Continuous RX mode instructs the Sequence Manager to stay in a receiving state forever (RX_PKT state), rather than shutting down the sequence after a 802.15.4 packet has been received. For continuous RX mode, it is assumed that another device has been deployed as a continuous transmitter. The length of the continuous transmitter’s TX buffer, will also be the length of the continuous receiver’s RX buffer. For the receiver, in Continuous RX mode, the length of the buffer is determined by the DUAL_PAN_DWELL register. (Needless to say, Continuous RX mode should not be engaged simultaneously with Dual PAN mode, since DUAL_PAN_DWELL is serving an alternate purpose). For Continuous RX mode, DUAL_PAN_DWELL should be programmed to the same value as the “length” byte of the continuous transmitter’s TX buffer. See step 2) above, for Continuous TX mode. In Continuous RX mode, the first byte received (after Preamble and SFD), will be the “length” byte, which can be read from the RX_FRM_LEN register of the receiving device. (It is up to the user to guarantee that this length byte on the TX device matches the contents of the DUAL_PAN_DWELL register on the RX devices, by correctly programming the 2 devices). Each subsequent byte which is received, will be written to the next sequential address of the Packet Buffer, starting at PB address 0. When the number of received bytes matches the contents of DUAL_PAN_DWELL register, the Packet Buffer’s address generation logic will circle back to PB address 0, and store the next received byte to this location. Then, each subsequent received byte, will be written to the next sequential address of the Packet Buffer. In this way, the

contents of TX buffer on the continuous transmitter, will be identical to the contents of the RX buffer on the continuous receiver (assuming no reception errors). To prepare for Continuous RX mode, the following steps should be taken:

1) Program DUAL_PAN_DWELL register with the contents of the “length” byte of the continuously-transmitting device’s TX Buffer

2) Assert the CONTINUOUS_EN bit

3) Start the Receive Sequence by writing Sequence R to XCVSEQ.

After Continuous RX mode has been entered, the SEQ_STATE register can be monitored to verify the Sequence Manager has reached the RX_PKT state, and remains in this state. The contents of the Packet Buffer can also be observed in realtime, to verify they match the contents of the TX device’s TX buffer. The Sequence Manager will remain in the RX_PKT state until one of the following events occurs:

1) CONTINUOUS_EN is deasserted by SW

2) SW aborts the Sequence R by writing Sequence I to XCVSEQ

3) An PLL Unlock occurs, aborting the Sequence

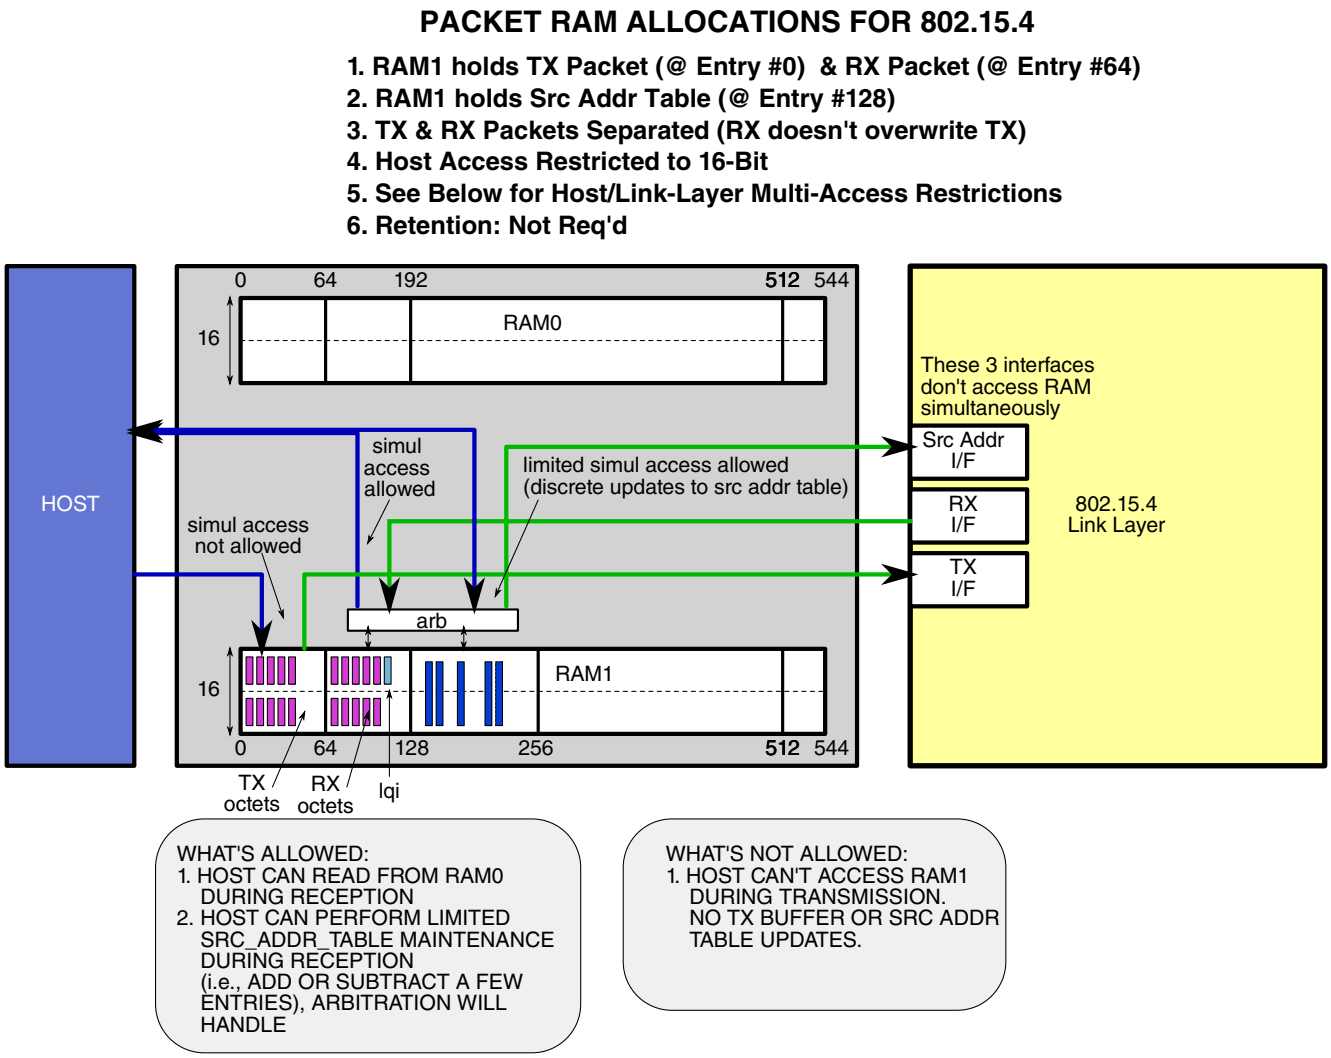
#### 64.5.2.4.3 Packet Storage

The 802.15.4 Link Layer has access to a Packet Buffer to store data to be transmitted, and to receive incoming packet data. The 802.15.4 Link Layer software prepares data to be transmitted, by loading the octets, in order, into the Packet Buffer. After reception, the octets received over the air are stored into the Packet Buffer, in the order they are received. The Packet Buffer contains separate spaces for TX and RX data, so incoming receive octets don’t overwrite previously-loaded content intended for transmission. The Packet Buffer is large enough to accommodate the longest 802.15.4 packet, 127 bytes, for both transmit and receive.

The 802.15.4 Packet Buffer is contained within the multi-protocol Packet RAM. In the Packet RAM, space has been allocated for 802.15.4 packets, with separate spaces for TX and RX. The Packet RAM is 16 bits wide, so the 802.15.4 Link Layer controller hardware will address the RAM in an interleaved fashion as it stores octets to, or fetches octets from, the RAM-based packet buffer. 802.15.4 will utilize space in RAM1, since this RAM is partitionable for multi-protocol operation (RAM0 is not). The 802.15.4 TX buffer space begins at RAM1 Entry #0, and 802.15.4 RX buffer space begins at RAM1 Entry #64. Separate TX and RX spaces means that incoming RX packets don’t overwrite TX packet data.

In addition, the 802.15.4 Link Layer controller includes acceleration for Source Address Matching (see Section Source Address Management). The hardware acceleration includes a Source Address Table, which is 128 entries by 16 bits wide. This table is also implemented in RAM1.

The partitioning of the Packet Buffer RAM1 amongst transmit, receive and source address matching sections for 802.15.4 is shown in the diagram below.



During packet reception, the MCU is allowed to access the RX packet buffer of RAM1, in order to download the packet while it's being received, if so desired. In cases where both the MCU and the 802.15.4 Link Layer controller attempt to access RAM1 during reception, internal hardware arbitration is provided to delay 802.15.4 Link Layer accesses to RAM1 until the MCU completes its access. The longest-duration continuous burst read

by the MCU of RAM1, given a maximum 802.15.4 packet length of 128 octets (127 data octets plus 1 LQI octet) is shorter than the required interval between 802.15.4 Link Layer updates, so the Link Layer can be waited without any possibility of overrun.

