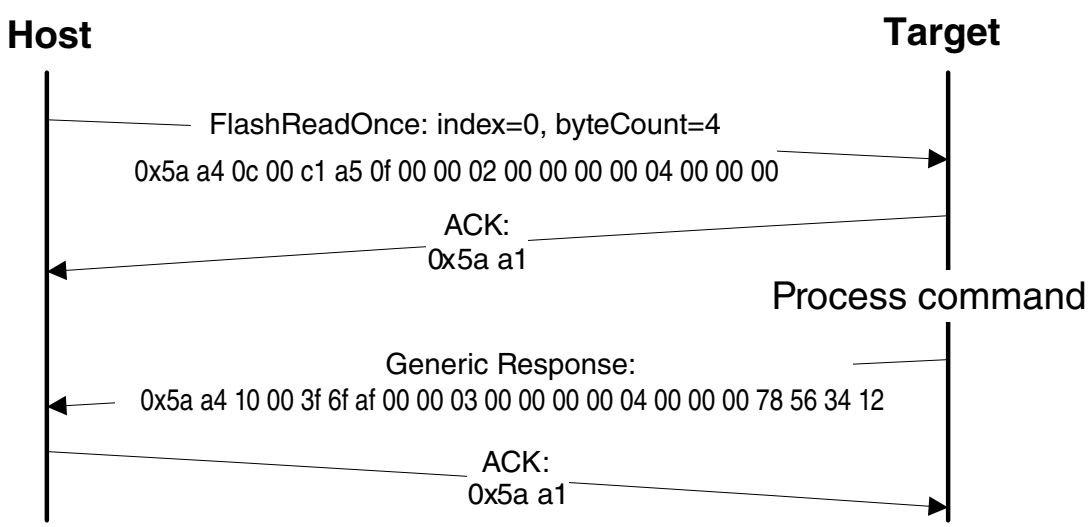

**Figure 27-14. Protocol Sequence for FlashReadOnce Command**

**Table 27-38. FlashReadOnce Command Packet Format (Example)**

| FlashReadOnce | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4 |
| | length | 0x0C 0x00 |
| | crc | 0xC1 0xA5 |
| Command packet | commandTag | 0x0F – FlashReadOnce |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x02 |
| | index | 0x0000_0000 |
| | byteCount | 0x0000_0004 |

**Table 27-39. FlashReadOnce Response Format (Example)**

| FlashReadOnce Response | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4 |
| | length | 0x10 0x00 |
| | crc | 0x3F 0x6F |
| Command packet | commandTag | 0xAF |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x03 |
| | status | 0x0000_0000 |
| | byteCount | 0x0000_0004 |
| | data | 0x1234_5678 |

**Response:** upon successful execution of the command, the target (Kinetis Bootloader) will return a FlashReadOnceResponse packet with a status code set to kStatus_Success, a byte count and corresponding data read from Program Once Field upon successful execution of the command, or will return with a status code set to an appropriate error status code and a byte count set to 0.

## 27.3.6.13 FlashReadResource command

The FlashReadResource command returns the contents of the IFR field or Flash Version ID, by given offset, byte count, and option. The FlashReadResource command uses 3 parameters: start address, byteCount, option.

**Table 27-40. Parameters for FlashReadResource Command**

| Byte # | Parameter | Command |
|---|---|---|
| 0 - 3 | start address | Start address of specific non-volatile memory to be read |
| 4 - 7 | byteCount | Byte count to be read |
| 8 - 11 | option | 0: IFR<br>1: Flash Version ID |

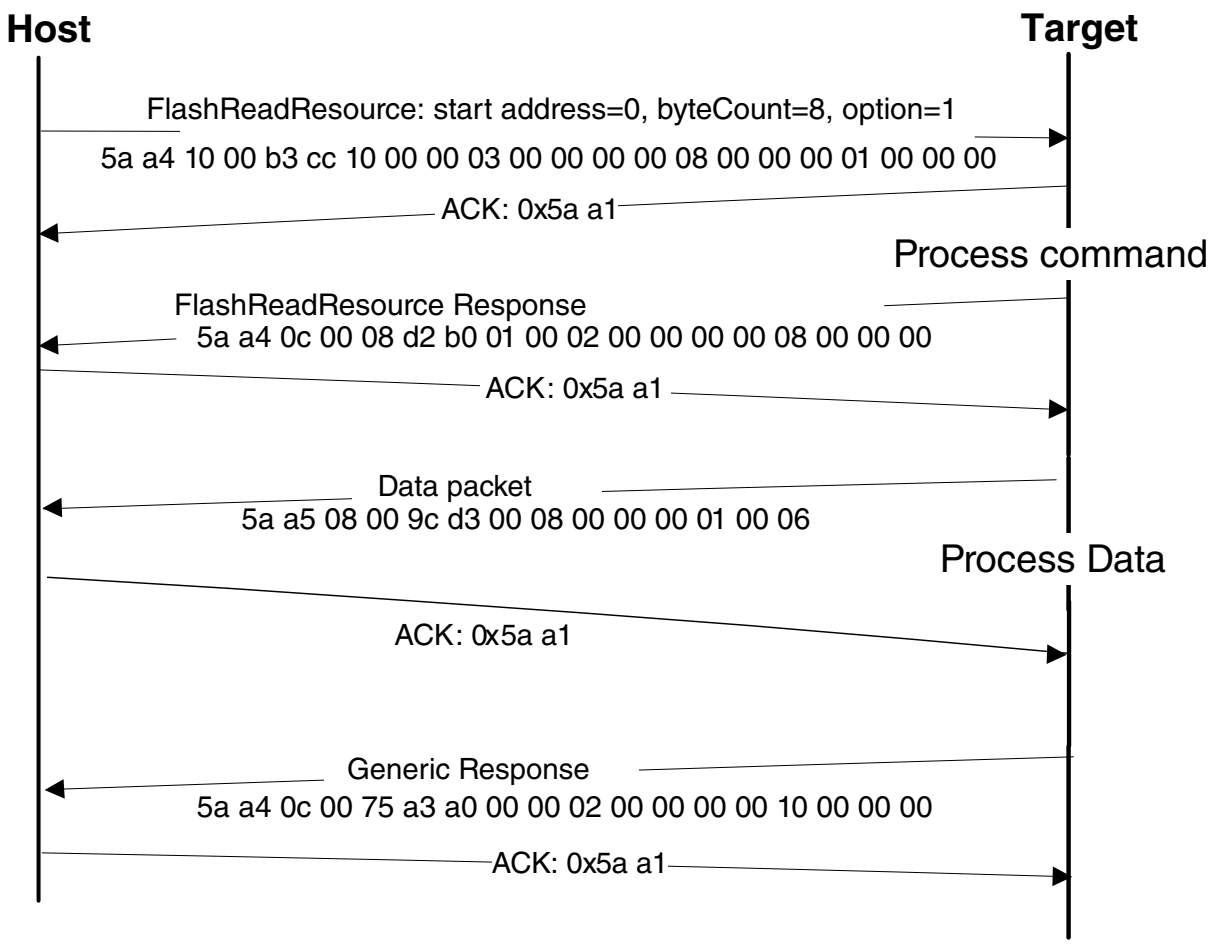

**Figure 27-15. Protocol Sequence for FlashReadResource Command**

**Table 27-41. FlashReadResource Command Packet Format (Example)**

| FlashReadResource | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4 |
| | length | 0x10 0x00 |
| | crc | 0xB3 0xCC |
| Command packet | commandTag | 0x10 – FlashReadResource |
| | flags | 0x00 |

*Table continues on the next page...*

**Table 27-41. FlashReadResource Command Packet Format (Example) (continued)**

| FlashReadResource | Parameter | Value |
|---|---|---|
| | reserved | 0x00 |
| | parameterCount | 0x03 |
| | startAddress | 0x0000_0000 |
| | byteCount | 0x0000_0008 |
| | option | 0x0000_0001 |

**Table 27-42. FlashReadResource Response Format (Example)**

| FlashReadResource Response | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4 |
| | length | 0x0C 0x00 |
| | crc | 0xD2 0xB0 |
| Command packet | commandTag | 0xB0 |
| | flags | 0x01 |
| | reserved | 0x00 |
| | parameterCount | 0x02 |
| | status | 0x0000_0000 |
| | byteCount | 0x0000_0008 |

**Data phase:** The FlashReadResource command has a data phase. Because the target (Kinetis Bootloader ) works in slave mode, the host must pull data packets until the number of bytes of data *specified in the byteCount parameter of FlashReadResource command* are received by the host.

## 27.3.6.14 FlashSecurityDisable command

The FlashSecurityDisable command performs the flash security disable operation, by comparing the 8-byte backdoor key (provided in the command) against the backdoor key stored in the flash configuration field (at address 0x400 in the flash).

The backdoor low and high words are the only parameters required for FlashSecurityDisable command.

**Table 27-43. Parameters for FlashSecurityDisable Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Backdoor key low word |

*Table continues on the next page...*

**Table 27-43. Parameters for FlashSecurityDisable Command (continued)**

| Byte # | Command |
|---|---|
| 4 - 7 | Backdoor key high word |

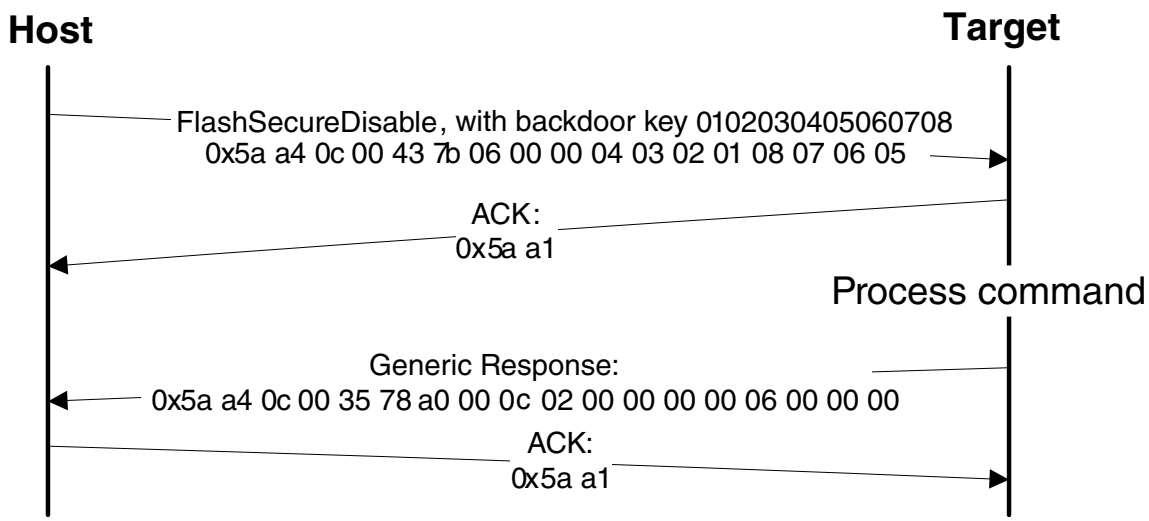

**Figure 27-16. Protocol Sequence for FlashSecurityDisable Command**

**Table 27-44. FlashSecurityDisable Command Packet Format (Example)**

| FlashSecurityDisable | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x0C 0x00 |
| | crc16 | 0x43 0x7B |
| Command packet | commandTag | 0x06 - FlashSecurityDisable |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x02 |
| | Backdoorkey_low | 0x04 0x03 0x02 0x01 |
| | Backdoorkey_high | 0x08 0x07 0x06 0x05 |

The FlashSecurityDisable command has no data phase.

**Response:** The target (Kinetis Bootloader) will return a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command, or set to an appropriate error status code.

### 27.3.6.15 FillMemory command

The FillMemory command fills a range of bytes in memory with a data pattern. It follows the same rules as the WriteMemory command. The difference between FillMemory and WriteMemory is that a data pattern is included in FillMemory command parameter, and there is no data phase for the FillMemory command, while WriteMemory does have a data phase.

**Table 27-45. Parameters for FillMemory Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Start address of memory to fill |
| 4 - 7 | Number of bytes to write with the pattern<br>• The start address should be 32-bit aligned.<br>• The number of bytes must be evenly divisible by 4. (Note: for a part that uses FTFE flash, the start address should be 64-bit aligned, and the number of bytes must be evenly divisible by 8). |
| 8 - 11 | 32-bit pattern |

- To fill with a byte pattern (8-bit), the byte must be replicated 4 times in the 32-bit pattern.
- To fill with a short pattern (16-bit), the short value must be replicated 2 times in the 32-bit pattern.

For example, to fill a byte value with 0xFE, the word pattern would be 0xFEFEFEFE; to fill a short value 0x5AFE, the word pattern would be 0x5AFE5AFE.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll, FlashEraseRegion, or FlashEraseAllUnsecure command.
- Writing to flash requires the start address to be .
- If the VerifyWrites property is set to true, then writes to flash will also perform a flash verify program operation.

When writing to RAM, the start address need not be aligned, and the data will not be padded.

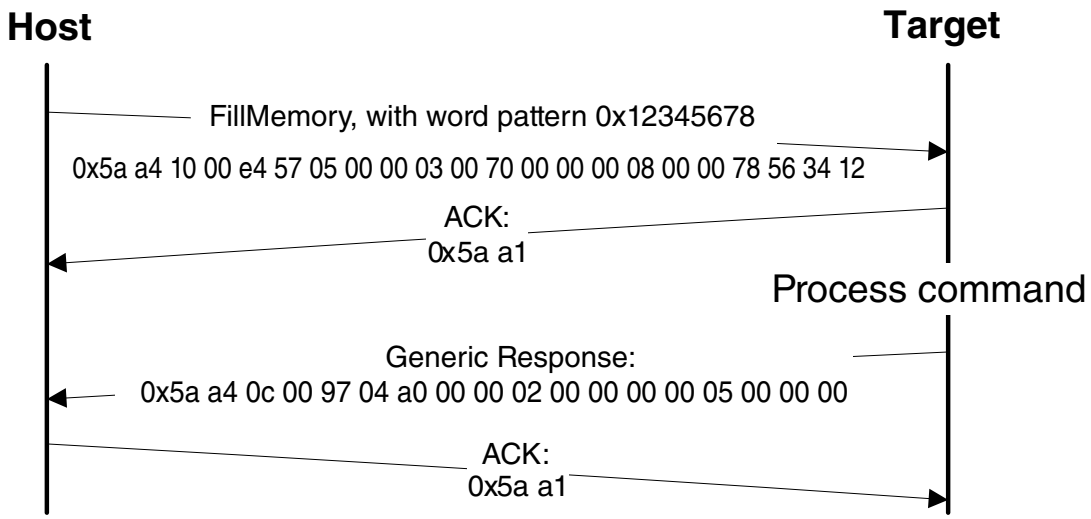

**Figure 27-17. Protocol Sequence for FillMemory Command**

**Table 27-46. FillMemory Command Packet Format (Example)**

| FillMemory | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x10 0x00 |
| | crc16 | 0xE4 0x57 |
| Command packet | commandTag | 0x05 – FillMemory |
| | flags | 0x00 |
| | Reserved | 0x00 |
| | parameterCount | 0x03 |
| | startAddress | 0x00007000 |
| | byteCount | 0x00000800 |
| | patternWord | 0x12345678 |

The FillMemory command has no data phase.

**Response:** upon successful execution of the command, the target (Kinetis Bootloader) will return a GenericResponse packet with a status code set to kStatus_Success, or to an appropriate error status code.

## 27.3.6.16 WriteMemory command

The WriteMemory command writes data provided in the data phase to a specified range of bytes in memory (flash or RAM). However, if flash protection is enabled, then writes to protected sectors will fail.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll, FlashEraseRegion, or FlashEraseAllUnsecure command.
- Writing to flash requires the start address to be .
- The byte count will be rounded up to a multiple of , and the trailing bytes will be filled with the flash erase pattern (0xff).
- If the VerifyWrites property is set to true, then writes to flash will also perform a flash verify program operation.

When writing to RAM, the start address need not be aligned, and the data will not be padded.

The start address and number of bytes are the 2 parameters required for WriteMemory command.

**Table 27-47. Parameters for WriteMemory Command**

| Byte # | Command |
|---|---|
| 0 - 3 | Start address |
| 4 - 7 | Byte count |

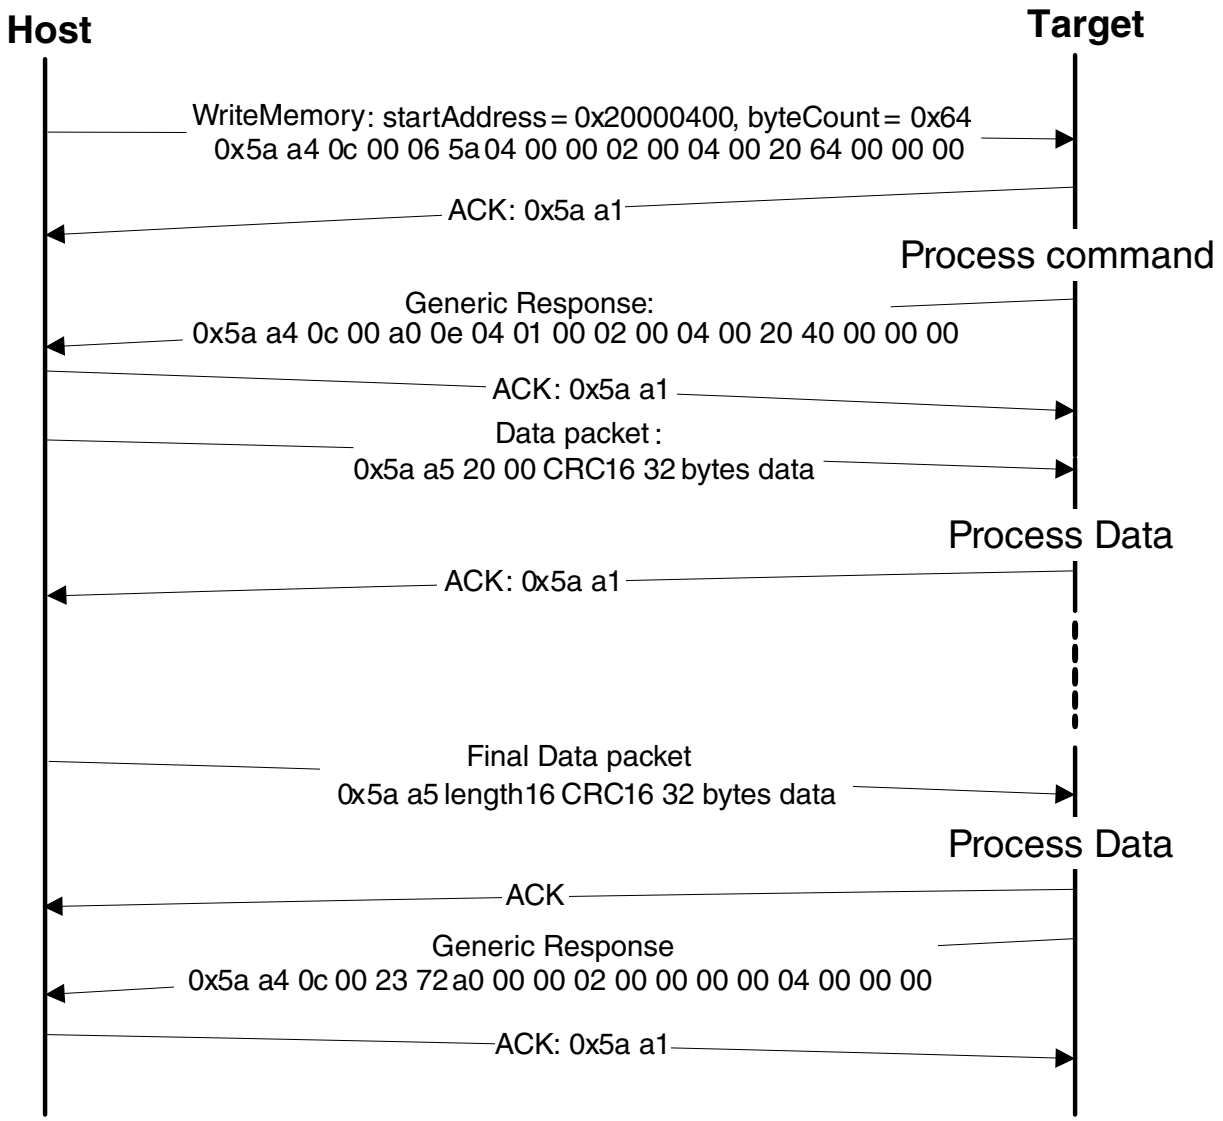

**Figure 27-18. Protocol Sequence for WriteMemory Command**

**Table 27-48. WriteMemory Command Packet Format (Example)**

| WriteMemory | Parameter | Value |
|---|---|---|
| Framing packet | start byte | 0x5A |
| | packetType | 0xA4, kFramingPacketType_Command |
| | length | 0x0C 0x00 |
| | crc16 | 0x06 0x5A |
| Command packet | commandTag | 0x04 - writeMemory |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x02 |
| | startAddress | 0x20000400 |
| | byteCount | 0x00000064 |

**Data Phase:** The WriteMemory command has a data phase; the host will send data packets until the number of bytes of data specified in the byteCount parameter of the WriteMemory command are received by the target.

**Response:** The target (Kinetis Bootloader ) will return a GenericResponse packet with a status code set to kStatus_Success upon successful execution of the command, or to an appropriate error status code.

### 27.3.6.17 Read memory command

The ReadMemory command returns the contents of memory at the given address, for a specified number of bytes. This command can read any region of memory accessible by the CPU and not protected by security.

The start address and number of bytes are the 2 parameters required for ReadMemory command.

**Table 27-49. Parameters for read memory command**

| Byte | Parameter | Description |
|---|---|---|
| 0-3 | Start address | Start address of memory to read from |
| 4-7 | Byte count | Number of bytes to read and return to caller |

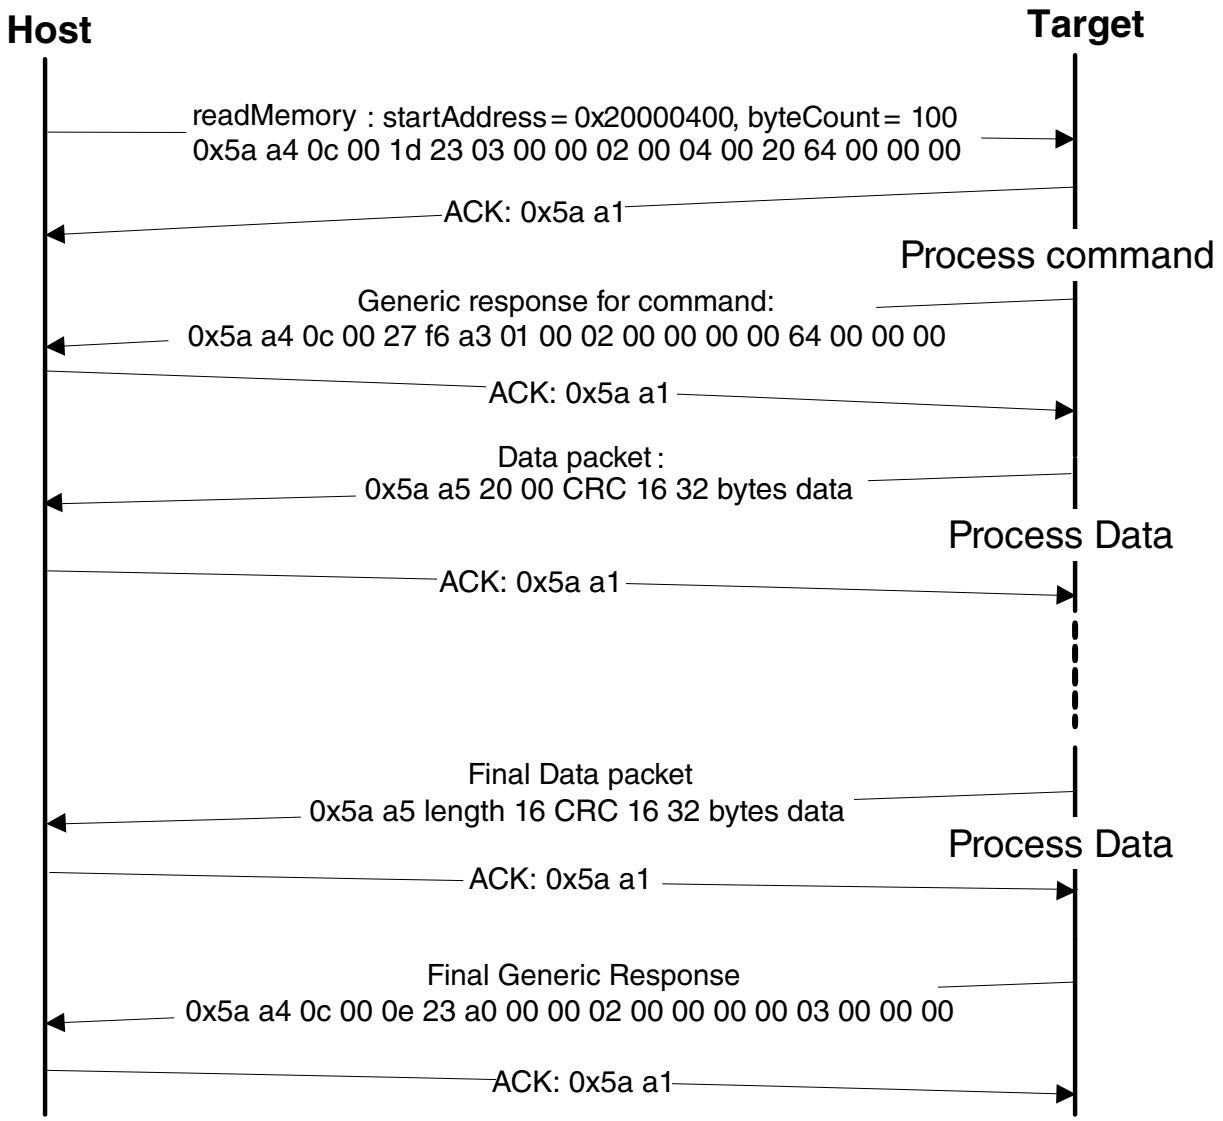

**Figure 27-19. Command sequence for read memory**

| ReadMemory | Parameter | Value |
|---|---|---|
| Framing packet | Start byte | 0x5A0xA4, |
| | packetType | kFramingPacketType_Command |
| | length | 0x0C 0x00 |
| | crc16 | 0x1D 0x23 |
| Command packet | commandTag | 0x03 - readMemory |
| | flags | 0x00 |
| | reserved | 0x00 |
| | parameterCount | 0x02 |
| | startAddress | 0x20000400 |
| | byteCount | 0x00000064 |

**Data Phase:** The ReadMemory command has a data phase. Since the target (Kinetis Bootloader) works in slave mode, the host need pull data packets until the number of bytes of data specified in the byteCount parameter of ReadMemory command are received by host.

**Response:** The target (Kinetis Bootloader) will return a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command, or set to an appropriate error status code.

### 27.3.7 Bootloader Exit state

The Kinetis Bootloader tries to reconfigure the system back to the reset state in the following situations:

- After completion of an Execute command, but before jumping to the specified entry point.
- After a peripheral detection timeout, but before jumping to the application entry point.

In general, all peripherals are reset. However, the application must consider the following situations:

- If VLPR mode is active during a system boot, then the bootloader will exit VLPR mode on entry (to bootloader operation), and VLPR mode will not be restored after exiting from the bootloader.
- If high speed clocking is selected in the Bootloader Configuration Area, then high speed clocks will be retained after exiting from the bootloader.
- Upon exit from the bootloader, the bootloader restores the VTOR register to its default value (0x0).

## 27.4 Kinetis Flash Driver API

To simplify flash code development, the Kinetis ROM Bootloader has flash driver APIs that user applications can use, and provides pointers to where these APIs are located. This section describes how to use each flash driver API provided in the Kinetis flash driver API tree.

**NOTE**

For more information on how to use the ROM-resident Flash Driver API from an application space, see the “Kinetis Flash Driver API” chapter of the latest “Kinetis Bootloader Reference Manual,” http://www.nxp.com/KBOOT.

### 27.4.1 Flash Driver Entry Point

The MCU ROM bootloader provides a flash driver API tree entry (flashDriver) that a user application can use to get the entry points for the whole flash API set that is supported by the bootloader.

**NOTE**

The flashloader and flash-resident bootloader do not support this feature (flash driver API tree).

To get the address of the entry point, the user application reads the word containing the pointer to the bootloader API tree at offset 0x1C of the bootloader's vector table. The vector table is placed at the base of the bootloader's address range.

### 27.4.2 Flash driver API Tree

The bootloader API tree is a structure that contains pointers to other structures, which have the function and data address for the bootloader. The Flash driver API tree entry is always the 5th word of the API tree.

The prototype of the entry point is:

```
flash_driver_interface_t flashDriver;
```

There are several slightly different versions of the flash driver API among different targets with ROM bootloader.

**Table 27-50. Different versions of the flash driver**

| Flash driver API version | Supported targets |
|---|---|
| V1.0 | KL03Z4 KL43Z4 KL33Z4 KL27Z4 KL17Z4 |
| V1.1 | KL27Z644 KL17Z644 |
| V1.2 | KL13Z644 KL33Z644 K80F256 K81F256 K82F256 KL81Z7 KL82Z7 KL28Z7 |

There are minor differences in the flash driver interface among the flash driver API versions. See the definitions below.

```
typedef union BootloaderVersion
{
    struct
    {
        uint32_t bugfix : 8; //!lt; bugfix version [7:0]
        uint32_t minor : 8;  //!lt; minor version [15:8]
```

```
        uint32_t major : 8;  //!lt; major version [23:16]
        uint32_t name : 8;   //!lt; name [31:24]
    } B;
    uint32_t version; //!lt; combined version numbers
} standard_version_t;

//! @brief Interface for the flash driver.
typedef struct FlashDriverInterface
{
#if !defined(FLASH_API_TREE_1_0)
    standard_version_t version; //!lt; flash driver API version number.
#endif

    status_t (*flash_init)(flash_config_t *config);

#if defined(FLASH_API_TREE_1_0)
    status_t (*flash_erase_all)(flash_config_t *config);
    status_t (*flash_erase_all_unsecure)(flash_config_t *config);
    status_t (*flash_erase)(flash_config_t *config, uint32_t start, uint32_t lengthInBytes);
#else
    status_t (*flash_erase_all)(flash_config_t *config, uint32_t key);
    status_t (*flash_erase_all_unsecure)(flash_config_t *config, uint32_t key);
    status_t (*flash_erase)(flash_config_t *config, uint32_t start, uint32_t lengthInBytes,
uint32_t key);
#endif

    status_t (*flash_program)(flash_config_t *config, uint32_t start, uint32_t *src,

*state);
    status_t (*flash_security_bypass)(flash_config_t *config, const uint8_t *backdoorKey);
    status_t (*flash_verify_erase_all)(flash_config_t *config, flash_margin_value_t margin);
    status_t (*flash_verify_erase)(flash_config_t *config,
                                   uint32_t start,
                                   uint32_t lengthInBytes,
                                   flash_margin_value_t margin);
    status_t (*flash_verify_program)(flash_config_t *config,
                                     uint32_t start,
                                     uint32_t lengthInBytes,
                                     const uint32_t *expectedData,
                                     flash_margin_value_t margin,
                                     uint32_t *failedAddress,
                                     uint32_t *failedData);
    status_t (*flash_get_property)(flash_config_t *config, flash_property_tag_t
whichProperty, uint32_t *value);

#if (!defined(FLASH_API_TREE_1_0)) && (!defined(FLASH_API_TREE_1_1))
    status_t (*flash_register_callback)(flash_config_t *config, flash_callback_t callback);
    status_t (*flash_program_once)(flash_config_t *config, uint32_t index, uint32_t *src,
uint32_t lengthInBytes);
    status_t (*flash_read_once)(flash_config_t *config, uint32_t index, uint32_t *dst,
uint32_t lengthInBytes);
    status_t (*flash_read_resource)(flash_config_t *config,
                                    uint32_t start,
                                    uint32_t *dst,
                                    uint32_t lengthInBytes,
                                    flash_read_resource_option_t option);
#endif
} flash_driver_interface_t;
```

The Freescale/NXP standard flash driver (C90TFS flash driver) is the basis for the flash driver API.

## 27.4.3 Quick demo using Kinetis Flash Driver API

The example code below uses the Kinetis Flash Driver API to erase a region of flash memory. For more code examples, get the latest Kinetis bootloader package at http://www.nxp.com/KBOOT/

```
bootloader_tree_t* tree;                  // pointer points to bootloader tree
flash_config_t flash_config;            // variable used to keep runtime state of flash driver

// Get bootloader API tree from ROM
tree = (bootloader_tree_t*)(*(uint32_t*)0x0880001c);

// Init flash driver.
status_t status = tree->flashDriver->flash_init(&flash_config);
if  (status == kStatus_Success)
   {
// Erase flash region from 0x800 to 0xc00.
     status = tree->flashDriver->flash_erase(&flash_config, 0x800, 1024);
   }
```

## 27.4.4 Flash driver data structures

### 27.4.4.1 flash_config_t

The `flash_config_t` data structure is a required argument for all flash driver API functions. `flash_config_t` is initialized by calling FLASH_Init. For other functions, an initialized instance of this data structure should be passed as an argument.

**Table 27-51. `flash_config_t` data structure**

| Offset (hex) | Size | Field | Description |
|---|---|---|---|
| 0 | 4 | PFlashBlockBase | Base address of the first PFlash block |
| 4 | 4 | PFlashTotalSize | Size of all combined PFlash blocks |
| 8 | 1 | PFlashBlockCount | Number of PFlash blocks |
| 9 | 1 | FlashMemoryIndex | Index of flash memory |
| A | 1 | FlashCacheControllerIndex | Index of flash cache controller |
| B | 1 | Reserved | Reserved |
| C | 4 | PFlashSectorSize | Size (in bytes) of sector of PFlash |
| 10 | 4 | PFlashCallback | Pointer to a callback function used to do extra operations during erasure (for example, service watchdog) |
| 14 | 4 | PFlashAccessSegmentSize | Size of FAC access segment |
| 18 | 4 | PFlashAccessSegmentCount | Count of FAC access segment |
| 1C | 4 | flashExecuteInRamFunctionInfo | Info struct of flash execute-in-ram function |

*Table continues on the next page...*

**Table 27-51. `flash_config_t` data structure (continued)**

| Offset (hex) | Size | Field | Description |
|---|---|---|---|
| 20 | 4 | FlexRAMBlockBase | • **FlexNVM device**: FlexRAM base address<br>• **non-FlexNVM device**: acceleration RAM memory base address |
| 24 | 4 | FlexRAMTotalSize | • **FlexNVM device**: FlexRAM size<br>• **non-FlexNVM device**: acceleration RAM memory size |
| 28 | 4 | DFlashBlockBase | • **FlexNVM device**: D-Flash memory (FlexNVM memory) base address<br>• **non-FlexNVM device**: unused |
| 2C | 4 | DFlashTotalSize | • **FlexNVM device**: FlexNVM memory total size<br>• **non-FlexNVM device**: unused |
| 30 | 4 | EEpromTotalSize | • **FlexNVM device**: the size (in bytes) of the EEPROM area that was partitioned from FlexRAM<br>• **non-FlexNVM device**: unused |

### `flash_config_t` prototype:

```
typedef struct _flash_config
{
    uint32_t PFlashBlockBase;                /*!< Base address of the first PFlash block */
    uint32_t PFlashTotalSize;                /*!< Size of all combined PFlash block. */
    uint8_t PflashBlockCount;                /*!< Number of PFlash blocks. */
    uint8_t FlashMemoryIndex;                /*!< Index of flash memory. */
    uint8_t FlashCacheControllerIndex        /*!< Index of flash cache controller. */
    uint8_t Reserved0;                       /*!< Reserved */
    uint32_t PFlashSectorSize;               /*!< Size in bytes of a sector of PFlash. */
    flash_callback_t PFlashCallback;         /*!< Callback function for flash API. */
    uint32_t PFlashAccessSegmentSize;        /*!< Size in bytes of a access segment of
PFlash. */
    uint32_t PFlashAccessSegmentCount;       /*!< Number of PFlash access segments. */
    uint32_t *flashExecuteInRamFunctionInfo; /*!< Info struct of flash execute-in-ram
function. */
    uint32_t FlexRAMBlockBase;               /*!< For FlexNVM device, this is the base
address of FlexRAM
                                                  For non-FlexNVM device, this is the base
address of acceleration RAM memory */
    uint32_t FlexRAMTotalSize;               /*!< For FlexNVM device, this is the size of
FlexRAM
                                                  For non-FlexNVM device, this is the size
of acceleration RAM memory */
    uint32_t DFlashBlockBase; /*!< For FlexNVM device, this is the base address of D-Flash
memory (FlexNVM memory);
                                   For non-FlexNVM device, this field is unused */
    uint32_t DFlashTotalSize; /*!< For FlexNVM device, this is total size of the FlexNVM
memory;
                                   For non-FlexNVM device, this field is unused */
    uint32_t EEpromTotalSize; /*!< For FlexNVM device, this is the size in byte of EEPROM
area which was partitioned
                                 from FlexRAM;
                                   For non-FlexNVM device, this field is unused */
} flash_config_t;
```

## 27.4.5 Flash driver API

This section describes each function supported in the flash driver API.

### 27.4.5.1 FLASH_Init

Checks and initializes the flash module for the other flash API functions.

**NOTE**

FLASH_Init must be always called before calling other API functions.

#### Prototype:

```
status_t FLASH_Init(flash_config_t *config);
```

**Table 27-52. Parameters**

| Parameter | Description |
|---|---|
| config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |

**Table 27-53. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config pointer is NULL. |
| 100 | kStatus_FLASH_SizeError | Returned flash is incorrect. |
| 0 | kStatus_Success | This function has performed successfully. |

#### Example:

```
flash_config_t flashInstance;
status_t status = FLASH_Init(&flashInstance);
```

### 27.4.5.2 FLASH_EraseAll

Erases the entire flash array.

#### Prototype:

```
status_t FLASH_EraseAll(flash_config_t *config, uint32_t key);
```

**Table 27-54. Parameters**

| Parameter | Description |
|---|---|
| config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| key | Key used to validate erase operation. Must be set to 0x6B65666B. |

**Table 27-55. Possible status response**

| Value | Constants | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config pointer is NULL. |
| 103 | kStatus_FLASH_AccessError | Command is not available under current mode/ security. |
| 104 | kStatus_FLASH_ProtectionViolation | Any region of the program flash memory is protected. |
| 107 | kStatus_FLASH_EraseKeyError | Key is incorrect. |
| 0 | kStatus_Success | This function has performed successfully. |

### Example:

```
status_t status = FLASH_EraseAll(&flashInstance, kFLASH_ApiEraseKey);
```

## 27.4.5.3 FLASH_EraseAllUnsecure

Erases the entire flash (including protected sectors) and restores flash to unsecured mode.

### Prototype:

```
status_t FLASH_EraseAllUnsecure(flash_config_t *config, uint32_t key);
```

**Table 27-56. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| Key | Key used to validate erase operation. Must be set to 0x6B65666B. |

**Table 27-57. Possible Status Response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config pointer is NULL. |
| 103 | kStatus_FLASH_AccessError | Command is not available under current mode/ security. |

*Table continues on the next page...*

**Table 27-57. Possible Status Response (continued)**

| Value | Constant | Description |
|---|---|---|
| 107 | kStatus_FLASH_EraseKeyError | Key is incorrect. |
| 0 | kStatus_Success | This function has performed successfully. |

### Example:

```
status_t status = FLASH_EraseAllUnsecure(&flashInstance, kFLASH_ApiEraseKey);
```

## 27.4.5.4 FLASH_Erase

Erases expected flash sectors specified by parameters. For Kinetis devices, the minimum erase unit is one sector.

### Prototype:

```
status_t FLASH_Erase(flash_config_t *config, uint32_t start, uint32_t lengthInBytes, uint32_t
      key);
```

**Table 27-58. Parameters**

| Parameters | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| Start | The start address of the desired flash memory to be erased.<br>The start address does not need to be sector aligned, but must be word-aligned. |
| lengthInBytes | The length, given in bytes (not words or long words) to be erased. Must be word-aligned. |
| Key | Key is used to validate erase operation. Must be set to 0x6B65666B. |

**Table 27-59. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config pointer is NULL. |
| 100 | kStatus_FLASH_AlignmentError | Start or lengthInBytes; is not long word-aligned. |
| 102 | kStatus_FLASH_AddressError | The range to be erased is not a valid flash range. |
| 103 | kStatus_FLASH_AccessError | Command is not available under current mode/ security. |
| 104 | kStatus_FLASH_ProtectionViolation | The selected program flash sector is protected. |
| 107 | kStatus_FLASH_EraseKeyError | Key is incorrect. |
| 0 | kStatus_Success | This function has performed successfully. |

### Example:

```
status_t status = FLASH_Erase (&flashInstance, 0x800, 1024, kFLASH_ApiEraseKey);
```

## 27.4.5.5 FLASH_Program

Programs the flash memory with data at locations that are passed in using parameters.

### Prototype:

```
status_t FLASH_Program(flash_config_t *config, uint32_t start, uint32_t *src, uint32_t
      lengthInBytes);
```

**Table 27-60. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| Start | The start address of the desired flash memory to be erased.<br>The start address does not need to be sector-aligned, but the start address must be word-aligned. |
| src | Pointer to the source buffer of data that is to be programmed into flash. |
| lengthInBytes | The length in bytes (not words or long words) to be erased; the length must also be word-aligned. |

**Table 27-61. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or src pointers are NULL. |
| 101 | kStatus_FLASH_AlignmentError | Start or lengthInBytes is not longword aligned. |
| 102 | kStatus_FLASH_AddressError | The range to be programmed is invalid. |
| 103 | kStatus_FLASH_AccessError | Command is not available under current mode/ security. |
| 104 | kStatus_FLASH_ProtectionViolation | The selected program flash address is protected. |
| 0 | kStatus_Success | This function has performed successfully. |

### Example:

```
uint32_t m_content[] = {0x01234567, 0x89abcdef};
status_t status = FLASH_Program (&flashInstance, 0x800, &m_content[0], sizeof(m_content));
```

**NOTE**

Before calling `flash_program`, make sure that the region to be programmed is empty and is not protected.

### 27.4.5.6 FLASH_GetSecurityState

Retrieves the current flash security status, including the security enabling state and the backdoor key enabling state.

#### Prototype:

```
status_t FLASH_GetSecurityState(flash_config_t *config, flash_security_state_t *state);
```

**Table 27-62. Parameters**

| Parameters | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| State | Pointer to the value returned for the current security status code:<br>**Table 27-63. Returned value**<br>kFLASH_SecurityStateNotSecure — 0 — Flash is under unsecured mode.<br>kFLASH_SecurityStateBackdoorEnabled — 1 — Flash is under secured mode and Backdoor is enabled.<br>kFLASH_SecurityStateBackdoorDisabled — 2 — Flash is under secured mode and Backdoor is disabled. |

**Table 27-64. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or state pointers are NULL. |
| 0 | kStatus_Success | This function has performed successfully. |

#### Example:

```
flash_security_state_t state;
status_t status = FLASH_GetSecurityState (&flashInstance, &state);
```

### 27.4.5.7 FLASH_SecurityBypass

Allows the user to bypass security with a backdoor key. If the MCU is in a secured state, then the FLASH_SecurityBypass function unsecures the MCU, by comparing the provided backdoor key with keys in the Flash Configuration Field.

#### Prototype:

```
status_t FLASH_SecurityBypass(flash_config_t *config, const uint8_t *backdoorKey);
```

**Table 27-65. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| backdoorKey | Pointer to the user buffer containing the backdoor key. |

**Table 27-66. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or backdoorKey pointers are NULL. |
| 103 | kStatus_FLASH_AccessError | The following condition causes this return value:<br>1. An incorrect backdoor key is supplied<br>2. Backdoor key access has not been enabled. |
| 0 | kStatus_Success | This function has performed successfully. |

### Example:

Assume that the flash range from 0x400 to 0x40c contains the following content after the last reset, which means that the backdoor key is valid and the backdoor key access has been enabled.

0x11 0x22 0x33 0x44 0x55 0x66 0x77 0x88 0xff 0xff 0xff 0xbf

```
uint8_t backdoorKey[] = {0x11, 0x22, 0x33, 0x44, 0x55, 0x66, 0x77, 0x88};
status_t status = FLASH_SecurityBypass (&flashInstance, & backdoorKey[0]);
```

## 27.4.5.8 FLASH_VerifyEraseAll

Checks if the entire flash has been erased to the specified read margin level.

To verify if the entire flash has been fully erased (after executing an FLASH_EraseAll), call FLASH_VerifyEraseAll.

### Prototype:

```
status_t FLASH_VerifyEraseAll(flash_config_t *config, flash_margin_value_t margin);
```

**Table 27-67. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |

*Table continues on the next page...*

**Table 27-67. Parameters (continued)**

| Parameter | Description |
|---|---|
| Margin1 | Read margin choice:<br>• kFLASH_MarginValueNormal 0<br>• kFLASH_MarginValueUser 1<br>• kFLASH_MarginValueFactory 2 |

**Table 27-68. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or backdoorKey pointers are NULL. |
| 103 | kStatus_FLASH_AccessError | An invalid margin choice is specified. |
| 105 | kStatus_FLASH_CommandFailure | The entire flash is not fully erased. |
| 0 | kStatus_Success | This function has performed successfully. |

### Example:

Assume that flash_erase_all has been successfully executed.

```
status_t status = flash_verify_erase_all (&flashInstance, kFLASH_MarginValueUser);
```

**NOTE**

For the choice of margin, see the FTFA chapter in the reference manual for detailed information.

## 27.4.5.9 FLASH_VerifyErase

Verifies the erasure of the desired flash area at a specified margin level. This function checks the appropriate number of flash sectors based on the desired start address and length, to see if the flash has been erased at the specified read margin level.

FLASH_VerifyErase is often called after successfully performing the FLASH_Erase API.

### Prototype:

```
status_t FLASH_VerifyErase(flash_config_t *config, uint32_t start, uint32_t lengthInBytes,
flash_margin_value_t margin);
```

**Table 27-69. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |

*Table continues on the next page...*

**Table 27-69. Parameters (continued)**

| Parameter | Description |
|---|---|
| Start | The start address of the desired flash memory to be verified. |
| lengthInBytes | The length, given in bytes (not words or long words) to be verified.<br>Must be word-aligned. |
| margin | Read margin choice as follows:<br>kFLASH_MarginValueNormal 0 kFLASH_MarginValueUser 1 kFLASH_MarginValueFactory 2 |

**Table 27-70. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or backdoorKey pointers are NULL. |
| 101 | kStatus_FLASH_AlignmentError | Start or lengthInBytes is not longword aligned. |
| 102 | kStatus_FLASH_AddressError | The range to be verified is not a valid flash range. |
| 103 | kStatus_FlashAccessError | The following situation causes this response:<br>1. Command is not available under current mode/ security<br>2. An invalid margin code is provided<br>3. The requested number of bytes is 0<br>4. The requested sector crosses a flash block boundary |
| 105 | kStatus_FLASH_CommandFailure | The flash range to be verified is not fully erased. |
| 0 | kStatus_Success | This function has performed successfully. |

**Example:**

Assume that flash region from 0x800 to 0xc00 has been successfully erased.

```
status_t status = FLASH_VerifyErase(&flashInstance, 0x800, 1024, kFLASH_MarginValueUser);
```

**NOTE**

For the choice of margin, see the FTFA chapter in the reference manual for detailed information.

### 27.4.5.10 FLASH_VerifyProgram

Verifies the data programmed in the flash memory (using the Flash Program Check Command), and compares it with expected data for a given flash area (as determined by the start address and length).

FLASH_VerifyProgram is often called after successfully doing FLASH_Program().

## Prototype:

```
status_t FLASH_VerifyProgram(flash_config_t *config,
                             uint32_t start,
                             uint32_t lengthInBytes,
                             const uint32_t *expectedData,
                             flash_margin_value_t margin,
                             uint32_t *failedAddress,
                             uint32_t *failedData);
```

**Table 27-71. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| Start | The start address of the desired flash memory to be verified. |
| LengthInBytes | The length, given in bytes (not words or long-words) to be verified. Must be word-aligned. |
| ExpectedData | Pointer to the expected data that is to be verified against. |
| Margin | Read margin choice as follows:<br>kFLASH_MarginValueUser 1 kFLASH_MarginValueFactory 2 |
| FailedAddress | Pointer to returned failing address. |
| FailedData | Pointer to return failing data. Some derivatives do not include failed data as part of the FCCOBx registers. In this instance, 0x00s are returned upon failure. |

**Table 27-72. Possible status response**

| Value | Contants | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or expectedData pointers are NULL. |
| 101 | kStatus_FlashAlignmentError | Start or lengthInBytes is not longword-aligned. |
| 102 | kStatus_FLASH_AddressError | The range to be verified is invalid. |
| 103 | kStatus_FLASH_AccessError | The following situation causes this response:<br>1. Command is not available under current mode/ security.<br>2. An invalid margin code is supplied. |
| 105 | kStatus_FLASH_CommandFailure | Either of the margin reads does not match the expected data. |
| 0 | kStatus_Success | This function has performed successfully. |

## Example:

Assume that flash region from 0x800 to 0x807 is successfully programmed with:

0x01 0x23 0x45 0x67 0x89 0xab 0xcd 0xef

```
uint8_t expectedData[] = {0x01, 0x23, 0x45, 0x67, 0x89, 0xab, 0xcd, 0xef };
status_t status = FLASH_VerifyProgram (&flashInstance, 0x800, 8,
                  &expectedData[0], kFlashMargin_User, NULL, NULL);
```

**NOTE**

For the choice of margin, see the FTFA chapter in the reference manual for detailed information.

### 27.4.5.11 FLASH_GetProperty

Returns the desired flash property, which includes base address, sector size, and other options.

## Prototype:

```
status_t flash_get_property(flash_driver_t * driver, flash_property_t whichProperty, uint32_t
* value);
```

**Table 27-73. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory to store driver runtime state. |
| whichProperty | The desired property from the list of properties.<br>**Table 27-74. Properties**<br>Definition / Value / Description:<br>kFLASH_PropertyPflashSectorSize / 0 / Get Flash Sector size<br>kFLASH_PropertyPflashTotalSize / 1 / Get total flash size<br>kFLASH_PropertyPflashBlockBaseAddr / 4 / Get flash base address<br>kFLASH_PropertyPflashFacSupport / 5 / Get FAC support status<br>kFLASH_PropertyPflashAccessSegmentSize / 6 / Get FAC segment size<br>kFLASH_PropertyPflashAccessSegmentCount / 7 / Get FAC segment count<br>kFLASH_PropertyVersion / 32 / Get version of Flash Driver API |
| Value | Pointer to the value returned for the desired flash property. |

**Table 27-75. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or value pointers are invalid. |
| 106 | kStatus_FLASH_UnknownProperty | Invalid property is supplied. |
| 0 | kStatus_Success | This function has performed successfully. |

## Example:

```
uint32_t propertyValue;
status_t status = FLASH_GetProperty (&flashInstance, kFLASH_PropertyPflashSectorSize,
&propertyValue);
```

## 27.4.5.12 FLASH_ProgramOnce

Programs a certain Program Once Field with the expected data for a given IFR region (as determined by the index and length).

- For each Program Once Field, FLASH_ProgramOnce can only allowed to be called once; otherwise, an error code is returned.
- For targets which do not support FLASH_ProgramOnce, the value of the FLASH_ProgramOnce pointer is 0.

### Prototype

```
status_t flash_program_once (flash_driver_t * driver, uint32_t index, uint32_t *src, uint32_t
      lengthInBytes);
```

**Table 27-76. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| Index | Index for a certain Program Once Field. |
| src | Pointer to the source buffer of data that is to be programmed into the Program Once Field. |
| Lengthinbytes | The length, in bytes (not words or long words) to be programmed. Must be word-aligned. |

**Table 27-77. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or src pointers are NULL. |
| 101 | kStatus_FLASH_AlignmentError | index or lengthInBytes is invalid. |
| 103 | kStatus_FLASH_AddressError | The following situation causes this response:<br>1. Command is not available under current mode/ security.<br>2. An invalid index is supplied.<br>3. The requested Program Once field has already been programmed to a non-FFFF value.<br>4. The requested sector crosses a flash block boundary. |
| 115 | kStatus_FLASH_CommandNotSupported | This function is not supported. |
| 0 | kStatus_Success | This function has performed successfully. |

### Example:

Assume the Program Once Field has not been programmed before.

```
uint32_t expectedData = 0x78563412;

status_t status = FLASH_ProgramOnce(&flashInstance, 0, &expectedData, 4);
```

**NOTE**

For the choice of index and length, see the FTFA chapter in RM for detailed information.

### 27.4.5.13 FLASH_ReadOnce

Reads a certain flash Program Once Field according to parameters passed by index and length.

For targets that do not support FLASH_ReadOnce, the value of the FLASH_ReadOnce pointer is 0.

#### Prototype:

```
status_t flash_read_once (flash_driver_t * driver, uint32_t index, uint32_t *dst, uint32_t
lengthInBytes);
```

**Table 27-78. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| Index | Index for a certain Program Once Field. |
| dst | Pointer to the destination buffer of data that stores data reads from the Program Once Field. |
| Lengthinbytes | The length, in bytes (not words or long words) to be read. Must be word-aligned. |

**Table 27-79. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or dst pointers are NULL. |
| 101 | kStatus_FlashAlignmentError | Index or lengthInBytes is invalid. |
| 103 | kStatus_FLASH_AddressError | The following situation causes this response:<br>1. Command is not available under current mode/ security.<br>2. An invalid index is supplied. |
| 115 | kStatus_FLASH_CommandNotSupported | This function is not supported. |
| 0 | kStatus_Success | This function has performed successfully. |

#### Example:

```
uint32_t temp;
      status_t status = FLASH_ReadOnce(&flashInstance, 0, &temp, 4);
```

**NOTE**

For the choice of index and length, see the FTFA chapter in RM for detailed information.

### 27.4.5.14 FLASH_SetCallback

Registers (like to write into a list) expected callback functions into the flash driver, for example, like a function that services a watchdog.

**Prototype:**

```
status_t FLASH_SetCallback(flash_config_t *config, flash_callback_t callback);
```

**Table 27-80. Parameters**

| Parameter | Description |
|---|---|
| Config | Pointer to `flash_config_t` data structure in memory, to store driver runtime state. |
| Callback | A pointer points to a function that is called during erasure.<br>A use for this function is to service the watchdog during an erase operation. |

**Table 27-81. Possible status response**

| Value | Constant | Description |
|---|---|---|
| 4 | kStatus_InvalidArgument | Config or dst pointers are NULL. |
| 115 | kStatus_FLASH_CommandNotSupported | This function is not supported. |
| 0 | kStatus_Success | This function has performed successfully. |

**Example:**

Assume that there is a function.

```
void led_toggle(void).
status_t status = FLASH_SetCallback(&flashInstance, led_toggle);
```

## 27.5 Peripherals Supported

This section describes the peripherals supported by the Kinetis ROM Bootloader. To use an interface for bootloader communications, the peripheral must be enabled in the BCA, as shown in Table 27-3. If the BCA is invalid (such as all 0xFF bytes), then all peripherals will be enabled by default.

### 27.5.1 LPI2C Peripheral

The Kinetis Bootloader in ROM supports loading data into flash via the LPI2C peripheral, where the LPI2C peripheral serves as the LPI2C slave. A 7-bit slave address is used during the transfer.

Customizing an LPI2C slave address is also supported. This feature is enabled if the Bootloader Configuration Area (BCA) (shown in Table 27-3) is enabled (tag field is filled with 'kcfg') and the i2cSlaveAddress field is filled with a value other than 0xFF. 0x10 is used as the default LPI2C slave address.

The maximum supported LPI2C baud rate depends on corresponding clock configuration field in the BCA. Typical supported baud rate is 400 kbps with factory settings. Actual supported baud rate may be lower or higher than 400 kbps, depending on the actual value of the clockFlags and the clockDivider fields.

Because the LPI2C peripheral serves as an LPI2C slave device, each transfer should be started by the host, and each outgoing packet should be fetched by the host.

- An incoming packet is sent by the host with a selected LPI2C slave address and the direction bit is set as write.
- An outgoing packet is read by the host with a selected LPI2C slave address and the direction bit is set as read.
- 0x00 will be sent as the response to host if the target is busy with processing or preparing data.

The following flow charts demonstrate the communication flow of how the host reads ping packet, ACK and response from the target.

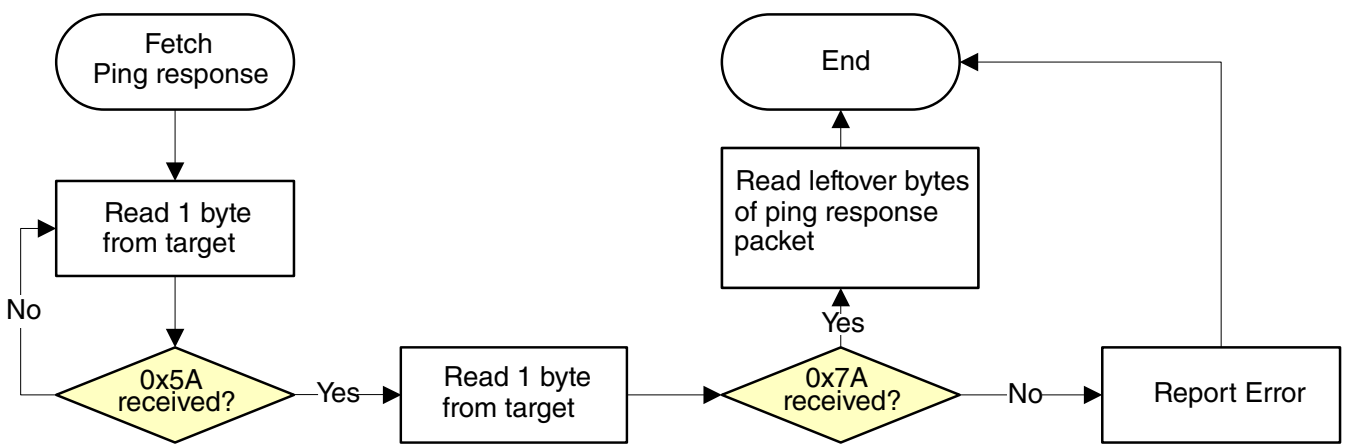

**Figure 27-20. Host reads ping response from target via LPI2C**

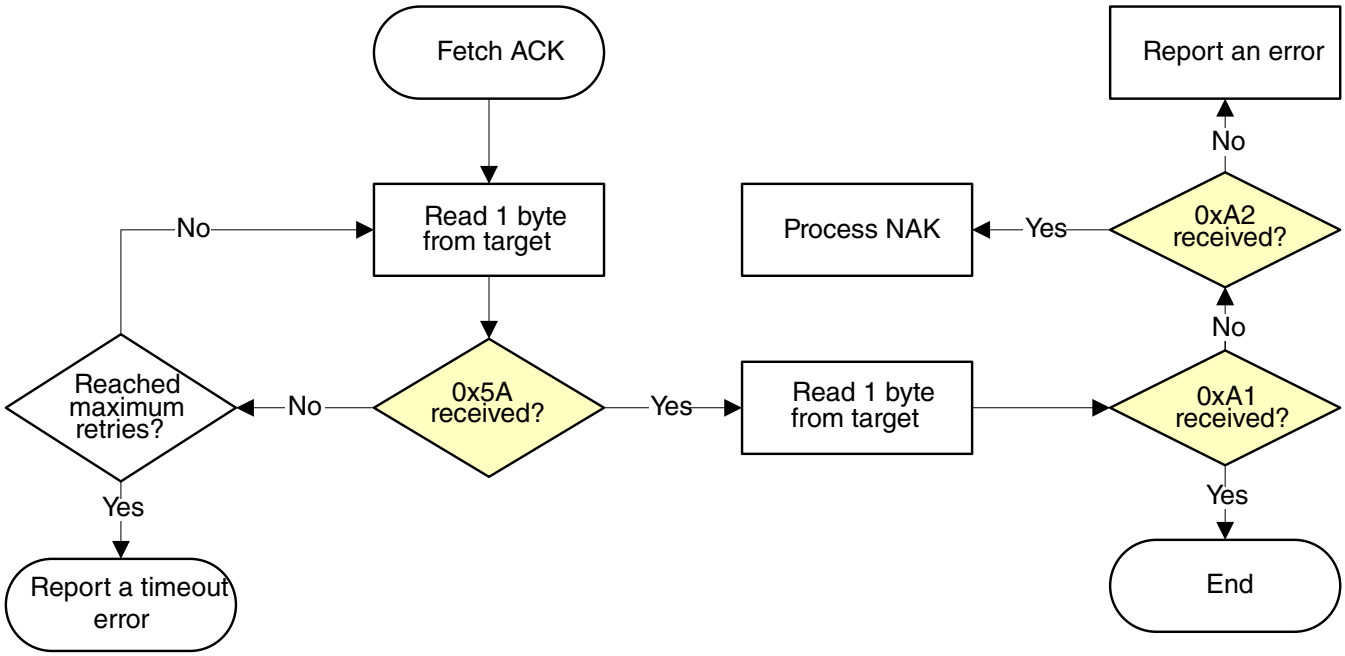

**Figure 27-21. Host reads ACK packet from target via LPI2C**

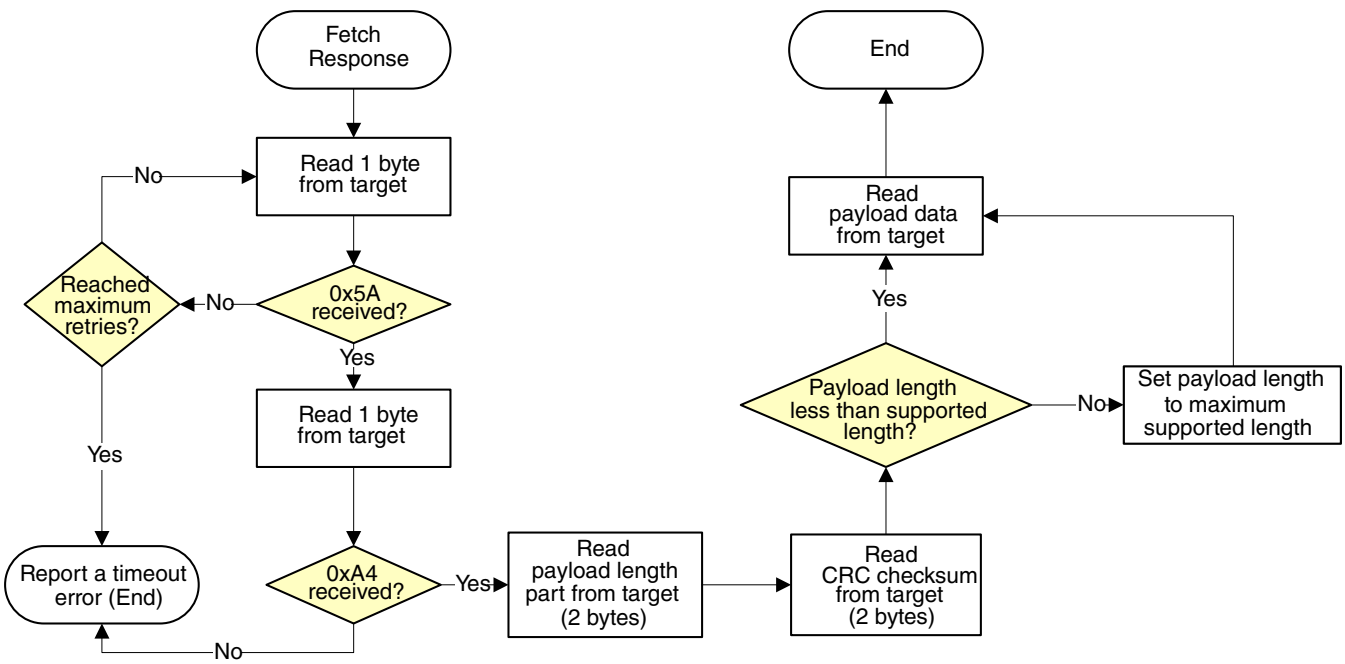

**Figure 27-22. Host reads response from target via LPI2C**

## 27.5.2 LPSPI Peripheral

The Kinetis Bootloader in ROM supports loading data into flash via the LPSPI peripheral, where the LPSPI peripheral serves as a LPSPI slave.

Maximum supported baud rate of LPSPI depends on the clock configuration fields in the Bootloader Configuration Area (BCA) shown in Table 27-3. The typical supported baud rate is 400 kbps with the factory settings. The actual baud rate is lower or higher than 400 kbps, depending on the actual value of the clockFlags and clockDivider fields in the BCA.

The LPSPI peripheral uses the following bus attributes:

- Clock Phase = 1 (Second Edge)
- Clock Polarity = 1 (Active Low)

Because the LPSPI peripheral in ROM serves as a SPI slave device, each transfer should be started by the host, and each outgoing packet should be fetched by the host.

The transfer on LPSPI is slightly different from I2C:

- Host will receive 1 byte after it sends out any byte.
- Received bytes should be ignored when host is sending out bytes to target
- Host starts reading bytes by sending 0x00s to target
- The byte 0x00 will be sent as response to host if target is under the following conditions:
  - Processing incoming packet
  - Preparing outgoing data
  - Received invalid data

The LPSPI bus configuration is:

- Phase = 1; data is sampled on rising edges
- Polarity = 1; idle is high
- MSB is transmitted first

For any transfer where the target does not have actual data to send, the target (slave) is responsible for ensuring that 0x00 bytes will be returned to the host (master). The host uses framing packets to identify real data and not "dummy" 0x00 bytes (which do not have framing packets).

The following flowcharts demonstrate how the host reads a ping response, an ACK and a command response from target via LPSPI.

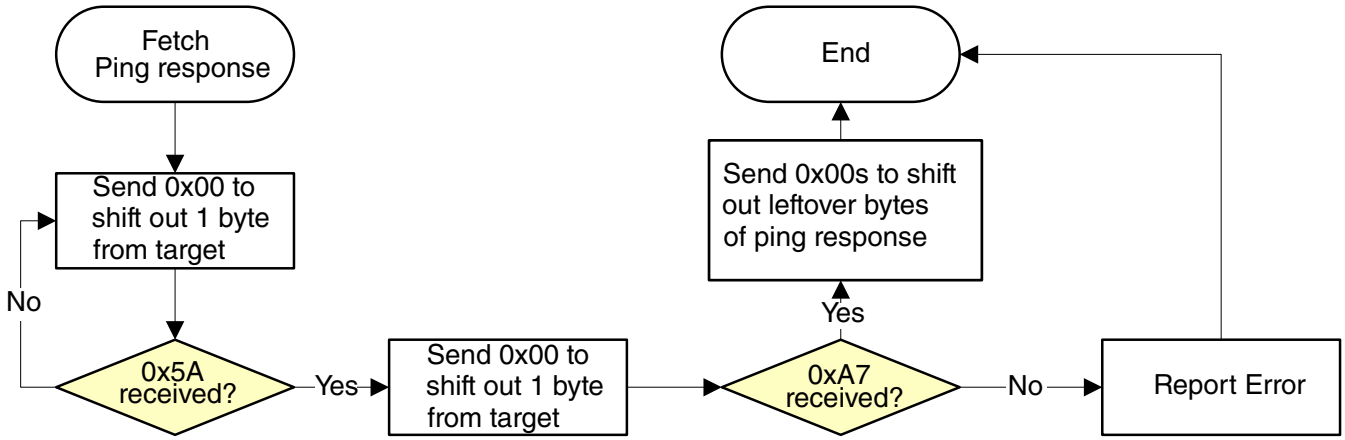

**Figure 27-23. Host reads ping packet from target via LPSPI**

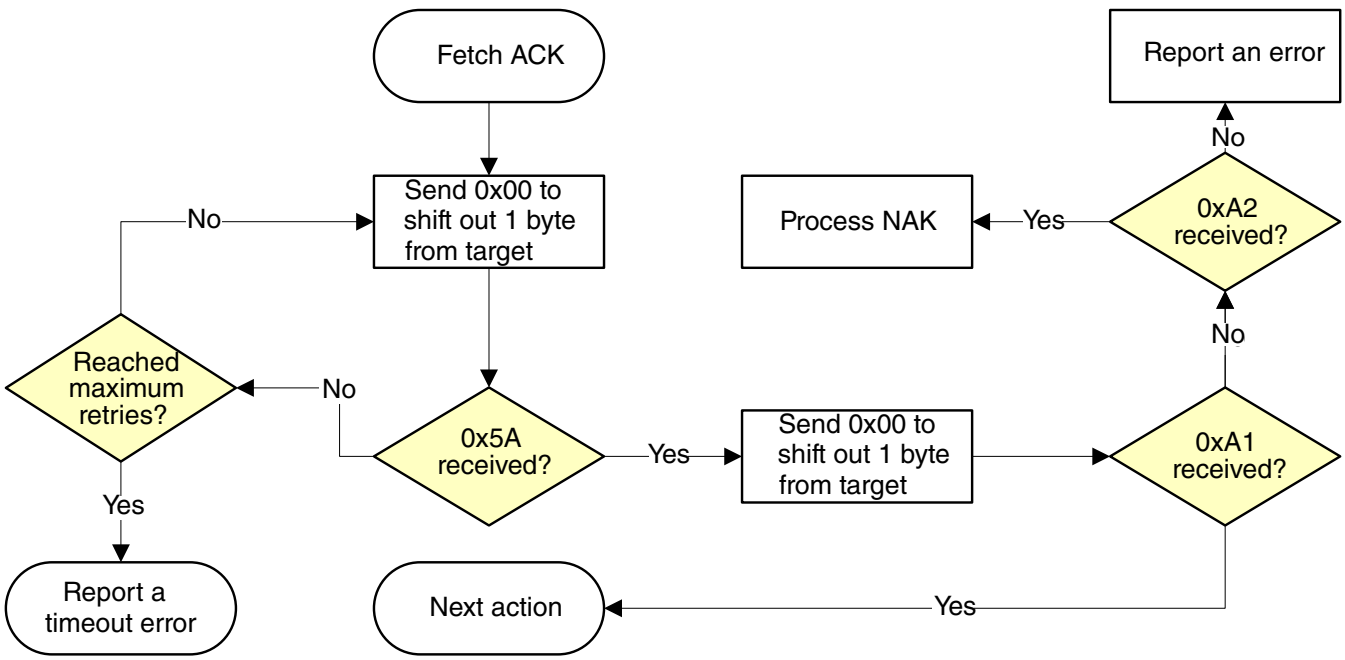

**Figure 27-24. Host reads ACK from target via LPSPI**

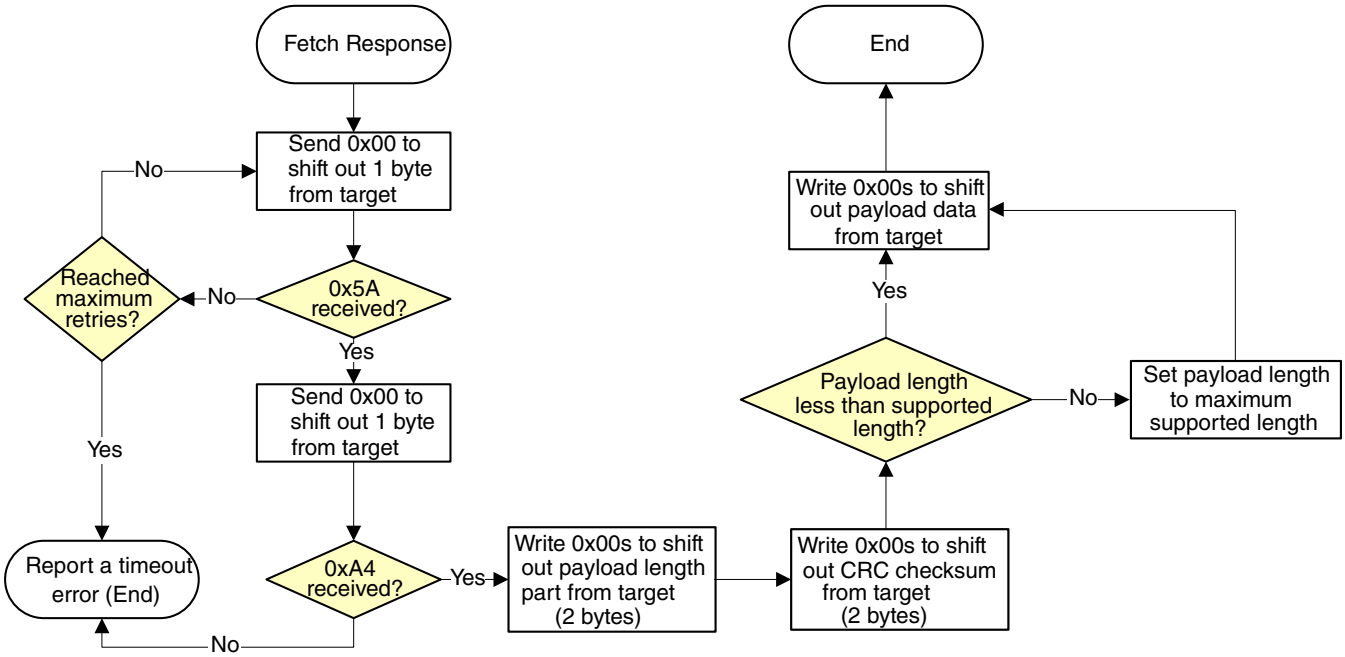

**Figure 27-25. Host reads response from target via LPSPI**

## 27.5.3 LPUART Peripheral

The Kinetis Bootloader integrates an autobaud detection algorithm for the LPUART peripheral, thereby providing flexible baud rate choices.

**Autobaud feature:** If LPUART*n* is used to connect to the bootloader, then the LPUART*n*_RX pin must be kept high and not left floating during the detection phase in order to comply with the autobaud detection algorithm. After the bootloader detects the ping packet (0x5A 0xA6) on LPUART*n*_RX, the bootloader firmware executes the autobaud sequence. If the baudrate is successfully detected, then the bootloader will send a ping packet response [(0x5A 0xA7), protocol version (4 bytes), protocol version options (2 bytes) and crc16 (2 bytes)] at the detected baudrate. The Kinetis Bootloader then enters a loop, waiting for bootloader commands via the LPUART peripheral.

**NOTE**

- The autobaud feature requires a ping packet with a higher accuracy (+/-3%), or the ping packet will be ignored as noise.
- The data bytes of the ping packet must be sent continuously (with no more than 80 ms between bytes) in a fixed LPUART transmission mode (8-bit data, no parity bit and 1 stop bit). If the bytes of the ping packet are sent one-by-one with more than 80 ms delay between them, then the

autobaud detection algorithm may calculate an incorrect baud rate. In this case, the autobaud detection state machine should be reset.

**Supported baud rates:** The baud rate is closely related to the MCU core and system clock frequencies. Typical baud rates supported are 9600, 19200, 38400, 57600, and 115200. Of course, to influence the performance of autobaud detection, the clock configuration in BCA can be changed.

**Packet transfer:** After autobaud detection succeeds, bootloader communications can take place over the LPUART peripheral. The following flow charts show:

- How the host detects an ACK from the target
- How the host detects a ping response from the target
- How the host detects a command response from the target

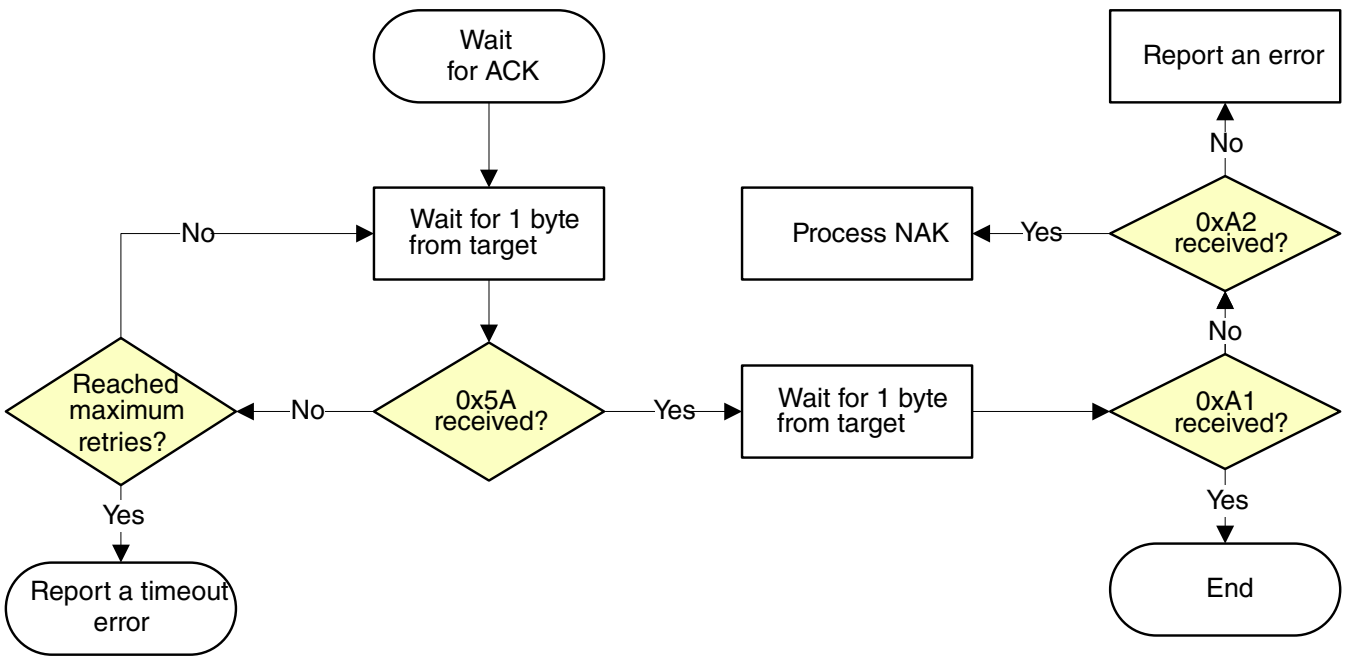

**Figure 27-26. Host reads an ACK from target via LPUART**

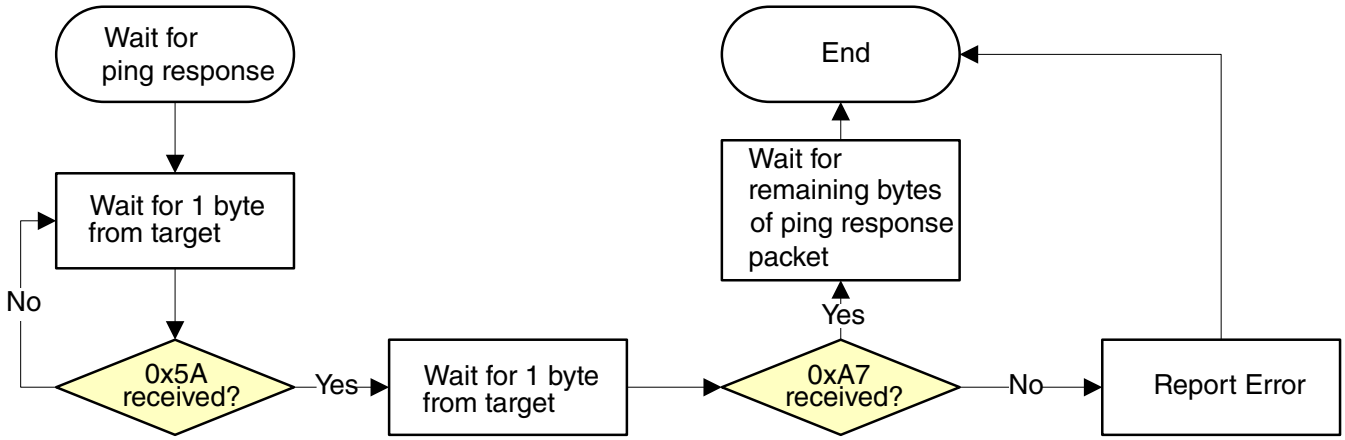

**Figure 27-27. Host reads a ping response from target via LPUART**

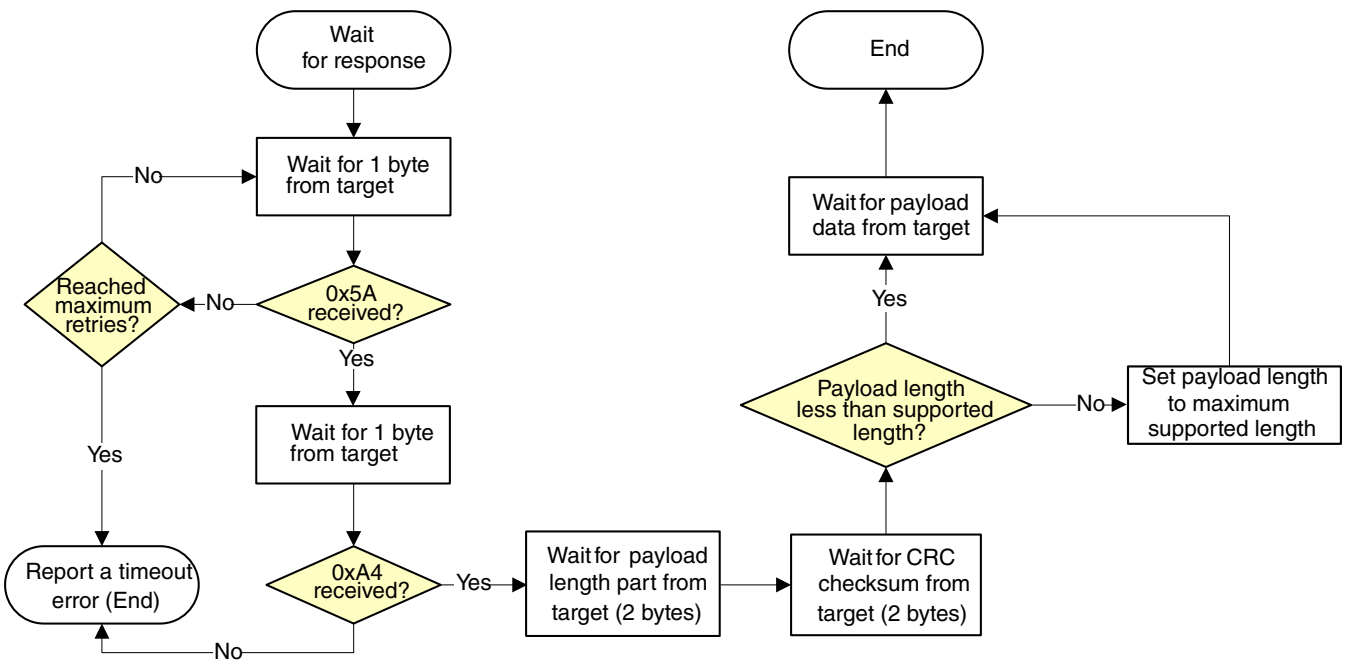

**Figure 27-28. Host reads a command response from target via LPUART**

## 27.5.4 USB peripheral

The Kinetis Bootloader in the ROM supports loading data into flash via the USB peripheral. The target is implemented as a USB HID class.

USB HID does not use framing packets; instead the packetization inherent in the USB protocol itself is used. The ability for the device to NAK Out transfers (until they can be received) provides the required flow control; the built-in CRC of each USB packet provides the required error detection.

### 27.5.4.1 Clock configuration

The ROM supports the crystal-less USB feature. If the USB peripheral is enabled, then the ROM enables the 48-MHz . The ROM also enables the USB clock recovery feature (by setting USBx_CLK_RECOVER_CTRL[CLOCK_RECOVER_EN] to 1 ).

### 27.5.4.2 Device descriptor

The Kinetis ROM configures the default USB VID/PID/Strings as below:

Default VID/PID:

- VID = 0x15A2
- PID = 0x0073

Default Strings:

- Manufacturer [1] = "Freescale Semiconductor Inc." (Note that Freescale Semiconductor is now NXP Semiconductors.)
- Product [2] = "Kinetis Bootloader"

You can customize the USB VID/PID/Strings with the Bootloader Configuration Area (BCA) of the flash. See Table 27-3. For example, the USB VID and PID can be customized by writing the new VID to the usbVid(BCA + 0x14) field and the new PID to the usbPid(BCA + 0x16) field of the BCA in flash. To change the USB strings, you need to prepare a structure (like the one shown below) in the flash, and then write the address of the g_languages structure to the usbStringsPointer(BCA + 0x18) field of the BCA.

```
g_languages = { USB_STR_0,
sizeof(USB_STR_0),
(uint_16)0x0409,
(const uint_8 **)g_string_descriptors,
g_string_desc_size};
the USB_STR_0, g_string_descriptors and g_string_desc_size are defined as below.
USB_STR_0[4] =    {0x02,
0x03,
0x09,
0x04
};
g_string_descriptors[4] =
{ USB_STR_0,
USB_STR_1,
USB_STR_2,
USB_STR_3};
g_string_desc_size[4] =
{ sizeof(USB_STR_0),
sizeof(USB_STR_1),
sizeof(USB_STR_2),
sizeof(USB_STR_3)};
```

You can make your own structure of USB_STR_1, USB_STR_2, USB_STR_3:

- USB_STR_1 is used for the manufacturer string.
- USB_STR_2 is used for the product string.
- USB_STR_3 is used for the serial number string.

By default, the 3 strings are defined as below:

```
USB_STR_1[] =
{  sizeof(USB_STR_1),
USB_STRING_DESCRIPTOR,
'F',0,
'r',0,
'e',0,
'e',0,
's',0,
'c',0,
'a',0,
'l',0,
'e',0,
' ',0,
'S',0,
'e',0,
'm',0,
'i',0,
'c',0,
'o',0,
'n',0,
'd',0,
'u',0,
'c',0,
't',0,
'o',0,
'r',0,
' ',0,
'I',0,
'n',0,
'c',0,
'.',0
};

USB_STR_2[] =
{  sizeof(USB_STR_2),
USB_STRING_DESCRIPTOR,
'U',0,
'S',0,
'B',0,
' ',0,
'C',0,
'O',0,
'M',0,
'P',0,
'O',0,
'S',0,
'I',0,
'T',0,
'E',0,
' ',0,
'D',0,
'E',0,
'V',0,
'I',0,
'C',0,
'E',0
};
```

```
USB_STR_3[] =
{  sizeof(USB_STR_3),
USB_STRING_DESCRIPTOR,
'M',0,
'C',0,
'U',0,
' ',0,
'H',0,
'I',0,
'D',0,
' ',0,
'G',0,
'E',0,
'N',0,
'E',0,
'R',0,
'I',0,
'C',0,
' ',0,
'D',0,
'E',0,
'V',0,
'I',0,
'C',0,
'E',0
};
```

### 27.5.4.3 Endpoints

The HID peripheral uses 3 endpoints:

- Control (0)
- Interrupt IN (1)
- Interrupt OUT (2)

The Interrupt OUT endpoint is optional for HID class devices, but the Kinetis Bootloader uses it as a pipe, where the firmware can NAK send requests from the USB host.

### 27.5.4.4 HID reports

There are 4 HID reports defined and used by the bootloader USB HID peripheral. The report ID determines the direction and type of packet sent in the report; otherwise, the contents of all reports are the same.

| Report ID | Packet Type | Direction |
|---|---|---|
| 1 | Command | OUT |
| 2 | Data | OUT |
| 3 | Command | IN |
| 4 | Data | IN |

For all reports, these properties apply:

| | |
|---|---|
| Usage Min | 1 |
| Usage Max | 1 |
| Logical Min | 0 |
| Logical Max | 255 |
| Report Size | 8 |
| Report Count | 34 |

Each report has a maximum size of 34 bytes. This is derived from the minimum bootloader packet size of 32 bytes, plus a 2-byte report header that indicates the length (in bytes) of the packet sent in the report.

**NOTE**

In the future, the maximum report size may be increased, to support transfers of larger packets. Alternatively, additional reports may be added with larger maximum sizes.

The actual data sent in all of the reports looks like:

| | |
|---|---|
| 0 | Report ID |
| 1 | Packet Length LSB |
| 2 | Packet Length MSB |
| 3 | Packet[0] |
| 4 | Packet[1] |
| 5 | Packet[2] |
| | ... |
| N+3-1 | Packet[N-1] |

This data includes the Report ID, which is required if more than one report is defined in the HID report descriptor. The actual data sent and received has a maximum length of 35 bytes. The Packet Length header is written in little-endian format, and it is set to the size (in bytes) of the packet sent in the report. This size does not include the Report ID or the Packet Length header itself. During a data phase, a packet size of 0 indicates a data phase abort request from the receiver.

## 27.6 Get/SetProperty Command Properties

This section lists the properties of the GetProperty and SetProperty commands.

## Table 27-82. Properties used by Get/SetProperty Commands, sorted by Value

| Property | Writable | Tag Value | Size | Description |
|---|---|---|---|---|
| CurrentVersion | No | 01h | 4 | Current bootloader version. |
| AvailablePeripherals | No | 02h | 4 | The set of peripherals supported on this chip. |
| FlashStartAddress | No | 03h | 4 | Start address of program flash. |
| FlashSizeInBytes | No | 04h | 4 | Size in bytes of program flash. |
| FlashSectorSize | No | 05h | 4 | The size in bytes of one sector of program flash.<br>This is the minimum erase size. |
| FlashBlockCount | No | 06h | 4 | Number of blocks in the flash array. |
| AvailableCommands | No | 07h | 4 | The set of commands supported by the bootloader. |
| VerifyWrites | Yes | 0Ah | 4 | Controls whether the bootloader will verify writes to flash. VerifyWrites feature is enabled by default.<br>0 - No verification is done.<br>1 - Enable verification. |
| MaxPacketSize | No | 0Bh | 4 | Maximum supported packet size for the currently active peripheral interface. |
| ReservedRegions | No | 0Ch | 16 | List of memory regions reserved by the bootloader. Returned as value pairs (<start-address-of-region>, <end-address-of-region>).<br>• If HasDataPhase flag is not set, then the Response packet parameter count indicates the number of pairs.<br>• If HasDataPhase flag is set, then the second parameter is the number of bytes in the data phase. |
| RAMStartAddress | No | 0Eh | 4 | Start address of RAM segment. The first parameter to GetProperty command identifies the segment. See the device specific memory map for number of RAM segments the device contains. |
| RAMSizeInBytes | No | 0Fh | 4 | Size in bytes of RAM segment. The first parameter to GetProperty command identifies the segment. See the device specific memory map for number of RAM segments the device contains. |
| SystemDeviceId | No | 10h | 4 | Value of the Kinetis System Device Identification register. |
| FlashSecurityState | No | 11h | 4 | Indicates whether Flash security is enabled<br>0 - Flash security is disabled<br>1 - Flash security is enabled |
| UniqueDeviceId | No | 12h | 16 | Unique device identification, value of Kinetis Unique Identification registers (16 for K series devices, 12 for KL series devices) |
| FacSupport | No | 13h | 4 | FAC (Flash Access Control) support flag<br>0 - FAC not supported<br>1 - FAC supported |
| FlashAcessSegmentSize | No | 14h | 4 | The size in bytes of 1 segment of flash |

*Table continues on the next page...*

**Table 27-82. Properties used by Get/SetProperty Commands, sorted by Value (continued)**

| Property | Writable | Tag Value | Size | Description |
|---|---|---|---|---|
| FlashAcessSegmentCount | No | 15h | 4 | FAC segment count (The count of flash access segments within the flash model.) |
| FlashReadMargin | Yes | 16h | 4 | The margin level setting for flash erase and program verify commands.<br>0 = Normal<br>1 = User (default)<br>2 = Factory |
| TargetVersion | No | 18h | 4 | SoC target build version number |

## 27.6.1 Property Definitions

Get/Set property definitions are provided in this section.

### 27.6.1.1 CurrentVersion Property

The value of this property is a 4-byte structure containing the current version of the bootloader.

**Table 27-83. Fields of CurrentVersion property:**

| Bits | [31:24] | [23:16] | [15:8] | [7:0] |
|---|---|---|---|---|
| Field | Name = 'K' (0x4B) | Major version | Minor version | Bugfix version |

### 27.6.1.2 AvailablePeripherals Property

The value of this property is a bitfield that lists the peripherals supported by the bootloader and the hardware on which it is running.

**Table 27-84. Peripheral bits:**

| Bit | [31:7] | [6] | [5] | [4] | [3] | [2] | [1] | [0] |
|---|---|---|---|---|---|---|---|---|
| Peripheral | Reserved | USB DFU | USB CDC | USB HID | Reserved | LPSPI Slave | LPI2C Slave | LPUART |

If the peripheral is available, then the corresponding bit will be set in the property value. All reserved bits must be set to 0.

### 27.6.1.3 AvailableCommands Property

This property value is a bitfield with set bits indicating the commands enabled in the bootloader. Only commands that can be sent from the host to the target are listed in the bitfield. Response commands such as GenericResponse are excluded.

The bit number that identifies whether a command is present is the command's tag value minus 1. 1 is subtracted from the command tag because the lowest command tag value is 0x01. To get the bit mask for a given command, use this expression:

```
mask = 1 << (tag - 1)
```

**Table 27-85. Command bits:**

| Bit | [31:18] | [17] | [16] | [15] | [14] | [13] | [12] | [11] | [10] | [9] | [8] | [7] | [6] | [5] | [4] | [3] | [2] | [1] | [0] |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Command | Reserved | ReliableUpdate | Reserved | FlashReadResource | FlashReadOnce | FlashProgramOnce | FlashEraseAllUnsecure | SetProperty | Reset | Call | Execute | ReceiveSBFile | GetProperty | FlashSecurityDisable | FillMemory | WriteMemory | ReadMemory | FlashEraseRegion | FlashEraseAll |

### 27.6.1.4 TargetVersion Property

The value of this property is a 4-byte structure containing the target version of the bootloader. The TargetVersion number returned returned for this device is 1.0.0.

**Table 27-86. Fields of TargetVersion property:**

| Bits | [31:24] | [23:16] | [15:8] | [7:0] |
|---|---|---|---|---|
| Field | Name = 'T' (0x4B) | Major version | Minor version | Bugfix version |

## 27.7 ROM API

The ROM API allows applications to integrate ROM bootloading services with Over the Air (OTA) update, where a firmware update image is downloaded into external memory (SPI flash) and authenticated before being written into internal flash. The ROM API is also used to authenticate regions of internal flash before enabling or jumping to that code, thus forming a chain of trust. This internal flash code may be a bootloader authenticating the main application image, or it may be a boot core authenticating the code for a secondary core before releasing it from reset.

### 27.7.1 ROM API

An application calls into the ROM API to provision and authenticate an SB file image. There are 3 function calls:

1. Call kb_init() to start an API session.
2. Call kb_execute() for image loading/authentication.
3. Call kb_deinit() to clean up API session.

Also see Table 27-96.

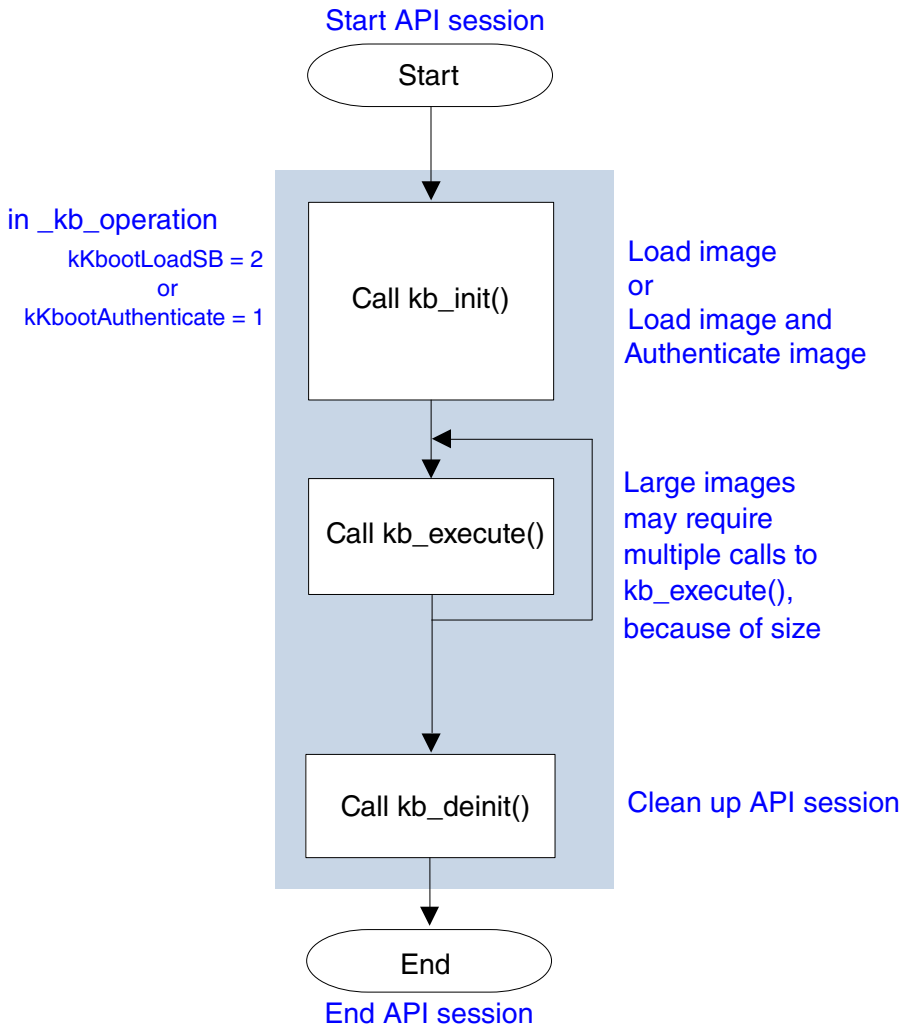

**Figure 27-29. ROM API Sessions**

## 27.7.2 ROM API RAM usage

The kb_session_ref_t structure is allocated by ROM. The initialization function kb_init() returns the kb_session_ref_t structure, and kb_session_ref_t is required to be passed in by other ROM API functions.

The kb_session_ref_t structure points to a fixed block of on-chip RAM for much of its memory use.

- After kb_init() is called, the application is not allowed to touch that fixed block of on-chip RAM (for-ROM-use-only) memory.

- After kb_deinit() is called, the application regains control of this fixed block of on-chip RAM memory, and thereafter the application can use it.
- The ROM will also make use of a buffer that was passed in via the _kb_options structure for temporary memory, thus reducing the overall size of the reserved memory. This is the easiest implementation but imposes restrictions on the application.

The kb_options_t structure provides all of the needed options to carry out the provisioning and authenticating tasks. Some of the structure members could be the functions to read from the external data source that the application is providing, using a pointer to the pre-authenticated function code available in the internal flash (or elsewhere).

## 27.8 Security

### 27.8.1 Introduction

This section defines the Kboot security architecture.

The Kboot security architecture provides 3 basic operations:

- **Signed image authentication:** which verifies RSA signatures over the entire image, using RSA public keys contained in the signed image.
- **Secure boot:** which provides the guarantee that unauthorized code cannot be executed on a given device.
- **Secure firmware update through SB files:** which authenticates the new firmware before committing the firmware to memory.

This security architecture is based on 2 image formats:

- **A format for signed images**. The signed image format is common and may contain executable code resident in internal flash (or other memories), or may even contain a firmware update image.
- **A format for firmware updates**. The firmware update image format is called Secure Binary (SB file). The SB format is signed using the common signed image format, and SB files are always encrypted.

The KBoot provides an API that integrates security architecture operations into customer applications.

## 27.8.2 Notation

| Operator | Definition |
|---|---|
| AES(K, x) | AES-256 encipherment algorithm applied to octet string *x* using key *K*. |
| BE(x) | Integer *x* represented as a big endian octet string with a length of the smallest number of octets required to properly represent *x*. |
| ceil(x) | Returns the smallest integer greater than or equal to a given number. |
| floor(x) | Returns the largest integer less than or equal to a given number. |
| HMAC(K, x) | HMAC-SHA256 algorithm applied to octet string *x* using key *K*. |
| Len(x) | Length in octets of *x*. |
| x MOD y | Integer remainder of *x* divided by *y*. |
| SHA256(x) | SHA-256 hash algorithm applied to octet string *x*. |
| a XOR b | Exclusive-OR between octet strings *a* and *b*. |
| a \|\| b | Concatentation of octet strings *a* and *b*. |
| [ hex-byte$_0$ … hex-byte$_{N-1}$ ] | Octet string of length N. Example: [ 55 10 04 a7 ]. |
| S ^ n | The octet string *S* repeated *n* times, forming a result of (Len(S) * n) octets. |
| x..y | An inclusive range of integers from *x* through *y*. |

| Symbol | Definition |
|---|---|
| DigestInfo | DER encdoded ASN.1 value of type DigestInfo. |
| EM | Encoded data to be signed with an RSA private key in RSASSA-PKCS1_v1_5. |
| H | SHA-256 hash of signed image. |
| HmacRangeCount | Number of HMAC ranges for a given section. |
| HmacRangeLen$_j$ | Number of cipher blocks for section HMAC *j* for a given section. |
| IPK | Public key contained in the image signing certificate. |
| k | Length in octets of the IPK. |
| K DEK | AES-256 data encryption key used to encrypt SB file sections. |
| K MAC | 256-bit HMAC key used to authenticate SB file header. |
| Offset$_x$ | Offset of region *x*. |
| PS | Padding used in *EM*. |
| RKH$_x$ | Hash of root public key number x. |
| RKTH | Root key table hash. |
| RPK | Public key contained in the root certificate. |
| SB$_x$ | Cipher block number *x* of an SB file. |

**NOTE**

Unless explicitly noted, all multi-byte values in the definitions below are to be stored in little endian format.

### 27.8.3 Use cases

All of these use cases are about establishing a trust relationship between pieces of code that run on the target device. The device's ROM is the trust root.

#### 27.8.3.1 Secure boot

Device manufacturers want to ensure that unauthorized images (code) cannot be executed on a given product. Secure boot provides this guarantee, which involves the device's ROM always executing when coming out of reset. When secure boot is enabled, to determine the authenticity of that image, the ROM bootloader will then examine the 1st user executable image resident in internal flash memory. If the image is authentic, then control is transferred to that image; this establishes a chain of trusted code from the ROM bootloader to the user boot image. This chain can be further extended, as described next.

In this architecture, the method used to verify the authenticity of the user boot image is to verify RSA signatures over the entire user boot image. The user boot image is signed with RSA private keys. The corresponding RSA public keys used for signature verification are contained in X.509 certificates that are contained in the signed user boot image.

#### 27.8.3.2 Secure firmware updates

If firmware updates are to be performed in the field when secure boot is enabled, then a secure firmware update mechanism is preferred; otherwise, inauthentic (not authentic) firmware may be written to the device, and may possibly prevent the device from booting. In the most basic sense, a secure firmware update simply performs an authentication of the new firmware before committing it (the new firmware) to memory. In this case, the chain of trust is extended from the old, currently executing code to the new code.