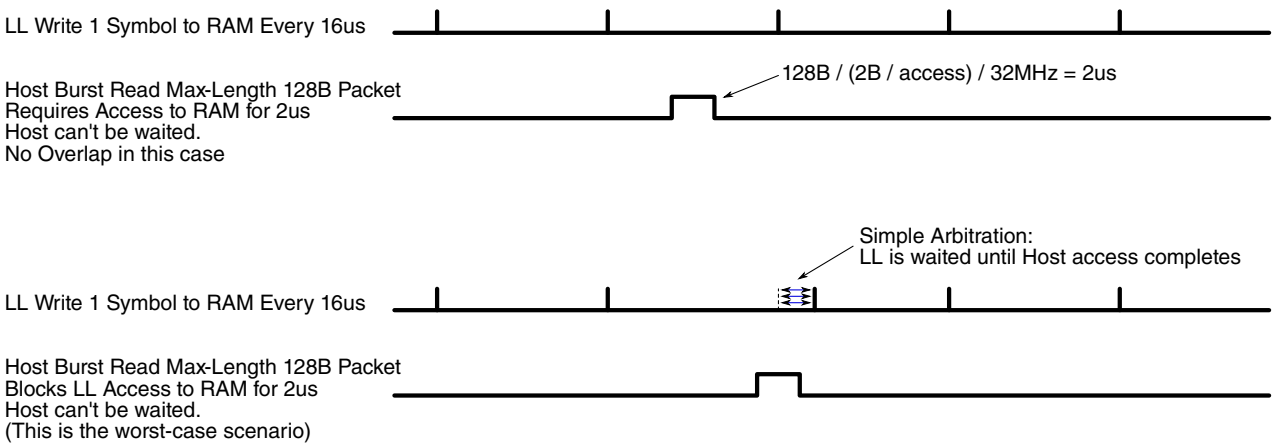
During packet reception, the MCU is allowed to access the Source Address Table partition of RAM1. Access to he Source Address Table is indirect, and is performed through the 802.15.4 Register Interface, specifically by programming SAM_TABLE register with the index of the table entry to be written or read, and the desired checksum in the case of write accesses. Because accesses to Source Address Table consist of discrete writes to 802.15.4 registers, and not long burst accesses, arbitration shall be able to accommodate Link Layer read accesses to the table while the Host access is underway, by delaying the Link Layer access until the Host completes.

During packet transmission, MCU access to RAM1 is not allowed. The 802.15.4 software must program the TX buffer before commanding a TX operation, and must not alter the Source Address Table once transmission has begun.

## Arbitration

Arbitration hardware has been provided to allow the MCU to download data from the Packet RAM while the packet is being received, in order to allow a headstart on software packet processing, if required by the application. In the SoC, there is no provisions to wait the MCU on IPS or APB bus accesses to the radio. Therefore, in case of simultaneous access attempts by the MCU and the 802.15.4 Link Layer to RAM1, arbitration hardware delays the Link Layer access to RAM1 until the MCU completes its access. In the intended scenario, 802.15.4 software sets a RX watermark interrupt, and on this interrupt, proceeds to download the contents of the Packet RX buffer in RAM1. Given the maximum length packet of 127 octets, plus 1 LQI octet, the maximum length read burst by the MCU would be 128 / (2 octets / access) / 32MHz = 2us. The update interval for the 802.15.4 Link Layer is the received symbol period of 16us. Since the longest wait interval the MCU could impose on the Link Layer does not exceed the Link Layer RAM1 update interval, there is no possibility of buffer overrun. The diagram below depicts 2 multi-access scenarios. In the first, the Host and Link Layer accesses do not overlap. In the second, overlap occurs, so arbitration is invoked, and the Link Layer access is slightly delayed.

**RAM ARBITRATION TO ALLOW SIMUL HOST/LL ACCESS DURING RECEPTION**



## 64.5.2.4.4 Memory Mapping

In the SoC memory map, space has been allocated to 802.15.4. Within the SoC, peripherals are allocated memory space in 4KB blocks, called IPS slots. 802.15.4 occupies one such slot. 802.15.4 address space consists of the 802.15.4 registers, as well as the Packet Buffer (RAM), which is memory-mapped into 802.15.4 memory space. The partitioning of address space for 802.15.4 is shown in the diagram below.

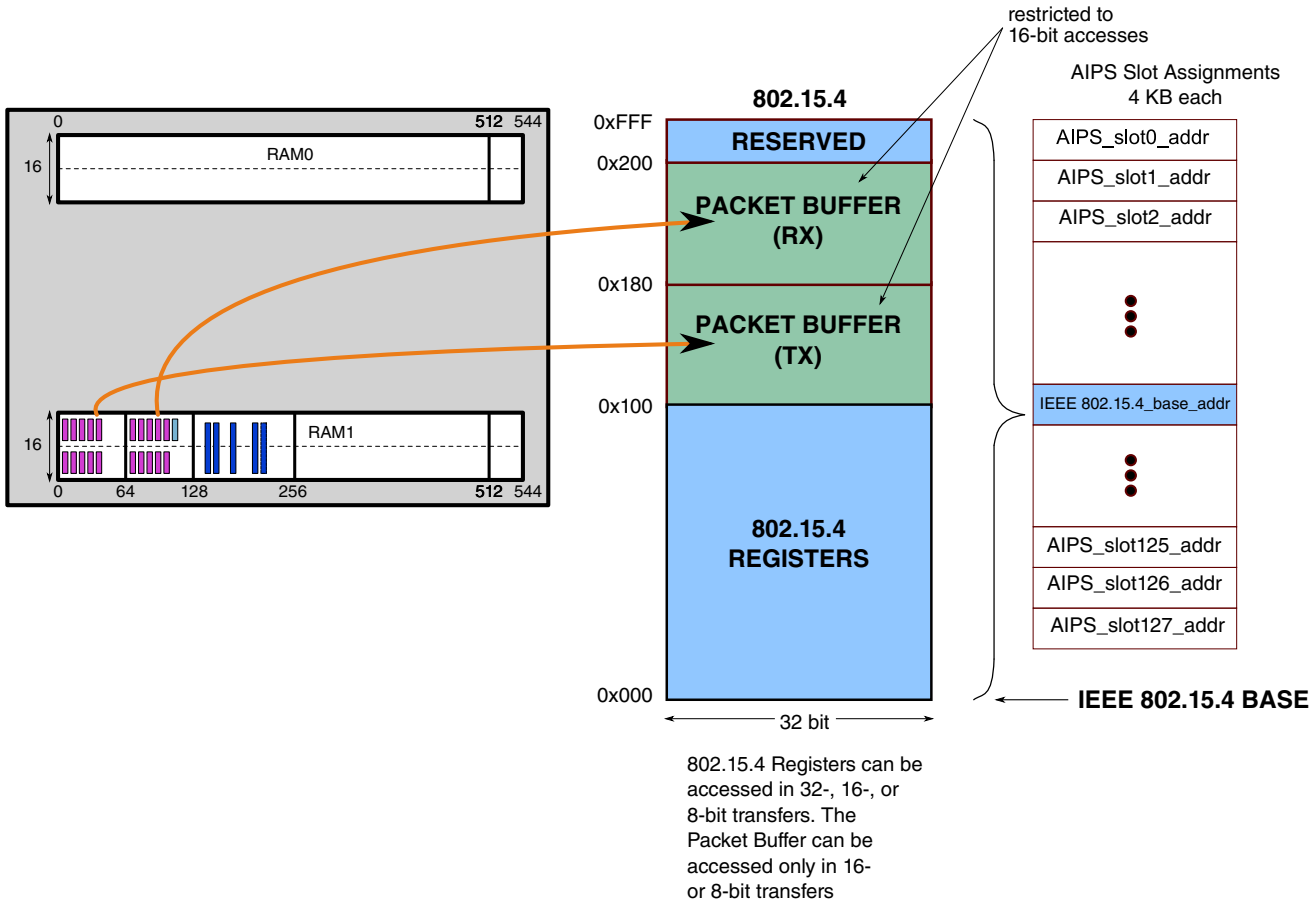


**Figure 64-149. 802.15.4 MEMORY MAPPING**

**NOTE**

See AIPS Memory Map for specific memory assignments details.

The Packet Buffer (RAM), is accessible by the MCU in 16-, or 8-bit accesses. The 802.15.4 Registers are accessible in 32-, 16-, or 8-bit accesses. The Source Address Table partition in RAM, is not accessible directly by the MCU, but via a prescribed protocol using the 802.15.4 SAM_TABLE register (see Section Source Address Management). Therefore, the table is not memory-mapped directly into 802.15.4 address space.

### 64.5.2.4.5 Event Timer

**OVERVIEW**

The 802.15.4 Link Layer Controller contains an internal Event Timer block that manages link layer timing.

The Event Timer consists of a prescaler and a 24-bit counter which increment whenever the 32MHz reference oscillator is operating (i.e., the controller is not in Deep Sleep Mode). Interrupts to the MCU may be generated when the current time of the counter matches several pre-determined values set in programmable registers. The current time is accessible at any time via a read operation, as well as, programmable via a write operation.

The Event Timer provides the following functions:

- Timer to generate current system time
- Interrupt generation at pre-determined system times
- Abort an RX sequence at pre-determined system time
- Latches timestamp value during packet reception
- Initiates timer-triggered sequences

**Note:** The Event Timer is actually a 28-bit value, with 24 integer bits and 4 fractional bits. For most operations involving the Event Timer, such as interrupt-generation and sequence-triggering, only the integer portion need be considered, and the fractional component can be ignored. Extended-precision (28-bit) Event Timer operations are required only to realize the increased accuracy required for entering and exiting Deep Sleep Mode. See Section Extended Precision Event Timer below.

## EVENT TIMER TIME BASE

The Event Timer's base clock (tmr_clk) is derived from a prescaler which is clocked by the 32MHz crystal source. The prescaler provides a counter input frequency of 62.5KHz, which sets the granularity and resolution of the current time. The 24-bit counter automatically rolls over upon reaching its maximum value, yielding a maximum possible Event Timer duration of 268.436 seconds.

## READING CURRENT TIME

"Current Time" is defined as the value of the Event Timer internal counter. This 24-bit value can be read as the upper 3 bytes of the EVENT_TMR register. The EVENT_TMR register resides at at address ZLL_BASE + 0x8, so the upper 3 bytes begin at ZLL_BASE + 0x9. The 24-bit value represents the integer component of the 28-bit Event Timer, which is all that is needed for most Event Timer operations. (For accessing the extended precision Event Timer, see Section Extended Precision Event Timer below.)

## SETTING CURRENT TIME

"Current Time" is defined as the value of the Event Timer internal counter. This 24-bit value is available as the upper 3 bytes of the EVENT_TMR register. The EVENT_TMR register resides at at address ZLL_BASE + 0x8, so the upper 3 bytes begin at ZLL_BASE + 0x9. The current time is programmable, but does not have to be

programmed. In the reset condition, the current time is set to zero. Current time advances from zero at the tmr_clk clock rate and rolls over to zero after reaching its maximum value.

The Event Timer can be updated in one of 2 ways:

EVENT_TMR_LD: Write the desired new EVENT_TMR value into the EVENT_TMR field of the EVENT_TMR register (upper 3 bytes), with the EVENT_TMR_LD bit set.