Another use case for a secure firmware update is to hide the application binary code during transit over public media (like the Internet). This is accomplished by encrypting the firmware update image. As the new firmware is written into device memory, it (the new firmware) is decrypted.

In this architecture, both cases of secure firmware update are supported. The SB file format is always encrypted and also may be signed. If the entire SB file is available before loading, then the ROM API may be used to authenticate it (the SB file). As an SB

file is loaded, it is decrypted. The ROM may support loading of SB files via serial interfaces such as USB, UART, and others. If an SB file is loaded in this way (over a serial interface), then authentication is not supported

#### 27.8.3.3 Extending the chain of trust

After secure boot has transferred CPU control to user code, then that user code may need to load additional pieces of code. This establishes another link in the chain of trust. The process can continue for as many nested submodules are required, with each parent code module authenticating the child (submodule). Another use case is to authenticate boot code for one or more secondary CPU cores, before releasing them (the secondary cores) from reset.

The ROM API is used from customer code to verify signatures on the additional code images. Using the ROM API to verify signatures gives complete control (which additional code must be signed and how that code is organized in memory) to the customer code.

### 27.8.4 Security fields

#### 27.8.4.1 Keys

Keys are in 2 locations:

- In IFR fields
- In ROM API

Both sets of keys provide the same "key" function, but keys in the ROM API struct are only used by ROM API loading image/authentication session. Each ROM API session must provide its own keys. After calling kb_deinit():

- Keys provided by kb_init are not available any more.
- Keys in IFR fields will be still available (unless calling flash mass erase).

There are 3 keys:

- The 1st key is an AES-256 key encryption key (KEK) called the SBKEK. The SBKEK key is used only for unwrapping additional keys stored in an SB file.

- The 2nd "key" is actually not a key, but is a SHA-256 hash of a table of hashes of RSA public keys. This hash is called the root key table hash (RKTH). RKTH is used to lock the public key in the root certificate against change.
- The 3rd key (USERKEK) is a separate AES-256 key held in IFR. This key is designated for customer use as a KEK and is not used by the loader. To distinguish the KEK key from the SBKEK key, this KEK key is called the USERKEK. USERKEK is programmable once and erasable via mass erase, but cannot be read by software. There is a hardware bus that feeds the USERKEK key directly into the crypto-accelerator.

How the keys are used:

- For secure boot, RKTH are values in the IFR index 0x94 - 0x97.
- Through the command line, SBKEK are values in the IFR index 0x90 - 0x93.
- Through the ROM API, SBKEK / RKTH can also be provided by the user in kb_options_t. If a key value is zero, then the corresponding key in IFR will be used instead.
- For a user-defined situation, USERKEY in the IFR index can be used.

**Table 27-87. Keys**

| Key | Indices | Size (bytes) | Name | Description |
|---|---|---|---|---|
| 1st | 0x90 - 0x93 | 32 | SBKEK[1] | AES-256 key for SB key unwrapping. |
| 2nd | 0x94 - 0x97 | 32 | RKTH[2] | SHA-256 hash of root public key hash table. |
| 3rd | 0xB1 - 0xB4 | 32 | USERKEK | Customer write-only AES-256 key. |

1. If SBKEK has a value of 0xFFFF FFFF FFFF FFFF, then SBKEK will be processed as if it had a value of 0.
2. To generate the RKTH, a SHA-256 is computed over the root public key hash table (RKH table).

### 27.8.4.2 Flags

Several critical flags used for secure boot (and other purposes) are placed in write-once flash IFR (or OTP).

**Table 27-88. Flag words in IFR**

| Index | Bytes | Name | Description |
|---|---|---|---|
| 0x98 | 8 | ROM_SECURITY_FLAGS | ROM security settings |
| 0x99 | 8 | ROM_SECURITY_PROFILE | Security profile |
| 0x9C | 8 | ROM_REVOKE_RK0 | Root key #0 revocation flag |

*Table continues on the next page...*

**Table 27-88. Flag words in IFR (continued)**

| Index | Bytes | Name | Description |
|---|---|---|---|
| 0x9D | 8 | ROM_REVOKE_RK1 | Root key #1 revocation flag |
| 0x9E | 8 | ROM_REVOKE_RK2 | Root key #2 revocation flag |
| 0x9F | 8 | ROM_REVOKE_RK3 | Root key #3 revocation flag |

**Table 27-89. Flag word bit/field definitions**

| Index | Bit(s) | Name | Description |
|---|---|---|---|
| 0x98 | 1:0 | SECURE_BOOT_EN | 2'b00: Secure boot is disabled.<br>2'b10: Secure boot is enabled.<br>2'b01: Secure boot is enabled.<br>2'b11: Secure boot is disabled. |
| 0x98 | 3:2 | SECURE_BOOT_DEV_EN | 2'b00: Secure boot development mode is disabled.<br>2'b10: Secure boot development mode is enabled.<br>2'b01: Secure boot development mode is enabled.<br>2'b11: Secure boot development mode is disabled. |
| 0x98 | 4 | STOP_ON_FAILURE | If secure boot authentication fails:<br>• And if STOP_ON_FAILURE is set, then the ROM will enter an infinite loop.<br>• And if STOP_ON_FAILURE is not set, then the ROM will enter bootloader mode. |
| 0x99 | 16 | RSA4096_KEY | 4096-bit RSA keys required. |
| 0x9C | 63:0 | ROM_REVOKE_RK0 | Any bit being cleared causes root key table entry #0 to be revoked. |
| 0x9D | 63:0 | ROM_REVOKE_RK1 | Any bit being cleared causes root key table entry #1 to be revoked. |
| 0x9E | 63:0 | ROM_REVOKE_RK2 | Any bit being cleared causes root key table entry #2 to be revoked. |
| 0x9F | 63:0 | ROM_REVOKE_RK3 | Any bit being cleared causes root key table entry #3 to be revoked. |

The ROM_SECURITY_PROFILE at index 0x99 matches the bit masks defined by the _kb_security_profile enumeration in the ROM API.

**NOTE**

If ROM_SECURITY_PROFILE has a value of 0xFFFF FFFF FFFF FFFF, then it will processed as if it had a value of 0.

**Table 27-90. Additional IFR fields that affect secure boot and the ROM**

| Index | Bytes | Name | Description |
|---|---|---|---|
| 0x80 | 2 | SEC0 | Flash security - Primary |

*Table continues on the next page...*

**Table 27-90. Additional IFR fields that affect secure boot and the ROM (continued)**

| Index | Bytes | Name | Description |
|---|---|---|---|
| 0x81 | 2 | FSLACC | Flash security - Factory Security Level Access |
| 0x82 | 2 | MEEN | Flash security - Mass Erase Enable |
| 0x83 | 2 | KEYEN | Flash security - Backdoor Key Enable |
| 0x84 | 4 | FOPT | Used to customize MCU boot time configuration |
| 0xA0 | 2 | SEC1 | Security Qualifier |

For FOPT field definitions, see the Reset and Boot chapters.

## 27.8.5 Signed image structure

There is a single format used for signed data, whether the signed data is an SB file or is code located in internal flash. Using a single format for signed data allows the same API and code to be used for both

- authenticating a signed SB file,
- and authenticating a signed image in flash.

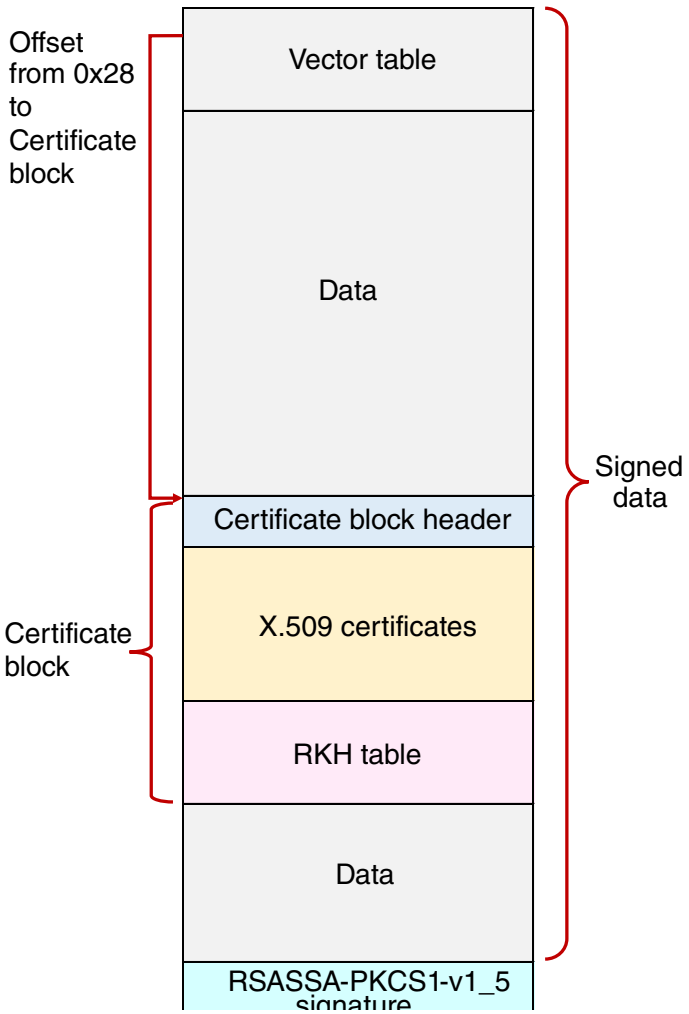

**Figure 27-30. Signed image structure**

In this diagram, data is shown both before and after the certificate block. This is optional; the certificate block may appear anywhere within the signed data.

- Images are signed using the RSASSA-PKCS1-v1_5 algorithm.
- The digest is computed using SHA-256.
- 2048-bit or 4096-bit RSA keys are supported.

### 27.8.5.1 Certificate block offset

A 32-bit offset called offsetToCertificateBlockInBytes, *which goes from the beginning of the signed image to the certificate block*, must reside at offset 0x28 from the start of the signed image. An executable code image in internal flash is expected to start with an NVIC vector table. The word at offset 0x28 is a reserved slot in the vector table. For SB files, offset 0x28 is reserved to hold offsetToCertificateBlockInBytes in the file header. If

signed code in flash does not begin with a vector table (such as for a signed library or similar secondary image), then the word at offset 0x28 must be reserved for the offsetToCertificateBlockInBytes field.

For example, if an image resides in flash at a non-zero address (say 0x8000), and its certificate block header is at address 0x24000, then the word at 0x8028 will contain the value 0x1C000.

Here is a standard Cortex-M4 NVIC vector table with the offset to the certificate block highlighted at offset 0x28.

| Offset | Used for |
|---|---|
| 0x00 | Initial SP |
| 0x04 | Reset |
| 0x08 | NMI |
| 0x0C | HardFault |
| 0x10 | MemManage |
| 0x14 | BusFault |
| 0x18 | UsageFault |
| 0x1C | *Reserved* |
| 0x20 | *Reserved* |
| 0x24 | *Reserved* |
| **0x28** | **offsetToCertificateBlockInBytes** |
| 0x2C | SVC |
| 0x30 | DebugMon |
| 0x34 | *Reserved* |
| 0x38 | SysTick |

### 27.8.5.2 Certificate block

The certificate block consists of the certificate block header, the certificate table, and the RKH table, concatenated together.

- The certificate block is allowed to reside anywhere within the signed image, but the certificate block must be fully contained within the signed data, such that the certificate block itself is signed.
- The certificate block offset is pointed to by the offsetToCertificateBlockInBytes.
- The most common constructions will have the certificate block placed at either the beginning of the signed data (after the vector table) or at the end of the signed data.

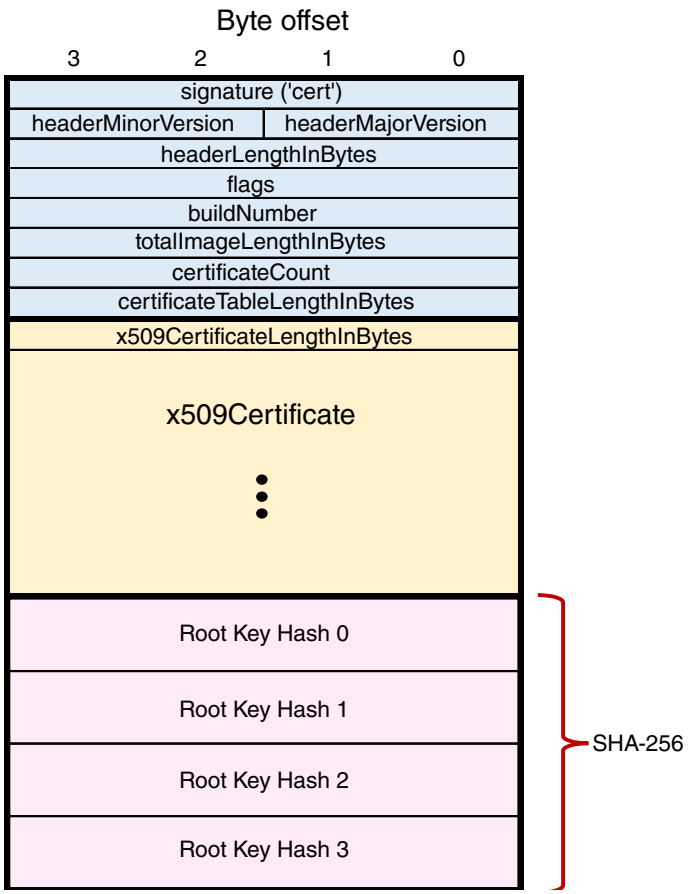

**Figure 27-31. Certificate block structure**

### 27.8.5.2.1 Certificate block header

The certificate block header is a structure containing the information required to properly verify a signed image. As described previously, it is pointed to by the offsetToCertificateBlockInBytes header offset field.

Let $Offset_{header}$ = (offsetToCertificateBlockInBytes)

The first word of the certificate block header must be 4-byte aligned.

Structure definition for the certificate block header:

```
struct certificate_block_header_t {
    uint32_t signature;
    uint16_t headerMajorVersion;
    uint16_t headerMinorVersion;
    uint32_t headerLengthInBytes;
    uint32_t flags;
    uint32_t buildNumber;
    uint32_t totalImageLengthInBytes;
    uint32_t certificateCount;
    uint32_t certificateTableLengthInBytes;
};
```

**Table 27-91. Certificate block header fields**

| Field | Description |
|---|---|
| signature | Always set to 'cert'. |
| headerMajorVersion | Set to 1. |
| headerMinorVersion | Set to 0. |
| headerLengthInBytes | Number of bytes that the header has, starting from the signature. headerLengthInBytes does not include the certificate table. |
| flags | Reserved for future use. |
| buildNumber | User-specified build number for the signed image. Allows the user to prevent reverting to old versions. The API compares the buildNumber against the minBuildNumber specified in kb_options_t. buildNumber must be a multiple of 4. |
| totalImageLengthInBytes | Length in bytes of the signed data |
| certificateCount | Must be greater than 0. |
| certificateTableLengthInBytes | Total length in bytes of the certificate table. certificateTableLengthInBytes must be a multiple of 4. |

The key field in the certificate header is totalImageLengthInBytes, which indicates the number of bytes of signed data, starting at offset 0 of the image. The entire certificate block must be contained within the signed data.

The signature field can be treated as 4-character string, without a terminating null byte, with a value of 'cert'. Represented as a 32-bit little endian constant, the value would be (('c') | ('e' << 8) | ('r' << 16) | ('t' << 24)).

### 27.8.5.2.2 Certificate table

Immediately following the certificate block header is the certificate table. It consists of a complete chain of one or more X.509 certificates, with each certificate prefixed with a length word.

$$\text{Let } Offset_{\text{certificate table}} = (\text{offsetToCertificateBlockInBytes} + \text{headerLengthInBytes})$$

Structure definition for the certificate table:

```
struct cert_entry {
    uint32_t x509CertificateLengthInBytes;
    uint8_t x509Certificate[];
};

struct cert_table {
    cert_entry entries[];
};
```

- The x509CertificateLengthInBytes field for each certificate must be set to the length of that certificate's data in bytes, rounded up to the next word (4-byte) alignment; therefore, x509CertificateLengthInBytes must be divisible by 4.

- Each x509Certificate contains the actual certificate data, and can be of variable length. There may be from 0-3 bytes of padding inserted after the certificate data.
- The cert_entry struct is repeated for certificateCount entries in the table.
- The total number of bytes occupied by the table must equal certificateTableLengthInBytes, and must always be divisible by 4.

There are restrictions on the certificates:

- Only X.509 v3 format certificates are supported.
- Must be DER-encoded.
- Must use RSA-2048 or RSA-4096 and SHA-256.
- All certificates must use RSA keys with a modulus bitlength greater than or equal to the RSA bitlength specified by the security profile. For example, a 4096-bit root key followed by a 2048-bit image key is allowed, if the security profile is set to 2048-bit keys.
- The SHA-256 hash of the public key contained in the first certificate in the table must be present in the RKH table.

The certificate table can contain one or more certificates:

- Certificates must be positioned in the table starting with the root certificate, followed by each subsequent certificate in the chain, in the order of signing. The final certificate in the table is called the image-signing certificate.
- Using a single certificate is allowed; in this case, the sole certificate must be self-signed and must not be a CA.
- If multiple certificates are used, then the root must be self-signed and all but the last certificate must be CAs.

The 2 most common configurations will be:

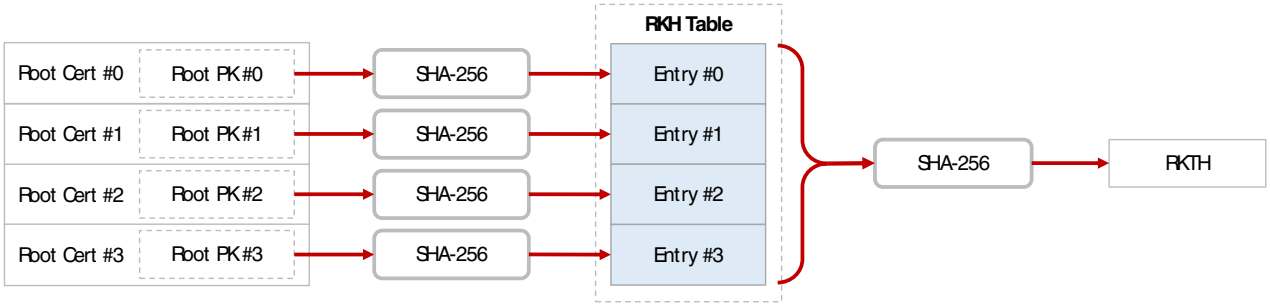
- One self-signed certificate.
- A self-signed root CA certificate, followed by an image signing certificate (which is itself signed by a root certificate).

#### 27.8.5.2.3 RKH table

Following the certificate table is a table containing SHA-256 hashes of up to 4 allowed root public keys. Multiple root public keys are supported to allow for key revocation.

```
Let Offset_RKHT = (offsetToCertificateBlockInBytes
                                          + headerLengthInBytes
                                          + certificateTableLengthInBytes)
```

The structure of this table is shown here:



The C definition of the table:

```
struct rkh_entry {
    uint8_t rkh[32];
};

struct rkh_table {
    rkh_entry entries[4];
};
```

Each entry in the table is a SHA-256 computed over the concatenation of an RSA public key's modulus and exponent (modulus || exponent). Both modulus and exponent must be in big endian byte order, with the minimum number of bytes required to represent the value. For instance, an exponent of 65537 would be represented by a 3-byte value of [01 00 01], while an exponent of 3 would be represented by a single byte of that value. The entire RKH table is itself hashed with SHA-256. This final hash is then stored in the RKTH field in IFR.

```
For i in 0..3:
                Let M_i = BE(Modulus_i)
                Let E_i = BE(Exponent_i)
                Let RKH_i = SHA256( M_i || E_i)
                Let RKTH = SHA256( RKH_0 || RKH_1 || RKH_2 || RKH_3 )
```

The number of hashes of keys in the RKH table must be from at least 1 through a maximum of 4. Unused table entries must be set to all 0 bytes.

The extra root public keys and root certificates must be created in advance and would be held in reserve in case a public key had to be revoked. The customer is responsible for implementing the mechanism to determine whether a key needs to be revoked, and then set the appropriate RK_REVOKE bit(s). This would usually be done through an authenticated connection with a server during a firmware update.

Note that only one of the root certificates whose keys are listed in the RKH table may be included in the certificate table at a time.

### 27.8.5.3 Signature

The signature itself is placed at offset totalImageLengthInBytes from the beginning of the image and must be in RSASSA-PKCS1-v1_5 format.

Let $Offset_{sig}$ = (totalImageLengthInBytes)

The first word of the signature must be 4-byte aligned.

A SHA-256 hash is computed over the entire image data from offset 0 through totalImageLengthInBytes. The resulting hash is then signed using RSASSA-PKCS1-v1_5 format with the RSA private key corresponding to the public key contained in the final certificate in the certificate table. See PKCS#1 for the complete details of RSASSA-PKCS1-v1_5.

For RSA-2048, the signature will be 256 bytes; for RSA-4096, it will be 512 bytes.

**NOTE**

DigestInfo is an encoding of the ASN.1 DigestInfo value with the following ASN.1 syntax. The fixed octet string used for the DigestInfo value in the algorithm above is for an AlgorithmIdentifier of SHA-256.

```
DigestInfo ::= SEQUENCE {
    digestAlgorithm AlgorithmIdentifier,
    digest OCTET STRING
}
```

## 27.8.6 SB file formats

The Secure Binary (SB) image format is a command-based firmware update image. The SB image format has a long history, and has been used on multiple STMP, i.MX, and Kinetis devices.

In addition to version 1.0 of SB image format, this section also defines the new version 2.0 of the SB image format. Version 2.0 updates the encryption scheme to use modern algorithms, and also adds support for signed images. SB format version 2.0 format only supports 256-bit AES keys.

The SB format is composed of 16-byte cipher blocks as its basic unit. All regions of the file are aligned to 16 bytes. The maximum size of an SB file is $2^{31}$ - 1 cipher blocks, or $2^{39}$ - 128 bytes.

### 27.8.6.1 Regions

The layout of an SB 2.0 file is shown next. The header fields with a brighter blue background are the differences from the SB 1.x file and header layout.

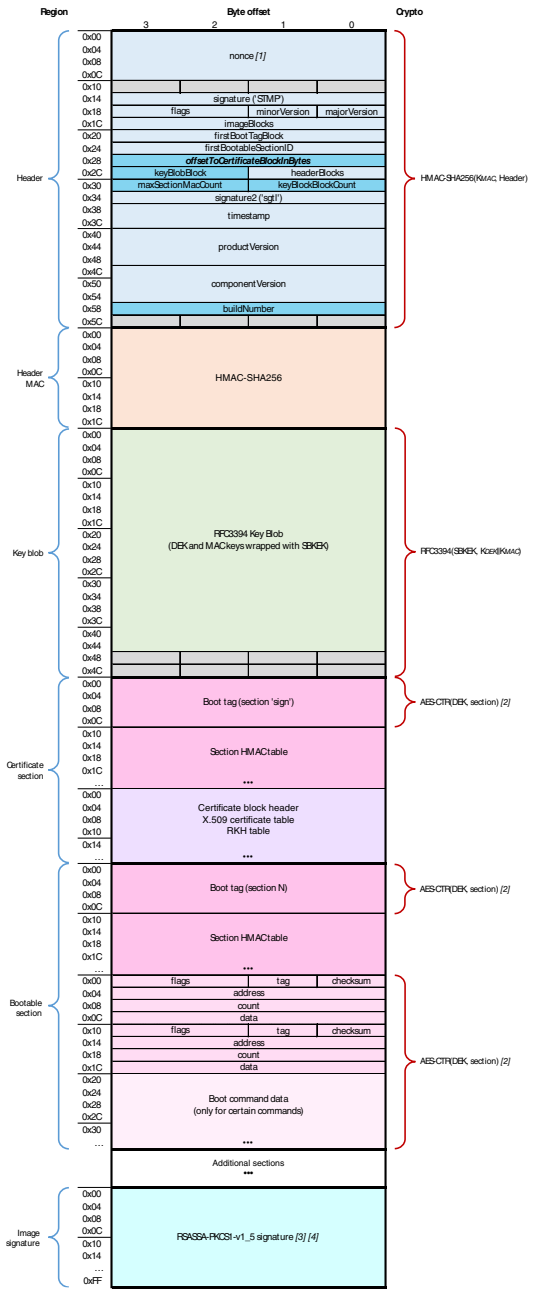


**Figure 27-32. SB format version 2.0 layout**

[1] 128-bit random nonce for AES-CTR with bit 31 cleared.

[2] AES-CTR uses nonce in header + cipher block offset in file for counter.

[3] Signature must be at offset of certificate_block_header_t::totalImageLengthInBytes and sign all data from 0 to signature.

[4] Signature will be either 256 or 512 bytes in length, depending on the RSA key size.

For your online reading convenience, SB format version 2.0 is shown next in 3 parts: top, middle, bottom.

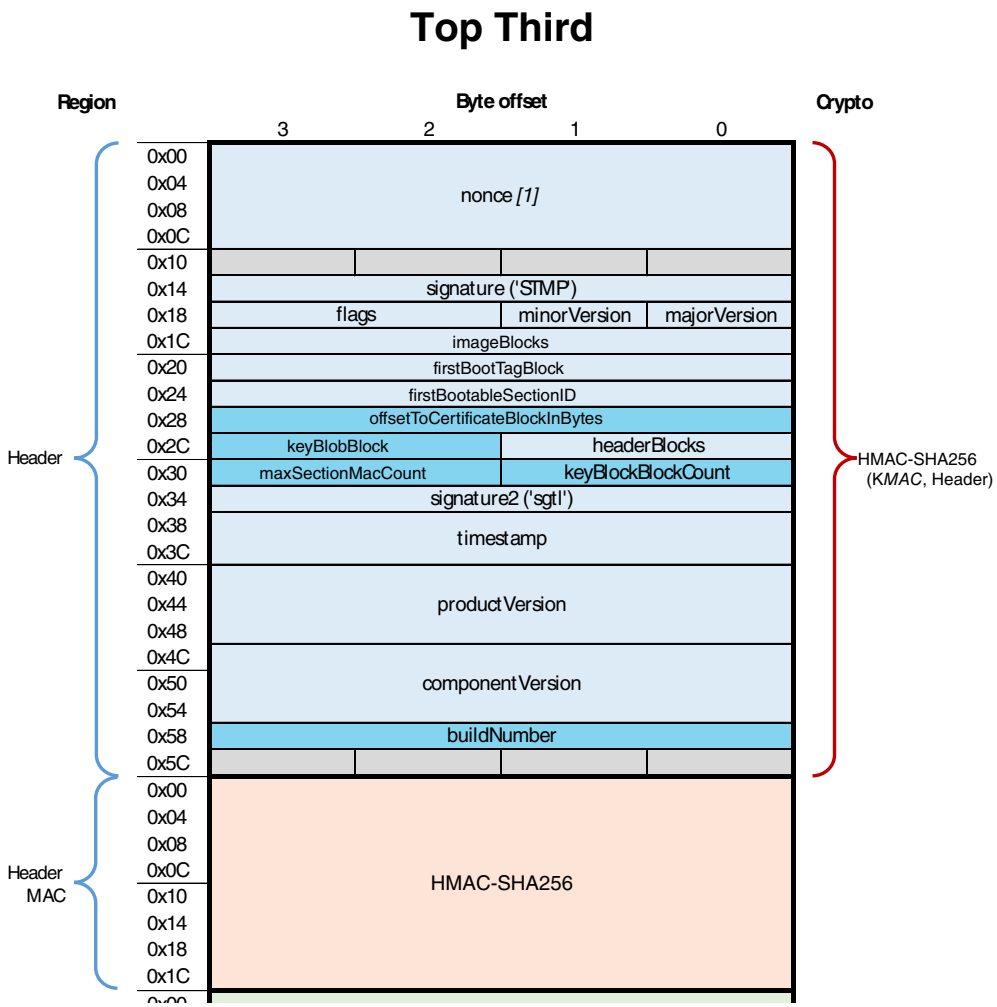

**Figure 27-33. SB format version 2.0 layout: top**

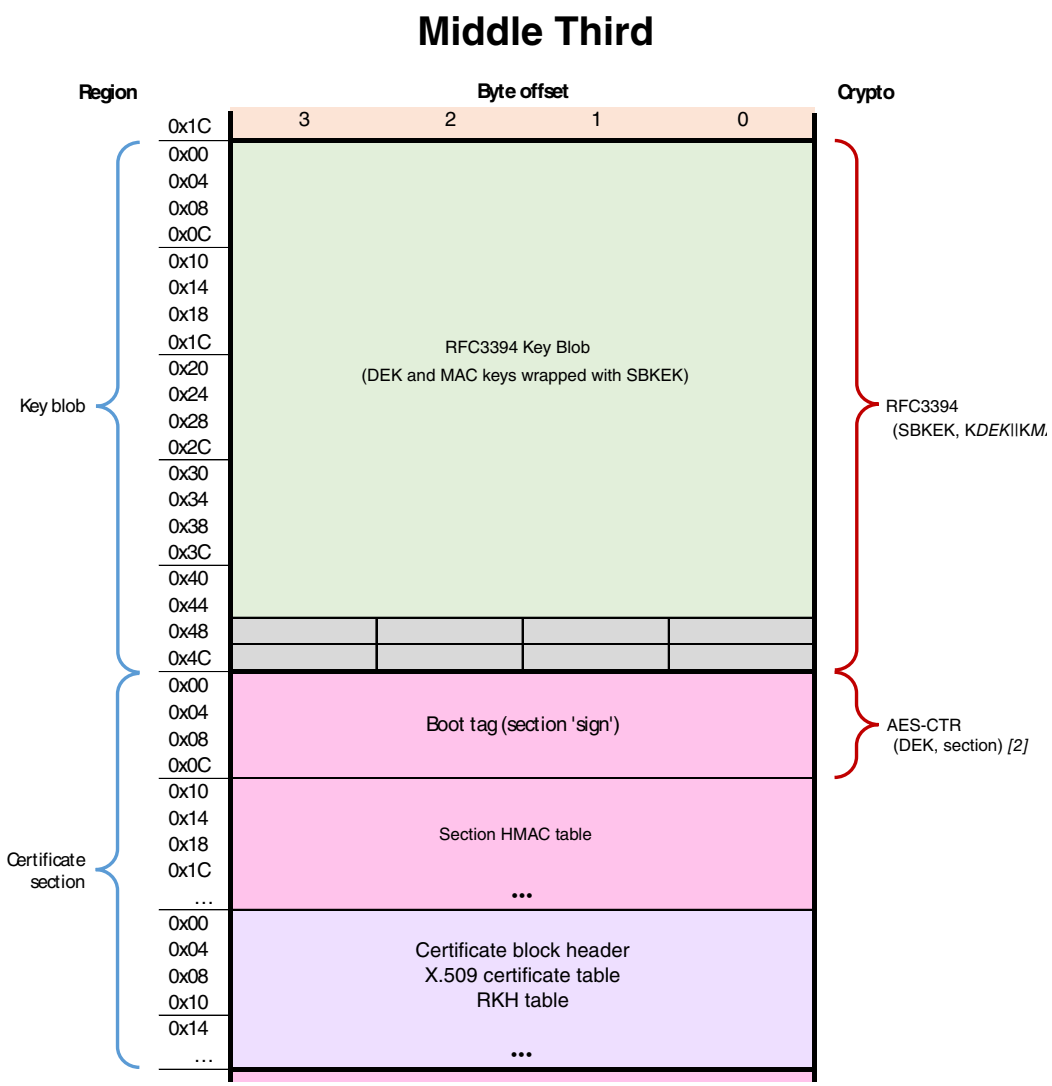

**Figure 27-34. SB format version 2.0 layout: middle**

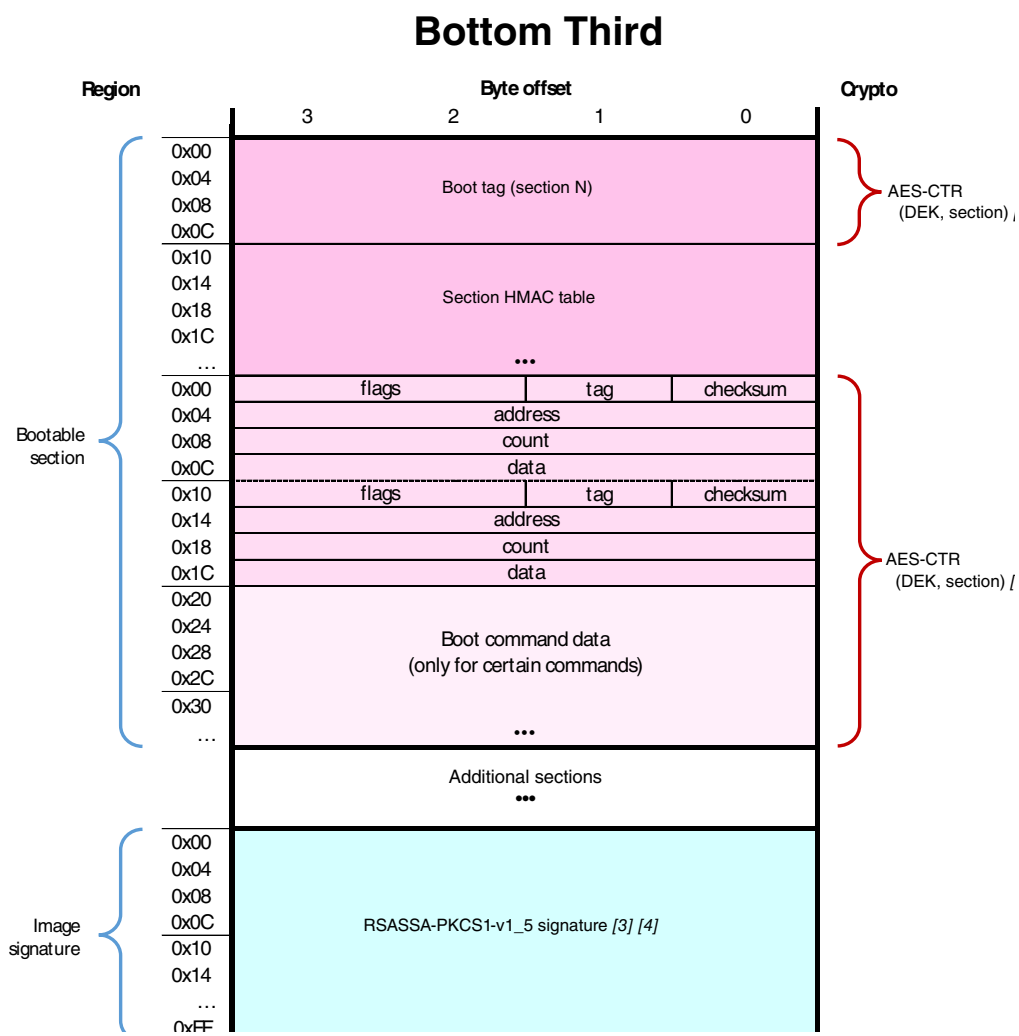

**Figure 27-35. SB format version 2.0 layout: bottom**

## 27.8.6.1.1 Header

Many of the SB 2.0 header fields are in the same position as the SB 1.0 format, including the magic numbers and format version. Other header fields were replaced.

```
struct version_t {
    uint32_t major;
    uint32_t minor;
    uint32_t bugfix;
};

struct sb2_header_t {
    uint32_t nonce[4]; //!< Nonce for AES-CTR.
    uint32_t _padding0;
    uint32_t signature;  //!< 'STMP'
    uint8_t majorVersion;
    uint8_t minorVersion;
    uint16_t flags;
    uint32_t imageBlocks;
    uint32_t firstBootTagBlock;
    uint32_t firstBootableSectionID;
    uint32_t offsetToCertificateBlockInBytes;
```

```
    uint16_t headerBlocks;
    uint16_t keyBlobBlock;
    uint16_t keyBlobBlockCount;
    uint16_t maxSectionMacCount;
    uint32_t signature2;  //!< 'sgtl'
    uint64_t timestamp;
    version_t productVersion;
    version_t componentVersion;
    uint32_t buildNumber;  //!< User build number.
    uint32_t _padding1;
};
```

## Table 27-92. Header fields

| Field | Description |
|---|---|
| nonce | 128-bit random nonce for AES-CTR. Bit 31 is cleared.<br>The nonce is a 128-bit random value with bit 31 cleared. This allows the use of a 32-bit modular add instead of a full 128-bit add, while still supporting messages up to 2 (31 - 1) cipher blocks. See RFC5297 for more details. (RFC5297 specifies clearing bits 31 and 63, so that either 32- or 64-bit adds may be used. Because we only use 32-bit adds, bit 63 does not need to be cleared on the nonce.) |
| signature | Always set to 'STMP', big endian.<br>The two signature fields (signature, signature2) can be treated as 4-character strings without null-terminating bytes. The signature must be set to 'STMP'. That is, the byte 0 is 'S' and byte 3 is 'P'. Represented as a 32-bit little endian constant, the value would be (('S') \| ('T' << 8) \| ('M' << 16) \| ('P' << 24)). signature2 must be 'sgtl', thus in 32-bit little endian form would be (('s') \| ('g' << 8) \| ('t' << 16) \| ('l' << 24)). |
| majorVersion | Set to 2. |
| minorVersion | Set to 0. |
| flags | See the table below. |
| imageBlocks | Size of the entire image in blocks. |
| firstBootTagBlock | Offset in cipher blocks, from start of file to the block containing the first boot tag. |
| firstBootableSectionID | Unique identifier of the section to start booting from. |
| offsetToCertificateBlockInBytes | Offset in bytes to the certificate block header for a signed SB file. If the file is not signed, then offsetToCertificateBlockInBytes field will be 0. |
| headerBlocks | Size of the entire image header in blocks. |
| keyBlobBlock | Block number where the key blob starts. |
| keyBlobBlockCount | Number of cipher blocks occupied by the key blob. |
| maxSectionMacCount | Maximum number of HMAC table entries used in all sections of the SB file. |
| signature2 | Always set to 'sgtl', big endian. Also see signature above. |
| timestamp | Timestamp (in microseconds) size 1-1-2000 00:00, when the image was created. |
| productVersion | User-controlled product version, not used by the loader. |
| componentVersion | User-controlled component version, not used by the loader. |
| buildNumber | User-controlled build number. Compared with minBuildNumber from the kb_options_t struct passed into the API. |

## Table 27-93. Header flags

| Bit(s) | Flag | Description |
|---|---|---|

*Table continues on the next page...*

**Table 27-93. Header flags (continued)**

| | | |
|---|---|---|
| 0 | - | Reserved |
| 1 | - | Reserved |
| 2 | - | Reserved |
| 3 | ROM_SIGNED | The SB file is signed if set. offsetToCertificateBlockInBytes must be set appropriately.<br>**NOTE:** The ROM_SIGNED and ROM_CIPHER_MODE flags do not directly affect security; these 2 flags are only used for convenience and reference. |
| 5:4 | ROM_CIPHER_MODE | Block cipher mode used to encrypt section data.<br>2'b00 - AES-CTR<br>2'b01 - Reserved<br>2'b10 - Reserved<br>2'b11 - Reserved |
| 15:6 | - | Reserved |

### 27.8.6.1.2 Header MAC

The header MAC (HMAC) is a message authentication code that provides authentication of the SB file header using a secret key. The header MAC is computed with the HMAC-SHA256 algorithm [5][6] using a 256-bit secret key called K MAC. The HMAC is generated over the entire header plus the section table, including any required padding. HMAC is 32 bytes in size.

As soon as the header, MAC, and key blob are all available, the loader will recompute the MAC and compare the computed MAC with the MAC stored in the file. If the computed-MAC-to-stored-MAC compare fails, then the load is aborted with an error.

The MAC must follow the header and must start on an even block boundary.

### 27.8.6.1.3 Key blob

The key blob wraps two 256-bit keys using the RFC3394 algorithm, which provides integrity and authenticity over the wrapped keys. The two keys in the key blob are:

- Data Encryption Key ($K_{DEK}$): the KDEK is used to encrypt section data in the SB file.
- MAC Key ($K_{MAC}$): the KMAC is used for header HMAC and section HMACs.

The content of the key blob can be represented by this structure:

```
struct key_blob_t {
    uint8_t k_dek[32];
    uint8_t k_mac[32];
};
```

Both keys are uniquely generated each time that an SB file is built. The keys are wrapped with the SBKEK that is programmed into the target device's IFR or OTP. The key blob must follow the header MAC and must start on an even block boundary. Padding also must be added after the key blob, so that the following region starts on an even block boundary.

The key blob (containing the two 256-bit keys) will be 72 bytes in length; therefore, 8 bytes of padding are required.

#### 27.8.6.1.4 Sections

The content of SB files is divided into an arbitrary number of sections, each with a unique ID. Every section is preceded with a boot tag that acts as a header, plus an HMAC table. A section may be either a bootable section that contains boot commands, or a data section containing data not used by the loader. There must be at least 1 bootable section for an SB file to be valid.

##### 27.8.6.1.4.1 Boot tag

Boot tags prefix a section with the information about that section, and the boot tags form a linked list within the SB file, allowing the loader to sequentially search for a given section.

- Boot tags are always encrypted using AES-CTR.
- A boot tag is actually a ROM_TAG_CMD boot command. See Appendix A for the definition of boot commands.
- The C structure definition for a boot tag command is shown next, and the boot tag structure is the same as the boot_command_t structure.

```
struct boot_tag_t {
    uint8_t checksum;
    uint8_t tag;
    uint16_t flags;
    uint32_t address;
    uint32_t count;
    uint32_t data;
};
```

**Table 27-94. Boot tag fields**

| Field | Description |
|---|---|
| checksum | Simple checksum of the other fields of boot_command_t |
| tag | 0x01 or ROM_TAG_CMD |
| flags | Section flags |
| address | Unique 32-bit identifier for this section.<br>Each section has a 32-bit unique ID, specified in the address field of the boot tag. |

*Table continues on the next page...*

**Table 27-94. Boot tag fields (continued)**

| Field | Description |
|---|---|
| count | The number of cipher blocks that the data for this section occupy.<br>The number of cipher blocks of section content is specified by the count field. The offset in cipher blocks to the next boot tag is denoted NextSectionOffset. It includes the size of the MAC table. |
| data | Section MAC table entry count |

**Table 27-95. Section flags**

| Bit(s) | Flag | Description |
|---|---|---|
| 0 | ROM_SECTION_BOOTABLE | • If ROM_SECTION_BOOTABLE is set, then the section is bootable and contains a sequence of bootloader commands.<br>• If ROM_SECTION_BOOTABLE is cleared, then the section is a data section and will be skipped by the loader. |
| 1 | ROM_SECTION_CLEARTEXT | The section is *unencrypted* if set. Note that unencrypted bootable sections are not supported. |
| 14:2 | - | Reserved |
| 15 | ROM_LAST_TAG | Indicates that there are no more sections in the image.<br>The flag ROM_LAST_TAG must be set on the boot tag for the last section, and indicates that there are no more sections in the image.<br>If the ROM_LAST_TAG flag is set, then there will not be another boot tag following the current one. In this case, NextSectionOffset would indicate the number of cipher blocks to either the end of the SB file, or to the RSA signature in the case of a signed SB file.<br>Let NextSectionOffset = ((boot_tag_t::data + 1) * 2) + boot_tag_t::count |

### 27.8.6.1.4.2 Section MAC table

Following the boot tag is a table of MACs used to verify the integrity and authenticity of section data. These MACs are computed using the HMAC-SHA256 algorithm with the K MAC key from the SB file's key blob. The number of MACs for a section is configurable by the user to trade between memory utilization and protection granularity.

The boot tag data field contains a count of the section MAC table entries that apply to section contents. The minimum count is 1. Unencrypted data sections are still required to have a MAC table.

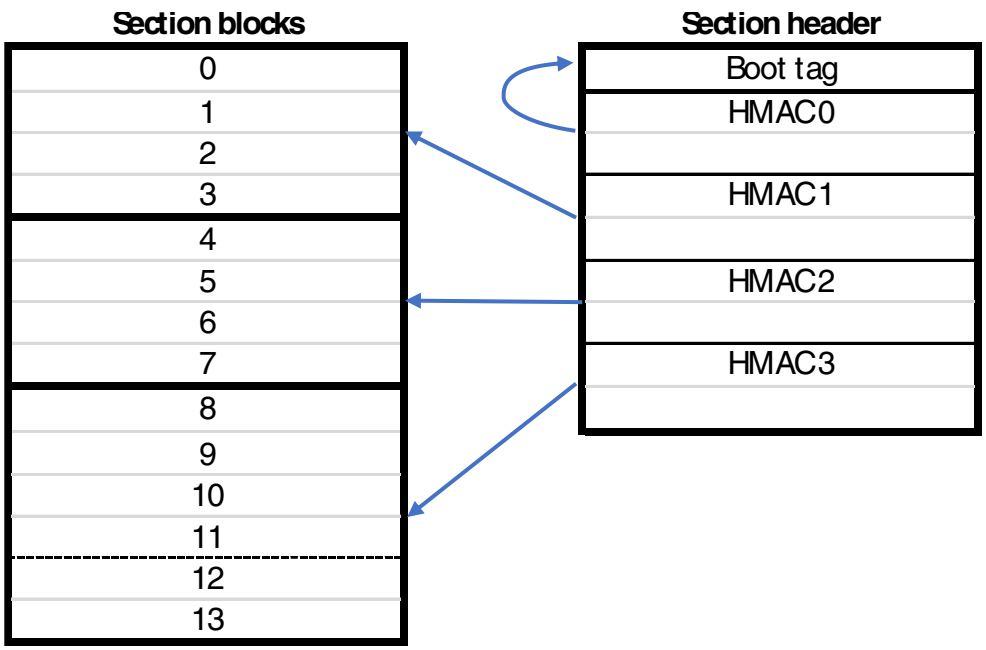
The first HMAC in the table is always the HMAC for the boot tag cipher block. Thus, the actual number of HMACs in the table (boot_tag_t::data + 1). The number of HMACs that apply to section contents is denoted HmacRangeCount.

```
Let HmacRangeCount = boot_tag_t::data
```

The section content cipher blocks are split into HmacRangeCount contiguous sequences of cipher blocks. These sequences are referred to as HMAC ranges. The number of cipher blocks in each HMAC range is denoted HmacRangeLen. Because the section length may not be evenly divisible by HmacRangeCount, the last HMAC range may contain more cipher blocks than the rest.

```
For j in 0..(HmacRangeCount - 1) do:
  HmacRangeLen_j  =  floor(boot_tag_t::count / HmacRangeCount)
  If j ==  (HmacRangeCount - 1) then:
    HmacRangeLen_j =  HmacRangeLen_j + boot_tag_t::count MOD
           HmacRangeCount
```

Here is an example showing how the section MAC table relates to section contents.



The variable values for this example are:

- boot_tag_t::count = 14
- boot_tag_t::data = 3
- HmacRangeCount = 3
- $HmacRangeLen_0 = 4$
- $HmacRangeLen_1 = 4$
- $HmacRangeLen_2 = 6$

The complete algorithm follows.

```
Let i = 0..boot_tag_t::count
Let S_i = AES-CTR  encrypted section cipher blocks
Let S_boot-tag  = boot tag cipher block
SH_0 = HMAC(K_MAC, S_boot-tag )
For j in 0..(HmacRangeCount - 1) do:
  Let b = floor(boot_tag_t::count / HmacRangeCount) * j
  Let q = HmacRangeLenj
  Let R j = S_b + 0  || S_b + 1  || … || S_b + q - 1
```

$$\text{Let } SHj+1 = HMAC(K_{MAC}, R_j)$$
$$\text{Let } SMT = SH_0 \,||\, SH_1 \,||\, \ldots \,||\, SH_{HmacRangeCount}$$

Section MAC table contents are never encrypted. The input to the HMACs is the AES-CTR output for the boot tag and section cipher blocks.

#### 27.8.6.1.4.3 Bootable section

A section that has the ROM_SECTION_BOOTABLE section flag set is called a bootable section. It contains a sequence of boot commands that are processed by the loader to perform a firmware update. Appendix A documents the structure of bootable section contents and boot commands.

Bootable sections may not be unencrypted.

#### 27.8.6.1.4.4 Data section

Any section for which the ROM_SECTION_BOOTABLE section flag is cleared is a data section. The loader does not examine the contents of such sections; it simply skips over them. Data sections may optionally be unencrypted by setting the ROM_SECTION_CLEARTEXT flag. The certificate block header is an example of a data section.

### 27.8.6.1.5 Certificate block header

As with all signed images supported by this design, a signed SB file must have a certificate block header. The certificate header in a signed SB file is stored in a data section with a tag of 'sign'. This section must have its ROM_SECTION_CLEARTEXT flag set to mark it as unencrypted. It also must have the ROM_SECTION_BOOTABLE flag cleared to cause the SB loader to skip the certificate header when executing the SB file.

The certificate chain and RKH table are also included in the 'sign' section, since they must always immediately follow the certificate block header. The 'sign' section itself may be at any position within the sequence of sections, though usually would be the first or last.

### 27.8.6.1.6 Signature

An SB file may optionally be signed. If signed, a signature in RSASSA-PKCS1-v1_5 format is appended to the end of the file. The digest is computed over the entire SB file except for the signature itself.

The imageBlocks field in the header includes the signature, if present, in the block count for the SB file.

### 27.8.6.2 Signed SB files

SB files that are signed will have the same structure as a signed image in internal flash.

Signed SB file must have some fields set to valid values.

- The offsetToCertificateBlockInBytes field in the file's header contains the offset to the certificate header.
- The certificate header and certificate(s) must be contained within an unencrypted, data-only section with an ID of 'sign'. This restriction is so that the SB loader can easily skip over the signature related structures (the SB file is presumed to have been authenticated prior to loading).
- The ROM_SIGNED flag is set in the header flags field.
- The signature in RSASSA-PKCS1-v1_5 format is appended to the tail end of the file.

### 27.8.6.3 Encryption

The contents of SB 2.0 files are always encrypted. The file's header is not encrypted, but is authenticated with an HMAC-SHA256. Several fields must be set with valid values.

- nonce must be set to a cryptographically secure random number, with bit 31 cleared.
- flags must have ROM_CIPHER_MODE set to 2'b00 to select AES-CTR.
- keyBlobBlock and keyBlobBlockCount must both be set to non-zero values.

Section contents are encrypted using AES-256 in CTR mode [9]. The 128-bit counter value for each cipher block of the file is equal to the nonce field from the file's header plus the offset from the beginning of the file of the cipher block being encrypted. Only a 32-bit add is required.

This code demonstrates how to compute the counter value for CTR mode.

```
uint32_t counter[4];
counter[0] = header->nonce[0];
counter[1] = header->nonce[1];
counter[2] = header->nonce[2];
counter[3] = header->nonce[3] + cipher_block_offset;
```

The 4 words of the nonce and counter are treated as little endian. Thus, it is actually the MSB of the last byte of the nonce that is cleared when bit 31 is cleared.

Data sections may optionally have the ROM_SECTION_CLEARTEXT flag set, in which case they are not encrypted. However, the boot tag for such sections is still encrypted, and there must be a MAC table.

## 27.8.7 Using SB files

SB files are always encrypted and may be signed.

- To authenticate an image (which is either signed code or an SB file), call the loader ROM API from the user application code.
- To perform authentication during secure firmware updates, the full SB file must be available.

To perform secure firmware updates:

1. When a user application receives an encrypted SB file containing new firmware, the user application stores the encrypted SB file in external SPI flash or in a similar memory.
2. To authenticate a SB file, use the ROM API.
3. To decrypt and load the SB file, use the ROM API.
4. Secure boot considerations:
   - If you are using secure boot, then before rebooting into it (the flash), use the ROM API to authenticate the new firmware in flash. If this final authentication fails, then the new firmware should be made non-executable (by erasing and writing over critical regions of it, like the vector table).
   - If you are not using secure boot, then the code written to flash can still be signed, to support this final authentication step.

### 27.8.7.1 Authenticate and load using a Secure Binary (SB) file

Two operations are available through the ROM API (load and authenticate a signed image, load an image but do not authenticate that image). The enum _kb_operation defines the two operations. The struct _kb_options defines which operation is selected.

```
typedef  enum _kb_operation {
    kKbootAuthenticate = 1,  //!< Authenticate a signed image.
    kKbootLoadSB = 2,        //!< Load an SB file.
 } kb_operation_t;
```

| | |
|---|---|
| kKbootAuthenticate | Load and authenticate a signed image |
| kKbootLoadSB | Load an SB file (but do not authenticate that file) |

### 27.8.7.2 Functions

**Table 27-96. Functions**

<table>
<tr><th>Function</th><th></th><th>Description</th></tr>
<tr><td>kb_init()</td><td>Initializes Kboot ROM API for a given operation<br><br><pre>status_t kb_init(kb_session_ref_t *session,
                 const kb_options_t *options);</pre></td><td>kb_init() uses the options provided by the application in the second argument.<br>• Every call to kb_init() should be paired with a call to kb_deinit().<br>• On return from kb_init(), the session parameter will be set to a new Kboot session reference. This session reference should then be passed to other ROM API calls.<br>• The options parameter is a pointer to a struct containing the option settings for the operation that is being initialized.<br><br><table><tr><th>Parameter</th><th>Description</th></tr><tr><td>session</td><td>On return from ROM API, the session parameter will be set to the new Kboot session reference; the session reference should then be passed to other ROM API calls.</td></tr><tr><td>options</td><td>Pointer to the struct containing the option settings for the operation that is being initialized</td></tr></table></td></tr>
<tr><td>kb_deinit()</td><td>Cleans up the Kboot ROM API session<br><br><pre>status_t kb_deinit(kb_session_ref_t session);</pre></td><td>After kb_deinit() returns, the session parameter must not be reused for any Kboot API calls.</td></tr>
<tr><td>kb_execute()</td><td>Perform the operation configured during initialization<br><br><pre>status_t kb_execute(kb_session_ref_t session,<br><br>const uint8_t *data,<br><br>uint32_t dataLength);</pre></td><td>The user application may call the kb_execute() function repeatedly, passing in sequential chunks of data from the boot image (SB file) that are to be processed. Kboot will perform the selected operation on this data and then return. The user application may call the kb_execute() function with as much or as little data as it wishes, which can be used to select the granularity of time given to the application inbetween executing the operation.<br><br><table><tr><th>Parameter</th><th>Description</th></tr><tr><td>session</td><td>Kboot session reference</td></tr><tr><td>data</td><td>Buffer of boot image data provided to Kboot by the application</td></tr><tr><td>dataLength</td><td>Length in bytes of the data in the buffer provided to Kboot</td></tr></table><br><table><tr><th>Return code</th><th>Description</th></tr><tr><td>kStatus_Success</td><td>The operation has completed successfully</td></tr><tr><td>kStatus_Fail</td><td>An error occurred while executing the operation</td></tr></table></td></tr>
</table>

**Table 27-96. Functions**

| Function | | Description | |
|---|---|---|---|
| | | **Return code** | **Description** |
| | | kStatus_MoreData | No error occurred, but Kboot needs more data to continue processing the boot image |

**Table 27-97. ROM API parameters**

| Parameter | | Code |
|---|---|---|
| ROM API version | Current Kboot API version | `enum _kb_api_version {`<br>`  kKbootApiVersion = 1,`<br>`};` |
| Operation | Operation selected, either load image and authenticate, or load image (but no not authenticate) | `typedef  enum _kb_operation {`<br>`  kKbootAuthenticate = 1,  //!< Authenticate a signed image.`<br>`  kKbootLoadSB = 2,  //!< Load an SB file.`<br>`} kb_operation_t;` |
| Memory region (in flash) | `address`: the starting address of of where you are loading the secure boot code image to, in RAM or flash | `typedef struct _kb_region {`<br>`  uint32_t address;`<br>`  uint32_t length;`<br>`} kb_region_t;` |
| | `length`: the length of the secure boot code image in RAM or flash, starting at the starting address | |
| | If a memory region is not specified, then all memory (RAM or flash, depending on what you are using for the secure boot image) is available, except for the ROM-reserved region. | |
| Security | RSA 4096-bit key size | `enum _kb_security_profile {`<br>`  kKbootMinRSA4096 = (1 << 20),`<br>`};` |

## 27.8.7.3 Initialization options

To configure the operation, define and pass the struct _kb_options into kb_init().

```
//! @brief Memory region definition.
typedef struct _kb_region {
    uint32_t address;
    uint32_t length;
} kb_region_t;

typedef struct _kb_options {
    uint32_t version;        //!< Should be set to #kKbootApiVersion.
    uint8_t *buffer;        //!< Caller-provided buffer used by Kboot.
    uint32_t bufferLength;
    kb_operation_t op;
    union {
         //! Settings for  #kKbootAuthenticate operation.
```

```
        struct {
            uint32_t profile;
            uint32_t minBuildNumber;
            uint32_t maxImageLength;
            uint32_t *userRHK;
        } authenticate;

         //! Settings for  #kKbootLoadSB operation.
        struct {
            uint32_t profile;
            uint32_t minBuildNumber;
            uint32_t regionCount;
             const kb_region_t *regions;
            uint32_t overrideSBBootSectionID;
            uint32_t *userSBKEK;
        } loadSB;
    };
} kb_options_t;
```

## Table 27-98. Initialization parameters

| Parameter | Description |
|---|---|
| address | The address of the region in flash that has the code image |
| length | Starting at the address parameter, the length defines the size of the region in flash (with the code image) |
| version | The version of the Kboot API in the device |
| buffer | Is a pointer to memory provided by the caller, which Kboot will use during execution of the operation. The minimum buffer size is the size of each certificate in the chain + 432 bytes per certificate. |
| bufferLength | Starting at the buffer address, the bufferLength defines the size of the buffer |
| op | The value of op defines the API operation selected (either load & authenticate the image, or just load the image) |
| profile | Is a mask that specifies which features are required in the SB file or in the image being processed. This includes the minimum AES and RSA key sizes.<br>• For profile mask constants, see the _kb_security_profile enum.<br>• The image being loaded or authenticated must match the profile, or an error will be returned. |
| minBuildNumber | Is an optional field that can be used to prevent version rollback. The ROM API will check the build number of the image, and if the build number is less than minBuildNumber, it will fail with an error. |
| maxImageLength | Used to verify the offsetToCertificateBlockInBytes value at the beginning of a signed image.<br>• Set maxImageLength to the length of the SB file.<br>• If verifying an image in flash, then maxImageLength can be set to the internal flash size or set to a large number (like 0x10000000). |
| userRHK | Can optionally be used by the user to override the RHK in IFR. If userRHK is not NULL, then userRHK points to a 32-byte array containing the SHA-256 of the root certificate's RSA public key. |
| profile | ? |
| regionCount | ? |
| regions | Points to an array of memory regions that the SB file being loaded is allowed to access. If regions is NULL, then all memory is accessible by the SB file. This feature is required to prevent a malicious image from erasing good code or from erasing RAM contents while it (RAM) is being loaded, only for the application to find that the image is inauthentic when it gets to the end of the section. |

*Table continues on the next page...*

**Table 27-98. Initialization parameters (continued)**

| Parameter | Description |
|---|---|
| overrideSBBootSectionID | Lets the caller override the default section of the SB file that is processed during a kKbootLoadSB operation. By default, the section specified in the firstBootableSectionID field of the SB header is loaded. If overrideSbBootSectionID is non-zero, then the section with the given ID will be loaded instead. |
| userSBKEK | Allows a user to provide their own AES-256 key (for unwrapping keys in an SB file during the kKbootLoadSB operation).<br>• userSBKEK should point to a 32-byte AES-256 key.<br>• If userSBKEK is NULL, then the IFR SBKEK will be used.<br>• After kb_init() returns, the caller should zero out the data pointed to by userSBKEK, because the ROM API will have installed the key in the crypto accelerator. |

### 27.8.7.4 Security profile flags

There are security profile flags that can be passed via the profile field of kb_options_t. The same security profile flags are used for the ROM_SECURITY_PROFILE IFR field.

```
enum _kb_security_profile {
    kKbootMinRSA4096 = (1 << 16),
};
```

| Bit(s) | Flag | Description |
|---|---|---|
| 15:0 | - | Reserved |
| 16 | kKbootMinRSA4096 | Specifies a minimum RSA key size of 4096 bits |
| 31:17 | - | Reserved |

The default profile with no bits set is:

- Encryption is not required for Secure Binary (SB) files.
- AES-256
- RSA-4096

Because only AES-256 is supported and 256 bits is the maximum AES key size, the profile does not require a minimum AES key size setting.

## 27.8.8 Security considerations

#### 27.8.8.1 General

Additional root RSA keys must be created in advance, so that their hash can be placed into the RKH table. This means that those keys are effectively sitting on a shelf somewhere. If an attacker is able to gain access to the first root private key, then there is a great likelihood that they may gain access to the other pregenerated root private keys. Physical and other protections can reduce this potential problem.

Pre-authentication and loading are separate steps. If the SB file is stored in external memory such as a SPI flash memory, this leads to a possibility of an attacker swapping SPI flash devices after authenticating the SB file (assuming it is signed) but before loading. Obviously the attacker would need physical access to the device, so this attack cannot be performed remotely. SB files being encrypted addresses this potential attack vector, but relies on a pre-shared secret key. To protect further, the customer can sign the code that is loaded into flash by the SB file. Then, after the load, but before switching to the new code, they can call the ROM API to authenticate what was written into flash. If authentication fails, they would wipe/mark the bad image. This is applicable whether using secure boot or not. If secure boot is enabled, then it provides another layer of defense, in that a modified image can never be executed even if it is successfully programmed.

The SBKEK is readable by software using a flash controller command.

#### 27.8.8.2 Hardware

If using secure boot or secure firmware update:

- Flash security must be enabled.
- Mass erase should be disabled.
- Flash security backdoor key can be enabled or not: it is optional. If the flash security backdoor key is enabled, then the backdoor key should only be used in special circumstances, such as product return debugging.

When waking up from the VLLS low power state via a non-reset wakeup source, this device cannot boot into ROM. This means that secure boot will be bypassed. Fortunately, VLLS mode can only be entered by code that presumably has been authenticated at the last reset.

#### 27.8.8.3 Kboot integration

If secure firmware updates are to be performed on a device that also has the Kboot ROM enabled for serial bootloading, then there are security implications with this configuration that need to be taken into consideration. Flash security must be enabled. This will disable

the majority of Kboot commands. The only method of writing to memory via serial interfaces when flash security is enabled is with encrypted SB files using the ReceiveSB command. For normal firmware updates, flash security must never be disabled using the back door key.

Signed SB files loaded over the Kboot serial interfaces will not be authenticated.

The minimum build number constraint is only supported when using the API. When loading SB files via the ROM's serial interface, the minimum build number is not checked. Thus, a customer who wishes to use the minimum build number to prevent version rollback, must load SB files using the API.

The allowed memory regions list is only supported when using the API. When loading SB files via the ROM's bootloader mode, all available memories are accessible.

## 27.8.9 Bootable section contents

A bootable section in an SB file contains a sequence of boot commands and any data required by those commands. The commands are processed in a linear sequence, starting with the first. Each boot command occupies a single cipher block, plus any cipher blocks required for data associated with that command.

### 27.8.9.1 Command structure

The C structure definition for a boot command:

```
struct boot_command_t {
    uint8_t checksum;
    uint8_t tag;
    uint16_t flags;
    uint32_t address;
    uint32_t count;
    uint32_t data;
};
```

checksum is a simple 8-bit checksum of each byte of boot_command_t, starting with tag. The checksum has a starting value of 0x5A. The tag field specifies the command. The other fields of boot_command_t have different meanings, depending on the actual command.

### 27.8.9.2 Available boot commands

| Tag Value | Mnemonic | Secure | Description |
|---|---|---|---|
| 0x00 | ROM_NOP_CMD | Y | No operation |
| 0x01 | ROM_TAG_CMD | Y | Boot tag |
| 0x02 | ROM_LOAD_CMD | Y | Load data into memory |
| 0x03 | ROM_FILL_CMD | Y | Fill memory with a pattern |
| 0x04 | - | - | Reserved |
| 0x05 | - | - | Reserved |
| 0x06 | - | - | Reserved |
| 0x07 | ROM_ERASE_CMD | Y | Erase flash sectors |
| 0x08 | - | - | Reserved |
| 0x09 | ROM_MEM_ENABLE_CMD | Y | Enable additional memory device |
| 0x0A | ROM_PROG_CMD | Y | Program persistent flash bits |

### 27.8.9.3 Command definition

#### 27.8.9.3.1 ROM_NOP_CMD

This command is a no-operation, and the bootloader simply skips over it. All fields except the m_tag fields are ignored by the bootloader, but should be set to 0. The ROM_NOP_CMD is used as command padding, if a bootable section following another bootable section is aligned to a value that required padding to be inserted.

| Field | Description |
|---|---|
| checksum | Simple checksum, which comes to 0x5a when all other fields are zeroes. |
| tag | 0x00 or ROM_NOP_CMD |
| flags | 0 |
| address | 0 |
| count | 0 |
| data | 0 |

#### 27.8.9.3.2 ROM_TAG_CMD

Used as a header for a section, specifying the section's ID, type, and size. Another way to think of it is as a linked list node.

The ROM_TAG_CMD command in not expected to appear within the command stream in a bootable section, and the bootloader will just ignore it if it is present. The purpose of this command definition is to describe the structure of the boot tag cipher block. Boot tags use the exact same structure as boot commands.

| Field | Description |
|---|---|
| checksum | Simple checksum of the other fields of boot_command_t. |
| tag | 0x01 or ROM_TAG_CMD |
| flags | Bit 0: ROM_SECTION_BOOTABLEBit 1: ROM_SECTION_CLEARTEXTBit 15: ROM_LAST_TAG |
| address | Unique 32-bit identifier for this section. |
| count | The number of cipher blocks that the data for this section occupies. |
| data | Section MAC table entry count. |

The flag ROM_LAST_TAG must be set on the boot tag for the last section. ROM_LAST_TAG is used to indicate that there are no more boot tags in the image.

### 27.8.9.3.3 ROM_LOAD_CMD

The ROM_LOAD_CMD command is followed by an arbitrary number of cipher blocks that contain data to be loaded into memory (starting at the location specified by the m_address field of boot_command_t). The count field contains the number of bytes to be loaded to this location in memory.

| Field | Description |
|---|---|
| checksum | Simple checksum of the other fields of boot_command_t. |
| tag | 0x02 or ROM_LOAD_CMD |
| flags | Bits 7:4: Memory group ID.Bits 15:8: Memory device ID. |
| address | Memory address to which the data will be stored. |
| count | Number of bytes to load. This is also the number of valid bytes in the data cipher blocks following this command. |
| data | CRC-32 over the data to be loaded. |

The number of cipher blocks following the command is ceil(count / 16). This means that there may be up to 15 bytes of padding in the last data cipher block.

There are no restrictions on alignment for the m_address or count fields. It is up to the loader implementation to decide how to best optimize loading of data. Thus, there is no guarantee on the order in which the data will be written to memory.

The data field contains a CRC-32 value computed over the data following the command header block. Any pad bytes in the last data cipher block are included in the CRC-32 calculation.

The flags field specifies the ID of the memory to which the data will be loaded. The ID is composed of a group ID and device ID. See The ROM_MEM_ENABLE_CMD for more information about memory IDs.

### 27.8.9.3.4 ROM_FILL_CMD

The ROM_FILL_CMD command is used to fill regions of memory with a bit pattern. The fill pattern is always a full 32 bits wide, but a byte-aligned fill length and target address are fully supported.

| Field | Description |
|---|---|
| checksum | Simple checksum of the other fields of boot_command_t. |
| tag | 0x03 or ROM_FILL_CMD |
| flags | Always 0. |
| address | The starting memory address to which the fill pattern will be written. |
| count | Number of bytes to fill. |
| data | The fill pattern. Always replicated across the word regardless of the pattern size. |

The fill pattern, regardless of its actual size, must be spread across the entire data field. So a pattern that is a byte wide must be replicated four times across data, and twice for half-word patterns. When filling, the pattern is adjusted so that the most significant byte is aligned with the first byte to be filled.

Note that this command is guaranteed to use word writes between any unaligned ragged edges. This enables using the fill command as a word poke operation to write to registers.

The fill command only supports the standard CPU memory map (internal flash, RAM, and registers).

### 27.8.9.3.5 ROM_ERASE_CMD

The ROM_ERASE_CMD command applies only to devices with an internal flash memory array. It will execute a flash erase command for either the entire flash array or for the range of memory specified in the command fields.

| Field | Description |
|---|---|
| checksum | Simple checksum of the other fields of boot_command_t. |
| tag | 0x07 or ROM_ERASE_CMD |
| flags | Bit 0: ROM_ERASE_ALL_MASK<br>• If set, erase all flash instead of only the specified range.<br>• If cleared, the address and count fields are used to determine the range of flash to erase. |

*Table continues on the next page...*

| Field | Description |
|---|---|
| | Bit 1: ROM_ERASE_ALL_UNSECURE_MASK<br>• If set, perform an erase all unsecure operation.<br>Bits 7:4: Memory group ID.<br>Bits 15:8: Memory device ID. |
| address | Start address of flash to erase. |
| count | Number of bytes of flash to erase. The end address is (address + count - 1). |
| data | 0 |

Bits 0 and 1 of the flags field determine whether the entire flash array will be erased, or if only a subset will be erased. If either ROM_ERASE_ALL_MASK or ROM_ERASE_ALL_UNSECURE_MASK are set, then the command will perform a mass erase operation. In addition to a mass erase, ROM_ERASE_ALL_UNSECURE_MASK programs the FSEC field to disable flash security. In this case, the address and count fields are ignored. ROM_ERASE_ALL_UNSECURE_MASK takes precedence over ROM_ERASE_ALL_MASK.

If ROM_ERASE_ALL_MASK and ROM_ERASE_ALL_UNSECURE_MASK are cleared, then the range of flash memory to erase is specified by the address and count command fields. Because flash memory can only be erased on a whole-sector basis, all flash sectors that are intersected by the address range will be erased. This applies even if the address range does not begin or end on an aligned sector boundary.

If an allowed memory region list is specified via the kb_options_t::loadSB.regions field when performing the kKbootLoadSB API operation, then the ROM_ERASE_ALL_MASK and ROM_ERASE_ALL_UNSECURE_MASK flags are ignored.

The memory group and device ID flags form a memory ID that specifies which part of memory that the erase operation will apply to. See ROM_MEM_ENABLE_CMD for more details about memory IDs. Note that ROM_ERASE_CMD ignores the memory ID and only applies to internal flash memory.

### 27.8.9.3.6 ROM_MEM_ENABLE_CMD

Enables additional, device specific memory areas. ROM_MEM_ENABLE_CMD is primarily used to enable QuadSPI.

| Field | Description |
|---|---|
| checksum | Simple checksum of the other fields of boot_command_t. |

*Table continues on the next page...*

| Field | Description |
|---|---|
| tag | 0x09 or ROM_MEM_ENABLE_CMD |
| flags | See below. |
| address | Start address of memory. |
| count | Number of bytes in the memory. |
| data | 0 |

The bitfields of the flags field are defined here. These bitfields also apply to the flags for ROM_LOAD_CMD and ROM_ERASE_CMD.

| Bits | Mnemonic | Description |
|---|---|---|
| 15:8 | DEVICE_ID_MASK | Type of memory device. |
| 7:4 | GROUP_ID_MASK | Group of memory device. |

The GROUP_ID_MASK field current has two defined values.

| Value | Definition |
|---|---|
| 0x0 | Internal 4GB memory space. |
| 0x1 | External memory space. |

There are several predefined values for the flags field.

| Value | Memory device |
|---|---|
| 0x0000 | Internal flash |
| 0x0100 | QuadSPI |
| 0x0400 | IFR0 (Index Flash Region) |
| 0x0900 | FlexSPI NOR flash |
| 0x1000 | Execute only region of internal flash |
| 0x0110 | SPI NAND |
| 0x0410 | SPI EEPROM |
| 0x0510 | I2C EEPROM |

Note that support for these memory devices is entirely device-dependant.

### 27.8.9.3.7 ROM_PROG_CMD

Used to write program once regions of internal flash (IFR).

| Field | Description |
|---|---|
| checksum | Simple checksum of the other fields of boot_command_t. |
| tag | 0x0A or ROM_PROG_CMD |
| flags | Bit 0: ROM_PROG_8BYTE_MASK Write an 8 byte index instead of 4 byte.<br>Bits 7:4: Memory group ID.<br>Bits 15:8: Memory device ID. |
| address | Index of word to write. |
| count | Data word 1. |
| data | Data word 2. |

The memory ID flags must be set to 0x0400, selecting memory IFR0.

## 27.9 Verifying the application in flash using CRC-32

Using CRC-32 and a given address range, the ROM bootloader supports performing an application integrity check.

**Before application integrity testing:** the following fields in the bootloader configuration area must be set:

- Set crcStartAddress to the start address that should be used for the CRC check.
- Set crcByteCount to the number of bytes to run the CRC check on, from the start address.
- Set crcExpectedValue to the value that the CRC calculation should result in.

**Application integrity testing:**

- If all of the above fields are unset (all 0xFF bytes for crcStartAddress, crcByteCount, and crcExpectedValue), then the ROM bootloader returns kStatus_AppCrcCheckInvalid.
- If any one of the above fields are set (crcStartAddress, crcByteCount, and crcExpectedValue), then the ROM bootloader checks if the given address range of the application is valid, and if the application resides in internal flash, by running a CRC check on the image in flash:
  - If the the given address range of the application is not valid (false), then the bootloader returns kStatus_AppCrcCheckOutOfRange.
  - If the given address range of the application is valid (true), then the CRC check is performed. The CRC32 algorithm in ROM uses a polynomial (0x04C1_1DB7), and the initial seed is 0xFFFF_FFFF.
    - If the CRC check fails, then the bootloader returns kStatus_AppCrcCheckFailed;
    - If the CRC check succeeds, then it returns kStatus_AppCrcCheckPassed.

**After application integrity testing:**

- If the bootloader returns kStatus_AppCrcCheckOutOfRange or kStatus_AppCrcCheckFailed, then an external pin (PTA6) will also be asserted, to indicate CRC check failure.

**NOTE**

PTA6 is only available on the 121 MAP BGA and 100 LQFP packages.

- The bootloader will only jump to the application if kStatus_AppCrcCheckPassed is returned; if kStatus_AppCrcCheckPassed is not returned, then the bootloader will stay active, and wait for further commands.

## 27.10 Kinetis Bootloader Status Error Codes

This section describes the status error codes that the Kinetis Bootloader returns to the host.

**Table 27-99. Kinetis Bootloader Status Error Codes, sorted by Value**

| Error Code | Value | Description |
|---|---|---|
| kStatus_Success | 0 | Operation succeeded without error. |
| kStatus_Fail | 1 | Operation failed with a generic error. |
| kStatus_ReadOnly | 2 | Requested value cannot be changed because it is read-only. |
| kStatus_OutOfRange | 3 | Requested value is out of range. |
| kStatus_InvalidArgument | 4 | The requested command's argument is undefined. |
| kStatus_Timeout | 5 | A timeout occurred. |
| kStatus_FlashSizeError | 100 | Not used. |
| kStatus_FlashAlignmentError | 101 | Address or length does not meet required alignment. |
| kStatus_FlashAddressError | 102 | Address or length is outside addressable memory. |
| kStatus_FlashAccessError | 103 | The FTFE_FSTAT[ACCERR] bit is set. |
| kStatus_FlashProtectionViolation | 104 | The FTFE_FSTAT[FPVIOL] bit is set. |
| kStatus_FlashCommandFailure | 105 | The FTFE_FSTAT[MGSTAT0] bit is set. |
| kStatus_FlashUnknownProperty | 106 | Unknown Flash property. |
| kStatus_FlashEraseKeyError | 107 | The key provided does not match the programmed flash key. |
| kStatus_FlashRegionExecuteOnly | 108 | The area of flash is protected as execute only. |
| kStatus_I2C_SlaveTxUnderrun | 200 | I2C Slave TX Underrun error. |
| kStatus_I2C_SlaveRxOverrun | 201 | I2C Slave RX Overrun error. |
| kStatus_I2C_AribtrationLost | 202 | I2C Arbitration Lost error. |
| kStatus_SPI_SlaveTxUnderrun | 300 | SPI Slave TX Underrun error. |

*Table continues on the next page...*

## Table 27-99. Kinetis Bootloader Status Error Codes, sorted by Value (continued)

| Error Code | Value | Description |
|---|---|---|
| kStatus_SPI_SlaveRxOverrun | 301 | SPI Slave RX Overrun error. |
| kStatus_SPI_Timeout | 302 | SPI tranfser timed out. |
| kStatus_SPI_Busy | 303 | SPI instance is already busy performing a transfer. |
| kStatus_SPI_NoTransferInProgress | 304 | Attempt to abort a transfer when no transfer was in progress. |
| kStatus_UnknownCommand | 10000 | The requested command value is undefined. |
| kStatus_SecurityViolation | 10001 | Command is disallowed because flash security is enabled. |
| kStatus_AbortDataPhase | 10002 | Abort the data phase early. |
| kStatus_Ping | 10003 | Internal: received ping during command phase. |
| kStatusRomLdrSectionOverrun | 10100 | The loader has finished processing the SB file. |
| kStatusRomLdrSignature | 10101 | The signature of the SB file is incorrect. |
| kStatusRomLdrSectionLength | 10102 | The section length in chunks is invalid. |
| kStatusRomLdrUnencryptedOnly | 10103 | An encrypted SB file has been sent and decryption support is not available. |
| kStatusRomLdrEOFReached | 10104 | The end of the SB file has been reached. |
| kStatusRomLdrChecksum | 10105 | The checksum of a command tag block is invalid. |
| kStatusRomLdrCrc32Error | 10106 | The CRC-32 of the data for a load command is incorrect. |
| kStatusRomLdrUnknownCommand | 10107 | An unknown command was found in the SB file. |
| kStatusRomLdrIdNotFound | 10108 | There was no bootable section found in the SB file. |
| kStatusRomLdrDataUnderrun | 10109 | The SB state machine is waiting for more data. |
| kStatusRomLdrJumpReturned | 10110 | The function that was jumped to by the SB file has returned. |
| kStatusRomLdrCallFailed | 10111 | The call command in the SB file failed. |
| kStatusRomLdrKeyNotFound | 10112 | A matching key was not found in the SB file's key dictionary to unencrypt the section. |
| kStatusRomLdrSecureOnly | 10113 | The SB file sent is unencrypted and security on the target is enabled. |
| kStatusRomLdrResetReturned | 10114 | The SB file reset operation has unexpectedly returned. |
| kStatusMemoryRangeInvalid | 10200 | Memory range conflicts with a protected region. |
| kStatus_UnknownProperty | 10300 | The requested property value is undefined. |
| kStatus_ReadOnlyProperty | 10301 | The requested property value cannot be written. |
| kStatus_InvalidPropertyValue | 10302 | The specified property value is invalid. |
| kStatus_AppCrcCheckPassed | 10400 | CRC check is valid and passed. |
| kStatus_AppCrcCheckFailed | 10401 | CRC check is valid but failed. |
| kStatus_AppCrcCheckInactive | 10402 | CRC check is inactive. |
| kStatus_AppCrcCheckInvalid | 10403 | CRC check is invalid, because the BCA is invalid or the CRC parameters are unset (all 0xFF bytes). |
| kStatus_AppCrcCheckOutOfRange | 10404 | CRC check is valid but addresses are out of range. |

*Table continues on the next page...*

## Table 27-99. Kinetis Bootloader Status Error Codes, sorted by Value (continued)

| Error Code | Value | Description |
|---|---|---|
| kStatus_ReliableUpdateSuccess | 10600 | Reliable update process has completed successfully. |
| kStatus_ReliableUpdateFail | 10601 | Reliable update process has failed. |
| kStatus_ReliableUpdateInactive | 10602 | Reliable update feature is inactive. |
| kStatus_ReliableUpdateBackupApplicationInvalid | 10603 | Backup application image is invalid. |
| kStatus_ReliableUpdateStillInMainApplication | 10604 | The next boot will still use the main application image. |
| kStatus_ReliableUpdateSwapSystemNotReady | 10605 | Cannot swap flash by default, because the swap system is not ready. |
| kStatus_ReliableUpdateBackupBootloaderNotReady | 10606 | Cannot swap flash, because there is no valid backup bootloader image. |
| kStatus_ReliableUpdateSwapIndicatorAddressInvalid | 10607 | Cannot swap flash, because the provided swap indicator is invalid. |

# Chapter 28
# Clock Distribution

## 28.1 Introduction

This chapter provides an overview of the system level clock architecture. This includes the clock generation, division, multiplexing, gating, and distribution for this device.

## 28.2 Clock control modules

The core of the clocking architecture is the System Clock Generator (SCG) module and the Peripheral Clock Controller (DTEST_EN_MASK) module. The SCG controls the configuration of the system level clocks while the PCC controls the distribution of the clocks to the peripheral modules. The following diagram shows the high-level conceptual implemention of the SCG and the PCC. Each of these modules will be described in the following sections.

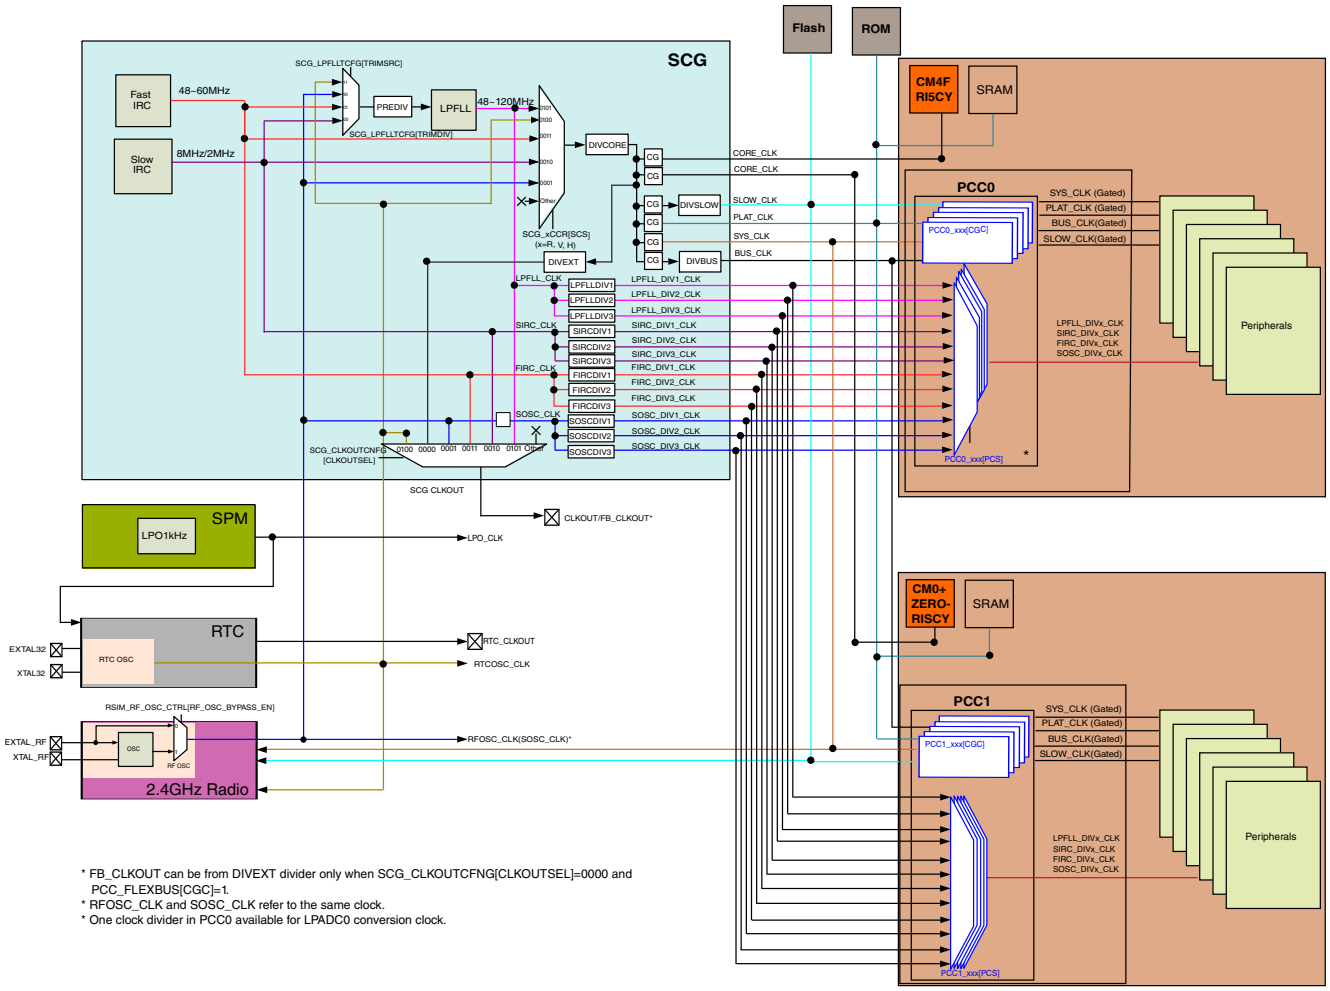


**Figure 28-1. Generic clocking architecture diagram**

## 28.2.1 System Clock Generation (SCG) module

The System Clock Generation (SCG) module provides a central location for accessing all of the system clock controls. The SCG controls the enables for most of the system clock sources as well as their configuration, the clock dividers and clock gates for all of the system clocks, and the dividers for the peripheral functional clocks. System clock sources that are tightly copupled with another module, such as the Real Time Clock Oscillator (RTCOSC) with the battery voltage domain ($V_{BAT}$) or the Low-Power Oscillator (LPO) and the System Power Manager (SPM), are controlled from those modules.

Each system clock resource has configuration registers in the SCG. These configuration registers provide control of the features as well as the enable for that clock source. These clock features can be output frequency ranges, trim controls, or frequency or phase detector settings. These controls enable the clocks to be configured to meet the needs of multiple applications. For details on the configuration of the clock sources, please refer to

the System Clock Generation chapter of the Reference Manual. Although the Real Time Clock (RTC) oscillator output can be used by the SCG, the RTC clock is a part of the battery backup domain and has its controls in that domain.

The SCG registers control the selection of the root clock for all of the system clocks. The root clock can be configured for each of the operational modes of the device to achieve the appropriate balance between performance and low-power. Once the root clock is selected, a divider can be set to reduce the frequency. While each system clock can have a divider, not all of them are implemented in each device. Please refer to the section SCG system output clocks to see which clock dividers are present in this device.

Finally, the SCG provides three groups of clocks to the Peripheral Clock Control (PCC) module that are used as the peripheral functional clocks. The three groups of clocks are the "Platform" clocks, the "Bus" clocks, and the "Slow" clocks. The "Platform" clocks are for peripherals that will most likely operate at the highest speeds produced by the device. This includes peripherals such as the Universial Serial bus (USB). The "Bus" clocks are for a majority of the peripherals that operate at equal frequencies as or lower frequencies than the platform clocks, but still need the performance of a fast clock. These peripherals can be timers or serial communication peripherals. The "Slow" clocks are for peripherals that do not have a high performance requirements. These peripherals can be certain timers or monitors.

## 28.2.2 Peripheral Clock Control (PCC) module

The Peripheral Clock Control (PCC) module controls all of the clocks that are distributed to the peripherals. Most peripherals have two clocks: the peripheral interface clock and the peripheral functional clock. The peripheral interface clock drives the peripheral's registers and system interface. There are three clocks that can be used for the peripheral interface clock: the "Platform" clock, the "Bus" clock, and the "Slow" clock. The "Platform" clock is used for high-speed peripherls that will operate at the highest clock rates that the device can produce. These peripherals will many times be bus masters in the system. The "Bus" clock is used for most peripherals. These are peripherals that still have performance requirements, but do not need to operate at the maximum operational frequency. The "Slow" clocks are for peripherals that do not require performance and are monitoring long term events.

The peripheral functional clock provides the clock for the peripherals primary operation. This could be the BAUD clock for a serial commincation peripheral or the counter clock in a timer. This allows the system bus clock to be reduced to save power while continuing to operate the peripheral without any configuration changes. As with the peripheral

interface clocks, there are groups of clocks for the peripheral functional clocks: the "Platform", "Bus", and "Slow" clock groups. Altough these clocks are used for similar groupings, the clocks are completely independent.

## 28.3 SCG input clock sources

The System Clock Generator (SCG) has multiple clock sources that can be selected as the root clock of the system clock outputs and their respective clock trees. The input clock sources for a given device may consist of Internal Reference Clocks (IRCs), crystal oscillators (OSCs), Phase Locked Loops (PLLs), and Frequency Locked Loops (FLLs). Typically, each device has at least one IRC, one external OSC, and either a PLL or FLL.

The following table lists the input clocks available in this device. For details on these clock sources and their configuration options, please refere to the SCG chapter.

**Table 28-1. Input clock sources**

| Clock | Frequencies | Source |
|---|---|---|
| Fast Frequency Internal Reference Clock (FIRC) | 48MHz<br>52MHz<br>56MHz<br>60MHz | SCG |
| Slow Frequency Internal Reference Clock (SIRC) | 2MHz<br>8MHz | SCG |
| Real Time Clock Oscillator (RTCOSC) | 32.768kHz | $V_{BAT}$ Domain |
| Radio Frequency Oscillator (RFOSC) | 26MHz<br>32MHz | Radio |
| Low-Power Frequency Locked Loop (LPFLL) | 48MHz<br>72MHz | SCG |

## 28.4 SCG system output clocks

The SCG module is the source of all system clocks. The different system clock trees are provided to allow flexible frequency configuration and gating control for the processor core, the platform modules, interfaces, and external memories. The system output clocks available in this devices are described in the following table.

**Table 28-2. System clock frequencies**

| System Clock | Source | Divider | Description |
|---|---|---|---|
| System Core Clock (CORE_CLK) | Any of the SCG input clock sources | ÷ 1 to 16 | The System Core Clock (CORE_CLK) is the main system clock and is the root of the processor core's clock tree. The CORE_CLK is generally the fastest clock in the system, but it can also run slower than peripheral functional clocks in order to save power. In general, all other system clock trees are fed from the CORE_CLK. |
| System Platform Clock (PLAT_CLK) | CORE_CLK | ÷ 1 | The System Platform Clock (PLAT_CLK) is used to clock platform modules that directly interface with the core processor or bus-matrix. These platform modules can include modules such as the Direct Memory Access (DMA) controller, the Crossbar Switch Lite (AXBS-Lite), or the Low-Power Local Memory (LPLMEM) caches. |
| System Bus Clock (BUS_CLK) | CORE_CLK | ÷ 1 to 16 | The System Bus Clock (BUS_CLK) is used to clock the majority of peripherals that require a low latency interface with the processor core or a bus master. Most timers, serial communications, LPADC peripherals use the BUS_CLK. |
| System Slow Clock (SLOW_CLK) | CORE_CLK | ÷ 1 to 16 | The System Slow Clock (SLOW_CLK) is used to clock the flash memory module. In addition, the SLOW_CLK can be used for peripherals that do not require low latency interfacing with the core processor or other bus masters. Peripherals and modules that are used for configuration of the MCU, such as the System Clock Generator (SCG), the System Power Manager (SPM), and the Multi System Mode Controller (MSMC) can use the SLOW_CLK as their clock source. |
| System External Clock (EXT_CLK) | CORE_CLK | ÷ 1 to 16 | The System External Clock (EXT_CLK) is used to clock peripherals that access external memories. These peripherals can include the External Bus Interface (FlexBus) module. |

## 28.5 SCG peripheral output clocks

The SCG module is the source of all peripheral functional clocks. The different peripheral clock trees are provided to allow flexible frequency configuration and gating control for the peripherals. The peripheral output clocks available in this devices are described in the following table.

**Table 28-3. System clock frequencies**

| Clock | Frequencies | Outputs | Divider |
|---|---|---|---|
| Fast Frequency Internal Resistor Capactitor Oscillator (FIRC) | 48MHz | Platform | ÷ 1 to 64 (powers-of-2)[1] |
| | 52MHz | Bus | ÷ 1 to 64 (powers-of-2)[1] |
| | 56MHz | Slow | ÷ 1 to 64 (powers-of-2)[1] |
| | 60MHz | | |
| Slow Frequency Internal Resistor Capactitor Oscillator (SIRC) | 2MHz | Platform | ÷ 1 to 64 (powers-of-2) |
| | 8MHz | Bus | ÷ 1 to 64 (powers-of-2) |

*Table continues on the next page...*

**Table 28-3. System clock frequencies (continued)**

| Clock | Frequencies | Outputs | Divider |
|---|---|---|---|
| | | Slow | ÷ 1 to 64 (powers-of-2) |
| Real Time Clock Oscillator (RTCOSC) | 32.768kHz | Platform | ÷ 1 |
| | | Bus | ÷ 1 |
| | | Slow | ÷ 1 |
| Radio Frequency Oscillator (RFOSC) | 26MHz | Platform | ÷ 1 to 64 (powers-of-2) |
| | 32MHz | Bus | ÷ 1 to 64 (powers-of-2) |
| | | Slow | ÷ 1 to 64 (powers-of-2) |
| Low-Power Frequency Locked Loop (LPFLL) | 48MHz | Platform | ÷ 1 to 64 (powers-of-2)[1] |
| | 72MHz | Bus | ÷ 1 to 64 (powers-of-2)[1] |
| | 96MHz | Slow | ÷ 1 to 64 (powers-of-2)[1] |
| | 120MHz | | |

1. Even though the clock source is capable of generating higher frequencies, the appropriate divider value should be used to keep the clocks below their maximum allowable values for each of the operational modes. Please refer to the the Clock frequencies section to determine the maximum frequencies for this device.

## 28.6 Clock definitions

The following table lists the clock used in this device.

**Table 28-4. Clock definitions**

| Clock | Description |
|---|---|
| SCG Input Clocks | |
| FIRC | Fast Frequency Internal Resistor Capacitor oscillator - Clock input from the FIRC oscillator with a frequency of 48 Mhz, 52 MHz, 56 MHz, or 60 MHz. |
| SIRC | Slow Frequency Internal Resistor Capacitor oscillator - Clock input from the SIRC oscillator with a frequency of 2 MHz or 8 MHz. |
| LPOSC | Low-Power Oscillator - Clock input from the Low-Power Oscillator module located in the System Power Management (SPM) module with a frequency of 1 kHz. |
| RTCOSC | Real Time Clock Oscillator - Clock input from the Real Time Clock (RTC) oscillator located in the Battery voltage domain ($V_{BAT}$) with a frequency of 32.768 kHz. |
| RFOSC | Radio Frequency Oscillator - Clock input from the Radio module with a frequency of 26 MHz of 32 MHz depending on the external crystal connected to the oscillator. |
| LPFLL | Low-Power Frequency Locked Loop - Clock input from the Low-Power Frequency Locked Loop with a frequency of 48MHz, 72MHz, 96MHz, or 120MHz. |
| System Output Clocks | |
| CORE_CLK | System Core Clock - The clock provided to the processor cores and tighly coupled memories, modules, and peripherals. The CORE_CLK is derived from one of the SCG's input clock sources. |
| SYS_CLK | System Clock - The clock provided to cross bar masters. The SYS_CLK is derived from the CORE_CLK. |

*Table continues on the next page...*

**Table 28-4. Clock definitions (continued)**

| Clock | Description |
|---|---|
| PLAT_CLK | System Platform Clock - The clock provided to the platform modules and peripherals. The PLAT_CLK is derived from the CORE_CLK. |
| BUS_CLK | System Bus Clock - The clock provided to the system buses to interface with low latency peripherals such as timer and serial communication peripherals. The BUS_CLK is derived from the CORE_CLK. |
| SLOW_CLK | System Slow Clock - The clock provided to the flash memory and configuration peripherals. The SLOW_CLK is derived from CORE_CLK. |
| EXT_CLK | System External Clock - The clock provided to peripherals that interface with external memories. The EXT_CLK is derived from the CORE_CLK. |
| PCC Input Clocks | |
| SIRC_PLAT | SIRC Platform Clock - Clock from the SIRC intended for use with modules using the Platform Interface clock. |
| SIRC_BUS | SIRC Bus Clock - Clock from the SIRC intended for use with modules using the Bus Interface clock. |
| SIRC_SLOW | SIRC Slow Clock - Clock from the SIRC intended for use with modules using the Slow Interface clock. |
| FIRC_PLAT | FIRC Platform Clock - Clock from the FIRC intended for use with modules using the Platform Interface clock. |
| FIRC_BUS | FIRC Bus Clock - Clock from the FIRC intended for use with modules using the Bus Interface clock. |
| FIRC_SLOW | FIRC Slow Clock - Clock from the FIRC intended for use with modules using the Slow Interface clock. |
| RTCOSC_PLAT | RTCOSC Platform Clock - Clock from the RTCOSC intended for use with modules using the Platform Interface clock. |
| RTCOSC_BUS | RTCOSC Bus Clock - Clock from the RTCOSC intended for use with modules using the Bus Interface clock. |
| RTCOSC_SLOW | RTCOSC Slow Clock - Clock from the RTCOSC intended for use with modules using the Slow Interface clock. |
| RFOSC_PLAT | RFOSC Platform Clock - Clock from the RFOSC intended for use with modules using the Platform Interface clock. |
| RFOSC_BUS | RFOSC Bus Clock - Clock from the RFOSC intended for use with modules using the Bus Interface clock. |
| RFOSC_SLOW | RFOSC Slow Clock - Clock from the RFOSC intended for use with modules using the Slow Interface clock. |
| LPFLL_PLAT | LPFLL Platform Clock - Clock from the LPFLL intended for use with modules using the Platform Interface clock. |
| LPFLL_BUS | LPFLL Bus Clock - Clock from the LPFLL intended for use with modules using the Bus Interface clock. |
| LPFLL_SLOW | LPFLL Slow Clock - Clock from the LPFLL intended for use with modules using the Slow Interface clock. |

## 28.7 Clock gating

Gating the clock of modules that are not operating helps reduce the power consumed during operation. This in turn increases the battery life for mobile devices. Clocks should only be enabled to peripherals when they are needed.

Each peripheral has independent clock gates for both the peripheral interface clock and the peripheral functional clock. This clock gating is controlled through the peripheral's PCC register. Clearing the CGC filed of the PCCn register will disable the peripheral interface clock, while clearing the PCS field of the PCCn register will disable the peripheral functional clock.

The SCG also has the ability to clock gate the peripheral functional clocks of groups of peripherals at the same time. Setting the xxxDIVn field of the SCG_xxxDIV register to 0x00 will disable the clock divider and clock gate the output of the clock. All peripherals that use this clock as their functional clock will be clock gated at the same time.

The CORE_CLK and SLOW_CLK are always enabled in any of the "Run" or "Wait" modes. If CORE_CLK and SLOW_CLK are not used in the low power stop modes, they will be disabled by the Multi System Mode Controller (MSMC) and System Power Manager (SPM) modules.

## 28.8 Module clock assignments

The table below provides the mapping between the device modules and the associated system clock trees.

The table below provides the mapping between the device modules and the associated system clock trees.

**Table 28-5. Clock assignments**

| Module Name | Bus Interface Clock | PCC Clock Gate | Peripherial Functional Clock | Clock Domain[1] | I/O Interface Clocks |

| VREF | SLOW_CLK | Yes | — | PCC0 | — |

1. PPC0 controls CM4F domain,and PPC1 controls CM0+ domain.
2. It is bus interface clock domain.
3. SAI_MCLK doesn't blong to PCC clock domain.

# Chapter 29
# System Clock Generator (SCG)

## 29.1 Chip-specific SCG information

### 29.1.1 LPFLL configuration

The LPFLLCFG[FSEL] is used to select frequency. For this device, LPFLL is factory default trimmed to 72 MHz, nominal conditions trim value for 72 MHz is automatically loaded at reset. To use the LPFLL 48 MHz as clock source, the user must first trim the LPFLL to 48 MHz.

## 29.2 Introduction

The system clock generator (SCG) module provides the system clocks of the MCU. The SCG contains a frequency-locked loop (LPFLL), a slow internal reference clock (SIRC), a fast internal reference clock (FIRC), and the system oscillator clock (SOSC). The LPFLL trimming is controlled by the either the SOSC reference clock, ROSC reference clock, SIRC reference clock or FIRC reference clock. The SCG can select either the output clock of the LPFLL, or a SCG reference clock (SIRC, FIRC, and SOSC) as the source for the MCU system clocks. The SCG also supports operation with crystal oscillators, which allows an external crystal, ceramic resonator, or another external clock source to produce the external reference clock (which are also available as clock sources for the MCU systems clocks).

### 29.2.1 Features

Key features of the SCG module are:

- Low Power Frequency Locked-Loop (LPFLL):

    - Programmable multiplier for up to 4 different frequency ranges
    - Internal reference clocks or oscillators reference clocks can be used as the LPFLL source for trimming purposes
    - Can be selected as the clock source for the MCU system clocks
    - 3 programmable post-divider clock outputs, which can be used as a clock source for other on-chip peripherals
- 2 Internal reference clock (IRC) generators:
    - Slow IRC clock with programmable High and Low frequency range, with each range having a set of 8 trim bits for accuracy
    - Fast IRC clock with programmable High and Low frequency range, with 3 sets of trim bits for accuracy
    - Either the slow or the fast clock can be selected as the clock source for the MCU system clocks
    - 3 programmable post-divider clock outputs for each IRC, which can be used as clock sources for other on-chip peripherals
- System Crystal Oscillator:
    - Can be used as a source for the LPFLL
    - Can be selected as the clock source for the MCU system clocks
- External clock from the Real Time Counter (RTC):
    - Can be used as a source for the LPFLL
    - Can be selected as the clock source for the MCU
- Clock monitor with reset and interrupt request capability for SOSC, ROSC clocks

The next figure shows the SCG module block diagram.