EVENT_TMR_ADD: Write the desired *increment* to the EVENT_TMR value into the EVENT_TMR field of the EVENT_TMR register (upper 3 bytes), with the EVENT_TMR_ADD bit set. The increment will be added to the current value of EVENT_TMR to become the new EVENT_TMR value. Since the Event Timer value is 24-bits, the addition is modulo $2^{24}$.

Needless to say, EVENT_TMR_LD and EVENT_TMR_ADD are mutually exclusive, and no more than 1 of these bits should be set.

The 24-bit value represents the integer component of the 28-bit Event Timer, which is all that is needed for most Event Timer operations. (For accessing and updating the extended precision Event Timer, see Section Extended Precision Event Timer below.)

## LATCHING THE TIMESTAMP

During packet reception, the 802.15.4 link layer controller has the ability generate a timestamp, or to latch a copy of the "current time" while continuing to increment its internal counter. This timestamp value latched within the Event Timer corresponds to the beginning of a receive packet where the actual packet data begins after the SFD (Start-of-Frame-Delimiter) has been received. The timestamp[23:0] can be accessed by reading the read-only register of the same name, TIMESTAMP, which resides at address ZLL_BASE + 0xC. Once the timestamp has been latched, it shall remain valid until the *next* SFD detection.

## EVENT TIMER COMPARATORS

There are four 24-bit timer compare fields:

1. T1CMP[23:0] at address ZLL_BASE + 0x10
2. T2CMP[23:0] at address ZLL_BASE + 0x14
3. T3CMP[23:0] at address ZLL_BASE + 0x1C
4. T4CMP[23:0] at address ZLL_BASE + 0x20

And a special 16-bit timer compare field, for situations where the upper byte of EVENT_TMR is a don't-care.

- T2PRIMECMP[15:0] at address ZLL_BASE + 0x18

The TMR2IRQ status bit, can be set by a match to T2CMP or T2PRIMECMP. If register bit TC2PRIME_EN=1 (PHY_CTRL register, address ZLL_BASE + 0x04), then TMR2IRQ becomes set by a match to T2PRIMECMP (16-bit compare); if TC2PRIME_EN=0, then TMR2IRQ becomes set by a match to T2CMP (24-bit compare).

Each timer comparator has a enable bit that enables or disables the compare function. The enable bit is written to a 1 to enable the corresponding comparator, and the default condition is the timer compare disabled (reset to 0):

1. TMR1CMP_EN (for T1CMP)
2. TMP2CMP_EN (for T2CMP and T2PRIMECMP)
3. TMR3CMP_EN (for T3CMP)
4. TMR4CMP_EN (for T4CMP)

If a timer comparator is enabled using its associated bit, the corresponding interrupt status bit (TMRxIRQ) will be set by a timer compare match to its respective TxCMP register. If a timer comparator is disabled using its associated bit, the corresponding interrupt status bit (TMRxIRQ) will not be set by a timer compare match to its respective TxCMP register.

When enabled, all four fields can be continuously compared to the current value of the Event Timer counter. When a match occurs, the following corresponding internal status flags assert:

1. TMR1IRQ (T1CMP match)
2. TMR2IRQ (T2CMP or T2PRIMECMP match)
3. TMR3IRQ (T3CMP match)
4. TMR4IRQ (T4CMP match)

These 4 status bits all reside in the IRQSTS register at address ZLL_BASE + 0x0. The 4 interrupt status bits are write-1-to-clear. The status bit remains set until a 1 is written to the bit location in the IRQSTS register. Writing 0 to the bit, or reading the bit, will not change its state.

When a comparator match occurs and the internal status flag asserts, the following interrupt masks can enable an interrupt on the ipi_int_zigbee line to the MCU:

1. TMR1MSK, applies to TMRQ1IRQ
2. TMR2MSK, applies to TMRQ2IRQ
3. TMR3MSK, applies to TMRQ3IRQ
4. TMR4MSK, applies to TMRQ4IRQ

If the interrupt mask is set to 1 (masked), the respective interrupt status bit, TMRxIRQ, will not cause an interrupt on the ipi_int_zigbee line. If the interrupt mask is set to 0 (enabled), the respective interrupt status bit, TMRxIRQ, will cause an interrupt on ipi_int_zigbee. Timer mask bits, TMRxMSK, have no effect on the state of the TMRxIRQ interrupt status bits; they only allow (or prevent) the respective TMRxIRQ bit from generating an interrupt to the MCU on ipi_int_zigbee.

## INTENDED EVENT TIMER USAGE

It is intended that the system utilize the current time value and the timer compare functions of the Event Timer to schedule system events, including:

1. Generating time-based interrupts
2. Aborting an RX operation
3. Triggering transceiver operations

## GENERATING TIME-BASED INTERRUPTS

Generating time-based interrupts is accomplished by setting timer compare values relative to the current time, allowing the Event Timer counter to increment until a timer compare match is generated, and using this match to generate an interrupt to the host. The general procedure is as follows:

1. Disable the timer compare: set TMRxCMP_EN=0
2. Enable the timer compare interrupt mask: set TMRxMSK=1
3. Read the current time value from EVENT_TMR register
4. Determine an offset to this value to equal desired future time.
5. Write to EVENT_TMR register with the EVENT_TMR field set to this offset, and set EVENT_TMR_ADD=1
6. Re-enable the timer compare: set TMRxCMP_EN=1
7. Unmask the timer compare interrupt mask: set TMRxMSK=0
8. Wait for TMRxIRQ
9. After TMRxIRQ, program the appropriate TMRxCMP_EN bit to disable the compare function. If this is not done, the compare function will continue to run and generate another interrupt every time the counter rolls over and again matches the comparator.

## USING T3CMP TO ABORT AN RX OPERATION

The Event Timer provides a timer-based mechanism to automatically abort an RX operation. The 802.15.4 link layer is put into an RX operation when XCVSEQ[2:0] (PHY_CTRL register, address ZLL_BASE + 0x4) is set to 0x01. An RX autosequence will commence, and will begin a search for preamble. Software can program in advance,

a hardware timeout to occur, such that the RX autosequence can be automatically aborted by hardware after a certain amount of time elapses without a packet being detected. The general procedure is as follows:

1. Read the current time value from EVENT_TMR register
2. Add an offset to this value to equal desired future time to abort the RX operation.
3. Program register T3CMP[23:0] to value future time.
4. Program TC3TMOUT=1, (PHY_CTRL Register, address ZLL_BASE + 0x4) to 1, to enable hardware aborting of the RX operation.
5. Program XCVSEQ=1, to start the RX autosequence
6. When current time equals T3CMP[23:0], the 802.15.4 Sequence Manager aborts the RX autosequence, and the Sequence Manager returns to SEQ_IDLE state. The SEQIRQ interrupt status bit (IRQSTS Register, address ZLL_BASE + 0x0) will be set, and the TMR3IRQ interrupt status bit will also be set. The RXIRQ interrupt status bit will not be set, since no packet was received before the timeout. In the SEQ_CTRL_STATUS register (address ZLL_BASE + 0x78), the TC3_ABORTED status bit will also be asserted to indicate that the type of abort that occurred was a TMR3 timeout. This bit will self-clear at the start of the next autosequence.

As mentioned above, TMR3 with TC3TMOUT=1 can be used to abort an RX operation. Such an RX operation can be entered by launching a Sequence R (XCVSEQ=1), and can also be entered by launching a Sequence TR (XCVSEQ=4); after the TX operation of a Sequence TR completes, an RX operation begins, and can be aborted using this method. In addition, a Continuous CCA autosequence (XCVSEQ=5) can be aborted using this method. When a TMR3 timeout occurs with TC3TMOUT=1 during transceiver operations other than those listed above, TMR3 will not abort the autosequence, and TMR3 becomes merely a software timer, capable of setting TMR3IRQ and interrupting the MCU. The table below shows the effect of TMR3 timeouts on the 802.15.4 autosequences:

**Table 64-47. TMR3 Hardware Abort Functions**

| SEQUENCE | TC3TMOUT=0 | TC3TMOUT=1 |
|---|---|---|
| I | S/W timer | S/W timer |
| R | S/W timer | Abort sequence |
| T | S/W timer | S/W timer |
| C | S/W timer | S/W timer |
| TR | S/W timer | Abort sequence, (during receive operation only) |
| CCCA | S/W timer | Abort sequence |

## USING T2CMP OR T2PRIMECMP TO TRIGGER TRANSCEIVER OPERATIONS

The Event Timer provides a timer-based mechanism to automatically launch a transceiver autosequence. Using this method, a sequence can be scheduled for time in the future, and the MCU can be put into a reduced power state, without the need to wake up at the appropriate time to start the autosequence. The general procedure is as follows.

1. Read the current time value from EVENT_TMR register.
2. Add an offset to this value to equal desired future time to launch the autosequence.
3. For a 24-bit compare, program register T2CMP[23:0] to value future time, and set TC2PRIME_EN=0. For a 16-bit compare, program register T2PRIMECMP[15:0] to value future time, and set TC2PRIME_EN=1. Set TMRTRIGEN=1 and program the desired autosequence into XCVSEQ[2:0]. The Sequence Manager will not launch the sequence immediately because it sees TMRTRIGEN=1.
4. When current time equals T2CMP[23:0] (for a 24-bit compare), or T2PRIMECMP[15:0] (for a 16-bit compare), the Sequence Manager will launch the scheduled autosequence in accordance with the XCVSEQ[2:0] field. The TMR2IRQ interrupt status bit will become set simultaneous with the autosequence launch.
5. The MCU can wake up at this point (if TMR2MSK=0), or can elect to continue in low-power state until the autosequence completes, at which time SEQIRQ will become set. If SEQMSK=0, then SEQIRQ will interrupt the MCU at the completion of the transceiver operation.