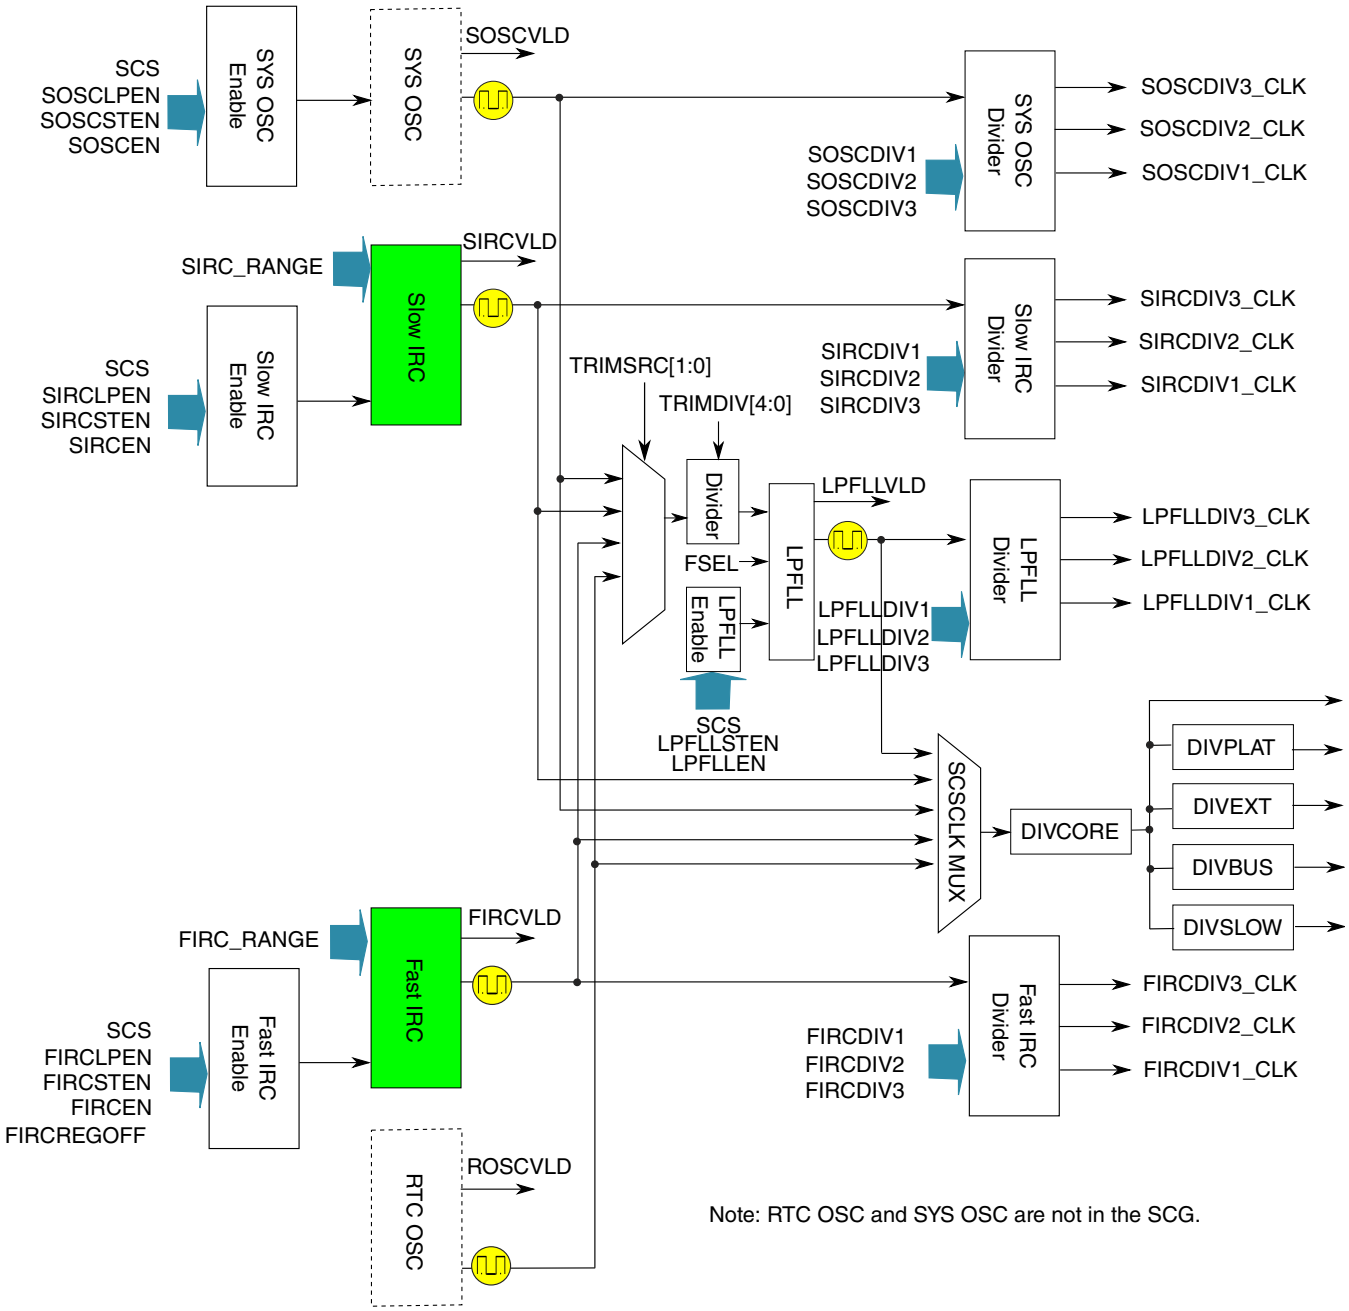

**Figure 29-1. System Clock Generator (SCG) block diagram**

**NOTE**

To identify the oscillator used in your specific MCU device, see chip specific configuration or clocking chapters.

## 29.3 Memory Map/Register Definition

This section includes the memory map and register definition.

The SCG registers can only be written when in supervisor mode. Write accesses when in user mode will result in a bus transfer error. Read accesses may be performed in both supervisor and user mode.

## 29.3.1 SCG register descriptions

**NOTE**

For any writeable SCG registers, only 32-bit writes are allowed. 8-bit or 16-bit writes will result in transfer errors.

### 29.3.1.1 SCG Memory map

SCG base address: 4002_C000h

| Offset | Register | Width (In bits) | Access | Reset value |

## 29.3.1.4 Clock Status Register (CSR)

### 29.3.1.4.1 Offset

| Register | Offset |
|---|---|
| CSR | 10h |

### 29.3.1.4.2 Function

This register returns the currently configured system clock source and the system clock dividers for the core (DIVCORE) and peripheral interface clock (DIVSLOW). The SCG_CSR reflects the configuration set by one of three clock control registers SCG_RCCR, SCG_VCCR, SCG_HCCR.

Note: Writing to this register will result in a transfer error.

## 29.3.1.5 Run Clock Control Register (RCCR)

### 29.3.1.5.1 Offset

| Register | Offset |
|---|---|
| RCCR | 14h |

### 29.3.1.5.2 Function

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in Run mode only. This register can only

be written using a 32-bit write. Selecting a different clock source when in RUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in RUN, new system clock divide ratios will not take affect until new clock source is valid.

**NOTE**

Switching to new system clock source and system clock dividers must be done once previous RCCR changes have been completed.

### 29.3.1.5.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 29.3.1.7 HSRUN Clock Control Register (HCCR)

### 29.3.1.7.1 Offset

| Register | Offset |
|---|---|
| HCCR | 1Ch |

### 29.3.1.7.2 Function

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in HSRUN mode only. This register can only be written using a 32-bit write. Selecting a different clock source when in HSRUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in HSRUN, new system clock divide ratios will not take affect until new clock source is valid.

**NOTE**

Switching to new system clock source and system clock dividers must be done once previous RCCR changes have been completed.

## 29.3.1.10 System OSC Divide Register (SOSCDIV)

### 29.3.1.10.1 Offset

| Register | Offset |
|---|---|
| SOSCDIV | 104h |

### 29.3.1.10.2 Function

The SCG_SOSCDIV register provides the control of 3 clock trees which can be used to provide optional peripheral functional clocks, or alternative module clocks. Each clock tree has optional dividers of the input SOSC clock. Changes to SOSCDIV should be done when System OSC is disabled to prevent glitches to output divided clock.

## 29.3.1.18 Fast IRC Status Register (FIRCSTAT)

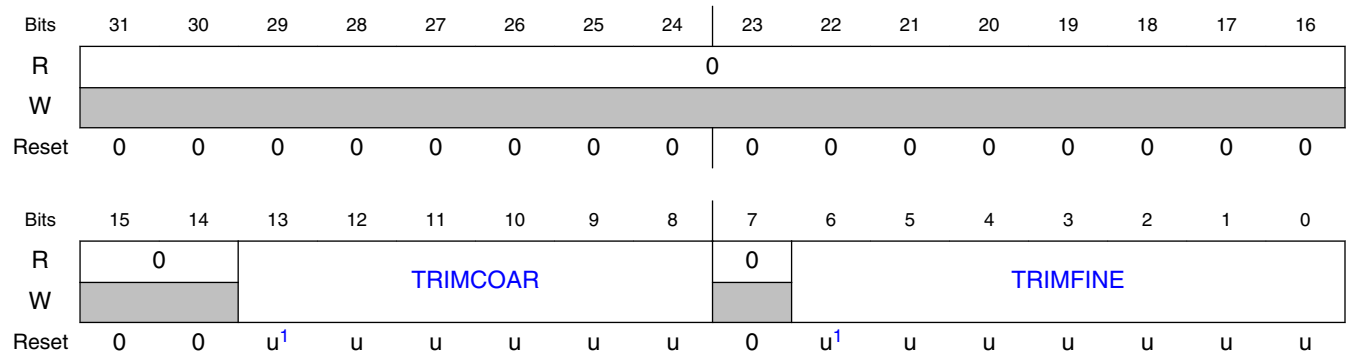
### 29.3.1.18.1 Offset

| Register | Offset |
|---|---|
| FIRCSTAT | 318h |

### 29.3.1.18.2 Function

This register is loaded from IFR during reset. This register is uploaded with the trim values generated by FIRC auto trimming which is enabled when FIRC is enabled and FIRCTREN=1 and FIRCTRUP=1. When FIRC auto trimming is enabled and FIRCTRUP is off (Note: TRIMSRC needs to be programmed to TRIMSRC=10 or TRIMSRC=11), writes to this register are allowed and values written to this register are used to trim FIRC clock.

### 29.3.1.18.3 Diagram



1. Reset values are loaded out of IFR.

### 29.3.1.18.4 Fields

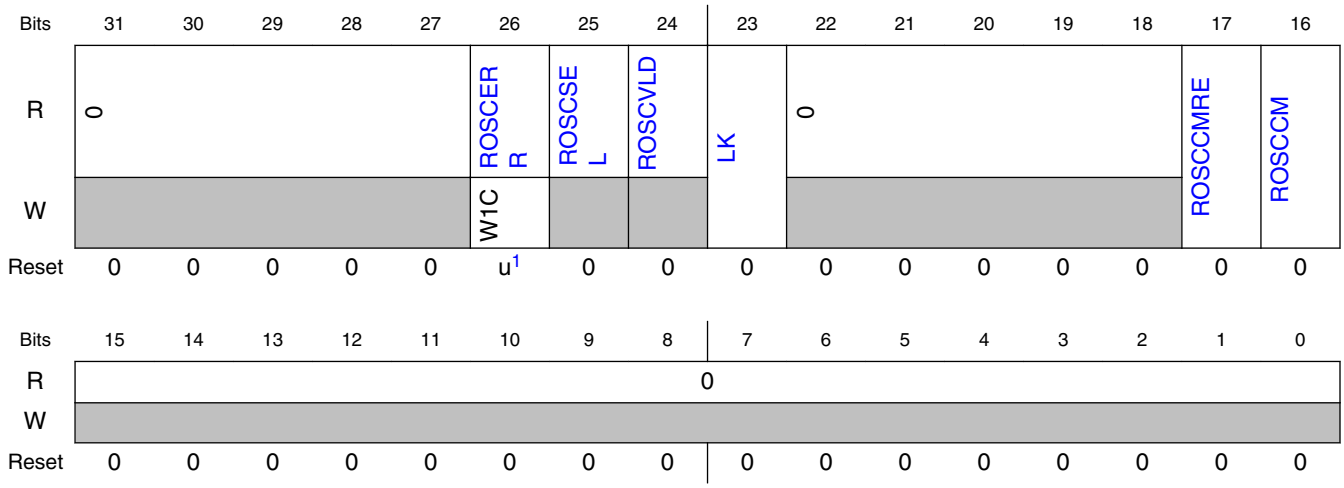
| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-14<br>— | Reserved |
| 13-8<br>TRIMCOAR | Trim Coarse<br>TRIMCOAR bits are used to coarsely trim the Fast IRC Clock to within approximately ±0.7% of the target frequency. When FIRC is enabled and auto trimming is enabled (FIRCTREN=1 and FIRCTRUP=1), then TRIMCOAR register gets uploaded with the trimmed coarse value. When FIRCTRUP=0, TRIMCOAR register is writable, to allow user programming of coarse trim values. |
| 7<br>— | Reserved |
| 6-0<br>TRIMFINE | Trim Fine Status<br>Once the Fast IRC Clock is trimmed to ±0.7% of the target frequency using the TRIMCOAR bits, the TRIMFINE bits can be used to trim the Fast IRC Clock to within ±0.04% of the target frequency. When FIRC is enabled and auto trimming is enabled (FIRCTREN=1 and FIRCTRUP=1), TRIMFINE register gets uploaded with the trimmed fine value. When FIRCTRUP=0, TRIMFINE register is writeable, to allow user programming of fine trim values. |

## 29.3.1.19 RTC OSC Control Status Register (ROSCCSR)

### 29.3.1.19.1 Offset

| Register | Offset |
|---|---|
| ROSCCSR | 400h |

## 29.3.1.19.2 Diagram



1. Reset values are loaded out of IFR.

## 29.4 Functional description

### 29.4.1 SCG Clock Mode Transitions

The following figure shows the valid clock mode transitions supported by SCG.

Slow IRC (SIRC) boot mode is not supported on this device.

## SCG Valid Mode Transitions

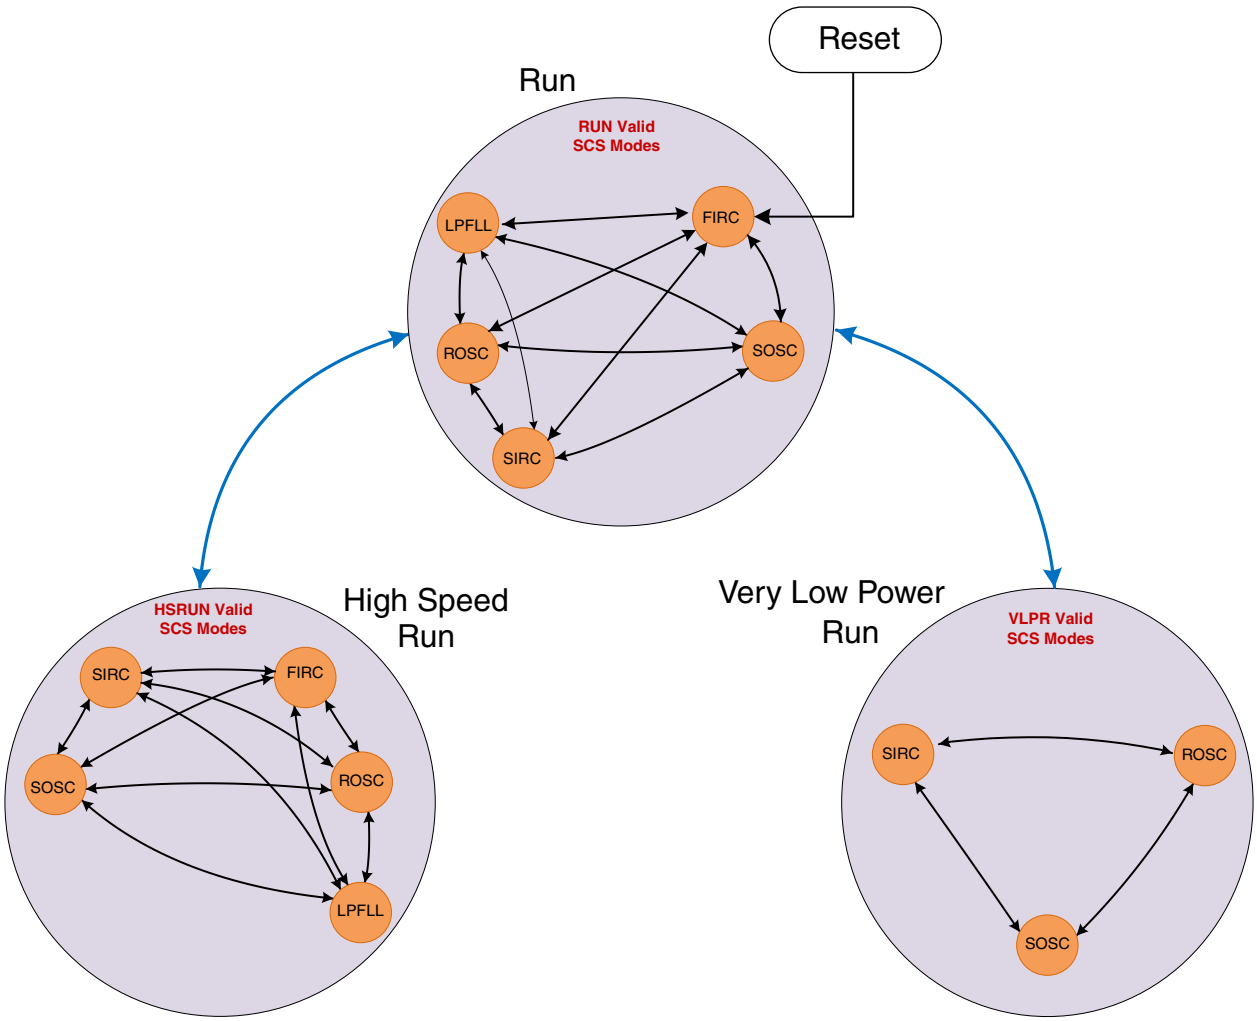

**Figure 29-2. SCG Valid Mode Transition Diagram**

The SCG will restrict programming into invalid clock modes and writes to SCS bits will be ignored. When a transition between run modes or a transition into wait mode occurs, the SCG completes the switch to the clock mode as defined in the SCG clock control register. When completed, the system switches to the selected run/wait mode.

The modes of operation listed in the following table are the valid modes for this implementation of the SCG.

## Table 29-1. SCG modes of operation

| Mode | Description |
|---|---|
| System Oscillator Clock (SOSC) | System Oscillator Clock (SOSC) mode is entered when all the following conditions occur:<br>• RUN MODE: 0001 is written to RCCR[SCS].<br>VLRUN MODE: 0001 is written to VCCR[SCS].<br>HSRUN MODE: 0001 is written to HCCR[SCS].<br>• SOSCEN = 1<br>• SOSCVLD = 1<br><br>In SOSC mode, SCSCLKOUT and system clocks are derived from the external System Oscillator Clock (SOSC). |
| Slow Internal Reference Clock (SIRC) | Slow Internal Reference Clock (SIRC) mode is entered when all the following conditions occur:<br>• RUN MODE: 0010 is written to RCCR[SCS].<br>VLRUN MODE: 0010 is written to VCCR[SCS] and 1 is written to SIRCCSR[SIRCLPEN].<br>HSRUN MODE: 0010 is written to HCCR[SCS].<br>• SIRCEN = 1<br>• SIRCVLD = 1<br><br>In SIRC mode, SCSCLKOUT and system clocks are derived from the slow internal reference clock. Two frequency ranges are available for SIRC clock as described in the SIRCCFG[RANGE] register definition. Changes to SIRC range settings will be ignored when SIRC clock is enabled. |
| Fast Internal Reference Clock (FIRC) | Fast Internal Reference Clock (FIRC) mode is the default clock mode of operation and is entered when all the following conditions occur:<br>• RUN MODE: 0011 is written to RCCR[SCS].<br>VLRUN MODE: Invalid mode. Programming SCG into FIRC mode will be ingored.<br>HSRUN MODE: 0011 is written to HCCR[SCS].<br>• FIRCEN = 1<br>• FIRCVLD = 1<br><br>In FIRC mode, SCSCLKOUT and system clocks are derived from the fast internal reference clock. Two frequency range settings are available for FIRC clock as described in the FIRC[RANGE] register definition. Changes to FIRC range settings will be ignored when FIRC clock is enabled. |
| Real Time Clock Oscillator (RTCOSC) | Real Time Clock Oscillator (RTCOSC) mode is entered when all the following conditions occur:<br>• RUN MODE: 0100 is written to RCCR[SCS].<br>VLRUN MODE: 0100 is written to VCCR[SCS].<br>HSRUN MODE: 0100 is written to HCCR[SCS].<br>• ROSCVLD = 1<br><br>In RTCOSC mode, SCSCLKOUT and systems clocks are derived from the external RTC Oscillator Clock (RTCOSC). |
| Low Power FLL (LPFLL) | Low Power FLL (LPFLL) mode is entered when all the following conditions occur:<br>• RUN MODE: 0101 is written to RCCR[SCS].<br>VLRUN MODE: Invalid mode. Programming SCG into LPFLL mode will be ingored. |

*Table continues on the next page...*

## Table 29-1. SCG modes of operation (continued)

| Mode | Description |
|---|---|
| | HSRUN MODE: 0101 is written to HCCR[SCS].<br>• LPFLLEN = 1<br>• LPFLLVLD = 1<br><br>In LPFLL mode, SCSCLKOUT and system clocks are derived from the Low Power FLL (LPFLL). By default the LPFLL will be running in open-loop mode using default trim values. In closed-loop mode (LPFLLTREN=1 and LPFLLTRUP=1) LPFLL will be auto trimmed using a selectable reference clock as specified by its corresponding SCG_LPFLLTCFG[TRIMSRC]. The LPFLL will lock its frequency to the LPFLL factor, as specified by the SCG_LPFLLCFG[FSEL]. |
| Stop | Entered whenever the MCU enters a Stop state. The power modes are chip specific. For power mode assignments, see the chapter that describes how modules are configured and SCG behaviour during Stop recovery. Entering Stop mode, all SCG clock signals are static including SCG system clocks (DIVCORE,,DIVEXT,DIVBUS,DIVSLOW).<br><br>There are exceptions - the following clocks can continue to run and stay enabled in the following cases:<br><br>SIRC is available in Normal Stop and VLPS mode when all the following conditions become true:<br>• SIRCCSR[SIRCEN] = 1<br>• SIRCCSR[SIRCSTEN] = 1<br>• SIRCCSR[SIRCLPEN] = 1 in VLPS<br><br>FIRC is available only in Normal Stop mode when all the following conditions become true:<br>• FIRCCSR[FIRCEN] = 1<br>• FIRCCSR[FIRCSTEN] = 1<br><br>SOSC is available in following low power stop modes (Normal Stop, VLPS, LLS) when all the below conditions are true. In VLLS stop mode, SOSCLK is disabled.<br>• SOSCCSR[SOSCEN] = 1<br>• SOSCCSR[SOSCSTEN] = 1<br>• SOSCCSR[SOSCLPEN] = 1 (required only for Low Power Stop modes (VLPS and LLS)<br><br>LPFLL is available in Normal Stop mode when all the following conditions become true:<br>• LPFLLCSR[LPFLLEN] = 1<br>• LPFLLCSR[LPFLLSTEN] = 1 |

# Chapter 30
# Peripheral Clock Controller (PCC)

## 30.1 Chip-specific PCC information

### 30.1.1 Peripheral source to the PCC

The PCC module has the following peripheral clock sources as input:

- Clock option 0: Clock is off / External clock selected (if available)

  Only LPADC and I2S support external clock:

  - The external clock to I2S is I2S0_MCLK from PTB5 or PTE19.
  - The external clock to LPADC is the output of LPADCIRC.
- Clock option 1: System OSC
- Clock option 2: SIRC
- Clock option 3: FIRC
- Clock option 4: Reserved
- Clock option 5: Reserved
- Clock option 6: LPFLL
- Clock option 7: Reserved

## 30.2 Introduction

The Peripheral Clock Control (PCC) module provides clock control and configuration for on-chip peripherals. Each peripheral has its own clock control and configuration register.

## 30.3 Features

The PCC module enables software to configure the following clocking options for each peripheral:

- Interface clock gating
- Functional clock source selection
- Functional clock divide values

Below is a block diagram of the PCC module:

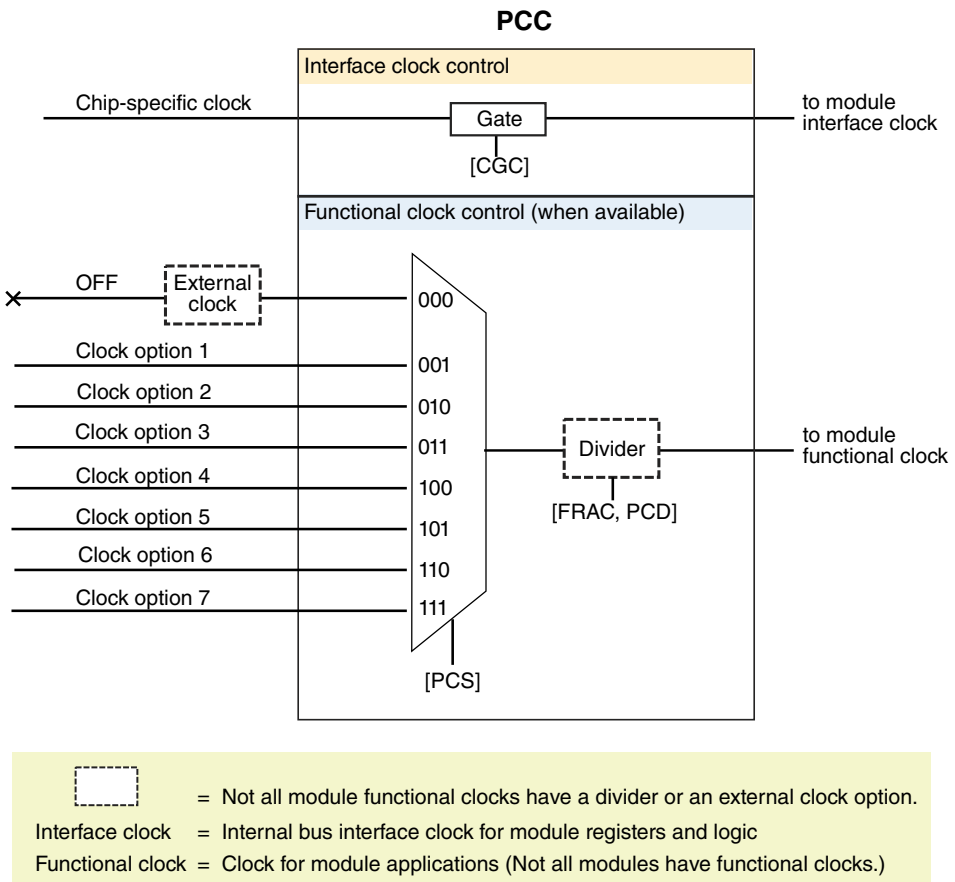

**Figure 30-1. PCC Block Diagram**

## 30.4 Functional description

The PCC module provides on-chip peripherals (modules) their own dedicated PCC registers for clock gating and configuration options. Each module's PCC register contains a clock gating control bit (CGC) for the module's interface clock. Before a module can be used, its interface clock must be enabled (CGC = 1) in the module's PCC register.

If a module has a functional clock, its PCC register may provide options for the clock source, selected by programming the Peripheral Clock Select (PCS) field. Optionally, a module may also have a clock divider, selected by programming the Peripheral Clock Divider (PCD) field along with a Fraction (FRAC) field. Before configuring a functional clock, the module's interface clock must be disabled (CGC = 0).

## 30.5 Memory map and register definition

Each module has its own dedicated PCC register, which controls the clock gating, clock source and divider (when applicable) for that specific module. See each module's PCC register for details.

PCC registers can be written only in supervisor mode using 32-bit accesses.

**NOTE**

To configure the clocking options available to a given module or to modify an existing configuration, first disable the module's interface clock by writing 0 to its CGC bit.

### 30.5.1 PCC0 register descriptions

#### 30.5.1.1 PCC0 Memory map

| 23-4<br>— | This read-only bit field is reserved and always has the value 0. |
| 3<br>FRAC | Peripheral Clock Divider Fraction<br>This read/write bit field sets the fraction multiply value for the fractional clock divider used as a clock source. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)].<br>This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked.<br>**NOTE:** When dividing by 1 (PCD = 000), do not set the FRAC bit; otherwise, the output clock is disabled.<br>0b - Fractional value is 0.<br>1b - Fractional value is 1. |
| 2-0<br>PCD | Peripheral Clock Divider Select<br>This read/write bit field is used for peripherals that require a clock divider. Divider output clock = Divider input clock x [(FRAC+1)/(PCD+1)].<br>This field can be written only when the clock is disabled (CGC = 0). Similarly, if the INUSE flag is set, this field is locked.<br>000b - Divide by 1.<br>001b - Divide by 2.<br>010b - Divide by 3.<br>011b - Divide by 4.<br>100b - Divide by 5.<br>101b - Divide by 6.<br>110b - Divide by 7.<br>111b - Divide by 8. |

## 30.5.1.37 PCC LPDAC0 Register (PCC_LPDAC0)

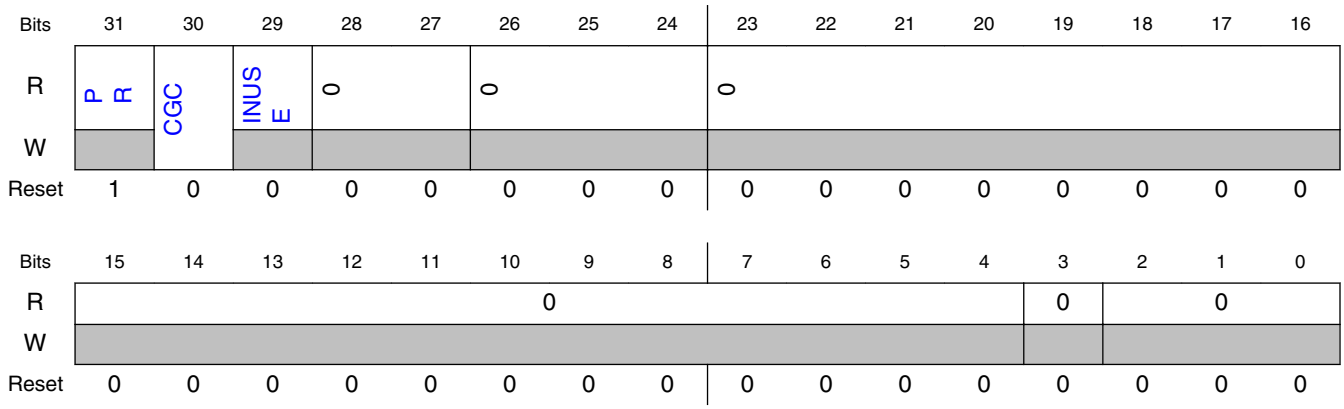
### 30.5.1.37.1 Offset

| Register | Offset |
|---|---|
| PCC_LPDAC0 | 130h |

### 30.5.1.37.2 Function

This register is for the LPDAC0 module.

### 30.5.1.37.3 Diagram



### 30.5.1.37.4 Fields

| Field | Function |
|---|---|
| 31<br>PR | Present<br>This bit shows whether the peripheral is present on this device.<br>0b - Peripheral is not present.<br>1b - Peripheral is present. |
| 30<br>CGC | Clock Gate Control<br>This read/write bit enables the interface clock for the peripheral, allowing access to the module's registers. It also controls whether the clock selection and divider options can be modified.<br>0b - Clock disabled. The current clock selection and divider options are not locked and can be modified.<br>1b - Clock enabled. The current clock selection and divider options are locked and cannot be modified. |
| 29<br>INUSE | In use flag<br>This read-only bit shows that this peripheral is being used by another core. That is, software on another core has already configured the clocking options of this peripheral. For example, if CPU0 software has set this peripheral's CGC bit first, it sees the INUSE bit as cleared. However, if software on another core has set this peripheral's CGC bit first, CPU0 software sees the INUSE bit as set.<br>0b - Peripheral is not being used.<br>1b - Peripheral is being used. Software cannot modify the existing clocking configuration. |
| 28-27<br>— | This read-only bit field is reserved and always has the value 0. |

# Chapter 31
# Power Management

## 31.1 Introduction

This chapter describes various chip power modes and functionality of the each modules in these modes.

## 31.2 Power supply and power domain summary

This section describes the power supply and the power domain of this device.

### 31.2.1 Power supply

This device requires a 1.71 V to 3.6 V $V_{DD}$ operating voltage supply. Several independent supplies can be provided to specific peripherals.

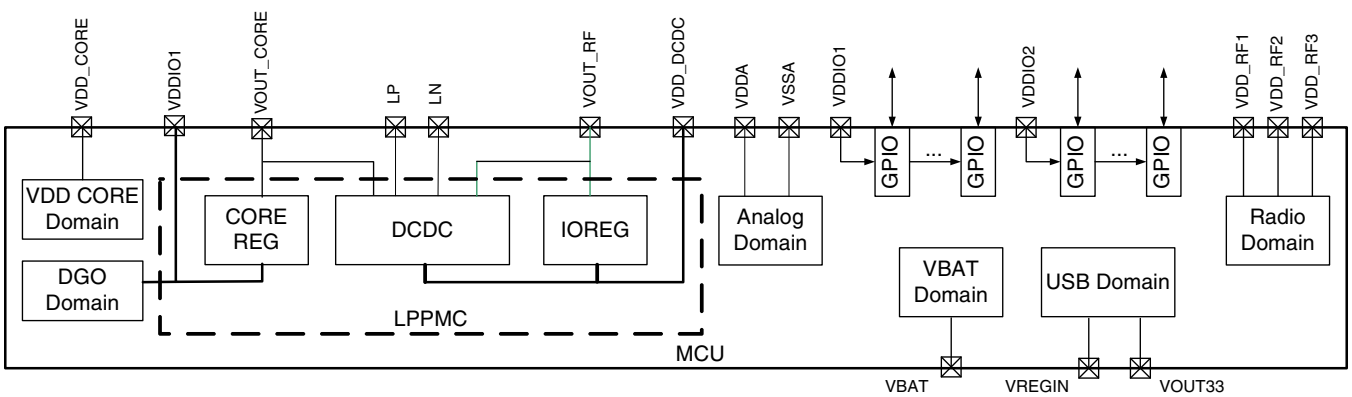

**Figure 31-1. Power supply overview**

#### 31.2.1.1 VDD_DCDC

VDD_DCDC is the power supply input for DCDC and 1.8 V IOREG regulator.

#### 31.2.1.2 VDD_CORE

VDD_CORE is the power supply input for internal VDD core domain. It powers the core, memory which includes flash and SRAM, and other digital peripherals.

VDD_CORE can be from external or internal power regulator, such as DCDC or PMC internal regulator.

VDD_CORE supports input voltage range from 1.2±5% V to 1.45 V.

- When 1.3 V < VDD_CORE_IN < 1.45 V, the device can support high speed run mode, and the maximum core clock can be 72 MHz.
- When 1.14 V < VDD_CORE_IN < 1.3 V, the device can support only the normal run mode, the maximum core clock can be 48 MHz.

#### 31.2.1.3 VDDIOx

VDDIOx power the I/O rings.

- VDDIO1 powers the I/O ring 1, including PTA, PTB, PTC, and PTD.
- VDDIO2 powers the I/O ring 2, including PTE.

VDDIO1 can also power the core regulator and DGO domain.

VDDIO1 and VDDIO2 can be powered independently.

Each VDDIOx can be powered from an external power supply or from an internal IO regulator.

#### 31.2.1.4 VDDA/VSSA

VDDA is the power supply for analog peripherals, such as LPADC, VREF, and LPDAC. It is the maximum of VDDIO1 and VDDIO2.

VSSA is the analog ground for analog peripherals, such as LPADC, VREF, and LPDAC.

#### 31.2.1.5 VDD_RFx

VDD_RF1 (VDD_RFSY), VDD_RF2 (VDD_RFHF) and VDD_RF3 (VDD_RFLF) are the power supplies for the 2.4 GHz radio module.

The radio module power supplies can be powered from external source or generated by the on-chip DCDC.

VDD_RFx input voltage range is from 1.5 V to 3.6 V.

#### 31.2.1.6 VBAT

VBAT is the power supply input for peripherals in VBAT domain.

The peripheral function and register data inside VBAT domain can be maintained when all the other powers are OFF.

#### 31.2.1.7 VREGIN

VREGIN is the power supply input for USB regulator. The USB regulator output can power the USB transceiver or serve as the other power supply like VDD.

VREGIN input voltage range is from 2.7 V to 5.5 V.

#### 31.2.1.8 VOUT_CORE

VOUT_CORE is the power output from the LDO regulator (core regulator) or one of the outputs from the DCDC regulator.

The VOUT_CORE can be connected to VDD_CORE_IN as the power supply for core domain. VOUT_CORE provides an output voltage of 1.2 V to 1.4 V, and a maximum output current of 100 mA.

Both the LPPMC and DCDC voltage outputs can provide 100 mA output current. The default, after a power-on-reset, the VOUT_CORE will be from the LPPMC.

#### 31.2.1.9 VOUT_RF

VOUT_RF is the power output from the internal IO regulator (IOREG) or one of the dual outputs of the DCDC regulator. The VOUT_RF provides the supply voltage for an internal or external RF module. The VOUT_RF provides an output voltage of 1.5 V to 1.8 V, with a maximum output current of 100 mA on either the IOREG or DCDC outputs.

The VOUT_RF can be connected to VDDIO1 or VDDIO2 as the power supply for padring 1 or padring 2. The VOUT_RF can be connected to VDDA as the power supply for analog modules.

The VOUT_RF can be connected to VDD_RFx as the power supply for 2.4 GHz radio module.

#### 31.2.1.10 LP and LN

The LP and LN pins require an external inductor to be connected to the DCDC regulator module.

### 31.2.2 Power domains

The following table describe the power domain of this device.

**Table 31-1. Modules power domain summary**

| Module | Domain |
|---|---|
| Digital Tamper | $V_{BAT}$ |
| Low Voltage Power Regulator (LVPREG) | $V_{BAT}$ |
| Real Time Clock (RTC) | $V_{BAT}$ |
| Real Time Clock Oscillator (RTCOSC) | $V_{BAT}$ |
| Flash (FTFE) | $V_{DD_CORE}$ |
| $V_{BAT}$ Register File – 32 Bytes | $V_{BAT}$ |
| Low-Power Analog-to-Digital Converter 0 (LPADC0) | $V_{DDA}$ |
| 12-bit Low Power Digital-to-Analog Converter 0 (LPDAC0) | $V_{DDA}$ |
| VREF 2.1V/1.2V | $V_{DDA}$ |
| System Power Manager (SPM) Drivers | $V_{DDIO1}$ |
| Multi System Mode Controller (MSMC) | $V_{DDIO1}$ (DGO) |
| Low-Leakage Wake-up Unit 0 (LLWU0) | $V_{DDIO1}$ (DGO) |
| Low-Leakage Wake-up Unit 1 (LLWU1) | $V_{DDIO1}$ (DGO) |
| Low-Power Frequency Locked Loop (LPFLL) | $V_{DDIO1}$ (DGO) |
| Fast Internal Resister/Capaciter Oscillator (FIRC) | $V_{DDIO1}$ (DGO) |

*Table continues on the next page...*

## Table 31-1. Modules power domain summary (continued)

| Module | Domain |
|---|---|
| Slow Internal Resister/Capaciter Oscillator (SIRC) | $V_{DD_CORE}$ |
| Low-Power Timer 0 (LPTMR0) | $V_{DDIO1}$ (DGO) |
| Low-Power Timer 1 (LPTMR1) | $V_{DDIO1}$ (DGO) |
| Low-Power Timer 2 (LPTMR2) | $V_{DDIO1}$ (DGO) |
| System Power Management (SPM) | $V_{DDIO1}$ (DGO) |
| GPIO pins Port A, B, C, D | $V_{DDIO1}$ |
| Low-Power Comparator 0 (LPCMP0) | $V_{DDIO1}$ (DGO) |
| GPIO pins Port E | $V_{DDIO2}$ |
| Low-Power Comparator 1 (LPCMP1) | $V_{DDIO2}$ (DGO) |
| Input/Output Regulator (IOREG) | $V_{DD_DCDC}$ |
| Joint Test Action Group (JTAG) | $V_{DD_CORE}$ |
| Serial Wire Debug version 2.0 (SWD) | $V_{DD_CORE}$ |
| External Watchdog Monitor (EWM) | $V_{DD_CORE}$ |
| System Clock Generator (SCG) | $V_{DD_CORE}$ |
| AXBS | $V_{DD_CORE}$ |
| Resource Domain Controller (RDC) | $V_{DD_CORE}$ |
| Read-Only Memory 0 (ROM0) | $V_{DD_CORE}$ |
| ROM Resource Domain Controller MRC | $V_{DD_CORE}$ |
| M4 AIPS 0 | $V_{DD_CORE}$ |
| M0+ AIPS 0 | $V_{DD_CORE}$ |
| M4 Core | $V_{DD_CORE}$ |
| M0+ Core | $V_{DD_CORE}$ |
| M4 Instruction/Data Cache (LPLMEM) 4kB | $V_{DD_CORE}$ |
| M0+ Instruction/Data Cache (LPLMEM) 4kB | $V_{DD_CORE}$ |
| Asynchronous Wake-up Interrupt Controller (AWIC) | $V_{DD_CORE}$ |
| Memory Mapped Division / Square Root (MMDVSQ) | $V_{DD_CORE}$ |
| SRAM | $V_{DD_CORE}$ |
| Direct Memory Access Controller 0 (DMA0) - 16ch | $V_{DD_CORE}$ |
| Direct Memory Access Controller 1 (DMA1) - 8ch | $V_{DD_CORE}$ |
| Direct Memory Access Multiplexer 0 (DMAMUX0) | $V_{DD_CORE}$ |
| Direct Memory Access Multiplexer 1 (DMAMUX1) | $V_{DD_CORE}$ |
| Peripheral Clock Control (PCCx) | $V_{DD_CORE}$ |
| Watchdog 0 (WDOG0) | $V_{DD_CORE}$ |
| Watchdog 1 (WDOG1) | $V_{DD_CORE}$ |
| True Random Number Generator (TRNG) | $V_{DD_CORE}$ |
| Cryptographic Acceleration Engine version 3 (CAEv3) | $V_{DD_CORE}$ |
| Flexible Input/Ouput 0 (FlexIO0) | $V_{DD_CORE}$ |
| Low-Power Inter-Integrated Circuit 0 (LPI2C0) | $V_{DD_CORE}$ |
| Low-Power Inter-Integrated Circuit 1 (LPI2C1) | $V_{DD_CORE}$ |

*Table continues on the next page...*

**Table 31-1. Modules power domain summary (continued)**

| Module | Domain |
|---|---|
| Low-Power Inter-Integrated Circuit 2 (LPI2C2) | $V_{DD_CORE}$ |
| Low-Power Inter-Integrated Circuit 3 (LPI2C3) | $V_{DD_CORE}$ |
| Low-Power Serial Peripheral Interface 0 (LPSPI0) | $V_{DD_CORE}$ |
| Low-Power Serial Peripheral Interface 1 (LPSPI1) | $V_{DD_CORE}$ |
| Low-Power Serial Peripheral Interface 2 (LPSPI2) | $V_{DD_CORE}$ |
| Low-Power Serial Peripheral Interface 3 (LPSPI3) | $V_{DD_CORE}$ |
| Low-Power Universal Asynchronous Receive/Transmit 0 (LPUART0) | $V_{DD_CORE}$ |
| Low-Power Universal Asynchronous Receive/Transmit 1 (LPUART1) | $V_{DD_CORE}$ |
| Low-Power Universal Asynchronous Receive/Transmit 2 (LPUART2) | $V_{DD_CORE}$ |

| Low-Power Periodic Interrupt Timer 0 (LPIT0) | $V_{DD_CORE}$ |
| Low-Power Periodic Interrupt Timer 1 (LPIT1) | $V_{DD_CORE}$ |
| Timer / PWM Module 0 (TPM0) - 6ch | $V_{DD_CORE}$ |
| Timer / PWM Module 1 (TPM1) - 2ch | $V_{DD_CORE}$ |
| Timer / PWM Module 2 (TPM2) - 6ch | $V_{DD_CORE}$ |
| Timer / PWM Module 3 (TPM3) - 2ch | $V_{DD_CORE}$ |
| Rapid GPIO (RGPIO) | $V_{DD_CORE}$ |
| PORTA – E logic | $V_{DD_CORE}$ |
| Trigger Multiplexer 0 (TRGMUX0) | $V_{DD_CORE}$ |
| Time Stamp Timer Module (TSTMR) | $V_{DD_CORE}$ |
| USB0 | $V_{DD_CORE}$ |
| USB SRAM | $V_{DD_CORE}$ |
| Euro Mastercard Visa Secure Identity Module 0 (EMVSIM0) | $V_{DD_CORE}$ |
| Serial Audio Interface 0 (SAI) | $V_{DD_CORE}$ |
| 2.4 GHz Radio Digital Logic | $V_{DD_CORE}$ |
| Single Inductor Multiple Ouput DC/DC (SIMO DCDC) | $V_{DD_DCDC}$ |
| 2.4 GHz Radio Analog | $V_{DD_RF}$ |
| Radio OSC | $V_{DD_RF}$ |
| USB VREG | $V_{REGIN}$ |
| USB LS/FS Tranceiver | $V_{OUT33}$ |

## 31.3 On-chip regulator summary

This section describes the various on-chip regulators of this device.

### 31.3.1 DCDC regulator

The dual output DCDC regulator requires one single external inductor to generate two outputs. The external inductor must be connected between LP and LN.

The DCDC input power supply is from VDD_DCDC. It supports input voltage range from 2.1 V to 4.25 V.

One output is configurable from 1.0 V to 1.4 V. It is connected to the VOUT_CORE. The other output is configurable from 1.5 V to 1.8 V. It is connected to the VOUT_RF.

### 31.3.2 LPPMC regulator

The LPPMC integrates a 1.2 V output linear regulator.

The power input to this regulator is from VDDIO1 and ranges from 1.71 V to 3.6 V.

The output of this regulator is connected to the VOUT_CORE which shares the output pin with one output of the DCDC.

### 31.3.3 IOREG regulator

The IOREG is a linear regulator that provides a 1.8 V or 1.5 V output. Its output is connected to VOUT_RF.

This IOREG regulator's power input is from VDD_DCDC. It supports input voltage range from 1.95 V to 4.25 V.

The VOUT_RF is shared with one of the outputs of the DCDC.

### 31.3.4 USB regulator

The USB voltage regulator module is a LDO linear voltage regulator to provide 3.3 V power from an input power supply varying from 2.7 V to 5.5 V. It is the power supply for USB domain. Its input is VREGIN and its output is VOUT33.

## 31.4 Typical power supply schematic

This section describes the chip power modes and functionality of the each modules in these modes.

### 31.4.1 Typical power supply schematic 1

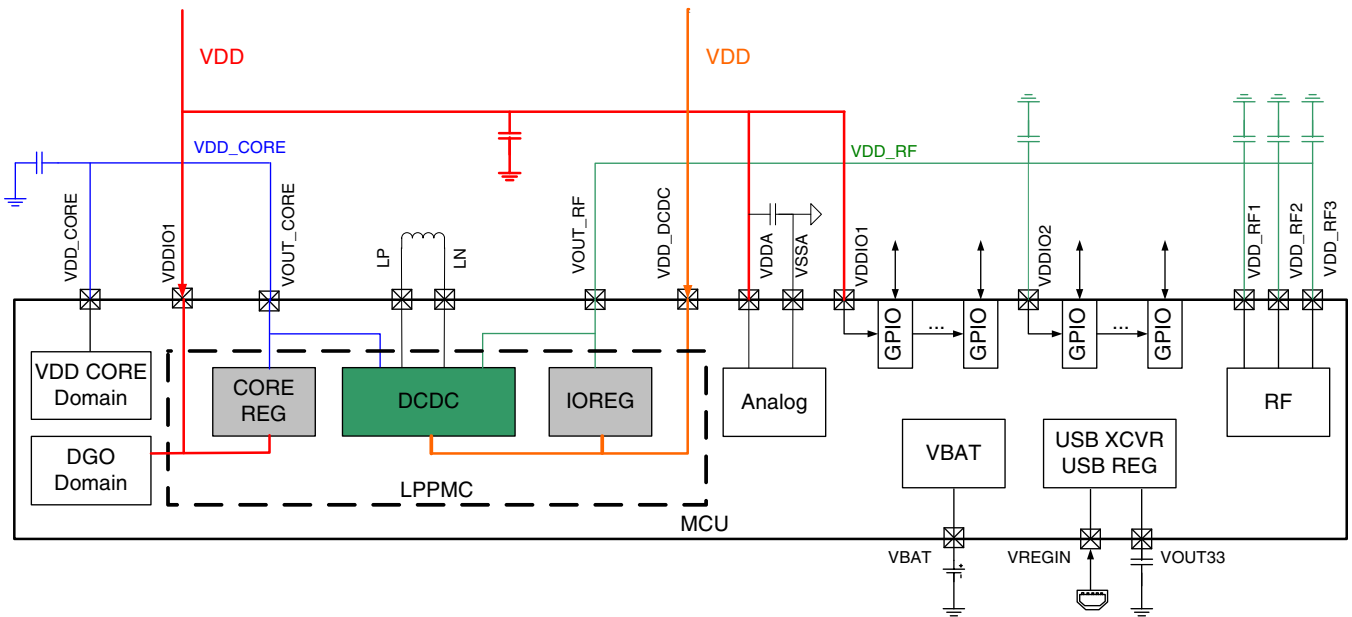

**Figure 31-2. MCU core powered by DCDC**

In this configuration, the VDDIO1 input provides power to the DGO domain modules, and the GPIO pins powered by VDDIO. These GPIO pins interface with 1.8 V to 3.6 V circuits. The LPPMC is also powered by the VDDIO1 input pin and from a POR, the LPPMC provides the VDD_CORE supply. After POR, the application code places the LPPMC in a standby/powered off mode.

The VDD_DCDC input provides power to the DCDC and the IOREG. The MCU's core ( CPU platform and SoC logic) is powered from the DCDC which provides a high efficiency buck output from VDD_DCDC input.

The other output of the DCDC provides VOUT_RF which powers the radio module, via the VDD_RF1/2/3 inputs. The VOUT_RF is also used to power GPIO pins that are powered via the VDDIO2 input. These GPIO pins interface with 1.71 V to 1.8 V circuits.

## 31.4.2 Typical power supply schematic 2

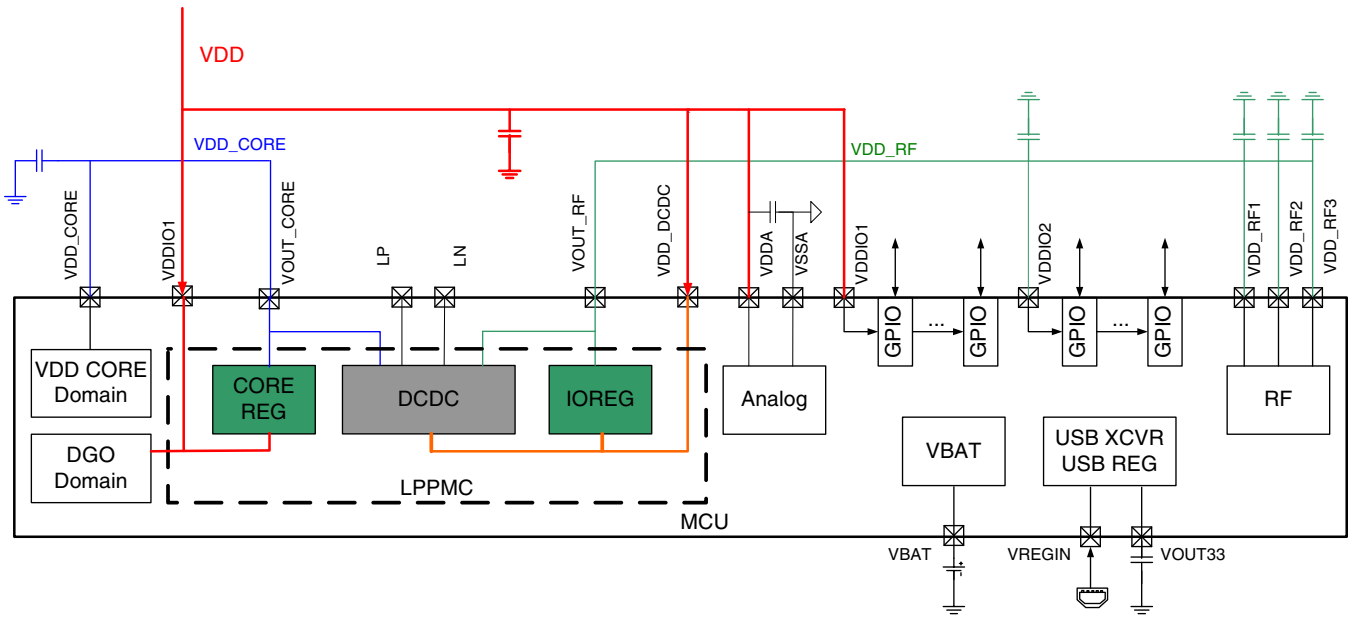

**Figure 31-3. MCU core powered by LPPMC with DCDC bypassed**

In this configuration, VDDIO1, VDD_DCDC, and VDDA are supplied with the same external voltage source in the range of 1.8 V -3.6 V. The LPPMC provides the VOUT_CORE which powers the core and the SoC logic. The IOREG provides the VOUT_RF. Both the radio module and the GPIO powered by VDDIO2 are powered from the VOUT_RF output from the IOREG. This would be a typical pin configuration for lower pin count devices and simpler designs with two external voltage sources.

### 31.4.3 Typical power supply schematic 3

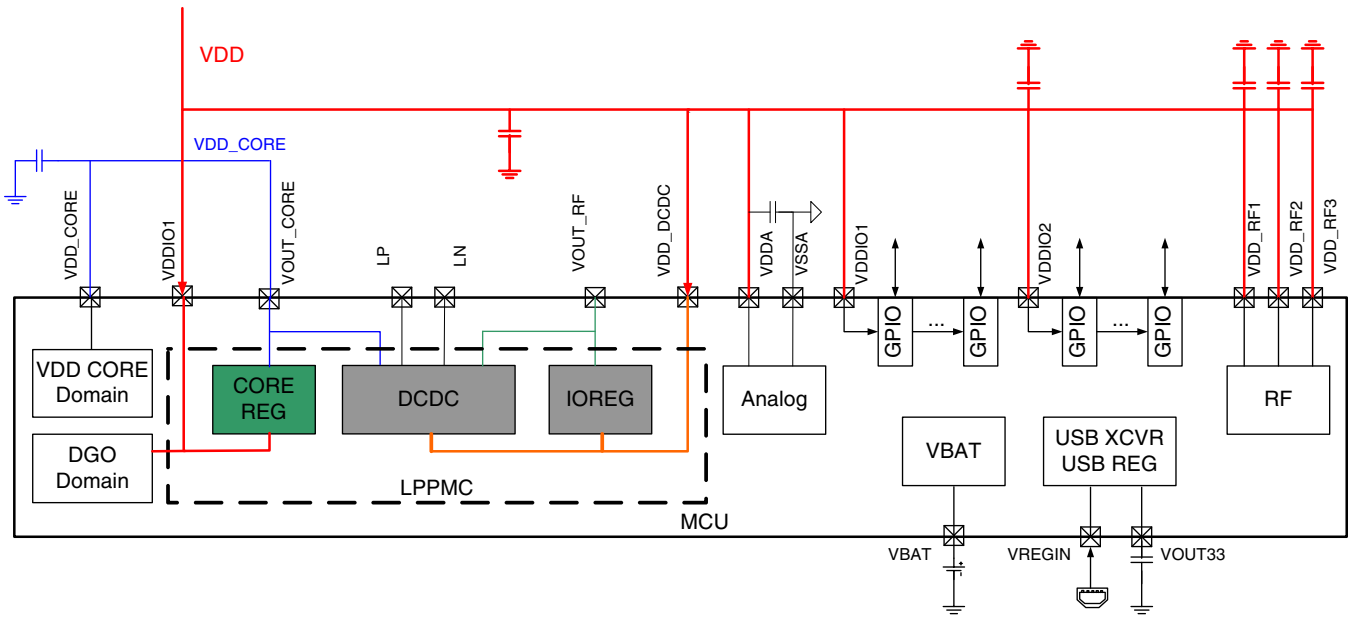

**Figure 31-4. MCU powered by one external supply**

This configuration is based on a simple application where only one external voltage supply is available.

## 31.5 Power up state

When power supply is applied on VDD_DCDC, the DCDC is bypassed by default. The VOUT_CORE is supplied by the LPPMC 1.2 V regulator and the VOUT_RF is supplied by the 1.8 V IOREG. The DCDC can be enabled as the main regulator.

## 31.6 Multi-Core power mode description

This device includes CM4F and CM0+ subsystem as well as RF subsystem.

For CM4F/CM0+ power mode, each includes HSRUN, RUN, PSTOP, STOP, VLPR/ VLPW/VLPS, LLS, VLLS, etc. Please refer to Power modes for details.

For RF power mode description, it includes RRUN, RLLS, RVLLS power modes. Please refer to Section Radio Power for details.

## 31.6.1 Core power structure overview

The following diagram is the overview of core power structure for this device.

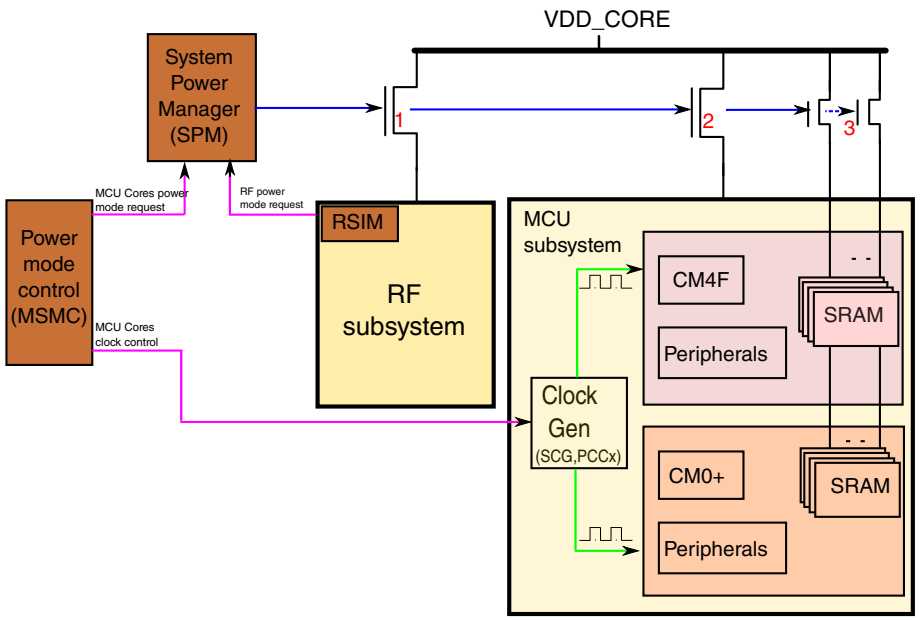

**Figure 31-5. VDD_CORE power structure**

Generally speaking, RF and MCU digital parts are powered from the power source (VDD_CORE) through independent power switches (1 and 2 in the diagram). The SPM controls them according to the CM4F/CM0+ power mode configuration in MSMC and RF power mode configuration in RSIM.

Besides above power control, clock control is the second level of power mode implementation. The clock generation modules like SCG, PCC0 and 1 can automatically switch ON/OFF clocks for CM4F and CM0+ subsystem based on their power modes.

Also separate power switches (3 in the diagram) are used to control each SRAM power in specific MCU low-power modes. See details in Power modes.

## 31.6.2 Power mode combinations

There are various power modes available across the subsystems for the user. The system power management (SPM) deals with the power mode requests from RF and MCU subsystems and select appropriate power control scheme. Clock control is implemented as fine optimization. Usually there are different targets across subsystem like high-performance in CM4F and low-power in RF/CM0+. To meet whole system target, there are general principles to determine whole system power status according to MCU/RF power mode. Below lists two general principles.

- Individual power switch control applies for MCU and RF. Basically it allows MCU and RF power mode to be independent. However, due to sharing same power source, some schemes adopted in the low-power mode, like voltage level adjustment in one subsystem, could be disabled if another subsystem needs to work at different voltage level; but the other irrelevant low-power schemes are kept. It might cause the power larger than the expectation. For example, if RF in RRUN mode, the total power is almost the same between MCU in VLPR mode and RUN with 8 MHz. In this case, MCU VLPR is fake VLPR mode to maintain RF in RRUN mode by keeping normal voltage level which is the same in MCU RUN mode.
- The same power supply applies for whole MCU subsystem including CM4F and CM0+ part. The clock control switches on/off clocks to account for the majority of MCU power difference. The MCU power mode is determined by the highest one from CM4F and CM0+ power modes with following order: HSRUN > RUN/STOP/PSTOP > VLPR/VLPW/VLPS > LLS > VLLS. For example, when CM4F in RUN while CM0+ in VLPS, MCU power mode is in RUN mode. In this case, trivial power difference could be observed with CM0+ in VLPS or Stop mode when CM4F is in RUN mode. Because both VLPS and Stop mode are the same to disable all clocks to have the same clock control behavior.

Generally speaking, it is two step determination. In the first step, it's clock control according to CM4F and CM0+ power mode to determine MCU expected power mode. In the second step, it's power control based on MCU and RF power mode to determine system power mode.

The following tables list all power mode combinations and corresponding power behaviors.

**Table 31-2. MCU power mode combinations**

| CM4F power mode[1] | CM0+ power mode[2] | Max CM4F core clock frequency | Max CM0+ core clock frequency | MCU power mode[3] |
|---|---|---|---|---|
| RUN | RUN | 48MHz | 48MHz | RUN |
| RUN | HSRUN | 72MHz | 72MHz | HSRUN |
| RUN | VLPR | 48MHz | 48MHz | RUN |
| RUN | VLPW | 48MHz | OFF | RUN |
| RUN | VLPS | 48MHz | OFF | RUN |
| RUN | STOP/PSTOP | 48MHz | OFF | RUN |
| RUN | LLS | 48MHz | OFF | RUN |
| RUN | VLLS | 48MHz | OFF | RUN |
| HSRUN | RUN | 72MHz | 72MHz | HSRUN |
| HSRUN | HSRUN | 72MHz | 72MHz | HSRUN |
| HSRUN | VLPR | 72MHz | 72MHz | HSRUN |
| HSRUN | VLPW | 72MHz | OFF | HSRUN |

*Table continues on the next page...*

## Table 31-2. MCU power mode combinations (continued)

| CM4F power mode[1] | CM0+ power mode[2] | Max CM4F core clock frequency | Max CM0+ core clock frequency | MCU power mode[3] |
|---|---|---|---|---|
| HSRUN | VLPS | 72MHz | OFF | HSRUN |
| HSRUN | STOP/PSTOP | 72MHz | OFF | HSRUN |

| VLLS | LLS | OFF | OFF | LLS |
| VLLS | VLLS | OFF | OFF | VLLS |

1. It is configured by SMC0_PMCTRL register of MSMC.
2. It is configured by SMC1_PMCTRL register of MSMC.
3. It can be read out from SMCx_PMCSTAT register of MSMC. Please note the PMSTAT[7:0] bits in both SMC0_PMCSTAT and SMC1_PMCSTAT registers refer to MCU power mode so their value are identical. The STOPSTAT[31:24] bits in SMCx_PMCSTAT register reflect separate CM4F or CM0+ clock status, so can be different.

## Table 31-3. System power mode

| MCU power mode[1] | RF power mode[2] | System power mode | |
|---|---|---|---|
| | | MCU power status | RF power status |
| RUN | RRUN | RUN | RRUN |
| RUN | RLLS | RUN | RLLS |
| RUN | RVLLS | RUN | RVLLS |
| HSRUN | RRUN | HSRUN | RRUN |
| HSRUN | RLLS | HSRUN | RLLS |
| HSRUN | RVLLS | HSRUN | RVLLS |
| VLP | RRUN | RUN | RRUN |
| VLP | RLLS | VLP | RLLS |
| VLP | RVLLS | VLP | RVLLS |
| LLS | RRUN | LLS | RRUN |
| LLS | RLLS | LLS | RLLS |
| LLS | RVLLS | LLS | RVLLS |
| VLLS | RRUN | VLLS | RRUN |
| VLLS | RLLS | VLLS | RLLS |
| VLLS | RVLLS | VLLS | RVLLS |

1. It can be read out from SMCx_PMCSTAT register of MSMC. Please note the PMSTAT[7:0] bits in both SMC0_PMCSTAT and SMC1_PMCSTAT registers refer to MCU power mode so their value are identical. The STOPSTAT[31:24] bits in SMCx_PMCSTAT register reflect separate CM4F or CM0+ clock status, so can be different.

2. It is configured by RSIM Power Control register. The user can read out relative bit in this register to determine RF power mode status.

**NOTE**

When RF OSC is used in MCU subsystem, RF must be in RRUN to keep RF OSC alive.

Due to the multi-core power mode combination, users must be careful to select appropriate power modes to meet the target. Please keep in mind – it takes some time for power mode transition depending on which kinds of power mode transition is ongoing. To guarantee the entry or exiting procedure complete, it's recommended to read relative power status register mentioned above.

**NOTE**

The stack and all interrupt handlers must be placed in Flash / RAM memory local to the core that will access the stack space or execute the interrupt vectors. In addition, all functions that execute the WFI or WFE instruction must also be placed in Flash / RAM memory local to the core that will execute the function.

To help the user debug these kinds of procedures via external debugger, this device also puts all key power status information (power mode, regulator mode, power supply status, etc) in MDM-AP System Power Status Register. Please refer to MDM-AP system Power Status register in debug chapter for details.

## 31.6.3 Recommended power mode combination

Considering the complexity of power design, below power mode combinations in Table 31-2 are recommended to easy the user for start-up. It's simplified into several combinations to either achieve high performance or low-power goal in one subsystem with minimum impact on the rest of this device.

**Table 31-4. Recommended power mode combination**

| CM4F power mode | CM0+ power mode | RF allowed mode |
|---|---|---|
| HSRUN | HSRUN | RRUN, RLLS, RVLLS |
| HSRUN | STOP/PSTOP | RRUN, RLLS, RVLLS |
| STOP/PSTOP | HSRUN | RRUN, RLLS, RVLLS |
| RUN | RUN | RRUN, RLLS, RVLLS |
| RUN | STOP/PSTOP | RRUN, RLLS, RVLLS |
| STOP/PSTOP | RUN | RRUN, RLLS, RVLLS |
| STOP/PSTOP | STOP/PSTOP | RRUN, RLLS, RVLLS |

*Table continues on the next page...*

**Table 31-4. Recommended power mode combination (continued)**

| CM4F power mode | CM0+ power mode | RF allowed mode |
|---|---|---|
| VLPR | VLPR/VLPW/VLPS | RLLS, RVLLS |
| VLPR/VLPW/VLPS | VLPR | RLLS, RVLLS |
| VLPS | VLPS | RLLS, RVLLS |
| LLS | LLS | RLLS, RVLLS |
| VLLS | VLLS | RVLLS |

## 31.7 Power mode description

### 31.7.1 RUN mode

RUN mode is the default mode after reset.

In RUN mode, user is allowed to adapt following different configurations to balance the performance and power.

#### 31.7.1.1 HSRUN

When the VIN_CORE voltage is higher than 1.3 V, the MCU VDD core domain is fully powered. The MCU can run at a faster frequency compared with in the normal RUN mode.

#### 31.7.1.2 VLPR

The regulator is in low power mode with limited output capability. Thus the core, system, bus, and flash clock maximum frequencies are restricted in this mode.

#### 31.7.1.3 Computation operation

Compute operation is an execution or compute-only mode of operation that keeps the CPU enabled with full access to the SRAM and flash read port, but places all other bus masters and bus slaves into their stop mode.

## 31.7.2 Wait mode

Wait mode allows peripherals to function while the core is in sleep mode, reducing power. NVIC remains sensitive to interrupts; peripherals continue to be clocked.

### 31.7.2.1 VLPW

The regulator is in low power mode with limited output capability. The core clock is gated off. The system, bus, and flash clocks continue to operate, although their maximum frequency is restricted.

## 31.7.3 Stop mode

Stop mode places chip in static state. LVD in low power modes depends on user configuration and MCU/RF arbitration.

### 31.7.3.1 PSTOP1

When configured for PSTOP1, both the system clock and bus clock are gated. All bus masters and bus slaves enter Stop mode, but the clock generators in the MCG and the on-chip regulator in the PMC remain in Run (or VLP Run) mode. Exit from PSTOP1 can be initiated by a reset or an asynchronous interrupt from a bus master or bus slave. If configured, an asynchronous DMA request can also be used to exit Partial Stop for the duration of a DMA transfer before the device is transitioned back into PSTOP1.

### 31.7.3.2 PSTOP2

When configured for PSTOP2, only the core and system clocks are gated and the bus clock remains active. The bus masters and bus slaves clocked by the system clock enter Stop mode, but the bus slaves clocked by bus clock remain in Run (or VLP Run) mode. The clock generators in the MCG and the on-chip regulator in the PMC also remain in Run (or VLP Run) mode. Exit from PSTOP2 can be initiated by a reset, an asynchronous interrupt from a bus master or bus slave clocked by the system clock, or a synchronous interrupt from a bus slave clocked by the bus clock. If configured, a DMA request (using the asynchronous DMA wakeup) can also be used to exit Partial Stop for the duration of a DMA transfer before the device is transitioned back into PSTOP2.

#### 31.7.3.3 PSTOP3

When configured for PSTOP3, only the core clocks are gated and the system and bus clocks remain active. The bus masters and bus slaves remain in Run (or VLP Run) mode. The clock generators in the SCG and the on-chip regulator in the SPM also remain in Run (or VLP Run) mode. Exit from PSTOP3 can be initiated by a reset, or a synchronous interrupt from a bus master or slave.

#### 31.7.3.4 VLPS

The regulator is in low power mode with limited output capability. The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.

### 31.7.4 Standby (LLS) mode

Standby mode is the state retention power mode.It permits following configurations to achieve various functionalities and power levels.

#### 31.7.4.1 SRAM retention

Each SRAM array can be optional configured to retain its content.

### 31.7.5 Shutdown (VLLSx) mode

Shutdown mode permits the lowest power level. Most peripherals are disabled (powered OFF). Only some modules can be used.

It permits following configurations to achieve various functionalities and power levels.

#### 31.7.5.1 SRAM retention

Each SRAM array can be optional configured to retain its content in VLLS2/3 modes.

#### 31.7.5.2 LPO off

The 1 kHz LPO clock can be optional off to further reduce the power consumption in shutdown mode.

#### 31.7.5.3 POR off

The POR circuit can be optional off to further reduce the power consumption in shutdown mode.

## 31.8 Entering and exiting power modes

Low power modes are entered by executing the WFI or WFE instruction. Which particular mode (Wait, STOP, Standby, or Shutdown) is entered depends on the configuration of the SMC and the status of the other core and Radio. For more information on this, refer to the SMC descriptions in the Multi System Mode Controller (MSMC), Table 31-2 and Table 31-3.

Upon execution of the WFI or WFE command, the core executing the command will internally signal all of its peripherals and wait for an acknowledge signal before fully moving into the commanded low power mode. Since the two cores execute code independently and have their own peripherals on independent crossbars, the low power entry times may not be exactly the same in complex applications that use multiple peripherals. This is important to remember and account for when designing and troubleshooting your applications.

Exiting low power modes differs depending on the mode entered. For WAIT (WAIT and VLPW) and STOP (STOP and VLPS) modes, the exit mechanism is via interrupt if the WFI instruction was executed or if the WFE instruction was executed when SEVONPEND = 1. For Standby (LLS) and Shutdown (VLLSx) modes, the wakeup sources are limited to LLWU generated wakeups (for a complete list of possible LLWU wakeup sources, consult the LLWU chapter), NMI_b, or RESET_b pin assertions. When the NMI_b pin or RESET_b pin has been disabled through the associated FTFE_FOPT settings, then these pins are ignored as wakeup sources. The wakeup flow from Shutdown or from RESET_b is always through reset. The wakeup flow from Standby will be the next instruction cycle or through the IRQ handler of the interrupt that causes the wakeup provided it is properly configured and interrupts are not globally masked.

Before executing the WFI instruction, the last register written to must be read back. This ensures that all register writes associated with setting up the low power mode being entered have completed before the MCU enters the low power mode. Failure to do this may result in the low power mode not being entered correctly.

On Shutdown recoveries, the I/O pins continue to be held in a static state after code execution begins, allowing software to reconfigure the system before unlocking the I/O. RAM can be optionally retained.

## 31.9 Power mode transitions

The following figure shows the power mode transitions. Any reset always brings the chip back to the normal run state. The Standby and Shutdown modes are the lowest power stop modes based on amount of logic or memory that is required to be retained by the application.

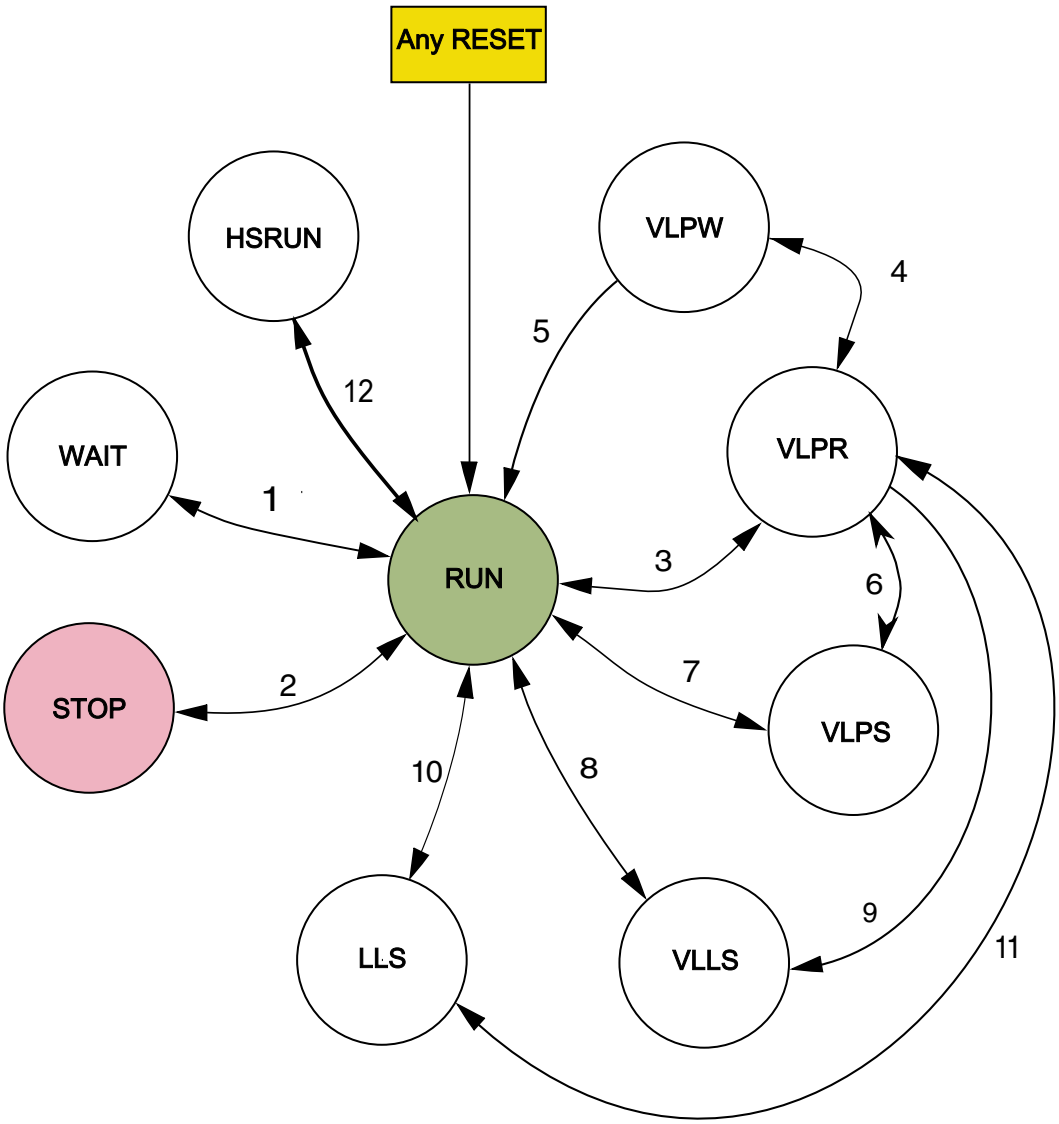

**Figure 31-6. Power mode state transition diagram**

## 31.10 Power modes shutdown sequencing

When entering Stop or other low-power modes, the clocks are shut off in an orderly sequence to safely place the chip in the targeted low-power state. All low-power entry sequences are initiated by the core executing a WFI instruction. The ARM core's outputs, SLEEPDEEP and SLEEPING, trigger entry to the various low-power modes:

- System level wait and VLPW modes equate to: SLEEPING & !SLEEPDEEP
- All other low power modes equate to: SLEEPING & SLEEPDEEP

When entering the non-wait modes, the chip performs the following sequence:

- Shuts off core clock and system clock to the ARM Cortex-M0+ core and Cortex-M4 core immediately.
- Polls stop acknowledge indications from the non-core crossbar masters (DMA), supporting peripherals (SPI, PIT, TRNG, etc.,) and the flash controller for indications that system clocks, bus clock and/or flash clock need to be left enabled to complete a previously initiated operation, effectively stalling entry to the targeted low power mode. When all acknowledges are detected, system clock, bus clock and flash clock are turned off at the same time.
- SCG and mode controller shut off clock sources and/or the internal supplies driven from the on-chip regulator as defined for the targeted low power mode.

In Wait mode, most of the system clocks are not affected by the low power mode entry. The core clock to the ARM Cortex-M0+ core and/or the ARM Cortex-M4 core is shut off. Some modules support stop-in wait functionality and have their clocks disabled under these configurations.

The debugger modules support a transition from Stop, Wait, VLPS, and VLPW back to a halted state when the debugger is enabled. This transition is initiated by setting the Debug Request bit in MDM-AP control register. As part of this transition, system clocking is re-established and is equivalent to normal Run/VLPR mode clocking configuration.

## 31.11 Flash program restrictions

The flash memory on this device must not be programmed or erased while operating in VLPR mode or HSRUN mode.

## 31.12 Module operation in low power modes

The following table illustrates the functionality of each modules while the chip is in each of the low power modes. The standard behavior is shown with some exceptions for Compute Operation (CPO) and Partial Stop2 (PSTOP2).

(Debug modules are discussed separately; see Debug in low power modes.) Number ratings (such as 2 MHz and 1 Mbit/s) represent the maximum frequencies or maximum data rates per mode. Also, these terms are used:

- FF = Full functionality. In VLPR and VLPW, the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- Async = Fully functional with alternate clock source, provided the selected clock source remains enabled
- SR = Module state is retained but not functional.

- LP = Module operates in a lower power state
- OFF = Modules are powered off or disabled.

**Table 31-5. Module operation in low power modes**

| Modules | VLPR | VLPW | STOP | VLPS | LLS | VLLS2/3 | VLLS0/1 |

3. It depends on MCU/RF arbitration and SPM LPSEL/BGEN bit.
4. It depends on MCU/RF arbitration and SPM LVDEN/BGEN/ALLREFN bit
5. It depends on MCU/RF arbitration and SPM POREN bit.
6. It depends on MCU/RF arbitration and SPM LPOEN/ALLREFN bit.

7. It depends on MCU/RF configuration and arbitration.
8. It depends on the configurations, see Table 1 for details.
9. Requires the VBAT supply to be properly powered.
10. It depends on SPM_CORELPCNFG[ALLREFEN] =1.
11. It depends on SPM_CORESC[VDDIOOVRIDE] = 1, SPM_CORELPCNFG[ALLREFEN] =1, and VDDIO2.

# Chapter 32
# Multi System Mode Controller (MSMC)

## 32.1 Chip-specific MSMC information

### 32.1.1 SRAM blocks with corresponding control bit

See SRAM memory map for the control bits of SRAMLPR and SRAMDSR.

### 32.1.2 Power mode transition in dual core application

In dual core applications, either core can initiate a transition to HSRUN mode. However, once in HSRUN, the same core that initiated the entry to HSRUN must also initiate the transition back to normal run mode.

When transitioning to Deep Sleep power modes (STOP mode and below), both cores must execute the WFI or WFE instruction. When this happens, the respective platform of each core will not necessarily move to the commanded low power mode at the same time. This is due to peripherals attached to said platform must acknowledge the low power mode transition command. Likewise, the platforms may not exit the low power mode at exactly the same time either. It is for this reason that all interrupt handlers and stack space for each core must reside in the respective core's local Flash / RAM memory space. Inter-domain accesses are possible but in some cases, a hard fault exception can be thrown as one core can become active and attempt to access memory in the inactive platform. Likewise, any function that executes the WFI or WFE command should be placed in local Flash / RAM memory.

## 32.2 Introduction

The Multi-System Mode Controller (MSMC) is responsible for sequencing the MCU into and out of all stop and run power modes.

Specifically, it monitors events to trigger transitions between power modes while controlling the power, clocks, and memories of the MCU to achieve the power consumption and functionality of that mode. Additionally, the MSMC will arbitrate between multiple cores in the MCU to provide each with the most optimal power mode without negatively impacting the functionality of other cores.

This chapter describes all the available power modes, the sequence followed to enter/exit each mode, and the functionality available while in each of the modes.

The following diagram illustrates the connections of the MSMC with other components in the system that are necessary to sequence the system through all power modes.

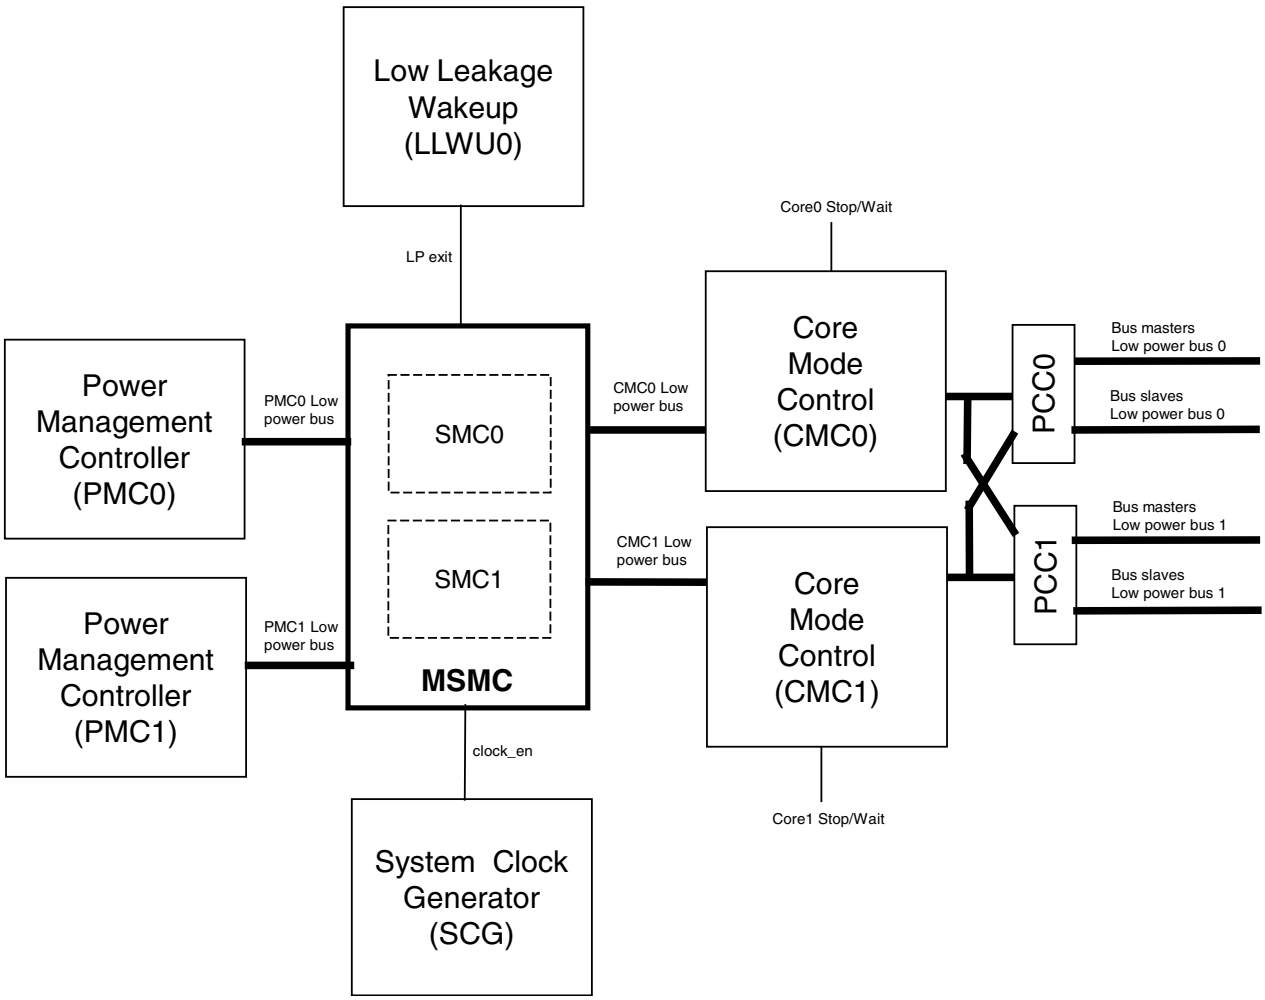

**Figure 32-1. Power management system components and connections**

## 32.3 Modes of operation

An ARM Cortex-M CPU has three primary modes of operation:

- Run
- Sleep
- Deep Sleep

The WFI or WFE instruction is used to invoke a Sleep, Deep Sleep or Standby modes for either Cortex family. Run, Wait, and Stop are the common terms used for the primary operating modes of the MSMC.

The following table shows the translation between the ARM CPU modes and MSMC power modes:

| ARM CPU mode | MSMC mode |
|---|---|
| Sleep | Wait |
| Deep Sleep | Stop |

In addition, the MSMC also augments Stop, Wait, and Run modes in a number of ways. Depending on the needs of the user application, a variety of run and stop modes are available that allow the user to adjust functionality, performance and power consumption.

The following table describes the power modes available to each core within the MCU.

**Table 32-1. Power modes**

| Mode | Description |
|---|---|
| Run (RUN) | The core can be run at full frequency and all functionality is available. This mode is also referred to as Normal Run mode. |
| High Speed Run (HSRUN) | Provides the highest performance mode at the fastest supported frequency. The core, system, bus, and flash clock maximum frequencies are unrestricted in this mode.[1] |
| Wait (WAIT) | Allows a core to enter a static, low power state with instant wakeup time, while still allowing peripherals to operate with full functionality. The core clock is gated off. The system clock continues to operate. Bus clocks, if enabled, continue to operate. |
| Stop (STOP) | Allows a core and its peripherals to enter a static, low power state with relatively fast wakeup times, while still allowing peripherals to operate with full asynchronous functionality. The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. |
| Very Low Power Run (VLPR) | Provides the lowest power operating mode to the core at a reduced frequency. The core, system, bus, and flash clock maximum frequencies are restricted in this mode.[1] |
| Very Low Power Wait (VLPW) | Allows a core to enter a static, very low power state, while still allowing peripherals to operate with full functionality at a reduced frequency. The core clock is gated off. The system, bus, and flash clocks continue to operate, although their maximum frequency is restricted.[1] |
| Very Low Power Stop (VLPS) | Allows a core and its peripherals to enter a static, very low power state with relatively fast wakeup times, while still allowing peripherals to operate with limited asynchronous functionality. The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. |
| Low Leakage Stop (LLS) | Allows a core and its peripherals to enter a low leakage, power gated state with relatively fast wakeup times, while still retaining the state of all logic. The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. Logic and I/O are retained, with wakeup only supported via the LLWU, NMI or Reset pins. |
| Very Low Leakage Stop (VLLS) | Allows a core and its peripherals to enter a very low leakage, power gated state.The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. Logic is power gated, with wakeup only supported via the LLWU, NMI or Reset pins. I/O states are latched. |

1. See the devices' chip configuration details for the maximum allowable frequencies.

## 32.4 Memory map and register descriptions

Information about the registers related to the system mode controller can be found here.

## 32.4.1 SMC0 register descriptions

Different MSMC registers reset on different reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

**NOTE**

The MSMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

**NOTE**

Before executing the WFI instruction, the last register written to must be read back. This ensures that all register writes associated with setting up the low power mode being entered have completed before the MCU enters the low power mode. Failure to do this may result in the low power mode not being entered correctly.

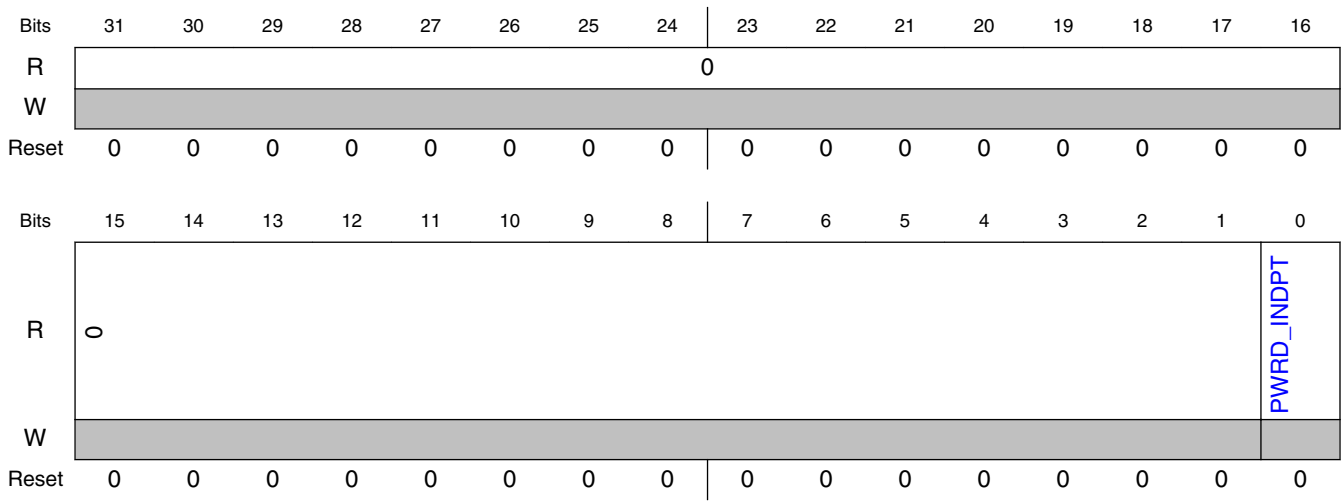
| PARAM | 4h |

## 32.4.1.3.2 Diagram



## 32.4.1.3.3 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>PWRD_INDPT | Power Domains Independent<br>When set, means each core is able to enter power modes independently of the other. When clear, means certain dependancies are enforced by the MSMC before each core is able to enter some power modes. See "Power mode transitions" section for detailed requirements for each core to enter a power mode. |

# 32.4.1.4 Power Mode Protection register (PMPROT)

### 32.4.1.4.1 Offset

| Register | Offset |
|---|---|
| PMPROT | 8h |

### 32.4.1.4.2 Function

This register provides protection for entry into any run or stop power mode. The enabling of the run or stop mode occurs by configuring the Power Mode Control register (PMCTRL).

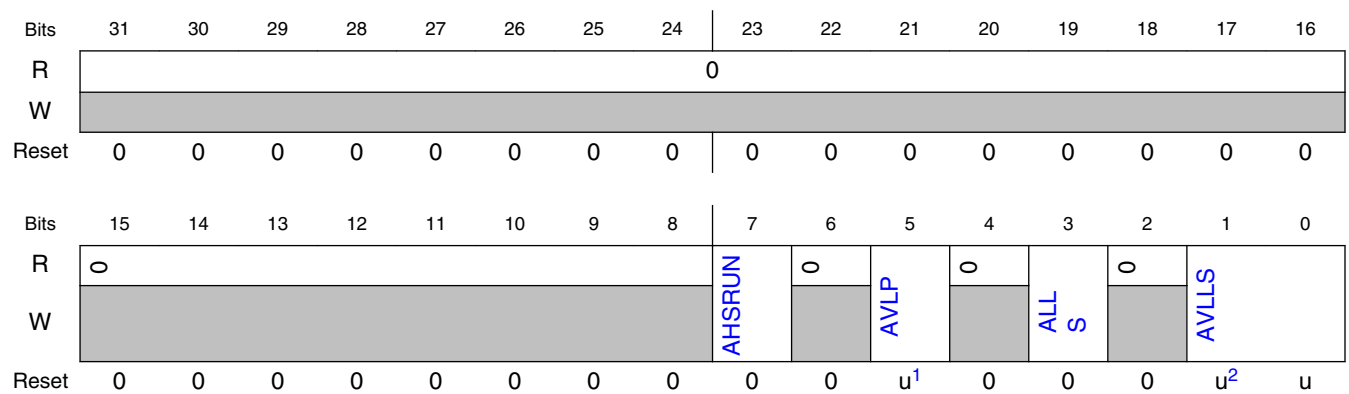
The PMPROT register can be written only once after any system reset.

If a core is configured for a disallowed or reserved power mode, the core remains in its current power mode. For example, if the core is in normal RUN mode and AVLP is 0, an attempt to enter VLPR mode using PMCTRL[RUNM] is blocked and PMCTRL[RUNM] remains 00b, indicating the core is still in Normal Run mode.

**NOTE**

This register is reset on Chip Reset and by reset sources that trigger Chip Reset (see the Reset section for more information).

### 32.4.1.4.3 Diagram



1. The reset value is 1 if booting in VLPR mode is supported and configured, otherwise it is 0.
2. The reset value is 10 on VLLS wakeup, otherwise it is 00.

### 32.4.1.4.4 Fields

| Field | Function |
|---|---|
| 31-8 | Reserved |

*Table continues on the next page...*

## 32.4.1.5 Power Mode Control register (PMCTRL)

### 32.4.1.5.1 Offset

| Register | Offset |
|---|---|
| PMCTRL | 10h |

### 32.4.1.5.2 Function

The PMCTRL register controls entry into low-power Run and Stop modes, provided that the selected power mode is allowed via an appropriate setting of the protection (PMPROT) register.

**NOTE**

This register is reset on Chip POR and by reset types that trigger Chip POR. See the Reset section details for more information.

### 32.4.1.5.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 32.4.1.7 System Reset Status (SRS)

### 32.4.1.7.1 Offset

| Register | Offset |
|---|---|
| SRS | 20h |

### 32.4.1.7.2 Function

This register includes read-only status flags to indicate the source of the most recent reset.

**NOTE**

The reset state of this register depends on the reset source:

- POR = 0x0000_0006
- LVD = 0x0000_0004
- VLLS Wakeup = 0x0000_0001
- VLLS Reset Wakeup = 0x0000_0111

## 32.4.1.10 System Reset Interrupt Enable (SRIE)

### 32.4.1.10.1 Offset

| Register | Offset |
|---|---|
| SRIE | 2Ch |

### 32.4.1.10.2 Function

This registers delays the assertion of a system reset for between 9 and 10 LPO clock cycles while an interrupt is generated. This allows software to perform a graceful shutdown or to abort the system reset provided the pending reset source is cleared by resetting the source of the reset and then clearing the pending flag. A Chip POR or fatal reset source cannot be delayed by this feature. The SRS will only update after the system reset occurs.

## 32.4.2 SMC1 register descriptions

Different MSMC registers reset on different reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

**NOTE**

The MSMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

**NOTE**

Before executing the WFI instruction, the last register written to must be read back. This ensures that all register writes associated with setting up the low power mode being entered have completed before the MCU enters the low power mode. Failure to do this may result in the low power mode not being entered correctly.

### 32.4.2.1 SMC1 Memory map

SMC1 base address: 4102_0000h

| Offset | Register | Width (In bits) | Access | Reset value |

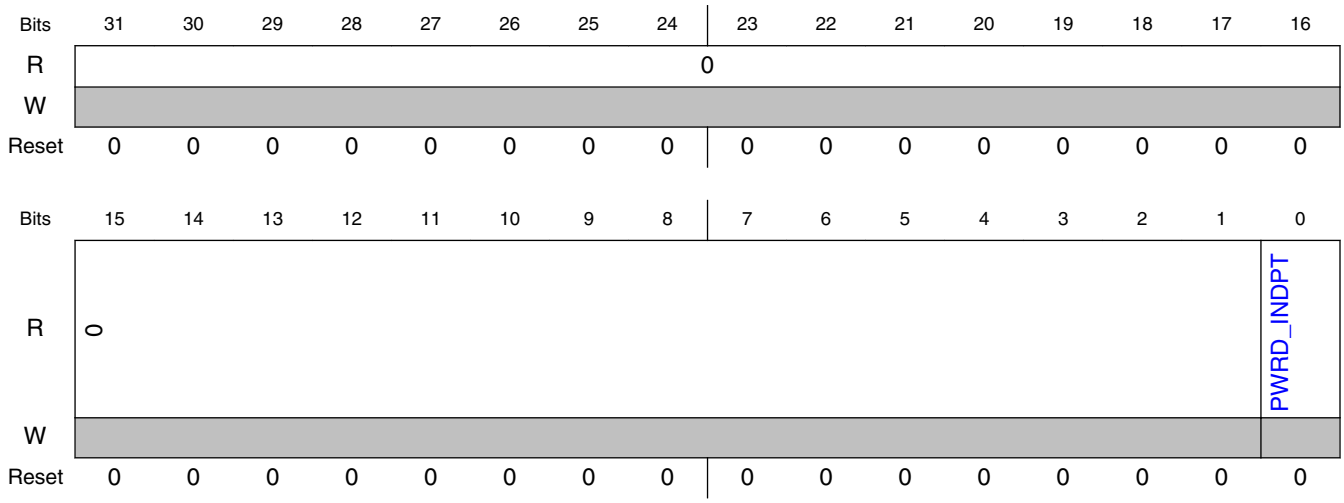
| PARAM | 4h |

#### 32.4.2.3.2 Diagram



#### 32.4.2.3.3 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>PWRD_INDPT | Power Domains Independent<br>When set, means each core is able to enter power modes independently of the other. When clear, means certain dependancies are enforced by the MSMC before each core is able to enter some power modes. See "Power mode transitions" section for detailed requirements for each core to enter a power mode. |

### 32.4.2.4 Power Mode Protection register (PMPROT)

#### 32.4.2.4.1 Offset

| Register | Offset |
|---|---|
| PMPROT | 8h |

#### 32.4.2.4.2 Function

This register provides protection for entry into any run or stop power mode. The enabling of the run or stop mode occurs by configuring the Power Mode Control register (PMCTRL).

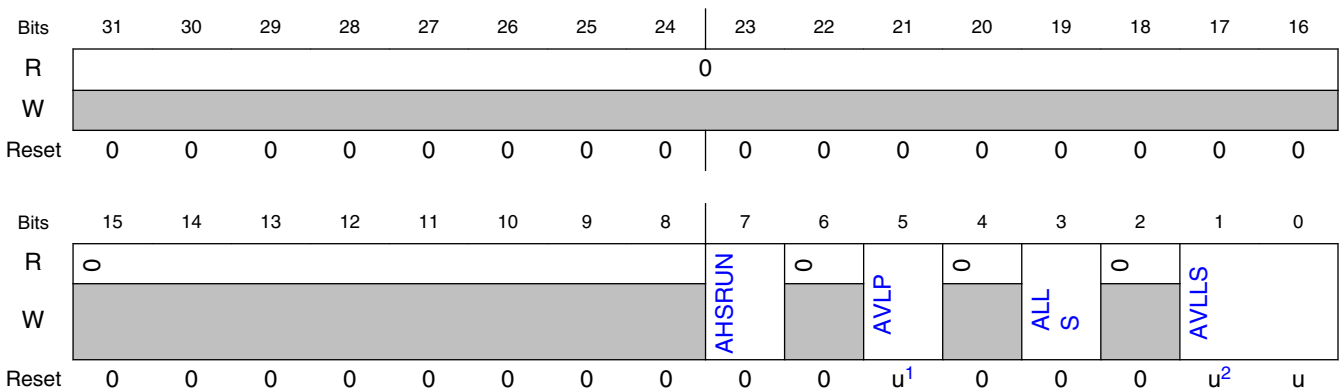
The PMPROT register can be written only once after any system reset.

If a core is configured for a disallowed or reserved power mode, the core remains in its current power mode. For example, if the core is in normal RUN mode and AVLP is 0, an attempt to enter VLPR mode using PMCTRL[RUNM] is blocked and PMCTRL[RUNM] remains 00b, indicating the core is still in Normal Run mode.

**NOTE**

This register is reset on Chip Reset and by reset sources that trigger Chip Reset (see the Reset section for more information).

### 32.4.2.4.3 Diagram



1. The reset value is 1 if booting in VLPR mode is supported and configured, otherwise it is 0.
2. The reset value is 10 on VLLS wakeup, otherwise it is 00.

### 32.4.2.4.4 Fields

| Field | Function |

## 32.4.2.5 Power Mode Control register (PMCTRL)

### 32.4.2.5.1 Offset

| Register | Offset |
|---|---|
| PMCTRL | 10h |

### 32.4.2.5.2 Function

The PMCTRL register controls entry into low-power Run and Stop modes, provided that the selected power mode is allowed via an appropriate setting of the protection (PMPROT) register.

**NOTE**

This register is reset on Chip POR and by reset types that trigger Chip POR. See the Reset section details for more information.

## 32.4.2.5.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | 0 | 0 | | | | | | PSTOPO | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | 0 | RUNM | | 0 | | | | | STOPM | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | u[1] | u | 0 | 0 | 0 | 0 | 0 | u[2] | u | u |

1. The reset value is 10 if booting in VLPR mode is supported and configured on this device, otherwise it is 00.
2. The reset value is 100 on VLLS wakeup , otherwise it is 000.

## 32.4.2.5.4 Fields

| Field | Function |
|---|---|
| 31-25<br>— | Reserved |
| 24<br>— | Reserved |
| 23-18<br>— | Reserved |
| 17-16<br>PSTOPO | Partial Stop Option<br>These bits control whether a Partial Stop mode is entered when STOPM=STOP. When entering a Partial Stop mode from RUN mode, the PMC and SCG remain fully powered, allowing the device to wakeup almost instantaneously at the expense of higher power consumption. In PSTOP2, only system clocks are gated allowing peripherals running on bus clock to remain fully functional. In PSTOP1, both system and bus clocks are gated.<br>00b - STOP - Normal Stop mode<br>01b - PSTOP1 - Partial Stop with system and bus clock disabled<br>10b - PSTOP2 - Partial Stop with system clock disabled and bus clock enabled<br>11b - PSTOP3 - Partial Stop with system clock enabled and bus clock enabled |

Writes to this field are blocked if the protection level has not been enabled using the PMPROT register. After any system reset, this field is cleared by hardware on any successful write to the PMPROT register.<br>**NOTE:** When set to STOP, the PSTOPO bits can be used to select a Partial Stop mode if desired.<br>000b - Normal Stop (STOP)<br>001b - Reserved<br>010b - Very-Low-Power Stop (VLPS)<br>011b - Low-Leakage Stop (LLS)<br>100b - Very-Low-Leakage Stop with SRAM retention(VLLS2/3)<br>101b - Reserved<br>110b - Very-Low-Leakage Stop without SRAM retention (VLLS0/1)<br>111b - Reserved |

## 32.4.2.6 Power Mode Status register (PMSTAT)

### 32.4.2.6.1 Offset

| Register | Offset |
|---|---|
| PMSTAT | 18h |

### 32.4.2.6.2 Function

PMSTAT is a read-only, one-hot register which indicates the current power mode of the system.