## EXTENDED PRECISION EVENT TIMER

For most 802.15.4 transceiver operations referencing the Event Timer, the 24-bit precision and the 62.5KHz update rate (16µs period) are sufficient. However, the required precision for maintaining the 802.15.4 timebase is tighter: 1 microsecond, instead of 16. As long as the 32MHz reference oscillator is running there is no difficulty maintaining that precision. However, when the link layer has to enter low-power state, and the reference oscillator must be switched off, and alternate clock source must be temporarily employed to keep the timebase running. This low power state is known as Deep Sleep Mode, or DSM. The alternate clock source, a 32KHz crystal oscillator, is equally as precise as the reference oscillator, but with a much longer period. At the instant the reference oscillator is turned off and the switchover to the 32KHz is made, the EVENT_TMR becomes frozen at its current state. After a period of DSM, when the precisely-programmed wakeup point is reached, the reference oscillator, which has been previously restarted, is re-engaged by the link layer, and the EVENT_TMR resumes counting where it left off. The precise duration of time for which the EVENT_TMR was frozen, is known to software, based on DSM programming parameters. The EVENT_TMR must be corrected for this "time slept", by adding to it an amount equal to "time slept", in microseconds (hence the requirement for microsecond precision). After the precise correction is made, the EVENT_TMR is now up-to-date, as if the DSM entry/exit had never happened, and all previously scheduled events will occur on time, within 1µs precision.

To realize the required microsecond precision, the actual Event Timer has been expanded to 28 bits, with 24 integer bits and 4 fractional bits, as shown in the diagram below.

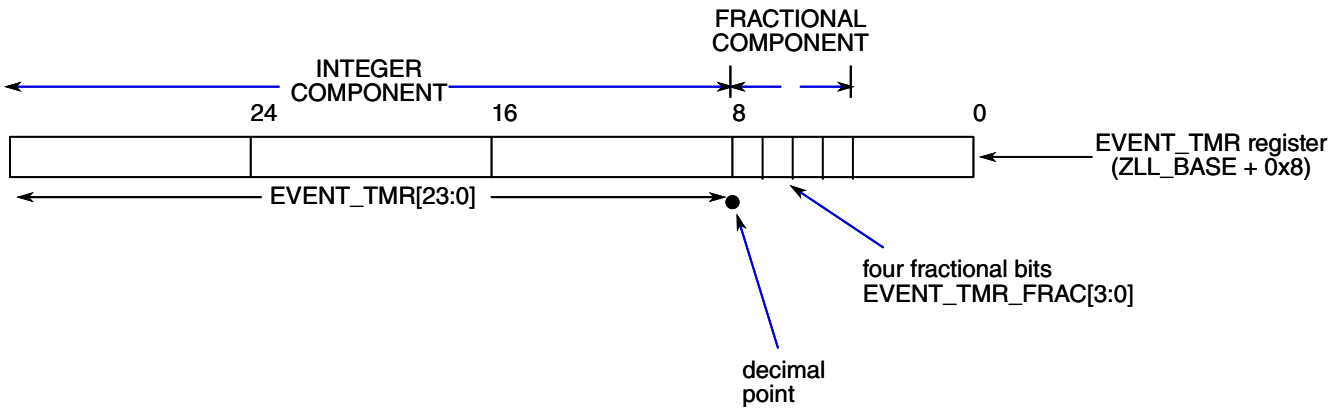

**Figure 64-150. Event Timer Integer and Fractional Components**

The 24-bit integer component is the EVENT_TMR value that has been referenced earlier in this section; most 802.15.4 operations require only the integer component, and the fractional component can be ignored. When the fractional bits are not required, writes to EVENT_TMR register (read-modify-write operations) with EVENT_TMR_LD=1 should leave the fractional bits unchanged. Transceiver operations which reference the EVENT_TMR (i.e., automatic sequence launching, and RX sequence aborting), reference only the integer component, as shown below.

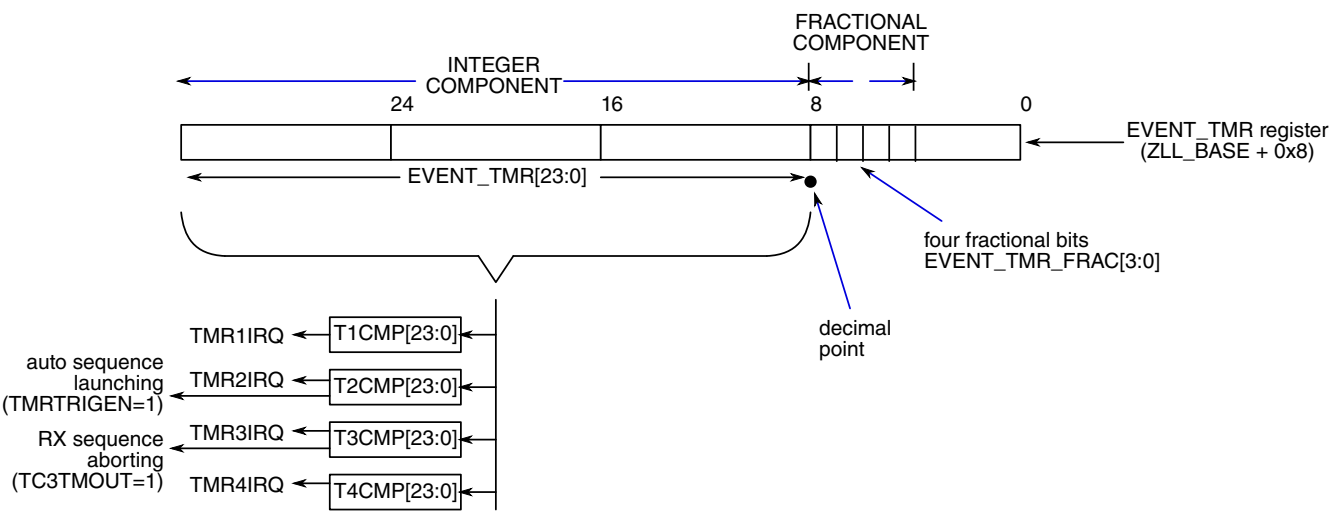

**Figure 64-151. Event Timer Hardware Referencing**

However, software EVENT_TMR updates to correct for "time slept" after a DSM cycle must make use of the full precision, including the fractional bits, in order to maintain microsecond accuracy. For example, say a DSM cycle was just completed in which the EVENT_TMR was frozen for exactly 163µs. The 163µs must be "added back" to the EVENT_TMR.

In this case the integer component is:

integer(163µs / 16µs) = **10**

And the fractional component is the remainder x 16:

(163µs / 16µs) - integer(163µs / 16µs) = 3/16 x 16 = **3**

So the value written to the EVENT_TMR with the EVENT_TMR_ADD bit set, accounting for the bit shifts to align to the integer and fractional components of the EVENT_TMR register, is:

(10 << 8) | (3 << 4), *or,*

EVENT_TMR = (10 << 8) | (3 << 4) | EVENT_TMR_ADD;

This operation adds 163µs to the EVENT_TMR current time, and after the update has occurred, the 802.15.4 timebase has been restored, as if no DSM cycle had occurred, within 1µs accuracy.

#### 64.5.2.4.6 Simultaneous CCA/RX

The 802.15.4 Link Layer controller features an autosequence that precedes a packet transmission with a CCA (Clear Channel Assessment), to ensure the channel is idle before transmitting. If the CCA indicates a busy channel, the autosequence ends after the CCA, without transmitting. In slotted mode, 2 CCA measurements take place, with the start points for the measurements 320us apart. Both must indicate an idle channel for transmission to proceed.

During intervals of severe network congestion, high node density, and packets which are heavily fragmented, the situation can arise where Device A is preparing to transmit a packet, or fragment, and performing pre-transmit CCA, and during the CCA, Device B attempts to transmit another packet or fragment to Device A. Previous NXP 802.15.4 transceivers were unable to receive a packet during CCA, so Device B's packet will be missed by Device A. For the Gen3 2.4GHz radio, the capability to receive-during-CCA has been added to 802.15.4. This capability is referred to as "Simultaneous CCA/RX".

To enable this capability, 3 enhancements have been made to the digital receiver and the 802.15.4 sequence manager:

1. CCA Mode 2 Algorithm Separated from 802.15.4 Demodulator
2. New 802.15.4 State Machine Transitions
3. New TSM Fast RX-to-TX Capability

**1. Separated CCA Mode 2 Algorithm**

One reason for the lack of prior support, is that the CCA Mode 2 algorithm has been tightly integrated with the 15.4 demodulator, so that both functions cannot simultaneously co-exist. The Gen3 digital receiver separates these functions, removing the CCA Mode 2 impediment to Simultaneous CCA/RX. See Chapter *Receiver Digital Module*, Section *IEEE 802.15.4 CCA mode 2*. (CCA Mode 1 does not utilize the demodulator, so such impediment exists.)

The legacy CCA Mode 2 hardware has been retained as a back-up. The control bit USE_DEMOD_CCA2 selects between legacy (1) and new CCA Mode 2 (0). This bit must be set to 0 to utilize Simultaneous CCA/RX. The following table summarizes the programmability associated with CCA Mode 2. The third column references table *IEEE 802.15.4 CCA mode 2 parameters* in Chapter *Receiver Digital Module*, Section *IEEE 802.15.4 CCA mode 2*

| REGISTER NAME | ADDRESS SPACE | ASSOCIATED CCA MODE 2 PARAMETER | DESCRIPTION |
|---|---|---|---|
| USE_DEMOD_CCA2 | XCVR | n/a | CCA Mode 2 hardware selector.<br>• 0: use new CCA Mode 2<br>• 1: use demodulator-based (legacy) CCA Mode 2 |
| CCA2_CORR_THRESH[7:0] | 802.15.4 | zb_cca2_thresh_corr[7:0] | Threshold used to compare correlation products. **Note:** this register is shared between the new and legacy CCA Mode 2 hardware |
| CCA2_CNT_THRESH[9:0] | XCVR | zb_cca2_thresh_cnt[9:0] | Threshold to compare count of correlation products exceeding CCA2_CORR_THRESH[7:0] |
| CCA2_SYM_THRESH[9:0] | XCVR | zb_cca2_thresh_sym[9:0] | Threshold used to detect repetition sequence addresses corresponding to correlation products that exceed CCA2_CORR_THRESH[7:0] |
| CCA2_REF_SEQ[7:0] | XCVR | zb_cca2_ref_seq[7:0] | Selection of the sequence addresses to be used. |
| CCA2_INTERVAL[1:0] | XCVR | zb_cca2_duration[1:0] | Specifies the CCA2 measurement window duration:<br>• 0x00 - 64 µs<br>• 0x01 - 128 µs<br>• 0x02 - 256 µs<br>• 0x03 - 512 µs |

**Note:** Set CCA2_DURATION=0x01 (128us) for 802.15.4 operation.

## 2. New 802.15.4 State Machine Transitions

Using Simultaneous CCA/RX, the 802.15.4 Link Layer controller needs to be able to anticipate preamble, and even SFD detection, during the states in which it is taking CCA measurement. Those states are RX_CCA1, for non-slotted, and RX_CCA2, for slotted operation. If preamble and/or SFD is detected in those states, the 802.15.4 sequence manager needs to transition to a packet reception state, and then receive the packet in its entirety as if the called sequence was Sequence R. To address this, these new state transitions have been added to the 802.15.4 Sequence Manager (ZSM) state machine:

- RX_CCA1 -> RX_PRE (preamble detected during 1st CCA but no SFD)
- RX_CCA1 -> RX_PKT (preamble + SFD detected during 1st CCA)
- RX_CCA2 -> RX_PRE (preamble detected during 2nd CCA but no SFD)
- RX_CCA2 -> RX_PKT (preamble + SFD detected during 1st CCA)

The following diagram highlights the new ZSM state transitions, in red:

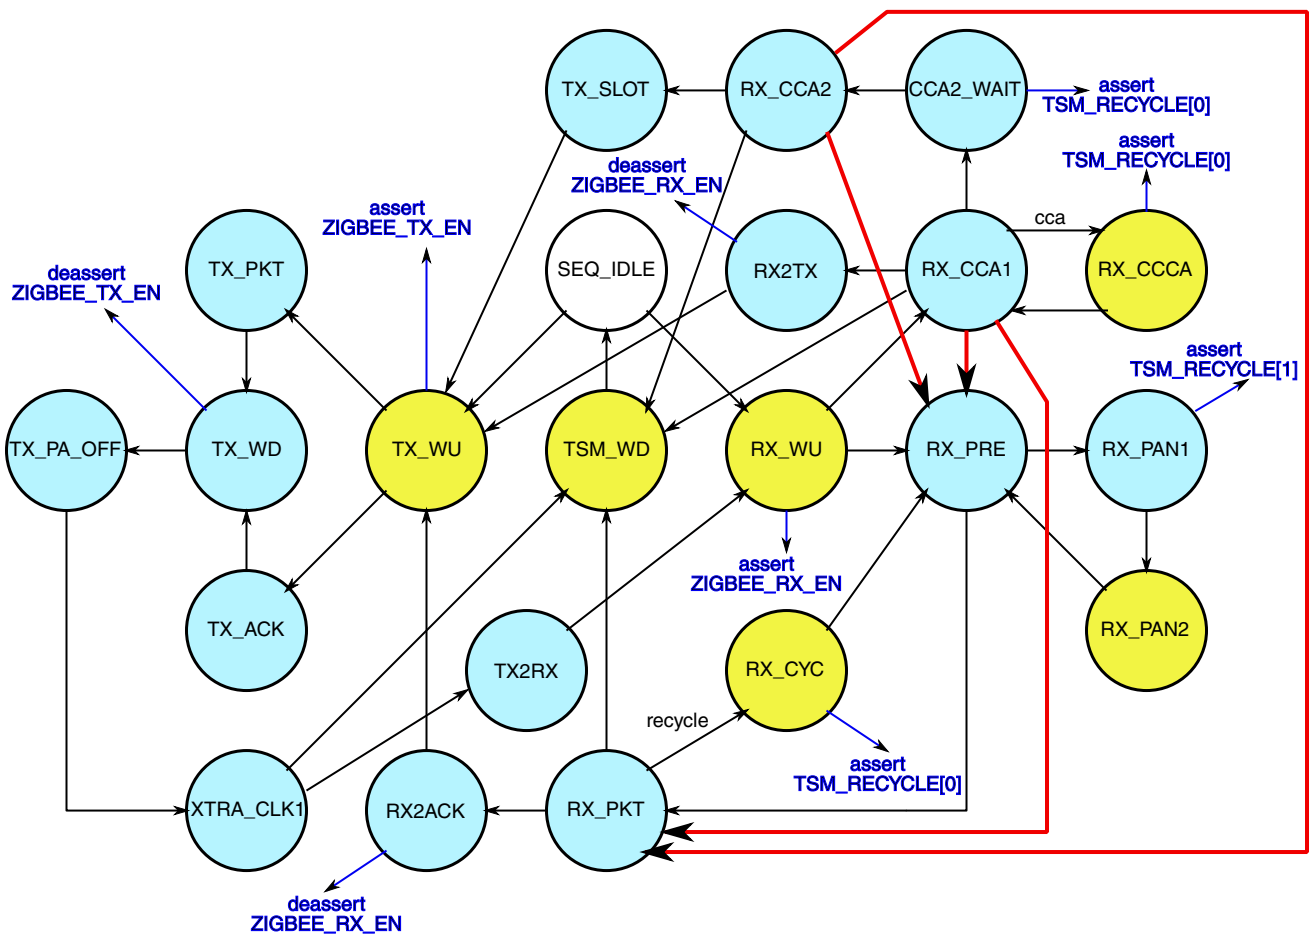

**Figure 64-152. NEW ZSM STATE TRANSITIONS FOR SIMUL CCA/RX**

False preambles may occur during the CCA states as well. False preambles occur when the 802.15.4 demodulator detects a sufficient number of consecutive 0 symbols to meet the preamble threshold, but the symbol which follows is neither a '0' nor a '7'. False preambles result in the 802.15.4 demodulator signal sfd_rst asserting either during, or after, the CCA state. If a false preamble is declared *within* the 128µs CCA window, then the fact that there was a false preamble has no bearing on the channel status, the CCA measurement determines channel status, as usual. If the false preamble is declared *after* the CCA window, the channel is assessed to be busy and the autosequence terminates without transmission, because the scheduled transmission time has been missed.

In defining the Simultaneous CCA/RX operation, 9 "scenarios", or cases, were developed to help ensure correct harwdare response to various permutations of preamble and SFD arrival times, preamble falsing, channel status, and RX packet goodness. These scenarios were used to guide the hardware design, for each of the 3 CCA modes, and for mode 3, both boolean combinations. The 9 scenarios are listed in the table below, with the correct hardware response indicated. The hardware response consists of a sequence of state transitions, as well as assertion (or non-assertion) of the various 802.15.4 interrupts. The final combination of asserted interrupts assists software in determining what transpired during the autosequence, and therefore what must be done next.

**Figure 64-153. SIMUL CCA/RX SCENARIOS**

A single register bit enables Simultaneous CCA/RX mode: SIMUL_CCA_RX. This bit resides in the CCA_CTRL register in 802.15.4 address space. By default SIMUL_CCA_RX=0, meaning that the new ZSM transitions are inhibited. Set this bit to 1, to enable the new transitions. Simultaneous CCA/RX works with any CCA Mode (1, 2, or 3), and works for both non-slotted (single CCA before TX) and slotted (2 CCA before TX) modes.

Note that to use the Simultaneous CCA/RX feature, software (not just hardware) needs to anticipate packet reception during a Sequence T (not just a Sequeunce TR). This may not exist today, since prior to Gen3, the 802.15.4 controller did not have this capability.

## 3. New TSM Fast RX-to-TX Capability

The 802.15.4 Sequence Manager (ZSM), makes use of the radio's all-protocol Transceiver Sequence Manager (TSM) to execute TX and RX warmup and warmdown sequences; TSM handles low-level commanding, with precise, programmable timing, of the analog and digital blocks in the transmit and receive chains, absolving the higher-level sequence managers from this responsibibility. TSM sequences have, in the past, been discrete TX or RX operations, with a required software command to initiate the sequence, and a return-to-idle after the sequence is complete, before a new sequence-start command can be issued. For 802.15.4 Simultaneous CCA/RX mode, it is highly desirable to be able to jump directly from the end of a CCA measurement, which is essentially an RX operation, to a packet transmit operation, without returning the TSM to IDLE in between, if CCA deems the channel to be free. A new TSM transition called Fast RX2TX accomplishes this. The 802.15.4 ZSM will signal to TSM when to perform such a transition, and TSM will respond by jumping from the RX ON phase, to a programmable point within the TX warmup. See Chapter *Transceiver Sequence Manager*, Section *FAST TSM Warmup and FAST RX2TX Transition* for more details on this TSM feature, and a description of the ZSM -> TSM signalling required to execute such a transition.

A single register bit enables TSM Fast RX-to-TX: FAST_RX2TX_EN. This bit resides in the TSM_FAST_CTRL1 register in XCVR address space. By default FAST_RX2TX_EN=0, meaning that this TSM capability is inhibited, and RX-to-TX transitions remain discrete RX and TX sequences (legacy).