### 32.4.2.6.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

1. The reset value is 0x04 if booting in VLPR mode is supported and configured on this device, otherwise it is 0x01.

### 32.4.2.6.4 Fields

| Field | Function |
|---|---|
| 31-24<br>STOPSTAT | Stop Entry Status<br>Returns the result of the previous stop mode entry, write 0x01 to clear this field (all other writes are ignored).<br>[0] - When set, indicates a Stop mode entry since this field was last cleared.<br>[1] - When set, indicates the system bus masters acknowledged the Stop mode entry.<br>[2] - When set, indicates the system clock peripherals acknowledged the Stop mode entry.<br>[3] - When set, indicates the bus clock peripherals acknowledged the Stop mode entry.<br>[4] - When set, indicates the slow clock peripherals acknowledged the Stop mode entry.<br>[5] - When set, indicates Stop mode entry completed.<br>[6] - Reserved.<br>[7] - Reserved. |
| 23-8<br>— | Reserved |
| 7-0<br>PMSTAT | Power Mode Status<br>**NOTE:** When debug is enabled, the PMSTAT will not update to STOP or VLPS<br>**NOTE:** When a Partial Stop Option is enabled, the PMSTAT will not update to STOP or VLPS<br>**NOTE:** If booting into VLPR mode is supported and configured on this device, the PMSTAT will update to VLPR shortly after the reset sequence is complete.<br>00000001b - Current power mode is RUN.<br>00000010b - Current power mode is any STOP mode.<br>00000100b - Current power mode is VLPR.<br>10000000b - Current power mode is HSRUN |

## 32.4.2.7 System Reset Status (SRS)

### 32.4.2.7.1 Offset

| Register | Offset |
|---|---|
| SRS | 20h |

### 32.4.2.7.2 Function

This register includes read-only status flags to indicate the source of the most recent reset.

**NOTE**

The reset state of this register depends on the reset source:

- POR = 0x0000_0006

- LVD = 0x0000_0004
- VLLS Wakeup = 0x0000_0001
- VLLS Reset Wakeup = 0x0000_0111

### 32.4.2.7.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 27-25<br>— | Reserved |
| 24<br>— | Reserved |
| 23-18<br>— | Reserved |
| 17 | Reserved |

*Table continues on the next page...*

| Field | Function |
|---|---|
| — | |
| 16<br>CORE0 | Core0 System Reset<br>Indicates the reset source was generated by a Core0 specific reset.<br>0b - Reset not generated from Core0 system reset source.<br>1b - Reset generated from Core0 system reset source. |
| 15<br>LOCKUP | Lockup Reset<br>Indicates a reset has been caused by the ARM core indication of a LOCKUP event.<br>0b - Reset not generated by core lockup or exception.<br>1b - Reset generated by core lockup or exception. |
| 14<br>SW | Software Reset<br>Indicates a reset has been caused by a software reset request from the ARM core (SYSRESETREQ).<br>0b - Reset not generated by software request from core.<br>1b - Reset generated by software request from core. |
| 13<br>WDOG | Watchdog Reset<br>Indicates a reset has been caused by a WatchDog timeout.<br>0b - Reset is not generated from the WatchDog timeout.<br>1b - Reset is generated from the WatchDog timeout. |
| 12<br>SCG | SCG Reset<br>Indicates a reset has been caused by a loss-of-clock or loss-of-lock event in the SCG. This is a fatal reset source and SRAM contents are not guaranteed.<br>0b - Reset is not generated from an SCG loss of lock or loss of clock.<br>1b - Reset is generated from an SCG loss of lock or loss of clock. |
| 11<br>STOPACK | Stop Timeout Reset<br>Indicates a reset has been caused by a timeout in the Stop mode entry logic. This timeout is generated if a peripheral does not acknowledge entry into any Stop mode within approximately one second.<br>0b - Reset not generated by Stop Controller Timeout.<br>1b - Reset generated by Stop Controller Timeout. |
| 10<br>RSTACK | Reset Timeout<br>Indicates a reset has been caused by a timeout in the system reset generaton logic. This is a fatal reset source and SRAM contents are not guaranteed.<br>0b - Reset not generated from Reset Controller Timeout.<br>1b - Reset generated from Reset Controller Timeout. |
| 9<br>MDM | MDM Reset<br>Indicates a reset has been caused by a reset request from the Miscellaneous Debug Module (MDM).<br>0b - Reset was not generated from the MDM reset request.<br>1b - Reset was generated from the MDM reset request. |
| 8<br>PIN | Pin Reset<br>Indicates a reset has been caused by external assertion of the RESET_b pin.<br>0b - Reset was not generated from the assertion of RESET_B pin.<br>1b - Reset was generated from the assertion of RESET_B pin. |
| 7<br>CORE | Core Reset<br>Indicates the last reset was a reset that only reset the core.<br>0b - Reset source was not core only reset.<br>1b - Reset source was core reset and reset the core only. |
| 6<br>— | Reserved |
| 5 | Fatal Reset |

*Table continues on the next page...*

| Field | Function |
|---|---|
| FATAL | Fatal Reset will assert if the system reset source was fatal. SRAM contents cannot be guaranteed following a fatal reset source.<br>0b - Reset was not generated by a fatal reset source.<br>1b - Reset was generated by a fatal reset source. |
| 4<br>WARM | Warm Reset<br>Warm Reset flag will assert whenever any of the system reset sources in this register assert (SRS[31:8]).<br>0b - Reset not generated by Warm Reset source.<br>1b - Reset generated by Warm Reset source. |
| 3<br>HVD | HVD Reset<br>Indicates a reset has been caused by a High Voltage Detect. SRAM contents cannot be guaranteed following a HVD reset source.<br>0b - Reset not generated by HVD.<br>1b - Reset generated by HVD. |
| 2<br>LVD | LVD Reset<br>Indicates a reset has been caused by a Low Voltage Detect. SRAM contents cannot be guaranteed following a LVD reset source.<br>0b - Reset not generated by LVD.<br>1b - Reset generated by LVD. |
| 1<br>POR | POR Reset<br>Indicates a reset has been caused by Power On Reset detection logic. SRAM contents cannot be guaranteed following a POR reset source.<br>0b - Reset not generated by POR.<br>1b - Reset generated by POR. |
| 0<br>WAKEUP | Wakeup Reset<br>Indicates a reset has been caused by a wakeup from VLLS mode.<br>0b - Reset not generated by wakeup from VLLS mode.<br>1b - Reset generated by wakeup from VLLS mode. |

## 32.4.2.8 Sticky System Reset Status (SSRS)

### 32.4.2.8.1 Offset

| Register | Offset |
|---|---|
| SSRS | 28h |

### 32.4.2.8.2 Function

The SSRS are only reset on POR/LVD/HVD/WAKEUP and remain set until cleared by software. The SSRS stores all system reset sources that have generated a system reset, since the last POR/LVD/HVD/WAKEUP, that have not been cleared by software. The SSRS does not update following a core software reset.

## 32.4.2.9 System Reset Interrupt Enable (SRIE)

### 32.4.2.9.1 Offset

| Register | Offset |
|---|---|
| SRIE | 2Ch |

### 32.4.2.9.2 Function

This registers delays the assertion of a system reset for between 9 and 10 LPO clock cycles while an interrupt is generated. This allows software to perform a graceful shutdown or to abort the system reset provided the pending reset source is cleared by resetting the source of the reset and then clearing the pending flag. A Chip POR or fatal reset source cannot be delayed by this feature. The SRS will only update after the system reset occurs.

## 32.5 Functional description

This section provides a complete functional description of the block.

### 32.5.1 Power mode transitions

A figure showing the power mode state transitions and a table defining triggers for the various state transitions can be found here.

The following figure shows the power mode state transitions available to each core. Any chip reset will initially bring both cores back to a RUN state. An exception is a POR event which could force core 1 to be disabled until re-enabled by core 0. In order to minimize peak power consumption, certain devices may also support reset to VLPR via nonvolatile configuration settings (e.g. Flash IFR or fuse), causing the MSMC to begin transitioning the MCU into VLPR mode during the reset recovery sequence.

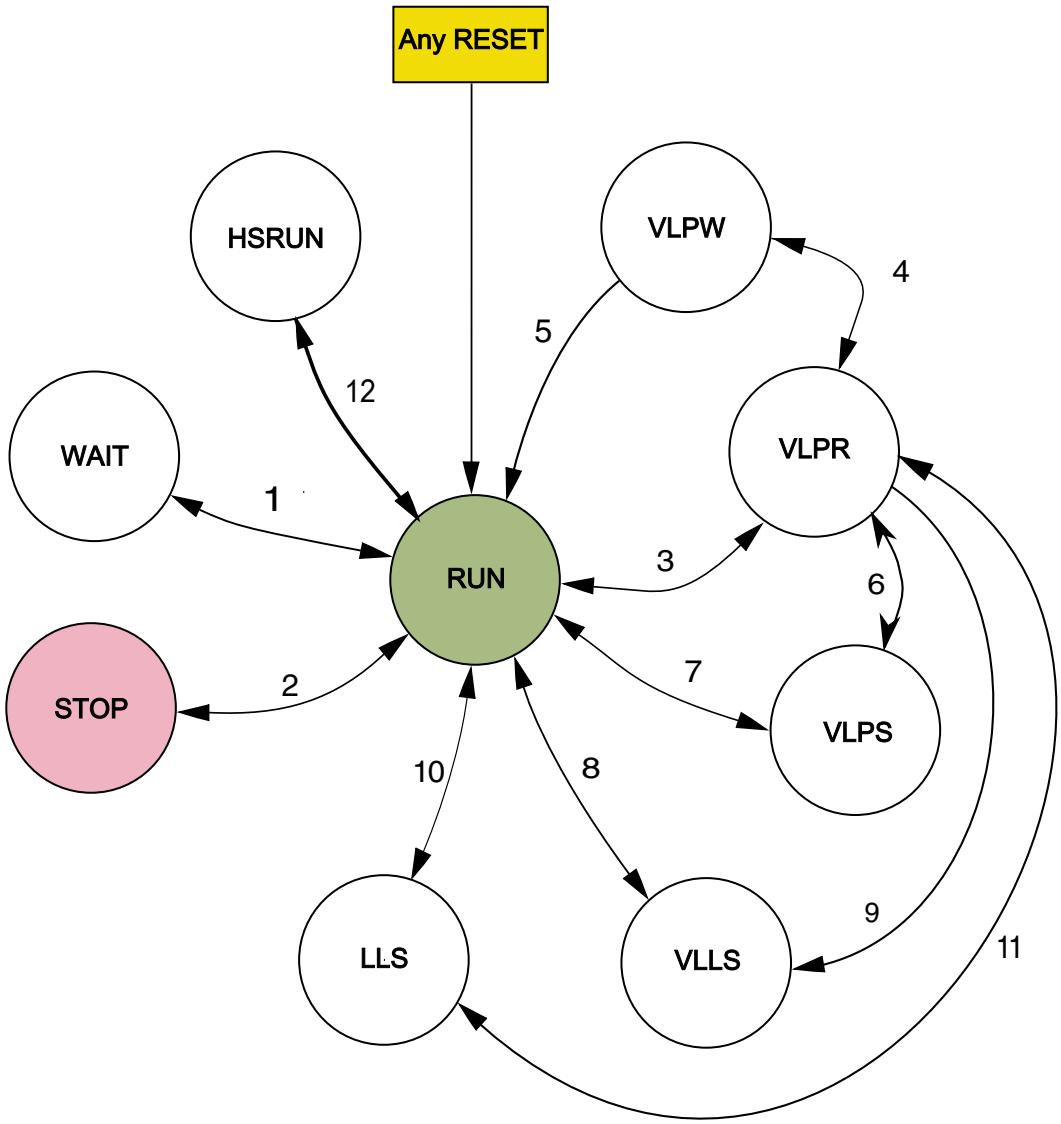

**Figure 32-2. Power mode state diagram**

The MSMC allows core 1 to enter/exit stop modes independently of core 0. For core 0 stop modes and the run mode of both cores, certain dependencies must be resolved before the MSMC will allow a power mode entry/exit to execute. As a general rule, the run mode for both cores will the highest power mode between the MSMC0 and MSMC1 RUNM settings. Likewise, the stop mode of core 0 will be the highest power mode between MSMC0 and MSMC1 STOPM settings, whereas the stop mode of core 1 will be

simply equal to the MSMC1 STOPM setting. The following tables describes in further detail the resulting power mode each core will receive for all combinations of STOPM and RUNM settings for both cores.

**Table 32-2. Core 0/1 RUNM result**

| MSMC0 PMCTRL[RUNM] setting | MSMC1 PMCTRL[RUNM] setting | Core 0 RUNM result[1] | Core 1 RUNM result |
|---|---|---|---|
| VLPR | VLPR | VLPR[2] | |
| | RUN | RUN | |
| | HSRUN | HSRUN | |
| RUN | VLPR/RUN | RUN | |
| | HSRUN | HSRUN | |
| HSRUN | VLPR/RUN/HSRUN | HSRUN | |

1. If Core 1 is disabled, the MSMC1 RUNM setting is ignored and Core 0 RUNM is simply equal to the MSMC0 RUNM setting
2. If a core has entered VLPS/LLS/VLLS mode with RUNM=RUN, VLPR mode can still be entered if the other core sets its RUNM=VLPR i.e. the RUNM field from a core in VLPS/LLS/VLLS mode is bypassed. Once the stopped core receives a wakeup event, the system will transition back to RUN mode.

**Table 32-3. Core0/1 STOPM result**

| MSMC0 STOPM setting | MSMC1 STOPM setting | Core 0 STOPM result[1] | Core 1 STOPM result |
|---|---|---|---|
| STOP/VLPS/LLS/VLLS | STOP | STOP | STOP |
| STOP | VLPS | STOP | VLPS |
| VLPS/LLS/VLLS | | VLPS | |
| STOP | LLS | STOP | LLS |
| VLPS | | VLPS | |
| LLS/VLLS | | LLS | |
| STOP | VLLS | STOP | VLLS |
| VLPS | | VLPS | |
| LLS | | LLS | |
| VLLS | | VLLS | |

1. If Core 1 is disabled, the MSMC1 STOPM setting is ignored and Core 0 STOPM is simply equal to the MSMC0 STOPM setting

The following table defines the trigger conditions required for each core to transition into or out of the power modes illustrated in the power mode state diagram above.

**Table 32-4. Power mode transition triggers for Core 0**

| Transition # | From | To | Trigger conditions[1] |
|---|---|---|---|
| 1 | RUN | WAIT | Sleep-now or sleep-on-exit executed with SLEEPDEEP=0 by Core 0.<br>See note.[2] |
| | WAIT | RUN | Core 0 Interrupt or Reset. |

*Table continues on the next page...*

## Table 32-4. Power mode transition triggers for Core 0 (continued)

| Transition # | From | To | Trigger conditions[1] |
|---|---|---|---|
| 2 | RUN | STOP | Core 0 STOPM=STOP[3] and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by both Core 0 and Core 1.<br>See note.[2] |
| | STOP | RUN | Core 0 Interrupt or Reset |
| 3 | RUN | VLPR | Core 0 RUNM=VLPR.[4] |
| | VLPR | RUN | Core 0 RUNM=RUN or Reset. |
| 4 | VLPR | VLPW | Sleep-now or sleep-on-exit executed with SLEEPDEEP=0 by Core 0.<br>See note.[2] |
| | VLPW | VLPR | Core 0 Interrupt. |
| 5 | VLPW | RUN | Reset. |
| 6 | VLPR | VLPS | Core 0 STOPM=VLPS/STOP and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by both Core 0 and Core 1.<br>See note.[2] |
| | VLPS | VLPR | Interrupt and VLPS mode was entered directly from VLPR. |
| 7 | RUN | VLPS | Core 0 STOPM=VLPS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by both Core 0 and Core 1.<br>See note.[2] |
| | VLPS | RUN | Interrupt and VLPS mode was entered directly from RUN or<br>Reset. |
| 8 | RUN | VLLS | Core 0 STOPM=VLLS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by both Core 0 and Core 1.<br>See note.[2] |
| | VLLS | RUN | LLWU0 wakeup, NMI or RESET_B pin. |
| 9 | VLPR | VLLS | Core 0 STOPM=VLLS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by both Core 0 and Core 1.<br>See note.[2] |
| 10 | RUN | LLS | Core 0 STOPM=LLS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by both Core 0 and Core 1.<br>See note.[2] |
| | LLS | RUN | LLWU0 wakeup, NMI pin (and LLS mode was entered directly from RUN) or<br>RESET_B pin. |
| 11 | VLPR | LLS | Core 0 STOPM=LLS and |

*Table continues on the next page...*

## Table 32-4. Power mode transition triggers for Core 0 (continued)

| Transition # | From | To | Trigger conditions[1] |
|---|---|---|---|
| | | | Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by both Core 0 and Core 1.<br>See note.[2] |
| | LLS | VLPR | LLWU0 wakeup or NMI pin (and LLS mode was entered directly from VLPR). |
| 12 | RUN | HSRUN | Core 0 RUNM=HSRUN |
| | HSRUN | RUN | Core 0 RUNM=RUN or Reset. |

1. "Core 0 STOPM" and "Core 0 RUNM" referenced in this table is the resulting setting after taking both MSMC0 and MSMC1 STOPM/RUNM settings into account (see previous tables).
2. If debug is enabled, the core clock remains to support debug.
3. If PMCTRL[STOPM]=STOP and PMCTRL[PSTOPO]=01 or 10 for either MSMC0 or MSMC1, then only a Partial Stop mode is entered instead of STOP
4. In order to limit peak current, certain devices allow PMPROT[AVLP] and PMCTRL[RUNM] bits to be set on any Reset via nonvolatile configuration settings (e.g. Flash IFR or fuse), causing the MSMC to transition the core from RUN->VLPR during the reset recovery sequence.

## Table 32-5. Power mode transition triggers for Core 1

| Transition # | From | To | Trigger conditions |
|---|---|---|---|
| 1 | RUN | WAIT | Sleep-now or sleep-on-exit executed with SLEEPDEEP=0 by Core 1.<br>See note.[1] |
| | WAIT | RUN | Core 1 Interrupt or Reset. |
| 2 | RUN | STOP | Core 1 STOPM=STOP[2] and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1.<br>See note.[1] |
| | STOP | RUN | Core 1 Interrupt or Reset |
| 3 | RUN | VLPR | Core 1 RUNM=VLPR.[3] |
| | VLPR | RUN | Core 1 RUNM=RUN or Reset. |
| 4 | VLPR | VLPW | Sleep-now or sleep-on-exit executed with SLEEPDEEP=0 by Core 1.<br>See note.[1] |
| | VLPW | VLPR | Core 1 Interrupt. |
| 5 | VLPW | RUN | Reset. |
| 6 | VLPR | VLPS | Core 1 STOPM=VLPS/STOP and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1.<br>See note.[1] |
| | VLPS | VLPR | Interrupt and VLPS mode was entered directly from VLPR. |
| 7 | RUN | VLPS | Core 1 STOPM=VLPS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1. |

*Table continues on the next page...*

**Table 32-5. Power mode transition triggers for Core 1 (continued)**

| Transition # | From | To | Trigger conditions |
|---|---|---|---|
| | | | See note.[1] |
| | VLPS | RUN | Interrupt and VLPS mode was entered directly from RUN or Reset. |
| 8 | RUN | VLLS | Core 1 STOPM=VLLS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1.<br>See note.[1] |
| | VLLS | RUN | LLWU1 wakeup, NMI or RESET_B pin. |
| 9 | VLPR | VLLS | Core 1 STOPM=VLLS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1.<br>See note.[1] |
| 10 | RUN | LLS | Core 1 STOPM=LLS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1.<br>See note.[1] |
| | LLS | RUN | LLWU1 wakeup, NMI pin (and LLS mode was entered directly from RUN) or<br>RESET_B pin. |
| 11 | VLPR | LLS | Core 1 STOPM=LLS and<br>Sleep-now or sleep-on-exit with SLEEPDEEP=1 executed by Core 1.<br>See note.[1] |
| | LLS | VLPR | LLWU1 wakeup or NMI pin (and LLS mode was entered directly from VLPR). |
| 12 | RUN | HSRUN | Core 1 RUNM=HSRUN |
| | HSRUN | RUN | Core 1 RUNM=RUN or Reset. |

1. If debug is enabled, the core clock remains to support debug.
2. If PMCTRL[STOPM]=STOP and PMCTRL[PSTOPO]=01 or 10 for MSMC1, then only a Partial Stop mode is entered instead of STOP
3. In order to limit peak current, certain devices allow PMPROT[AVLP] and PMCTRL[RUNM] bits to be set on any Reset via nonvolatile configuration settings (e.g. Flash IFR or fuse), causing the MSMC to transition the core from RUN->VLPR during the reset recovery sequence.

## 32.5.2 Run modes

The MSMC supports the following run modes:

- Normal Run (RUN)
- Very Low-Power Run (VLPR)
- High Speed Run (HSRUN)

#### 32.5.2.1 Run (RUN) mode

This is the normal operating mode for the device.

This mode is selected after any reset. In order to reduce peak power consumption, on certain devices, the MSMC can begin transitioning a core into VLPR mode during the reset recovery sequence if it has been configured for VLPR boot mode via nonvolatile configuration settings (e.g. Flash IFR or fuse). When the ARM processor exits reset, it sets up the stack, program counter (PC), and link register (LR):

- The processor reads the start SP (SP_main) from vector-table offset 0x000
- The processor reads the start PC from vector-table offset 0x004
- LR is set to 0xFFFF_FFFF.

To reduce power in this mode, clocks to unused modules can be disabled using their corresponding clock gating control bits in the Peripheral Clock Control modules (see PCC chapter) or compute operation can be enabled via the Miscellaneous Control Module (see MCM chapter).

#### 32.5.2.2 Very Low Power Run (VLPR) mode

VLPR mode is designed to provide the lowest power operating mode to the core at a reduced frequency. See the PMC chapter for additional power options available in this mode. Before entering this mode, the following conditions must be met:

- The maximum frequencies of the system, bus, flash, and core are restricted. See the Power Management details about which frequencies are supported.
- Mode protection must be set to allow VLP modes, that is, PMPROT[AVLP] is 1.
- PMCTRL[RUNM] must be set to VLPR in both SMC0 and SMC1 or, alternatively, one core is in VLPS/LLS/VLLS mode while the other core sets its PMCTRL[RUNM] to VLPR.
- Flash programming/erasing is not allowed.

**NOTE**

While in VLPR mode, do not modify the clock source in the SCG module or any clock divider registers. Module clock enables in the PCC can be set, however should only be cleared one at a time to limit load transitions.

To reenter Normal Run mode, clear PMCTRL[RUNM] in either SMC0 or SMC1. PMSTAT is a read-only status register that can be used to determine when the system has completed an exit to RUN mode. When PMSTAT=RUN, the system can run at full speed in any clock mode.

Any reset always causes an exit from VLPR and returns a core to RUN mode after the exiting its reset flow. Alternatively, certain devices can be configured for VLPR boot in which the MSMC will initiate VLPR entry during the reset flow.

To further reduce power in this mode, clocks to unused modules can be disabled using their corresponding clock gating control bits in the Peripheral Clock Control modules (see PCC chapter) or compute operation can be enabled via the Miscellaneous Control Module (see MCM chapter).

#### 32.5.2.3 High Speed Run (HSRUN) mode

HSRUN mode is designed to provide the highest performance mode to the core at the fastest supported frequency. See the PMC chapter for additional power options available in this mode. Before entering this mode, the following conditions must be met:

- The maximum allowable change in frequency of the system, bus, flash or core clocks is restricted to x2.
- Mode protection must be set to allow HSRUN modes, that is, PMPROT[AHSRUN] is 1.
- PMCTRL[RUNM] must be set to HSRUN in either SMC0 or SMC1.
- Flash programming/erasing is not allowed. (Not all devices contain on-chip flash.)
- Stop mode entry is not allowed.

To reenter normal RUN mode, clear the RUNM register in both the SMC0 and SMC1. PMSTAT is a read-only status register that can be used to determine when the system has completed an exit to RUN mode. Any reset will also clear RUNM and cause the core to exit to normal RUN mode after exiting its reset flow.

### 32.5.3 Wait modes

The MSMC supports the following wait modes.

- Wait (WAIT)
- Very-Low Power Wait (VLPW)

#### 32.5.3.1 Wait (WAIT) mode

WAIT mode is designed to allow a core to enter a static, low power state with instant wakeup times, while still allowing peripherals to operate with full functionality. WAIT mode is entered when the ARM core enters the Sleep-Now or Sleep-On-Exit mode while SLEEDEEP is cleared. The core enters a low-power state in which it is not clocked, but peripherals continue to be clocked provided they are enabled. Clock gating to the peripheral is enabled via the PCC module.

When an interrupt request occurs, the core exits WAIT mode and resumes processing in RUN mode, beginning with the stacking operations leading to the interrupt service routine.

A system reset will also cause an exit from WAIT mode, returning the core to normal RUN mode.

#### 32.5.3.2 Very Low Power Wait (VLPW) mode

VLPW mode is designed to allow a core to enter a static, very low power state, while still allowing peripherals to operate with full functionality at a reduced frequency. VLPW mode is entered when the ARM core enters the Sleep-Now or Sleep-On-Exit mode while SLEEPDEEP is cleared and the core is in VLPR mode. The ARM CPU enters a low-power state in which it is not clocked, but peripherals continue to be clocked provided they are enabled. Clock gating to the peripheral is enabled via the PCC module.

VLPR mode restrictions also apply to VLPW.

When an interrupt from VLPW occurs, the device returns to VLPR mode to execute the interrupt service routine.

When an interrupt request occurs, the CPU exits VLPW mode and resumes processing in VLPR mode, beginning with the stacking operations leading to the interrupt service routine.

A system reset will cause an exit from VLPW mode, returning the device to normal RUN mode.

### 32.5.4 Stop modes

The MSMC supports a wide variety of stop modes for each core ranging from:

- a stopped core, with all I/O, logic, and memory states retained, and certain asynchronous mode peripherals operating

to:

- a powered down core, with only I/O and a small register file retained, very few asynchronous mode peripherals operating

The choice of stop mode depends upon the user's application, and how power usage and state retention versus functional needs and recovery time may be traded off.

The stop mode for a core can be selected by setting the appropriate fields in PMPROT and PMCTRL register fields in SMC0 and SMC1 (see "Power mode transitions" section for details).

The following stop modes are supported:

- Normal Stop (STOP)
- Very Low Power Stop (VLPS)
- Low Leakage Stop (LLS)
- Very Low Leakage Stop (VLLS)

#### 32.5.4.1 Stop (STOP) mode

STOP mode is designed to allow a core and its system to enter a static, low power state with relatively fast wakeup times, while still allowing peripherals to operate with full asynchronous functionality. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in STOP mode and see the PMC chapter for additional power options available in this mode.

A core can enter STOP mode by executing Sleep-Now or Sleep-On-Exit with SLEEPDEEP=1 while the core's STOPM equates to STOP (see "Power mode transitions" section for details). Note that a core's PSTOPO field can be set to enable a partial stop mode, allowing instantaneous wakeup at the expense of power consumption.

A module capable of providing an asynchronous interrupt can trigger an exit from STOP mode and return the device to normal RUN mode. When an interrupt request occurs, the core exits STOP mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

A system reset will also cause an exit from STOP mode, returning the device to normal RUN mode.

### 32.5.4.2 Very Low Power Stop (VLPS) mode

VLPS mode is designed to allow a core and its system to enter a static, very low power state with relatively fast wakeup times, while still allowing peripherals to operate with limited asynchronous functionality. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in VLPS mode and see the PMC chapter for additional power options available in this mode.

A core can enter VLPS mode by executing Sleep-Now or Sleep-On-Exit with SLEEPDEEP=1 while the core's STOPM either equates to VLPS or equates to STOP with RUNM=VLPR (see "Power mode transitions" section for details).

A module capable of providing an asynchronous interrupt can trigger an exit from VLPS mode and return the device to the run mode from which VLPS was entered (i.e. RUN or VLPR mode). When an interrupt request occurs, the core exits VLPS mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

A system reset will also cause an exit from VLPS mode, returning the device to normal RUN mode.

### 32.5.4.3 Low Leakage Stop (LLS) mode

LLS mode is designed to allow a core and its system to enter a low leakage, power gated state with relatively fast wakeup times, while still retaining the state of all logic. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in LLS mode and see the PMC chapter for additional power options available in this mode.

A core can enter LLS mode by executing Sleep-Now or Sleep-On-Exit with SLEEPDEEP=1 while the core's STOPM equates to LLS (see "Power mode transitions" section for details).

Before entering LLS mode, the user should configure the Low Leakage Wake-up unit (LLWU) to enable the desired pins and/or peripherals as wake-up sources . The available wake-up sources to the LLWU are detailed in the chip configuration details for this device.

Once configured, the LLWU can trigger an exit from LLS mode and return the device to the run mode from which LLS was entered (i.e. RUN or VLPR mode) with a pending LLWU interrupt. When an LLWU wakeup request occurs, the core exits LLS mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine. In the LLWU interrupt service routine (ISR), the user can read the LLWU module wake-up flags to determine the source of the wakeup.

A pin reset will also cause an exit from LLS mode, returning the device to normal RUN mode. When exiting LLS via the reset pin, the PIN and WAKEUP bits within the SRS register will be set.

**NOTE**

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully recover from LLS mode after an LLWU wakeup event.

### 32.5.4.4 Very Low Leakage Stop (VLLS) modes

VLLS mode is designed to allow a core and its system to enter a very low leakage, power gated state. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in VLLS mode and see the PMC chapter for additional power options available in this mode.

A core can enter VLLS mode by executing Sleep-Now or Sleep-On-Exit with SLEEPDEEP=1 while the core's STOPM equates to VLLS (see "Power mode transitions" section for details).

Before entering VLLS mode, the user should configure the Low Leakage Wake-up unit (LLWU) to enable the desired pins and/or peripherals as wake-up sources . The available wake-up sources to the LLWU are detailed in the chip configuration details for this device.

Once configured, the LLWU can trigger an exit from VLLS mode and return the device to RUN mode with a pending LLWU interrupt. When an LLWU wakeup request occurs, the core exits VLLS mode and begins executing the reset flow. In the LLWU interrupt service routine (ISR), the user can read the LLWU module wake-up flags to determine the source of the wakeup.

A pin reset will also cause an exit from VLLS mode, returning the device to normal RUN mode. When exiting VLLS via the reset pin, the PIN and WAKEUP bits within the SRS register will be set.

When entering VLLS, each I/O pin in the core's power domain is statically latched as configured before executing VLLS. Because all logic is powered off, all port and peripheral data is lost during VLLS. This data should be restored before writing the ACKISO bit in the power management module, after which I/O states are released to be driven by the restored logic.

### 32.5.5 Debug in low power modes

When the MCU is secure, the device disables/limits debugger operation. When the MCU is unsecure, the ARM debugger can assert two power-up request signals:

- System power up, via SYSPWR in the Debug Port Control/Stat register
- Debug power up, via CDBGPWRUPREQ in the Debug Port Control/Stat register

When asserted while in RUN, WAIT, VLPR, or VLPW, the MSMC drives a corresponding acknowledge for each signal i.e. CDBGPWRUPACK and CSYSPWRUPACK. When both requests are asserted, the mode controller handles attempts to enter STOP and VLPS by entering an emulated stop state. In this emulated stop state:

- all system clocks, except the core clock, are disabled,
- the debug module has access to core registers, and
- access to the on-chip peripherals is blocked.

No debug is available while the MCU is in LLS or VLLS modes. Since logic state is retained in LLS mode, all debug operation can continue after waking from LLS, even in cases where wakeup is due to a pin reset event.

Entering into a VLLS mode causes all of the debug controls and settings to be powered off. To give time to the debugger to sync with the MCU, the MDM AP Control Register includes a Very-Low-Leakage Debug Request (VLLDBGREQ) bit that is set to configure the Reset Controller Module (RCM) to hold the system in reset after the next recovery from a VLLS mode. This bit allows the debugger time to reinitialize the debug module before the debug session continues.

The MDM AP Control Register also includes a Very Low Leakage Debug Acknowledge (VLLDBGACK) bit that is set to release the ARM core being held in reset following a VLLS recovery. The debugger reinitializes all debug IP, and then asserts the VLLDBGACK control bit to allow the RCM to release the ARM core from reset and allow CPU operation to begin.

The VLLDBGACK bit is cleared by the debugger (or can be left set as is) or clears automatically due to the reset generated as part of the next VLLS recovery.

# Chapter 33
# System Power Manager (SPM)

## 33.1 Chip-specific SPM information

### 33.1.1 VDDIO voltage monitor

In this device, the VDDIO voltage monitor is connected to the VDDIO2 supply.

## 33.2 Introduction

The System Power Manager (SPM) contains and controls all three regulators including the CORE LDO, RF LDO, and DCDC. It manages switching between these regulators based on power mode change requests from MSMC or RADIO. In addition SPM module contains the POR (Power-on Reset), low voltage detect (LVD), and the high voltage detect (HVD) circuit which monitor and assure correct voltage levels.

## 33.3 Features

A list of included SPM features can be found here.

- Selectable Internal voltage regulator (CORE LDO, RF LDO, and DCDC)
- Active POR providing brown-out detect
- Low-voltage detect supporting two low-voltage trip points with four warning levels per trip point
- High-voltage detect supporting two high-voltage trip points
- Core Power Gate Control
- Radio Power Gate Control

The next figure shows the SPM module block diagram.

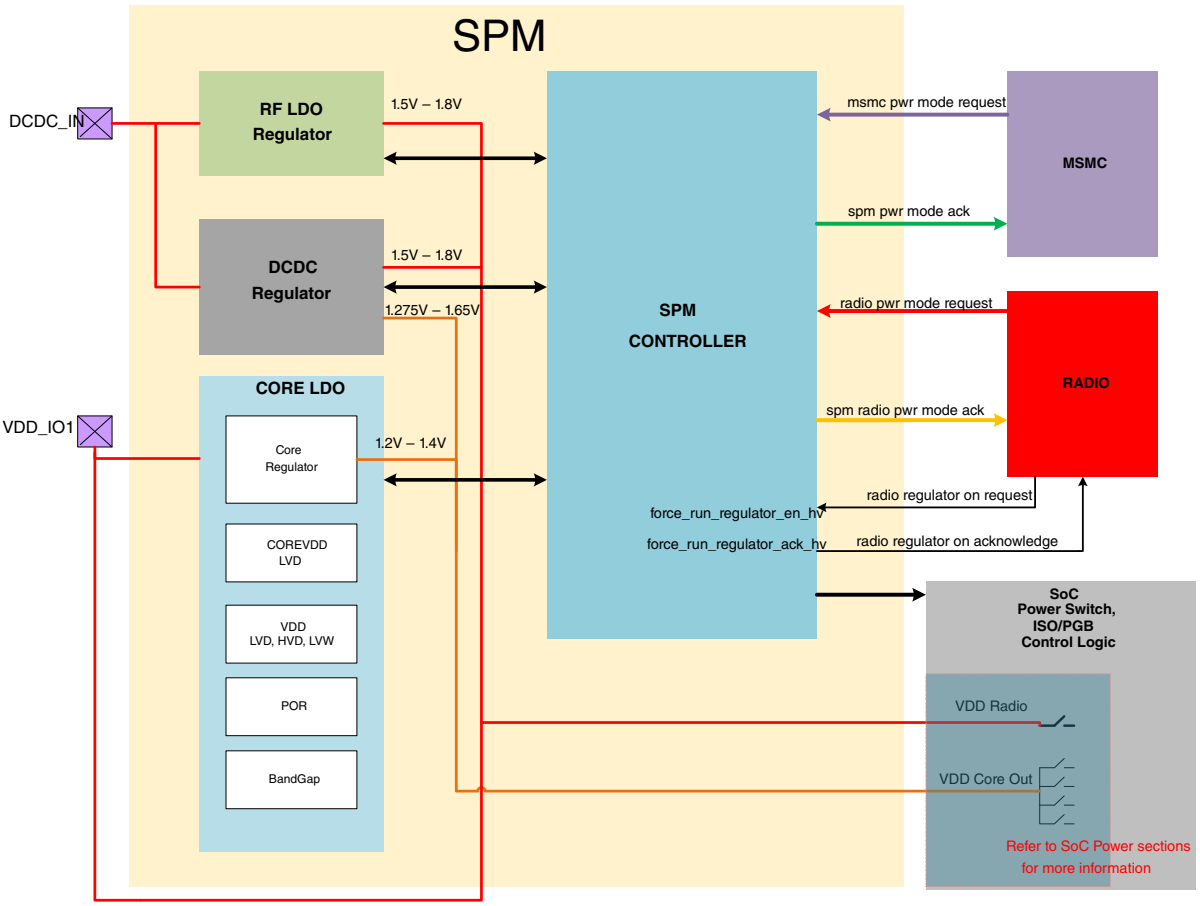

**Figure 33-1. System Power Manager (SPM) block diagram**

The next table shows description of SPM block diagram signals.

## 33.4 Memory map and register descriptions

Details about the SPM registers can be found here.

### 33.4.1 SPM register descriptions

**NOTE**

Different portions of SPM registers are reset only by particular reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

The SPM registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

**Do not write to any SPM address space that is not defined by registers below.**

### 33.4.1.1 SPM Memory map

SPM base address: 4002_8000h

| Offset | Register | Width (In bits) | Access | Reset value |

## 33.4.1.9 Low Voltage Detect Status and Control 1 register (LVDSC1)

### 33.4.1.9.1 Offset

| Register | Offset |
|---|---|
| LVDSC1 | 10Ch |

### 33.4.1.9.2 Function

This register contains status and control bits to support the low voltage detect function. This register should be written during the reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

Whether or not LVD is on in low power mode depends on MCU and RF mode arbitration and related configuration in CORELPCNFG. To protect systems that must have LVD always on, configure the Power Mode Protection (PMPROT) register of the SMC module (SMC_PMPROT) to disallow any very low power or low leakage modes from being enabled.

See the device's data sheet for the exact LVD trip voltages.

**NOTE**

The LVDV bits are reset solely on a POR Only event. The register's other bits are reset on POR or LVD event. For more information about these reset types, refer to the Reset section details.

### 33.4.1.9.3 Diagram

## 33.4.1.10 Low Voltage Detect Status and Control 2 register (LVDSC2)

### 33.4.1.10.1 Offset

| Register | Offset |
|---|---|
| LVDSC2 | 110h |

### 33.4.1.10.2 Function

This register contains status and control bits to support the low voltage warning function.

Whether or not LVD system is on in low power mode depends on MCU and RF mode arbitration and related configurations in CORELPCNFG.

See the device's data sheet for the exact LVD trip voltages.

**NOTE**

The LVW trip voltages depend on LVWV and LVDV.

**NOTE**

LVWV is reset solely on a POR Only event. The other fields of the register are reset on POR or LVD only event. For more information about these reset types, refer to the Reset section details.

## 33.4.1.10.3 Diagram

### 33.4.1.11 High Voltage Detect Status And Control 1 register (HVDSC1)

#### 33.4.1.11.1 Offset

| Register | Offset |
|---|---|
| HVDSC1 | 114h |

#### 33.4.1.11.2 Function

This register contains status and control bits to support the high voltage detect function. This register should be written during the reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

Whether or not HVD is on in low power mode depends on MCU and RF mode arbitration and related configuration in CORELPCNFG. To protect systems that must have HVD always on, configure the Power Mode Protection (PMPROT) register of the SMC module (SMC_PMPROT) to disallow any very low power or low leakage modes from being enabled.

See the device's data sheet for the exact HVD trip voltages.

**NOTE**

This register is reset solely on a POR Only event. For more information about these reset types, refer to the Reset section details.

**NOTE**

The HVDV and HVDRE field is reset solely on a POR only event. The register's other fields are reset on POR or LVD only event. For more information about these reset types, refer to the Reset section details.

## 33.5 Functional Description

### 33.5.1 Low-voltage detect (LVD) system

This device includes a system to guard against low-voltage conditions. This protects memory contents and controls MCU system states during supply voltage variations.

The system is comprised of a power-on reset (POR) circuit and a LVD circuit with a user-selectable trip voltage: high ($V_{LVDH}$) or low ($V_{LVDL}$). The trip voltage is selected by LVDSC1[LVDV].Whether or not the LVD system is on in low power modes depends on MCU and RF arbitration and configurations of CORELPCNFG.

Two flags are available to indicate the status of the low-voltage detect system:

- The Low Voltage Detect Flag in the Low Voltage Status and Control 1 Register (LVDSC1[LVDF]) operates in a level sensitive manner. LVDSC1[LVDF] is set when the supply voltage falls below the selected trip point (VLVD). LVDSC1[LVDF] is cleared by writing 1 to LVDSC1[LVDACK], but only if the internal supply has returned above the trip point; otherwise, LVDSC1[LVDF] remains set.
- The Low Voltage Warning Flag (LVWF) in the Low Voltage Status and Control 2 Register (LVDSC2[LVWF]) operates in a level sensitive manner. LVDSC2[LVWF] is set when the supply voltage falls below the selected monitor trip point (VLVW). LVDSC2[LVWF] is cleared by writing one to LVDSC2[LVWACK], but only if the internal supply has returned above the trip point; otherwise, LVDSC2[LVWF] remains set.

#### 33.5.1.1 LVD reset operation

By setting LVDSC1[LVDRE], the LVD generates a reset upon detection of a low-voltage condition. The low-voltage detection threshold is determined by LVDSC1[LVDV]. After an LVD reset occurs, the LVD system holds the MCU in reset until the supply voltage rises above this threshold. See also LVD reset settings in either the Reset Control Module or the Core Mode Control chapter for more information.

#### 33.5.1.2 LVD interrupt operation

By configuring the LVD circuit for interrupt operation (LVDSC1[LVDIE] set and LVDSC1[LVDRE] clear), LVDSC1[LVDF] is set and an LVD interrupt request occurs upon detection of a low voltage condition. LVDSC1[LVDF] is cleared by writing 1 to LVDSC1[LVDACK].

#### 33.5.1.3 Low-voltage warning (LVW) interrupt operation

The LVD system contains a Low-Voltage Warning Flag (LVWF) in the Low Voltage Detect Status and Control 2 Register to indicate that the supply voltage is approaching, but is above, the LVD voltage. The LVW also has an interrupt, which is enabled by setting LVDSC2[LVWIE]. If enabled, an LVW interrupt request occurs when LVDSC2[LVWF] is set. LVDSC2[LVWF] is cleared by writing 1 to LVDSC2[LVWACK].

LVDSC2[LVWV] selects one of the following trip voltages:

- Highest: $V_{LVWH}$
- Lowest: $V_{LVWL}$

## 33.5.2 High-voltage detect (HVD) system

This device includes a system to guard against high-voltage conditions.

The system is comprised of a HVD circuit with a user-selectable trip voltage: high ($V_{HVDH}$) or low ($V_{HVDL}$). The trip voltage is selected by HVDSC1[HVDV]. Whether or not the HVD system is on in low power modes depends on MCU and RF arbitration and configurations of CORELPCNFG.

A flag is available to indicate the status of the high-voltage detect system:

- The High Voltage Detect Flag in the High Voltage Status and Control 1 Register (HVDSC1[HVDF]) operates in a level sensitive manner. HVDSC1[HVDF] is set when the supply voltage rises above the selected trip point (VHVD). HVDSC1[HVDF] is cleared by writing 1 to HVDSC1[HVDACK], but only if the internal supply has returned below the trip point; otherwise, HVDSC1[LVDF] remains set.

### 33.5.2.1 HVD reset operation

By setting HVDSC1[HVDRE], the HVD generates a reset upon detection of a high-voltage condition. The high-voltage detection threshold is determined by HVDSC1[HVDV]. After an HVD reset occurs, the HVD system holds the MCU in reset until the supply voltage falls below this threshold. See also HVD reset settings in either the Reset Control Module or the Core Mode Control chapter for more information.

### 33.5.2.2 HVD interrupt operation

By configuring the HVD circuit for interrupt operation (HVDSC1[HVDIE] set and HVDSC1[HVDRE] clear), HVDSC1[HVDF] is set and an HVD interrupt request occurs upon detection of a high voltage condition. HVDSC1[HVDF] is cleared by writing 1 to HVDSC1[HVDACK].

### 33.5.3 Stop and VLPx Modes

The CORELPCNFG[LPSEL] and CORELPCNFG[BGEN] bits provide a means to optimize the device current consumption depending on the specific device use case when STOP or VLPx modes are being used.

The CORELPCNFG[LPSEL] bit controls the power state of the core LDO when in low power modes. The current that the core LDO can provide in the low power state is reduced but is still capable of providing significantly more current than most applications would require. Refer to the device data sheet for the maximum low power state current. It is recommended that the CORELPCNFG[LPSEL] bit remain cleared in both STOP and VLPx modes unless it is expected the core current consumption will exceed the maximum allowed low power state current. If CORELPCNFG[LPSEL] bit is to be set to one the CORELPCNFG[BGEN] bit must also be set to one.

If the core LDO is configured to be in low power state in STOP and VLPx modes, the CORELPCNFG[BGEN] bit can be cleared to zero. If the bandgap is required when in these modes, then the CORELPCNFG[BGEN] should be set to one. This will increase the current consumption so this bit should only be set when the bandgap is required to be on.

If it is required to keep the low voltage detect operating in STOP or VLPx modes, then the CORELPCNFG[BGEN] bit must also be set along with the CORELPCNFG[LVDEN] bit.

### 33.5.4 I/O retention

When in LLS mode, the I/O pins are held in their input or output state.

Upon wakeup, regulators selected by RCTRL[REGSEL] are re-enabled, performs a power-up sequence to full regulation, and releases the logic from state retention mode. The I/O are released immediately after a wake-up or reset event. In the case of LLS exit via a RESET pin, the I/O default to their reset state.

When in VLLS modes, the I/O states are held on a wake-up event (with the exception of wake-up by reset event) until the wake-up has been acknowledged via a write to REGSC[ACKISO]. In the case of VLLS exit via a RESET pin, the I/O are released and default to their reset state. In this case, no write to REGSC[ACKISO] is needed.

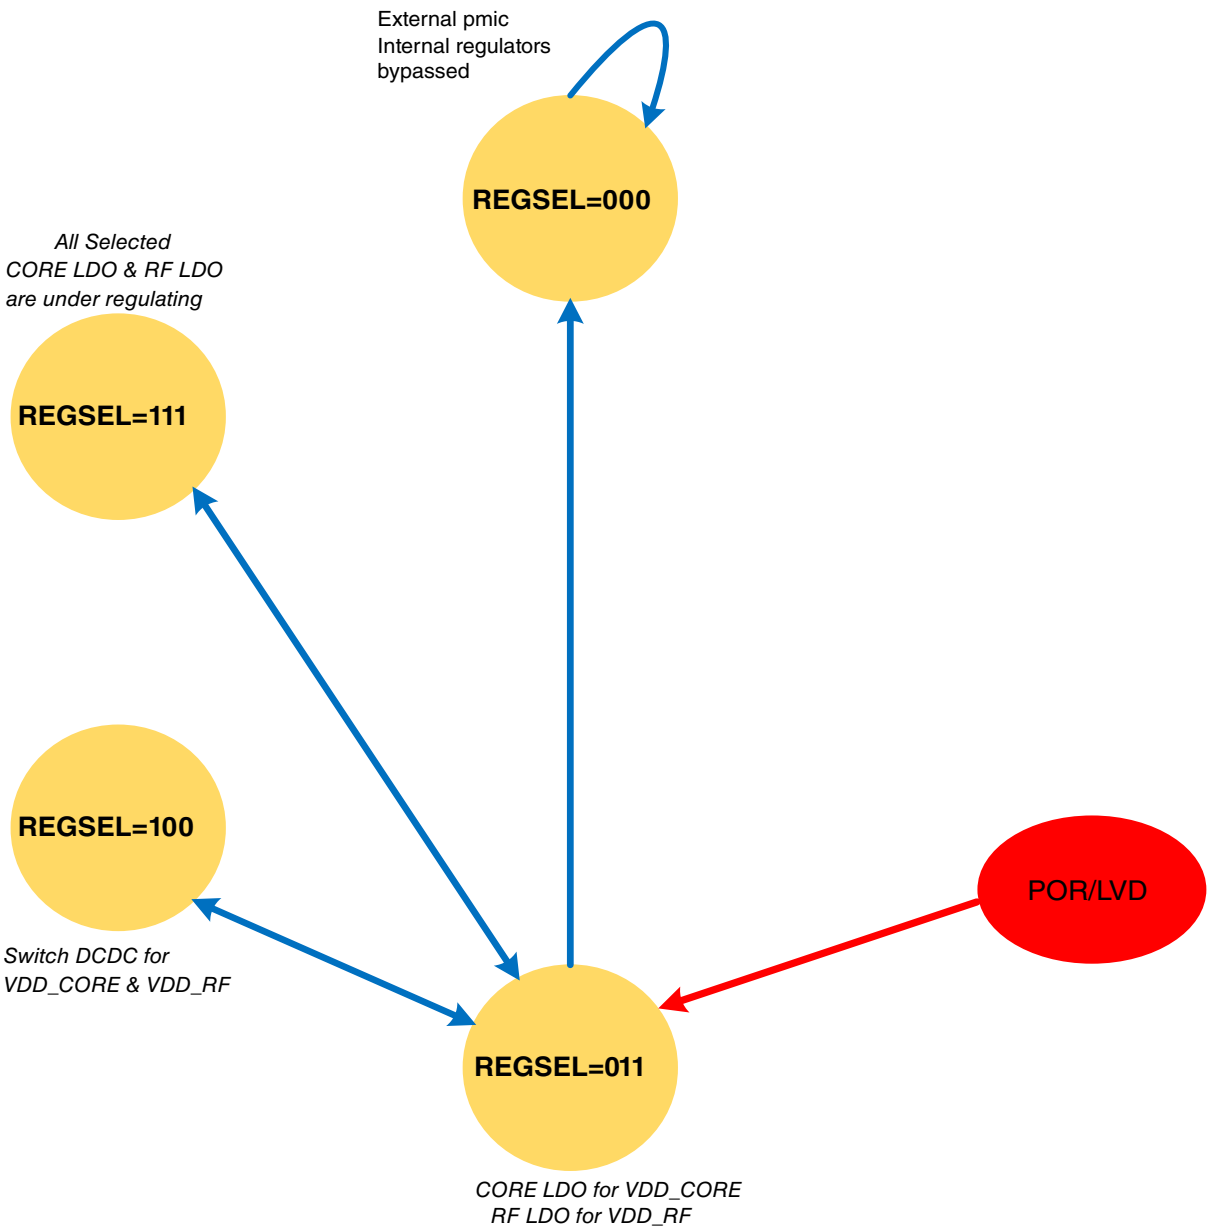
### 33.5.5 Regulators

The SPM has three regulators (CORE LDO Regulator, RF LDO Regulator, and DCDC) that supply power to the MCU including Cores, Memory Arrays, and On-Chip Radio.