Once enabled with FAST_RX2TX_EN=1, the ZSM will request a TSM Fast RX-to-TX warmup, by asserting fast_rx2tx_wu, when all of the the following conditions are met:

- 802.15.4 autosequence is T or TR
- Pre-TX CCA is enabled with CCABFRTX=1
- ZSM state is RX_CCA1 (non-slotted or slotted) or RX_CCA2 (slotted mode only)
- 128µs measurement timeout expires
- Neither preamble-detect nor SFD-detect are *currently* asserted
- Channel is deemed idle (CCA=0)

The TSM will respond to fast_rx2tx_wu by jumping from the "ON" phase of the RX operation to the "WARMUP" phase of the TX operation at the programmed point. Simultaneously, ZSM must jump to its TX_WU state to wait for the TX warmup to complete. This requires 2 new state transitions, to enable the Simultaneous CCA/RX feature, shown in red in the diagram below:

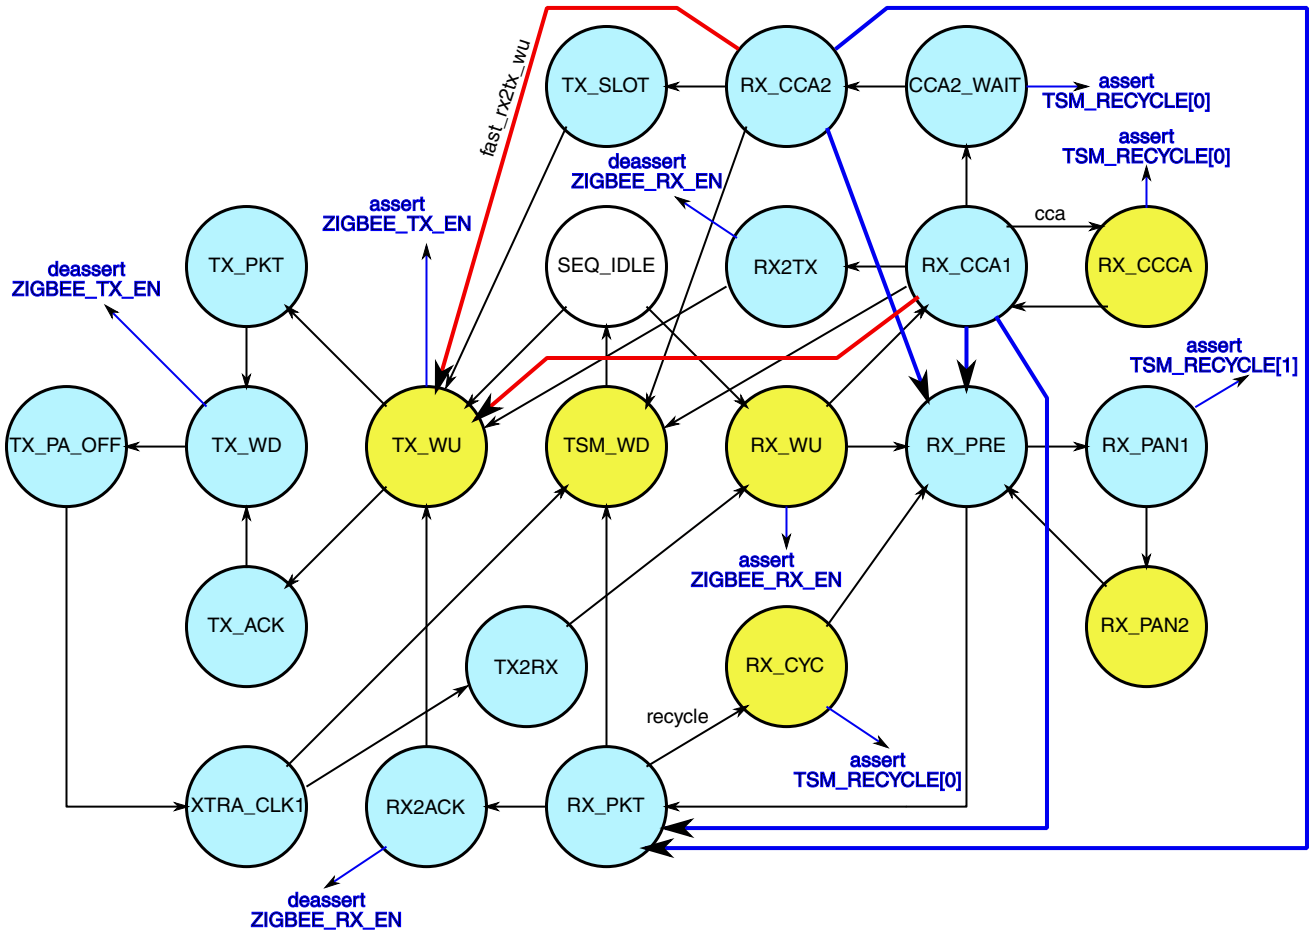

**Figure 64-154. ZSM STATE TRANSITIONS FOR FAST RX2TX**

Once the TX warmup completes, the 802.15.4 controller will transmit the packet as per the Sequence T command.

### 64.5.2.4.7 Manual DSM

When the 802.15.4 Link Layer anticipates long periods of inactivity, the Link Layer controller can be put into a Deep Sleep Mode (DSM), where all of its clocks are turned off. In addition, the 802.15.4 Link Layer can be configured to optionally turn off the RF Oscillator, if it is not otherwise needed by the SoC. Deep Sleep Mode results in dramatic power savings. The procedure described below, is called Manual DSM.

To make Manual DSM possible, the transceiver incorporates a low-frequency, high-precision Deep Sleep Timer, DSM_TIMER. This timer is clocked by a crystal-referenced 32.768KHz oscillator. The timer is 24-bit wide, yielding a 8.5 minute rollover (the maximum length of a deep sleep period).

The hardware to implement DSM within the SoC, is partitioned across several modules, and several power domains. This is to allow the maximum achievable power savings, by retaining full voltage for only those modules which need to be active in DSM, and placing the remaining modules in “state retention” mode. The diagram below depicts the partitioning of DSM hardware across the various modules, including the 802.15.4 Link Layer Controller.

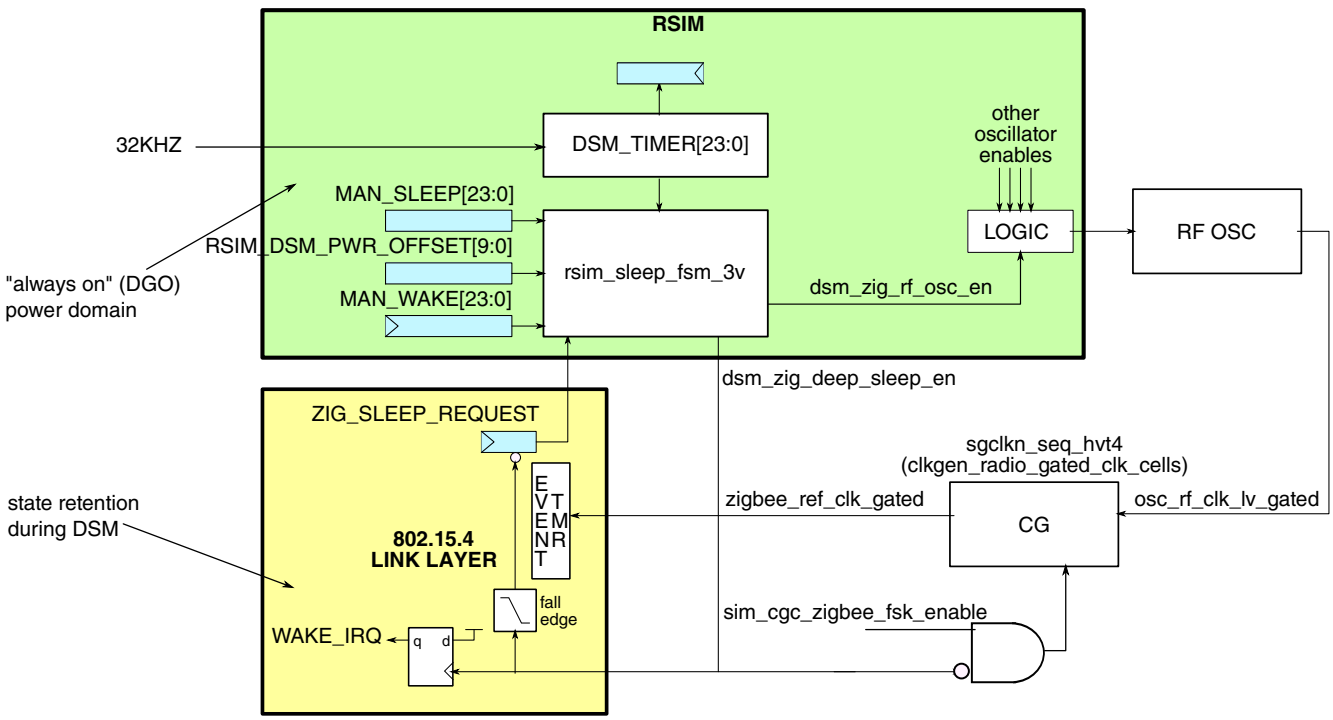

**Figure 64-155. MANUAL DSM BLOCK DIAGRAM**

The concept behind Manual DSM, as it is implemented for 802.15.4, is to allow the 802.15.4 timebase to be maintained for a period of time, while the RF Oscillator is turned off and much of the SoC is placed in state-retention. During DSM, the timebase management is temporarily transferred from the 802.15.4 EVENT_TMR to the low-power DSM_TIMER, and after DSM exit, timebase management is transferred back to the EVENT_TMR, under software control. During DSM, the EVENT_TMR is frozen. The total time spent in DSM is known to software, so that upon exiting DSM, the EVENT_TMR can be updated to correct for the precise amount of time it was frozen.

DSM entry and exit, and RF Oscillator re-start during Manual DSM, are governed by 5 registers, as described in the table below.

| Field | R/W | Description |
|---|---|---|
| MAN_SLEEP[23:0] | rw | If ZIG_SLEEP_REQUEST=1, enter DSM & freeze EVENT_TMR when MAN_SLEEP matches DSM_TIMER. |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | **NOTE:** This register resides in RSIM Address Space |
| RSIM_DSM_PWR_OFFSET[9:0] | rw | Determines the power and RF oscillator re-start times relative to MAN_WAKE<br>**NOTE:** This register resides in RSIM Address Space |
| MAN_WAKE[23:0] | rw | Exit Deep Sleep Mode, and resume EVENT_TMR, when MAN_WAKE matches DSM_TIMER<br>**NOTE:** This register resides in RSIM Address Space |
| ZIG_SLEEP_REQUEST | w | Enable a match on MAN_SLEEP[23:0] to DSM_TIMER[23:0], to enter Deep Sleep Mode, by writing a 1 to this bit. Cancel a pending sleep request by writing a 0 to it, if already set, at least 2 32.768KHz clock cycles prior to MAN_SLEEP[23:0] |
| DSM_TIMER[23:0] | r | Current State of the 32KHz Sleep Timer<br>**NOTE:** This register resides in RSIM Address Space |

## Procedure

The procedure to schedule a Manual DSM cycle (entry/exit) as well as to program the desired RF Oscillator re-start time, and the calculation to restore the 802.15.4 EVENT_TMR after a DSM cycle, is described below.

1. Software determines the future time at which it would like to enter DSM, by reading the DSM_TIMER, computing the number of 32KHz clock cycles remaining until the desired DSM start-time, and writing this value into MAN_SLEEP register. The value programmed into MAN_SLEEP should be no fewer than 4 clocks greater (in the future) than the current time as read from DSM_TIMER.
2. Software determines the future time at which it would like to exit DSM, by computing the number of 32KHz clock cycles remaining until the desired DSM exit-time, and writing this value into MAN_WAKE register.
3. Software writes a 1 to DSM_CTRL[ZIG_SLEEP_REQUEST]. This bit resides in 802.15.4 address space. This bit is write-only and always reads back 0. Writing this bit to 1 enables a DSM cycle to commence using the values programmed into MAN_SLEEP and MAN_WAKE.
4. MCU can go into a low power state (e.g., STOP, VLPS, or VLLSx)
5. When DSM_TIMER = MAN_SLEEP, the EVENT_TMR will be clock-gated so that it will remain frozen at its current count. The RF Oscillator will be turned off (unless overridden due to a non-802.15.4-related SoC requirement)

6. All hardware not in the low-voltage domain will be placed into state-retention, or other low-power state.
7. When DSM_TIMER = MAN_WAKE, clocking of the 802.15.4 Link Layer Controller will resume and the EVENT_TMR will be ungated (allowed to resume counting).
8. Software computes the time that the SoC was in DSM (and hence the time the EVENT_TMR was frozen), in microseconds, with the equation:
   **(MAN_WAKE – MAN_SLEEP) / 32768 * 1000000**
9. Software increments the 802.15.4 EVENT_TMR by this amount, by writing this value to the EVENT_TMR register with EVENT_TMR_ADD=1. **Note:** The 802.15.4 EVENT_TMR has an integer component (24 bits) and a fractional component (4 bits). The fractional component provides the microsecond precision to the Event Timer, so both components need to be accounted for when compensating for the DSM "time slept".
10. On the next 1MHz clock edge, the EVENT_TMR has been restored to where it would have been, had no DSM occurred, with 1.0-microsecond accuracy.

Note that the 1.0-microsecond accuracy quoted above, assumes an ideal 32.768KHz source. Any ppm error in the 32.768KHz source will degrade the microsecond accuracy proportionally to the magnitude of the error.

Once ZIG_SLEEP_REQUEST has been set to 1 to request Manual DSM, the request can be cancelled by writing a 0 to the bit. The cancellation must be performed at least 2 32.768KHz before the MAN_SLEEP[23:0] match to DSM_TIMER[23:0] to avoid a race condition to enter DSM.

The following timing diagram depicts an 802.15.4-driven DSM entry/exit cycle.

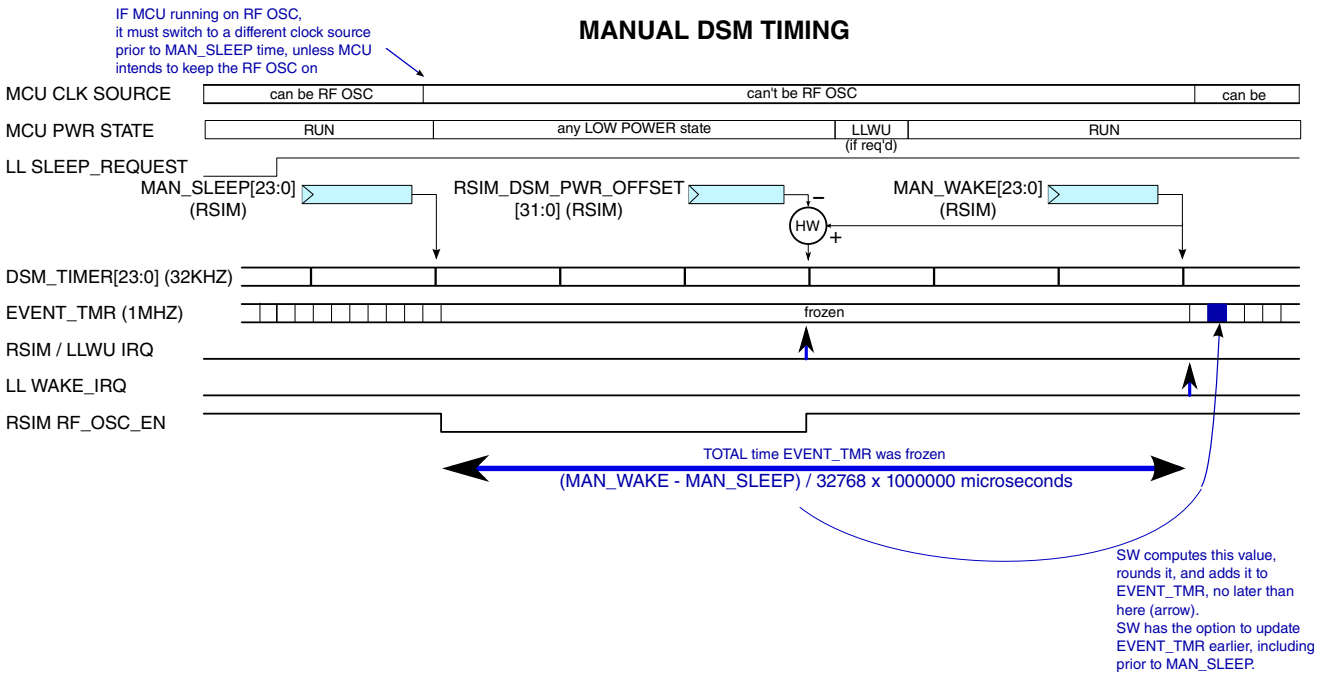

**Figure 64-156. 802.15.4 DEEP SLEEP TIMING**

## DSM Early Exit

Circumstances may arise where the Manual DSM cycle may occasionally need to be cut short, due to circumstances beyond the control of the radio. When this happens, the SoC, starting with the MCU, is awakened out of its low power state, long before the RSIM DSM_TIMER reaches MAN_WAKE. Therefore, software handling the event which triggered the wakeup, will determine if the radio needs to be awakened as well. If this is the case, software will advance the MAN_WAKE setting to a point in the near future, but no fewer than 4 32KHz clock cycles beyond the current time ascertained by reading DSM_TIMER. So, to execute a Manual DSM Early Exit, software shall read DSM_TIMER, add +4 to the value, and write the sum to the RSIM MAN_WAKE register. Software shall then wait for the 802.15.4 WAKE_IRQ interrupt, which will assert once the full radio wakeup from the low power state has completed. Software should then take whatever steps are necessary to configure the radio to respond to the conditions which triggered the early exit. Servicing of a DSM early exit interrupt is beyond the scope of this document.

### 64.5.2.4.8 Wake-On-Radio

The 802.15.4 Link Layer can take advantage of the automated sequence- and DSM-scheduling provided by Wake-On-Radio. Wake-On-Radio is one of two DSM control schemes that can be selected for 802.15.4, as an alternative to Manual DSM. See Chapter *Wake-On-Radio*.

Several changes to the 802.15.4 Link Layer Controller have been made to support Wake-On-Radio.

Interrupt WAKE_IRQ has been made dual-purpose. If Wake-On-Radio is disabled, i.e., WOR_CTRL[WOR_EN]=0, or Wake-On-Radio not assigned to 802.15.4, WAKE_IRQ performs its legacy function for Manual DSM. (See Section Manual DSM). If Wake-On-Radio is enabled, i.e., WOR_EN=1, and assigned to 802.15.4, this interrupt becomes WOR_IRQ, and has new functionality specific to Wake-On-Radio. See Chapter *Wake-On-Radio*, Section *Interrupt Management*, for more details on the meaning, and handling of WOR_IRQ.

In addition to WOR_IRQ, numerous interface changes have been made to support Wake-On-Radio. The changes allow, for example, WOR to manage 802.15.4's RF interrupts, inhibit timestamp updates, etc. The added port signals are listed in the table below, along with a description or each:

| WAKE-ON-RADIO INTERFACE SIGNAL | DIRECTION | DESCRIPTION |
|---|---|---|
| wor_event_tmr_add[27:0] | WOR -> 802.15.4 | The Event Timer "Addback" value computed by WOR to compensate for the amount of time Event Timer was frozen during DSM |
| wor_addback | WOR -> 802.15.4 | A 1µs-long pulse commanding the 802.15.4 Event Timer to auto-increment by the the amount appearing on wor_event_tmr_add[27:0] |
| wor_force_wake_irq | WOR -> 802.15.4 | Force WOR_IRQ to assert, due to an occurrence of one of the 3 WOR_IRQ interrupt triggers |
| wor_block_wake_irq | WOR -> 802.15.4 | Inhibit the legacy WAKE_IRQ assertion when WOR_EN=1 (this interrupt becomes WOR_IRQ) |
| tx_start_ext | WOR -> 802.15.4 | A 1µs-long pulse to the 802.15.4 command decoder to initiate a WOR-driven TX sequence |
| rx_start_ext | WOR -> 802.15.4 | A 1µs-long pulse to the 802.15.4 command decoder to initiate a WOR-driven RX sequence |
| seq_stop_ext | WOR -> 802.15.4 | A 1µs-long pulse to the 802.15.4 command decoder to stop (abort) a WOR-driven RX sequence |
| wor_allow_irq | WOR -> 802.15.4 | Inhibits RF interrupts, so that interrupt assertions can be managed based on WOR descriptor settings. Controlled dynamically by the WOR state machine. |
| timestamp_inhibit | WOR -> 802.15.4 | In Wake-On-Radio, the legacy 802.15.4 TIMESTAMP register becomes WOR TIMESTAMP0 (timestamp for SLOT0). |

*Table continues on the next page...*

| WAKE-ON-RADIO INTERFACE SIGNAL | DIRECTION | DESCRIPTION |
|---|---|---|
| | | This signal blocks this register from updating on SLOTS 1-3 |
| wake_irq_trig | WOR <- 802.15.4 | WOR uses this signal to cancel ZIG_SLEEP_REQUEST and transition from IN_DSM -> COMP_ADDBACK state |
| event_tmr[27:0] | WOR <- 802.15.4 | 802.15.4 Event Timer, used by WOR for timestamp capture |
| event_tmr_plus_1[27:0] | WOR <- 802.15.4 | 802.15.4 Event Timer + 1, used by WOR to schedule RF operation starts and stops |
| tx_irq_trig | WOR <- 802.15.4 | TXIRQ trigger, indicates the completion of a packet transmission, used by WOR to transition out of WAKE_SEQ_END state |
| rx_irq_trig | WOR <- 802.15.4 | RXIRQ trigger, indicates the completion of a good packet reception, used by WOR to transition out of WAKE_SEQ_END state |
| rx_status_for_wor[2:0] | WOR <- 802.15.4 | Internal RX status signals used by WOR to formulate TIMESTAMPx_STS[2:0] |
| timestamp_clk_en | WOR <- CGM <- 802.15.4 | Timestamp clock gate enable, the resultant clock is used by WOR to update the TIMESTAMP1,2, and 3 registers |

## 64.5.2.4.9 CCA/ED/LQI

### 64.5.2.4.9.1 Introduction

CCA/ED/LQI block resides inside 802.15.4 demodulator top. The purpose of this block is to perform the following operations: 1) Clear Channel Assessment: Modes 1, 2 and 3, 2) Energy Detection and 3) Link Quality Indicator.