Each of these regulators can be configured in High Power (HP) mode, Low Power (LP) mode, or Off mode. There is one exception - DCDC does not support Low Power mode. On Power-up, MCU will be come up on the Core LDO and RF LDO regulators with DCDC Off and power gated. External PMIC will also be supported that will allow bypass of the internal regulators and power-up on the PMIC. In RUN and HSRUN modes the RCTRL[REGSEL] selects the regulator or regulators that are enabled. In LP entry modes, the SPM will switch to the regulators selected by the LPCNTRL[REGSEL] register.

Below diagram illustrates valid regulator configurations:

# VALID REGULATOR CONFIGURATIONS



LEGEND:

REGSEL[0] = CORE LDO Select
REGSEL[1] = RF LDO Select
REGSEL[2] = DCDC Select

**Figure 33-2. VALID REGULATOR CONFIGURATIONS**

Transitions between the regulators are initiated either by the User programming a different regulator configuration in the RCTRL[REGSEL] when MCU is in RUN mode or by power mode request initiated by the Multi System Mode Controller (MSMC) or by the Radio. SPM will arbitrate between these two power mode request sources and service the first request it detects. Pending power mode request will get serviced after first is complete. When MSMC and SPM are requesting different power modes, SPM will transition to the higher power regulation selected between the MSMC/MCU and the Radio. (ex. MSMC sequences the SPM into VLPS with CORE LDO and RF LDO low power regulators selected. If Radio asserts a stop wake up request, SPM will sequence out of low power mode and switch to the regulator selected by the RCTRL[REGSEL] register. Note: In these cases the SPM will retain power gating to the CORE even though the Radio has requested and moved to RUN mode). Power mode transitions are not aborted but allowed to complete before SPM services the pending power mode request. So if MSMC starts a low power mode transition, a low power wake up request from Radio will not be serviced until SPM has fully completed and acknowledged the MSMC power mode request.

#### 33.5.5.1 DCDC

The DCDC converter module is a switching mode DC-DC converter supporting Buck and Bypass mode. It requires a single inductor to produce multiple switching outputs. The converter can be operated in continuous. This mode of operation is software configurable. An internal oscillator is included for use case where external oscillator is not available. The DCDC converter produces two switching outputs in Buck mode. They are VDD_CORE and VDD1p8, which both can produce up to 100mA continuous output current respectively. Typical switching frequency is 2MHz. DCDC conversion efficiency is typically 90%. In Buck mode, it supports operation with battery voltage from 2.1V to 4.25V. In Bypass mode, the DCDC converter is disabled. Individual supply signals need to be supplied with regulated supply accordingly.

DCDC by default is configured in off (Bypass) mode and not selected as the system regulator. To enable DCDC, the RCTRL[REGSEL[2]] needs to be set. When enabling the DCDC, it must be done while MCU is configured in RUN mode.

To switch to DCDC the following procedures are recommended:

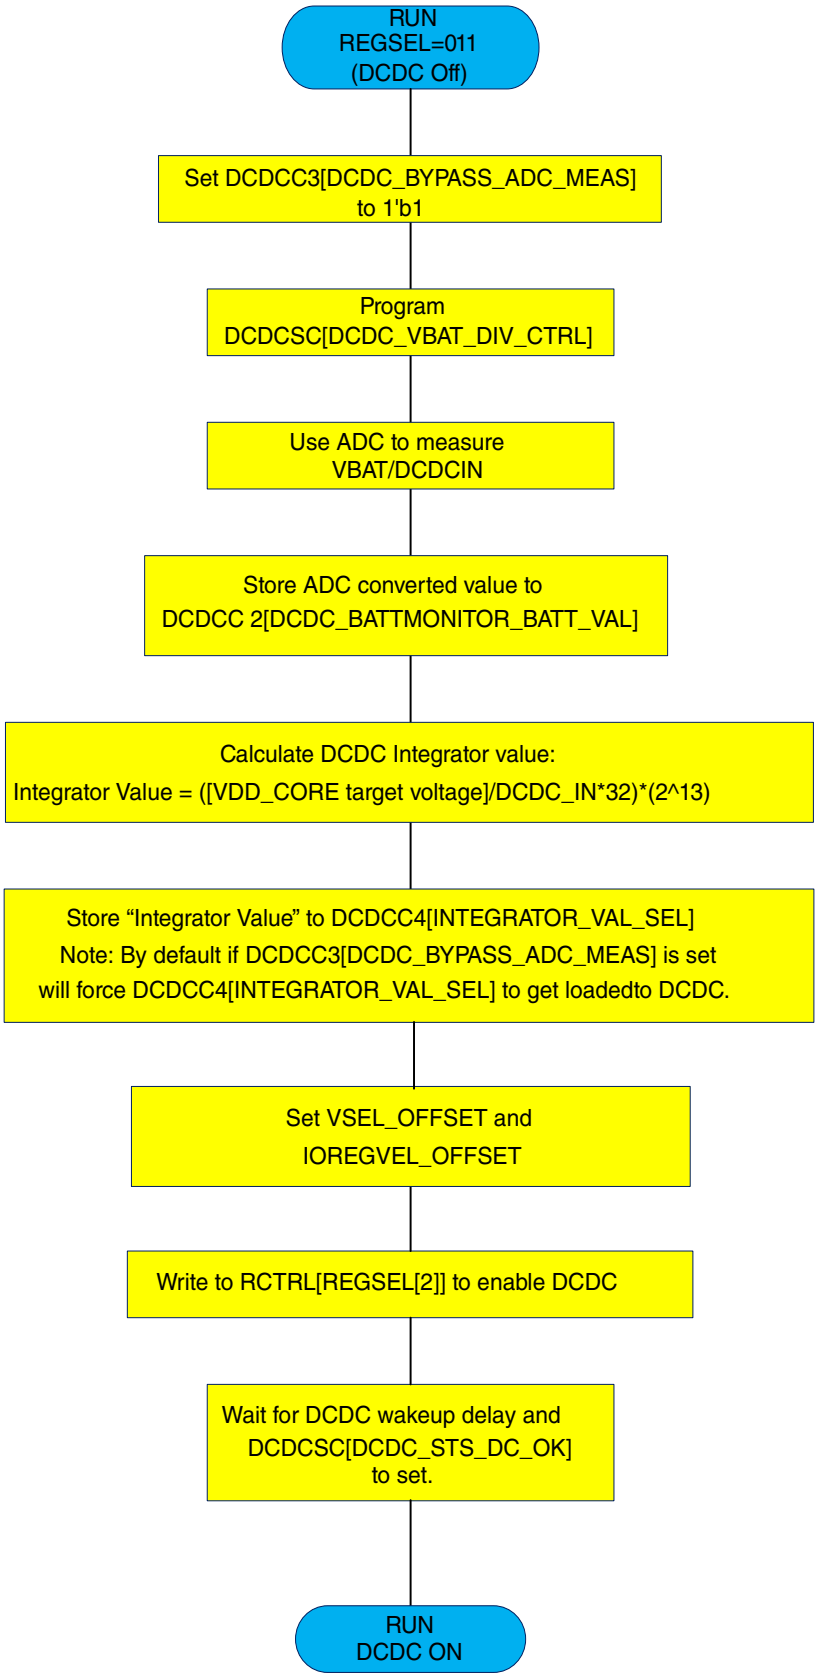


**Figure 33-3. RUN TO DCDC PROCEDURE**

#### 33.5.5.1.1 HSRUN

When entering HSRUN or exiting HSRUN with DCDC enabled the SPM automatically switched the VDD_CORE target value. On HSRUN entry SPM will set the VDD_CORE target value to one set in the DCDCC6[DCDC_HSVDD_TRIM] register. On HSRUN exit the SPM will set the VDD_CORE target value to one set in the DCDCC6[DCDC_VDD1P2CTRL_TRG_BUCK] register.

#### 33.5.5.1.2 Low Power Mode

When entering any of the low power modes, DCDC will get disabled at the end of low power entry. On exit from low power modes, SPM will automatically force DCDC disable step and enable DCDC if RCTRL[REGSEL[2]] was set prior to entering the low power mode. Hardware will clear DCDC disable step at end of DCDC low power wakeup delay. If in VLPR the RCTRL[REGSEL] are changed to switch off DCDC, on exit from VLPR, SPM will switch first to RUN with DCDC selected first and once in RUN mode will switch to the new RCTRL[REGSEL] settings as SPM will not support changing the selected RUN regulator while in a low power mode.

# Chapter 34
# Low-Leakage Wakeup Unit (LLWU)

## 34.1 Chip-specific LLWU information

### 34.1.1 Wake-up sources for Cortex-M4 core (CPU0)

The device uses the following inputs as wakeup sources to the LLWU0 module. The LLWU0_Px inputs are connections to external physical pins. The LLWU0_MxIF inputs are connections to the internal peripheral interrupt flags from different modules that can operate in low-power modes. The LLWU0_MxDR inputs are connections to the internal peripheral Asynchronous DMA or module Triggers from different modules that can operate in low-power modes.

**NOTE**

In addition to the LLWU0 wakeup sources, the device also wakes from low power modes when NMI or RESET pins are enabled and the respective pin is asserted.

**Table 34-1. Wakeup Sources for LLWU0 inputs**

| LLWU0 pin | Module source or pin name |
|---|---|
| LLWU_P0 | PTA1 |
| LLWU_P1 | PTA2 |
| LLWU_P2 | PTA22 |
| LLWU_P3 | PTA30 |
| LLWU_P4 | PTB1 |
| LLWU_P5 | PTB2 |
| LLWU_P6 | PTB4 |
| LLWU_P7 | PTB6 |
| LLWU_P8 | PTB7 |
| LLWU_P9 | PTB8 |

*Table continues on the next page...*

1. Set SPM_CORESC[VDDIOOVRIDE] for all PTE pins to wakeup from VLLS0/1
2. The corresponding LLWU0_PE[23: 22], LLWU0_PF[27], LLWU0_PDC2[27], and LLWU0_PMC[27] are reserved.

3. The corresponding LLWU0_PE[25: 24], LLWU0_PF[28], LLWU0_PDC2[28], and LLWU0_PMC[28] are reserved.
4. Set SPM_CORESC[USBOVRIDE] to wakeup from VLLS0 or VLLS1.
5. Requires the peripheral and the peripheral interrupt to be enabled. The LLWU's WUME bit enables the internal module flag as a wakeup input. After wakeup, the flags are cleared based on the peripheral clearing mechanism.
6. Set SPM_CORELPCNFG[ALLREFEN] to wakeup from VLLS0/1.
7. Set SPM_CORESC[VDDIOOVRIDE] and SPM_CORELPCNFG[ALLREFEN] to wakeup from VLLS0/1.
8. The corresponding LLWU0_ME[3] is reserved.
9. The corresponding LLWU0_ME[4] is reserved.
10. Set SPM_CORESC[VDDIOOVRIDE] to wakeup from VLLS0 or VLLS1.
11. The corresponding LLWU0_DE[3] is reserved.
12. The corresponding LLWU0_DE[7] is reserved.

### 34.1.2 Wake-up sources for Cortex-M0+ core (CPU1)

The device uses the following inputs as wakeup sources to the LLWU1 module. The LLWU1_Px inputs are connections to external physical pins. The LLWU1_MxIF inputs are connections to the internal peripheral interrupt flags from different modules that can operate in low-power modes. The LLWU1_MxDR inputs are connections to the internal peripheral Asynchronous DMA or module Triggers from different modules that can operate in low-power modes.

**NOTE**

In addition to the LLWU1 wakeup sources, the device also wakes from low power modes when NMI or RESET pins are enabled and the respective pin is asserted.

**Table 34-2. Wakeup Sources for LLWU1 inputs**

| LLWU1 pin | Module source or pin name |

1. The corresponding LLWU1_PE[23:22], LLWU1_PF[27], LLWU1_PDC2[27], and LLWU1_PMC[27] are reserved.
2. The corresponding LLWU1_PE[25:24], LLWU1_PF[28], LLWU1_PDC2[28], and LLWU1_PMC[28] are reserved.
3. Set SPM_CORESC[USBOVRIDE] to wakeup from VLLS0 or 1.
4. Requires the peripheral and the peripheral interrupt to be enabled. The LLWU's WUME bit enables the internal module flag as a wakeup input. After wakeup, the flags are cleared based on the peripheral clearing mechanism.
5. The corresponding LLWU1_ME[4] is reserved.
6. Set SPM_CORESC[VDDIOOVRIDE] to wakeup from VLLS0 or VLLS1.
7. The corresponding LLWU1_DE[3] is reserved.
8. The corresponding LLWU1_DE[7] is reserved.

## 34.2 Introduction

The LLWU module allows the user to select external pins and internal modules as interrupt wake-up sources from LLS/VLLS power modes. It also allows pins and/or modules to generate a temporary wake-up from LLS to allow servicing of DMA or trigger events. Digital filtering is also available for the external wakeup pins.

The RESET_B pin is an additional source for triggering an exit from low-leakage power modes, and causes the MCU to exit both LLS and VLLS through a reset flow. Input sources to the LLWU are described in the device's chip configuration details.

See AN4503: Power Management for Kinetis MCUs for further details on using the LLWU.

### 34.2.1 Features

The LLWU module features include:

- Support for up to 32 external input pins and up to 8 internal modules with individual enable bits for MCU interrupt from low leakage modes.
- Input sources may be external pins or from internal modules capable of running in LLS or VLLS. See the chip configuration information for wakeup input sources for this device.
- Support to configure internal modules or external pins as DMA or trigger sources for temporary wakeup from LLS.
- External input pins programmable for falling-edge, rising-edge, or any-edge detection.
- Support to enable external input pin and filter detection in all power modes (not only LLS/VLLS).
- Optional digital filters provided to qualify an external pin detect. Note that when the LPO clock is disabled, filters are disabled and bypassed.

### 34.2.2 Modes of operation

The LLWU module becomes functional on entry into a low-leakage power mode. After recovery from LLS, the LLWU is immediately disabled. After recovery from VLLS, the LLWU continues to detect wake-up events until the user has reinitialized the system and deasserted isolation. Detection of external pin/filter events can also optionally remain enabled in all power modes using the LLWU_PMC/LLWU_FMC registers.

#### 34.2.2.1 LLS mode

Wake-up events due to external pin inputs (LLWU_Px) and internal modules (LLWU_MxIF) configured as interrupts, result in an interrupt flow when exiting LLS. Exit due to a pin interrupt will trigger the LLWU interrupt service routine, but exit due to module interrupt will trigger only that module's interrupt service routine. Wake-up events due to internal module requests (LLWU_MxDF) and external pin inputs configured as DMA/trigger events, cause the system to temporarily exit LLS with the CPU clock disabled, allowing the DMA/trigger request to be serviced. When the DMA/trigger event is complete, the system will re-enter LLS.

**NOTE**

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully recover from LLS after an external pin event.

#### 34.2.2.2 VLLS modes

All wakeup and reset events result in VLLS exit via a reset flow. Exit due to a pin interrupt will also trigger the LLWU interrupt service routine, but exit due to module interrupt will trigger only that module's interrupt service routine.

#### 34.2.2.3 Non-low leakage modes

The LLWU is inactive in all non-low leakage modes, with the exception of external pin/filter detection which can explicitly be kept enabled during all power modes using the LLLWU_PMC/LLWU_FMC registers. The LLWU registers are accessible in non-low leakage modes and are available for configuring and reading status when bus transactions are possible.

When an external wake-up pin filter is first enabled in the LLWU_FILT register, filter operation begins immediately. To allow the filter to initialize, the user should wait at least five LPO clock cycles before entering a low leakage mode or before enabling filter detection for all power modes in the LLWU_FMC register.

### 34.2.3 Block diagram

The following figure is the block diagram for the LLWU module.

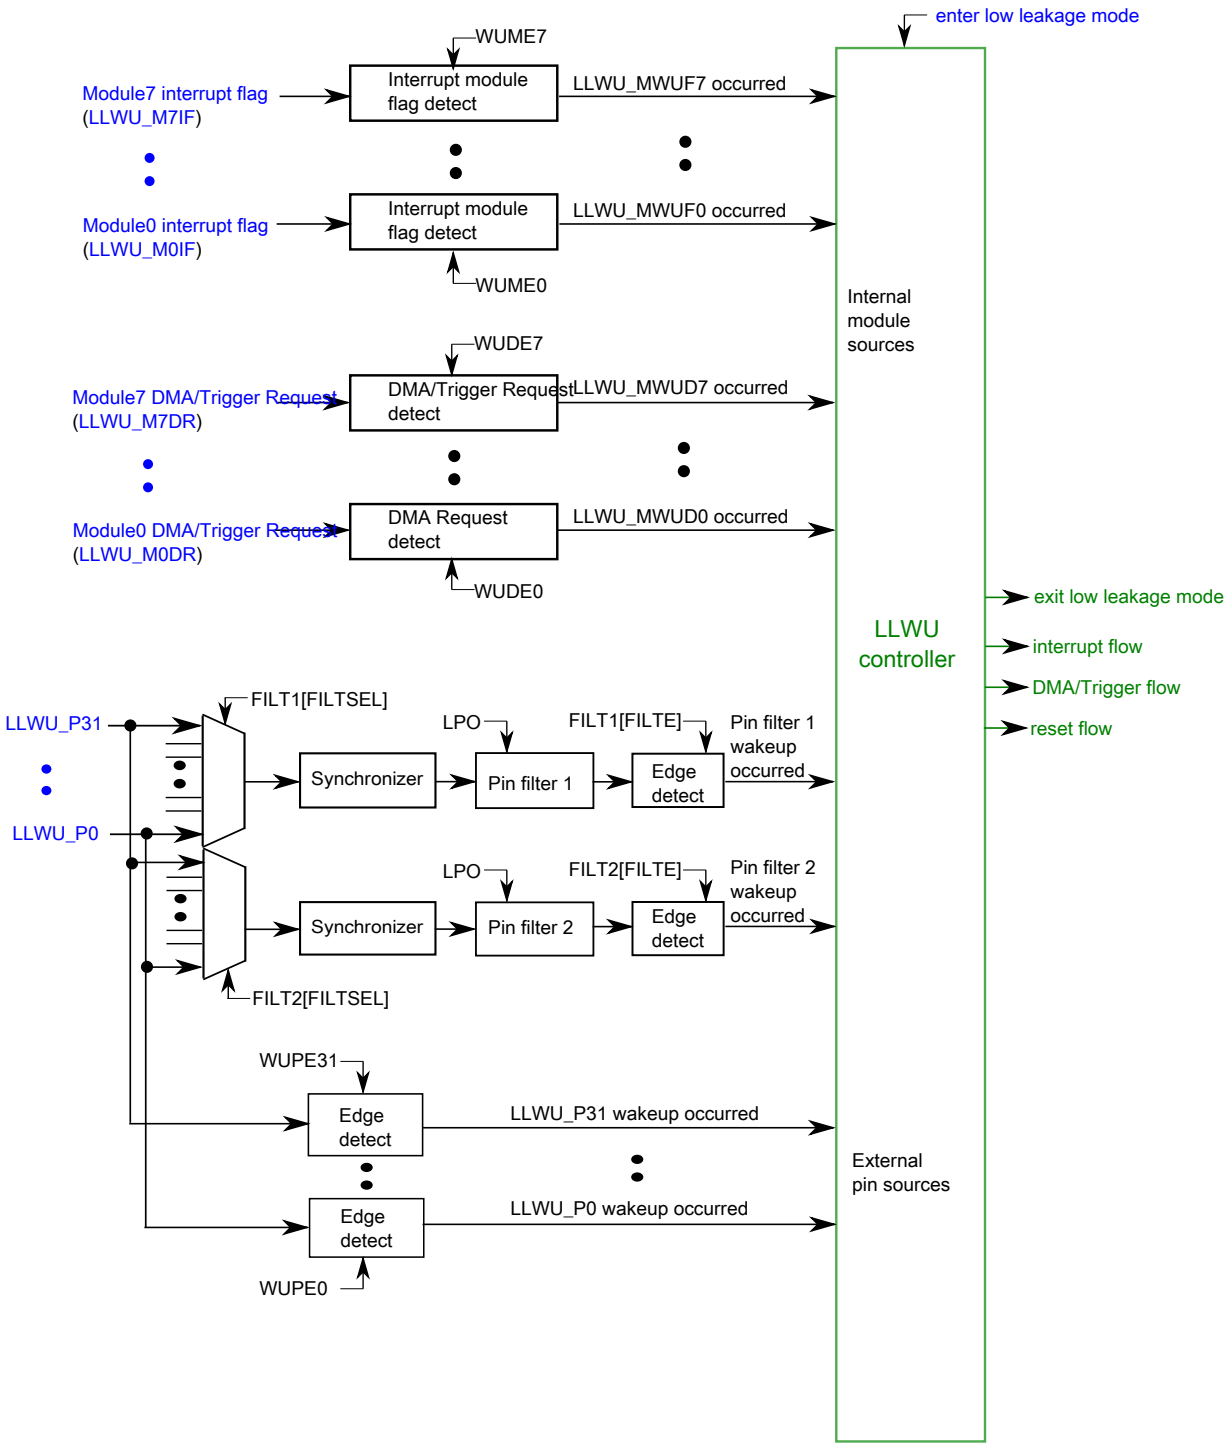

**Figure 34-1. LLWU block diagram**

## 34.3 LLWU signal descriptions

The signal properties of LLWU are shown in the table found here.

The external wakeup input pins can be enabled to detect either rising-edge, falling-edge, or on any change.

**Table 34-3. LLWU signal descriptions**

| Signal | Description | I/O |
|---|---|---|
| LLWU_Pn | External Pin Wakeup inputs (n = 0-31) | I |
| LLWU_MnIF | Internal Module Interrupt flag (n = 0-7) | I |
| LLWU_MnDR | Internal Module DMA/trigger request (n = 0-7) | I |

## 34.4 Memory map/register definition

Information about LLWU registers can be found here.

### 34.4.1 LLWU0 register descriptions

**NOTE**

The LLWU registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

Registers for Pin/Module sources marked "Reserved" in the LLWU chip configuration information will not be writable and will return 0 when read.

All LLWU registers are reset by Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. LLWU registers are unaffected by reset types that do not trigger Chip Reset not VLLS.

## 34.4.1.6 Module Interrupt Enable register (ME)

### 34.4.1.6.1 Offset

| Register | Offset |
|---|---|
| ME | 18h |

### 34.4.1.6.2 Function

The ME register contains the bits to enable an internal module interrupt as a wakeup source for inputs LLWU_M7IF - LLWU_M0IF.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If a module interrupt is not supported on a given device, the corresponding WUME*n* bit always reads as a 0.

#### 34.4.1.6.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 34.4.1.7 Module DMA/Trigger Enable register (DE)

#### 34.4.1.7.1 Offset

| Register | Offset |
|---|---|
| DE | 1Ch |

#### 34.4.1.7.2 Function

The DE register contains the bits to enable an internal module DMA/Trigger request as a wakeup source for inputs LLWU_M7DR - LLWU_M0DR.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If a module DMA/Trigger request is not supported on a given device, the corresponding WUDE*n* bit always reads as a 0.

## 34.4.1.8 Pin Flag register (PF)

### 34.4.1.8.1 Offset

| Register | Offset |
|---|---|
| PF | 20h |

### 34.4.1.8.2 Function

The PF register contains the wakeup flags indicating which wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUF*n* bit. The wakeup flag (WUF*n*), if set, will remain set if the associated WUPE*n* bit is cleared.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If an external wakeup pin is not supported on a given device, the corresponding WUF*n* bit always reads as a 0.

## 34.4.1.10 Pin DMA/Trigger Configuration 1 register (PDC1)

### 34.4.1.10.1 Offset

| Register | Offset |
|---|---|
| PDC1 | 38h |

### 34.4.1.10.2 Function

The PDC1 register configures the external wakeup input pins LLWU_P15-LLWU_P0 to generate an interrupt, DMA or a trigger request when detected. When configured as an interrupt, the interrupt is asserted when the edge programmed in the PE1 register is detected and remains asserted until the corresponding flag is cleared in the PF register. When configured as a DMA request, the request is asserted when the edge programmed in the PE1 register is detected and remains asserted until either the corresponding flag is cleared in the PF register or until the requested DMA transfer is complete. When configured as a trigger request, the trigger is asserted when the level programmed in the PE1 register is detected and remains asserted while the input pin is asserted. Note that when configured as a trigger request, the corresponding flag in the PF register will not be set.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If an external wakeup pin is not supported on a given device, the corresponding WUPDC*n* field always reads as 00.

## 34.4.1.11 Pin DMA/Trigger Configuration 2 register (PDC2)

### 34.4.1.11.1 Offset

| Register | Offset |
|---|---|
| PDC2 | 3Ch |

### 34.4.1.11.2 Function

The PDC2 register configures the external wakeup input pins LLWU_P31-LLWU_P16 to generate an interrupt, DMA or a trigger request when detected. When configured as an interrupt, the interrupt is asserted when the edge programmed in the PE2 register is detected and remains asserted until the corresponding flag is cleared in the PF register. When configured as a DMA request, the request is asserted when the edge programmed in the PE2 register is detected and remains asserted until either the corresponding flag is cleared in the PF register or until the requested DMA transfer is complete. When configured as a trigger request, the trigger is asserted when the level programmed in the

PE2 register is detected and remains asserted while the input pin is asserted. Note that when configured as a trigger request, the corresponding flag in the PF register will not be set.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If an external wakeup pin is not supported on a given device, the corresponding WUPDC*n* field always reads as 00.

## 34.4.1.12 Pin Filter DMA/Trigger Configuration register (FDC)

### 34.4.1.12.1 Offset

| Register | Offset |
|---|---|
| FDC | 48h |

### 34.4.1.12.2 Function

The FDC register contains the field to configure the external pin filters to generate an interrupt, DMA or a trigger request when detected. When configured as an interrupt, the interrupt is asserted when the edge programmed in the FILTEn field is detected and remains asserted until the corresponding flag is cleared in the FILTFn field. When configured as a DMA request, the request is asserted when the edge programmed in the FILTEn field is detected and remains asserted until either the corresponding flag is cleared in the FILTFn field or until the requested DMA transfer is complete. When configured as a trigger request, the trigger is asserted when the level programmed in the FILTEn register is detected and remains asserted while the input pin is asserted. Note that when configured as a trigger request, the corresponding flag in the FILTFn field will not be set.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

### 34.4.1.12.3 Diagram

## 34.4.1.13 Pin Mode Configuration register (PMC)

### 34.4.1.13.1 Offset

| Register | Offset |
|---|---|
| PMC | 50h |

### 34.4.1.13.2 Function

The PMC register configures the detection logic for the external wakeup input pins LLWU_P31-LLWU_P0 to remain enabled during all power modes, not just during LLS/VLLS.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If an external wakeup pin is not supported on a given device, the corresponding WUPMC*n* bit always reads as a 0.

## 34.4.2 LLWU1 register descriptions

**NOTE**

The LLWU registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

Registers for Pin/Module sources marked "Reserved" in the LLWU chip configuration information will not be writable and will return 0 when read.

All LLWU registers are reset by Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. LLWU registers are unaffected by reset types that do not trigger Chip Reset not VLLS.

## 34.4.2.6 Module Interrupt Enable register (ME)

#### 34.4.2.6.1 Offset

| Register | Offset |
|---|---|
| ME | 18h |

#### 34.4.2.6.2 Function

The ME register contains the bits to enable an internal module interrupt as a wakeup source for inputs LLWU_M7IF - LLWU_M0IF.

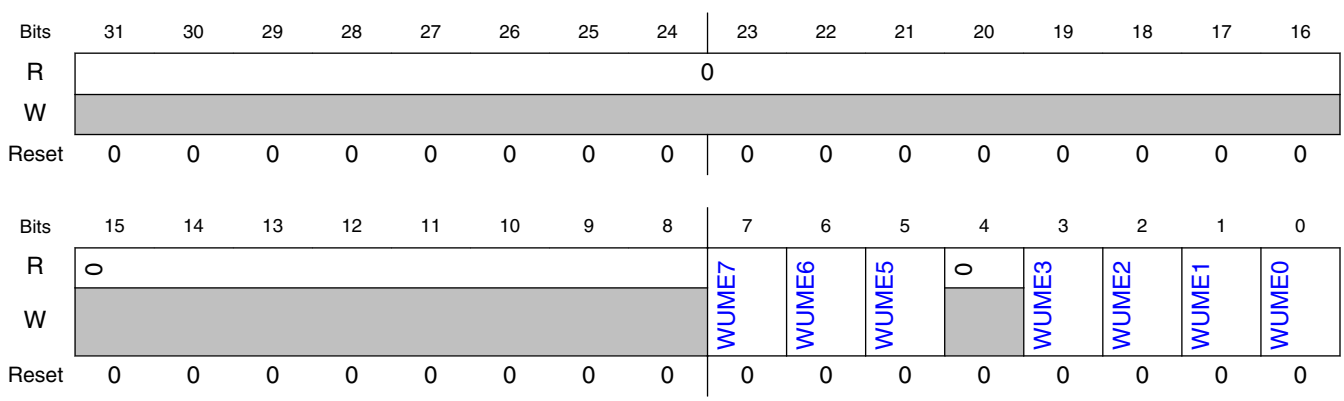
**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If a module interrupt is not supported on a given device, the corresponding WUME*n* bit always reads as a 0.

#### 34.4.2.6.3 Diagram



#### 34.4.2.6.4 Fields

| 7-0<br>WUDEn | DMA/Trigger wakeup enable for module n<br>Enables an internal module as a DMA/Trigger wakeup source.<br>0b - Internal module request not enabled as a DMA/Trigger wakeup source<br>1b - Internal module request enabled as a DMA/Trigger wakeup source |

## 34.4.2.8 Pin Flag register (PF)

### 34.4.2.8.1 Offset

| Register | Offset |
|---|---|
| PF | 20h |

### 34.4.2.8.2 Function

The PF register contains the wakeup flags indicating which wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUF*n* bit. The wakeup flag (WUF*n*), if set, will remain set if the associated WUPE*n* bit is cleared.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If an external wakeup pin is not supported on a given device, the corresponding WUF*n* bit always reads as a 0.

## 34.4.2.10 Pin DMA/Trigger Configuration 1 register (PDC1)

### 34.4.2.10.1 Offset

| Register | Offset |
|---|---|
| PDC1 | 38h |

### 34.4.2.10.2 Function

The PDC1 register configures the external wakeup input pins LLWU_P15-LLWU_P0 to generate an interrupt, DMA or a trigger request when detected. When configured as an interrupt, the interrupt is asserted when the edge programmed in the PE1 register is detected and remains asserted until the corresponding flag is cleared in the PF register. When configured as a DMA request, the request is asserted when the edge programmed in the PE1 register is detected and remains asserted until either the corresponding flag is cleared in the PF register or until the requested DMA transfer is complete. When configured as a trigger request, the trigger is asserted when the level programmed in the PE1 register is detected and remains asserted while the input pin is asserted. Note that when configured as a trigger request, the corresponding flag in the PF register will not be set.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If an external wakeup pin is not supported on a given device, the corresponding WUPDC*n* field always reads as 00.

### 34.4.2.10.3 Diagram

| Field | Function |
|---|---|
| 31-30: WUPDC15<br>29-28: WUPDC14<br>27-26: WUPDC13<br>25-24: WUPDC12<br>23-22: WUPDC11<br>21-20: WUPDC10<br>19-18: WUPDC9<br>17-16: WUPDC8<br>15-14: WUPDC7<br>13-12: WUPDC6<br>11-10: WUPDC5<br>9-8: WUPDC4<br>7-6: WUPDC3<br>5-4: WUPDC2<br>3-2: WUPDC1<br>1-0: WUPDC0 | Wakeup pin configuration for LLWU_Pn<br><br>Configures an external pin as an interrupt, DMA or trigger wakeup source.<br>00b - External input pin configured as interrupt<br>01b - External input pin configured as DMA request<br>10b - External input pin configured as trigger event<br>11b - Reserved |

## 34.4.2.11 Pin DMA/Trigger Configuration 2 register (PDC2)

### 34.4.2.11.1 Offset

| Register | Offset |
|---|---|
| PDC2 | 3Ch |

### 34.4.2.11.2 Function

The PDC2 register configures the external wakeup input pins LLWU_P31-LLWU_P16 to generate an interrupt, DMA or a trigger request when detected. When configured as an interrupt, the interrupt is asserted when the edge programmed in the PE2 register is detected and remains asserted until the corresponding flag is cleared in the PF register. When configured as a DMA request, the request is asserted when the edge programmed in the PE2 register is detected and remains asserted until either the corresponding flag is cleared in the PF register or until the requested DMA transfer is complete. When configured as a trigger request, the trigger is asserted when the level programmed in the PE2 register is detected and remains asserted while the input pin is asserted. Note that when configured as a trigger request, the corresponding flag in the PF register will not be set.

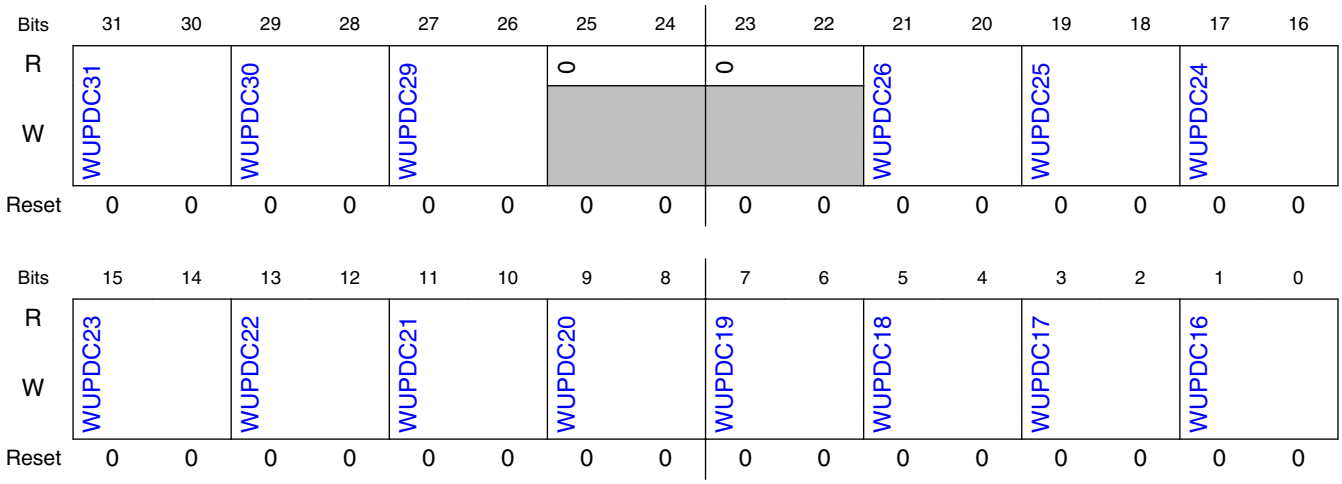
**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

**NOTE**

If an external wakeup pin is not supported on a given device, the corresponding WUPDC*n* field always reads as 00.

### 34.4.2.11.3 Diagram



### 34.4.2.11.4 Fields

## 34.4.2.12 Pin Filter DMA/Trigger Configuration register (FDC)

### 34.4.2.12.1 Offset

| Register | Offset |
|---|---|
| FDC | 48h |

### 34.4.2.12.2 Function

The FDC register contains the field to configure the external pin filters to generate an interrupt, DMA or a trigger request when detected. When configured as an interrupt, the interrupt is asserted when the edge programmed in the FILTEn field is detected and remains asserted until the corresponding flag is cleared in the FILTFn field. When configured as a DMA request, the request is asserted when the edge programmed in the FILTEn field is detected and remains asserted until either the corresponding flag is cleared in the FILTFn field or until the requested DMA transfer is complete. When configured as a trigger request, the trigger is asserted when the level programmed in the FILTEn register is detected and remains asserted while the input pin is asserted. Note that when configured as a trigger request, the corresponding flag in the FILTFn field will not be set.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS.

## 34.5 Functional description

The low-leakage wakeup unit (LLWU) module allows internal peripherals and external input pins as a source of wakeup from low-leakage modes.

The LLWU module contains pin enables for each external pin and internal module. For each external pin, the user can disable or select the edge type for the wakeup with the following options:

- Falling-edge
- Rising-edge
- Either-edge

Exit due to a pin event will trigger an LLWU interrupt after wakeup is complete. When an external pin is enabled as a wakeup source, the pin must be configured as an input pin. Detection logic for a pin can optionally remain enabled during all power modes using the LLWU_PMC register. A pin can also be configured to generate an interrupt from LLS/VLLS or a DMA/Trigger request for temporary wakeup from LLS.

The LLWU implements optional 3-cycle glitch filters, based on the LPO clock. A detected external pin is required to remain asserted until the enabled glitch filter times out. Additional latency of up to 2 cycles is due to synchronization, which results in a total of up to 5 cycles of delay before the detect circuit alerts the system to the wakeup or reset event when the filter function is enabled. Two wakeup detect filters are available for selected external pins. Glitch filtering is not provided on the internal modules. A filter can be configured to generate an interrupt from LLS/VLLS or a DMA/Trigger request for temporary wakeup from LLS.Detection logic for a filter can optionally remain enabled during all power modes using the LLWU_FMC register.

For internal module interrupts, the WUMEx bit enables the associated module interrupt as a wakeup source. Exit due to a module interrupt will not trigger an LLWU interrupt.

### 34.5.1 LLS mode

Wakeup events triggered from either an external pin input or an internal module interrupt, result in a CPU interrupt flow to begin user code execution. Pin events will trigger the LLWU interrupt routine, but module interrupts will only trigger the module's interrupt routine.

Wakeup events triggered from an internal module or external pin DMA/Trigger request, result in a temporary wake-up from LLS with CPU remaining clock gated to allow the DMA/Trigger request to be serviced. After the DMA/Trigger request is cleared, the system will re-enter LLS mode.

An LLS reset event due to RESET_B pin assertion causes an exit via a system reset. State retention data is lost, and the I/O states return to their reset state.

### 34.5.2 VLLS modes

For any LLWU wakeup from VLLS, recovery is always via a reset flow. Pin events will trigger the LLWU interrupt routine and module interrupts will trigger the module's interrupt routine. A VLLS exit event due to RESET_B pin assertion causes an exit via a system reset with I/O returning to their reset state immediately.

### 34.5.3 Initialization

For an enabled peripheral wakeup input, the peripheral flag must be cleared by software before entering LLS or VLLS mode to avoid an immediate exit from the mode.

Flags associated with external input pins, filtered and unfiltered, must also be cleared by software prior to entry to LLS or VLLS mode.

After enabling an external pin filter or changing the source pin, wait at least five LPO clock cycles to allow the filter to initialize before entering LLS or VLLS mode or before configuring the FMC register for operation in any power mode.

**NOTE**

After recovering from a VLLS mode, user must restore chip configuration before clearing the PMC ACKISO bit. In particular, pin configuration for enabled LLWU wake-up pins must be restored to avoid any LLWU flag from being falsely set when ACKISO is cleared.

# Chapter 35
# System Integration Module (SIM)

## 35.1 Introduction

### 35.1.1 Overview

This section provides an introduction to the system integration module (SIM) module. The SIM provides system control and chip configuration registers.

### 35.1.2 Features

The SIM includes the following features:

- Flash and System RAM size configuration
- Flexbus configuration

## 35.2 Memory Map and Registers

### 35.2.1 SIM register descriptions

#### 35.2.1.1 SIM Memory map

SIM base address: 4002_6000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 4h | Chip Control Register (CHIPCTRL) | 32 | RW | 0000_0000h |
| 24h | System Device Identification Register (SDID) | 32 | RO | See description. |
| 4Ch | Flash Configuration Register 1 (FCFG1) | 32 | RW | CAA9_0400h |
| 50h | Flash Configuration Register 2 (FCFG2) | 32 | RO | See description. |
| 58h | Unique Identification Register High (UIDH) | 32 | RO | See description. |
| 5Ch | Unique Identification Register Mid Middle (UIDM) | 32 | RO | See description. |
| 60h | Unique Identification Register Mid Low (UIDL) | 32 | RO | See description. |
| 64h | RF Mac Address Low (RFADDRL) | 32 | RO | See description. |
| 68h | RF MAC Address High (RFADDRH) | 32 | RO | See description. |
| 70h | MISC2 Register (MISC2) | 32 | RW | 0000_0000h |

## 35.2.1.2 Chip Control Register (CHIPCTRL)

### 35.2.1.2.1 Offset

| Register | Offset |
|---|---|
| CHIPCTRL | 4h |

### 35.2.1.2.2 Function

This register is used for chip control.

#### 35.2.1.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 35.3 Application information

This section describes applications supported by the SIM module.

# Chapter 36
# Interrupt Multiplexer (INTMUX)

## 36.1 About this module

### 36.1.1 Introduction

The Interrupt Multiplexer (INTMUX) expands the number of peripherals that can interrupt the core via 4 channels of the NVIC module.

- The INTMUX module has 8 channels that are assigned to 8 NVIC interrupt slots.
- Each INTMUX channel can provide up to 32 additional interrupt sources, which can be logically ORed or ANDed.
- The Interrupt Multiplexer (INTMUX) routes the interrupt sources to the interrupt outputs.

### 36.1.2 Features

INTMUX features:

- Supports 8 multiplex channels
- Each channel receives 32 interrupt sources and has 1 interrupt output
- Each interrupt source can be enabled or disabled
- Each channel supports *Logic AND* or *Logic OR* of all enabled interrupt sources

### 36.1.3 Block diagram

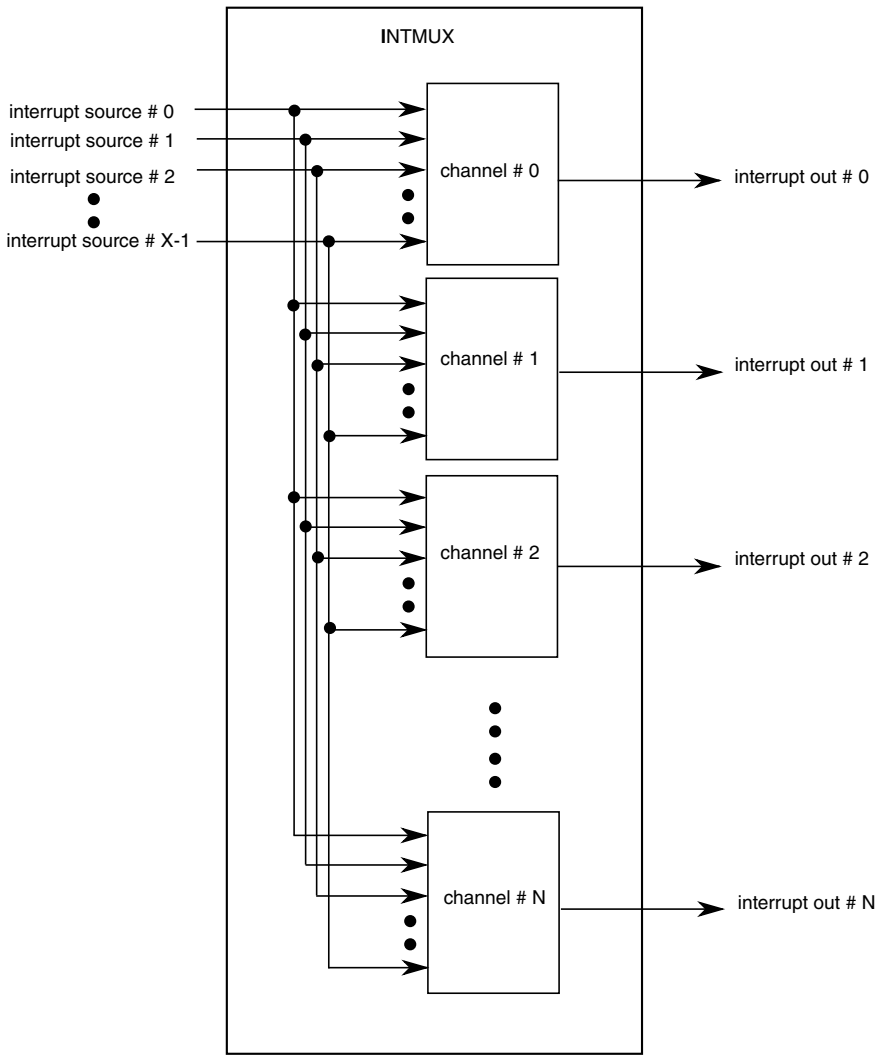

**Figure 36-1. INTMUX Block diagram**

N: Interrupt Channel Instance Number (N=7)

X: Interrupt Source Number for each channel (X=32)

## 36.2 Memory Map and register definition

This section includes the module memory map and detailed descriptions of all registers.

## 36.2.1 INTMUX0 register descriptions

### 36.2.1.1 INTMUX0 Memory map

INTMUX0 base address: 4004_F000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Channel n Control Status Register (CH0_CSR) | 32 | RW | 0000_0800h |

## 36.3 Functional Description

The Interrupt Multiplexer (INTMUX) routes the interrupt sources to the interrupt outputs.

There is one interrupt output for each channel available in the INTMUX. All interrupt sources are available to each channel. There are 8 multiplex channels, and there are 32 interrupt sources.

The INTMUX module provides interrupt status registers to monitor interrupt pending status and vector numbers. This module also implements the ability to logical AND or OR enabled interrupts on a given channel. Software resets can also be performed on a given channel.

See the chip specific Interrupt section for more information regarding the interrupt vectors and sources.

### 36.3.1 Configuring Output Channels

There is a single set of 32 source interrupts for the INTMUX. Each of the 8 output channels can be configured to output any combination of the source interrupts.

To enable source interrupts on a channel, write a mask value to the Channel n Interrupt Enable Register (CHn_IER_31_0). Each bit of these registers corresponds to one of the 32 source interrupts. Bit n enables source interrupt n on the given channel.

Further control for each output channel is available by selecting the Boolean operation to perform on pending interrupts. The default is logical OR, but logical AND can be selected via the CHn_CSR[AND] register bit.

### 36.3.2 INTMUX Vectors

The INTMUX is designed so that it integrates with the standard NVIC vector table. Each INTMUX source interrupt has a vector associated with it. These source vectors are intended to immediately follow the NVIC vectors in the vector table pointed to by the CPU's VTOR register. Interrupt service routine addresses can be placed in the INTMUX source vectors, just like NVIC vectors.

The ISR for each of the INTMUX output channels should read the CHn_VEC register to determine the highest priority active source interrupt out of those enabled for the given channel. The CHn_VEC[VECN] bitfield returns the source interrupt number plus 48, which accounts for the number of CPU and NVIC vectors. The VECN field starts at bit 2 of the CHn_VEC register, so reading the register as a whole will return the VECN field multiplied by 4. This is the offset in bytes of the active source vector from the start of the vector table (i.e., VTOR).

For instance, consider if source interrupt 12 was enabled on output channel 1 and became active. The ISR for channel 1 would read the entire CH1_VEC register to get the active vector offset of 240 (i.e., (48 + 12) × 4). It then adds this value to the value of VTOR. The word at the resulting address is the address of the active interrupt's ISR, which can then be invoked.

If multiple source interrupts become pending simultaneously on a single channel, the CHn_VEC[VECN] field will read as the highest priority vector number. Priority of source interrupts is determined by the source interrupt number. Lower numbers are higher priortity, with source interrupt 0 being highest priority.

**NOTE**

Unlike the NVIC, the INTMUX does not latch pending source interrupts. This means that the INTMUX output channel ISRs must check for and handle a 0 value of the CHn_VEC register to account for spurious interrupts.

# Chapter 37
# Trigger MUX (TRGMUX)

## 37.1 Chip-specific TRGMUX information

### 37.1.1 CPU0 Trigger Multiplexer input sources

The trigger multiplexer allows triggers from one module to initiate operations on other modules. The following table shows the inputs to the trigger mutliplexer instantiated on the CPU0 crossbar.

**Table 37-1. CPU0 TRGMUX Inputs**

| Mux Select | Source Module | Source Function |
|---|---|---|
| 0 | — | Disabled |
| 1 | LLWU0 | Trigger Event |
| 2 | LPIT0 | Channel 0 |
| 3 | LPIT0 | Channel 1 |

## 37.1.4 CPU1 Trigger Multiplexer outputs

The trigger multiplexer allows triggers from one module to initiate operations on other modules. The following table shows the outputs from the trigger mutliplexer instantiated on the CPU1 crossbar.

**Table 37-4. CPU1 TRGMUX Outputs**

| Destination Module | Destination Function | Number of Muxes |
|---|---|---|
| DMA MUX1 | Periodic Trigger | 4 |
| LPIT1 | Trigger | 4 |
| TPM3 | Input Capture, Trigger, Output Modulation | 3 |
| LPI2C3 | Host Request | 1 |
| LPSPI3 | Host Request | 1 |
| LPUART3 | RX Input, CTS Input, Modulation | 1 |
| LPCMP1 | Window, Trigger | 1 |
| DMA MUX0 | Periodic Trigger | 4 |
| LPIT0 | Trigger | 4 |
| TPM0 | Input Capture, Trigger, Output Modulation | 3 |
| TPM1 | Input Capture, Trigger, Output Modulation | 3 |
| TPM2 | Input Capture, Trigger, Output Modulation | 3 |
| FlexIO0 | Trigger | 4 |

## 37.2 Introduction

The trigger multiplexer (TRGMUX) module allows software to configure the trigger inputs for various peripherals.

## 37.3 Features

The TRGMUX module allows software to select the trigger source for peripherals. The block diagram below shows the trigger selection logic of the TRGMUX module.

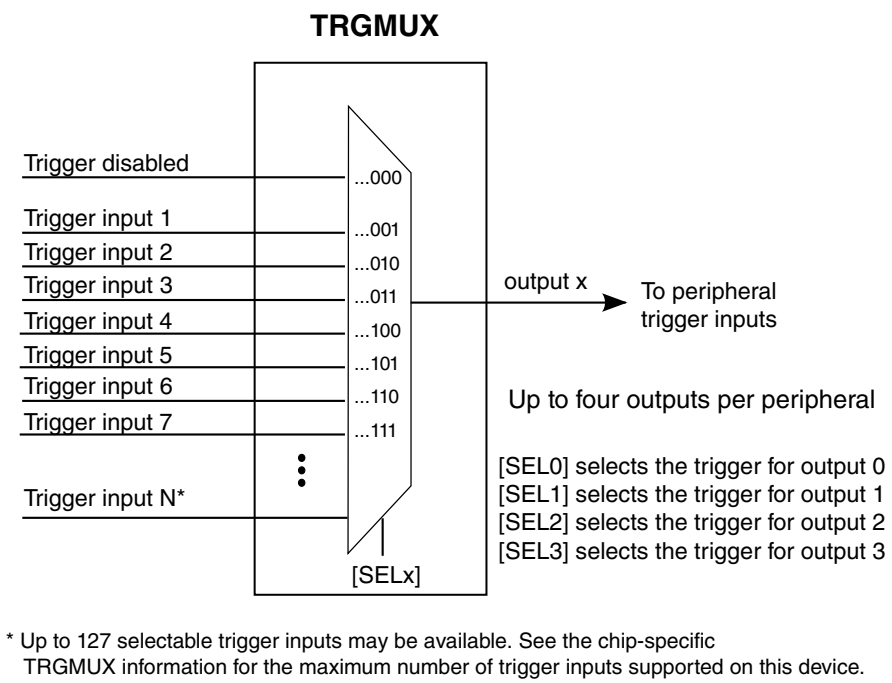

**Figure 37-1. TRGMUX block diagram**

Each peripheral has its own dedicated TRGMUX register. See each peripheral's TRGMUX register for details.

## 37.4 Memory map and register definition

The TRGMUX registers contain fields for selecting trigger sources for peripheral modules.

TRGMUX registers can be written only in supervisor mode.

## 37.4.1 TRGMUX0 register descriptions

### 37.4.1.1 TRGMUX0 Memory map