This block takes RSSI value, as an input, for computations related to CCA modes 1 and 3, Energy Detection and LQI. For CCA2, this block takes output of 802.15.4 correlators for detecting an 802.15.4 signal in the channel of interest.

At the output, it provides a signal called (cca) to indicate if the channel of interest is busy (cca=1) or idle (cca=0), the final computed energy value (cca1_ed_fnl) and Link Quality Indicator (LQI) value. The cca signal is further used to generate cca interrupt, according to the set interrupt mask. The cca1_ed_fnl is a signed 8 bit value that can be read back as a register. LQI is an unsigned 8 bit value that is written at the end of each valid packet that is received and is available to be read in the packet buffer.

#### 64.5.2.4.9.1.1 Block diagram

### 64.5.2.4.9.2 Memory Map and register definition

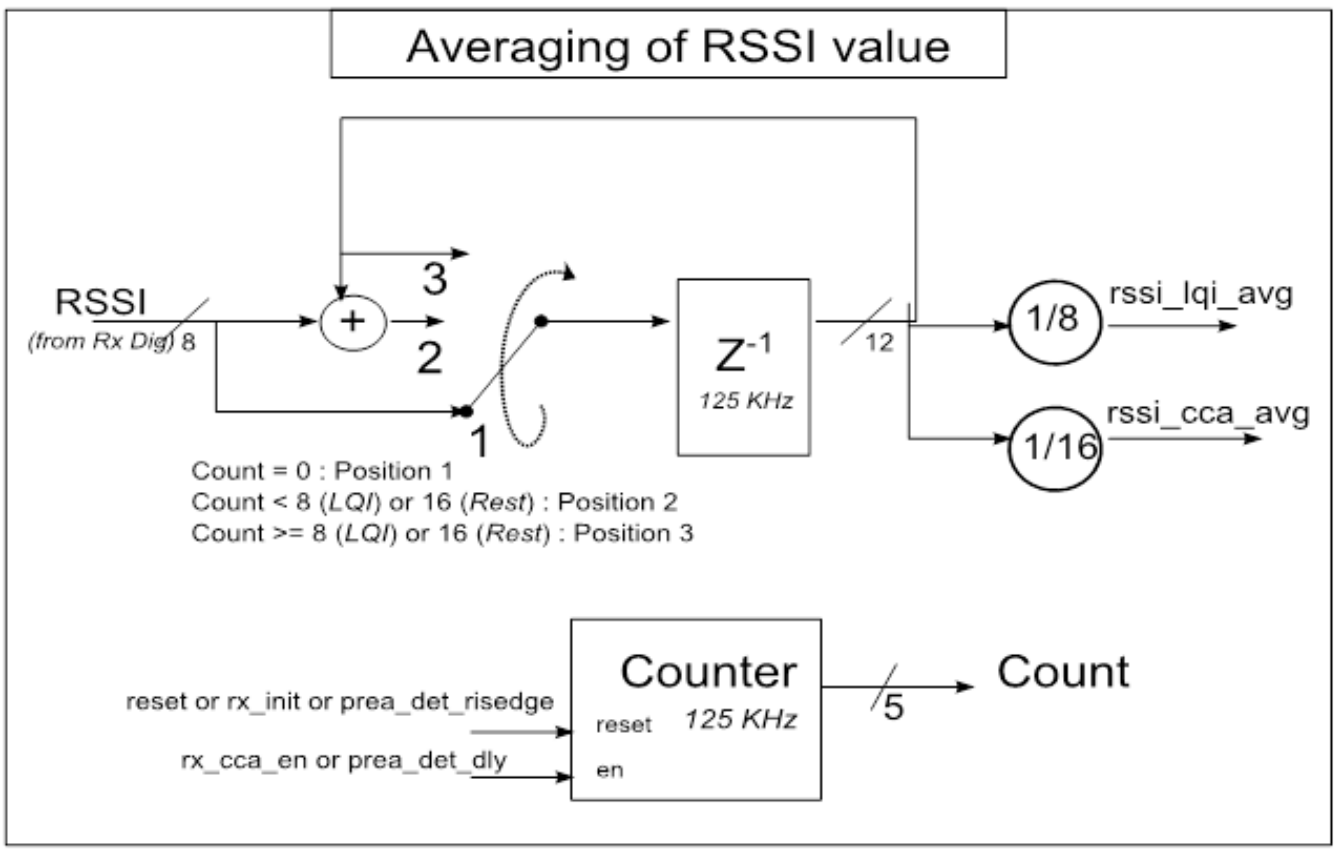
| Field | R/W | Description |
|---|---|---|
| LQI_VALUE[7:0] | r | 8-bit LQI value of each Rx packet |
| CCA1_ED_FNL[7:0] | r | 8-bit signed value to indicate last energy detected |
| CCA1_THRESH[7:0] | rw | 8-bit signed value to be compared against averaged signed RSSI value from Rx DIG block, to determine channel busy or idle |
| LQI_OFFSET_COMP[7:0] | rw | 8-bit value to offset average of signed RSSI value coming from Rx DIG, in order to compute 8-bit LQI value. |
| CCA3_AND_NOT_OR | rw | This register bit controls how CCA1 and CCA2 are combined to assert CCA3 mode:<br>1 : CCA1 AND CCA2<br>0: CCA1 OR CCA2 |
| CCA2_MIN_NUM_CORR_THRESH[2:0] | rw | 3-bit value to compare against number of correlation peaks within CCA2 time. |
| CCA2_NUM_CORR_PEAKS[3:0] | r | 4-bit value indicating number of correlation peaks detected in last CCA2 run |
| CCA2_CORR_THRESH[7:0] | rw | 8-bit value to be compared against correlation peak value during CCA2 operation. |
| LQI_START_AT_SFD | rw | Defines starting point for LQI computation during packet reception |

| Field | R/W | Description |
|---|---|---|
| | | 1: Begin computing LQI at SFD detect (new for KW41)<br>0: Begin computing LQI at preamble detect (legacy) |

### 64.5.2.4.9.3 Functional description

The following sections describe functional details of the module.

#### *64.5.2.4.9.3.1 RSSI Averaging*



The above picture shows how RSSI is averaged. 8-bit signed RSSI value from Rx Dig block is averaged for 128 us for CCA1/2/3/ED sequences. For LQI, it is averaged for 64 us. In both cases, the RSSI value is sampled at 125 KHz rate.

#### *64.5.2.4.9.3.2 CCA1*

When the 802.15.4 link layer is set up to perform CCA1 operation, rx_cca_en signal is asserted at the end of Rx warm up by the 802.15.4 Sequence Manager (ZSM). After rx_cca_en is asserted high, at the end of 128 us, i.e. count = 16, rssi_cca_avg is compared against 8-bit signed register cca1_thresh to assess CCA as follows:

If rssi_cca_avg >= cca1_thresh, CCA1 = 1, i.e. channel is busy.

Else CCA1 = 0, i.e. channel is idle.

#### *64.5.2.4.9.3.3 CCA2*

When the 802.15.4 link layer is set up to perform CCA2 operation, rx_cca_en signal is asserted at the end of Rx warm up by the 802.15.4 Sequence Manager (ZSM). During CCA2 operation, differential chip detection is enabled and automatic frequency correction is disabled, in order to receive correlation peaks related to all available 16 802.1.5.4 symbols. The signal max_corr_en is held high, in order to refresh maximum correlator value after each symbol period. 128 us after rx_cca_en is asserted high, i.e. count = 16, the number of maximum correlation peaks are counted which exceeded the value cca2_corr_thresh register. If the number of correlation peaks exceeds minimum desired number of correlation peaks (programmable register: cca2_num_corr_peaks), cca2 is asserted high to indicate the channel is busy and low otherwise, to indicate channel is idle.

#### *64.5.2.4.9.3.4 CCA3*

CCA mode 3 is a combination of CCA1 and CCA2. There are 2 combinations in which CCA mode 3 operates, based on the register setting of CCA3_AND_NOT_OR: 1) CCA1 OR CCA2 2) CCA1 AND CCA2. When the 802.15.4 link layer is set to perform CCA3, both CCA1 and CCA2 operations, as mentioned above and decides if the channel is busy or idle, according to the desired combination (i.e. AND/OR).

#### *64.5.2.4.9.3.5 Energy Detection*

During Energy Detection operation, the demodulator is expected to average RSSI value (from Rx_DIG) for 128 us, as mentioned above in the block diagram. At the end of 128 us, the register CCA1_ED_FNL is updated with this average energy value. Energy detection is similar to CCA1. Unlike CCA1, busy/idle signal is not generated.

#### *64.5.2.4.9.3.6 Link Quality Indicator*

LQI maps RSSI value (from Rx_DIG) to values between 0x00 and 0xFF, as shown in the following block diagram. Upon preamble detect, RSSI value is averaged for 64 us and mapped to LQI value. This latched LQI value is available in the register LQI_VALUE. Packet processor also appends this LQI value at the end of packet buffer.

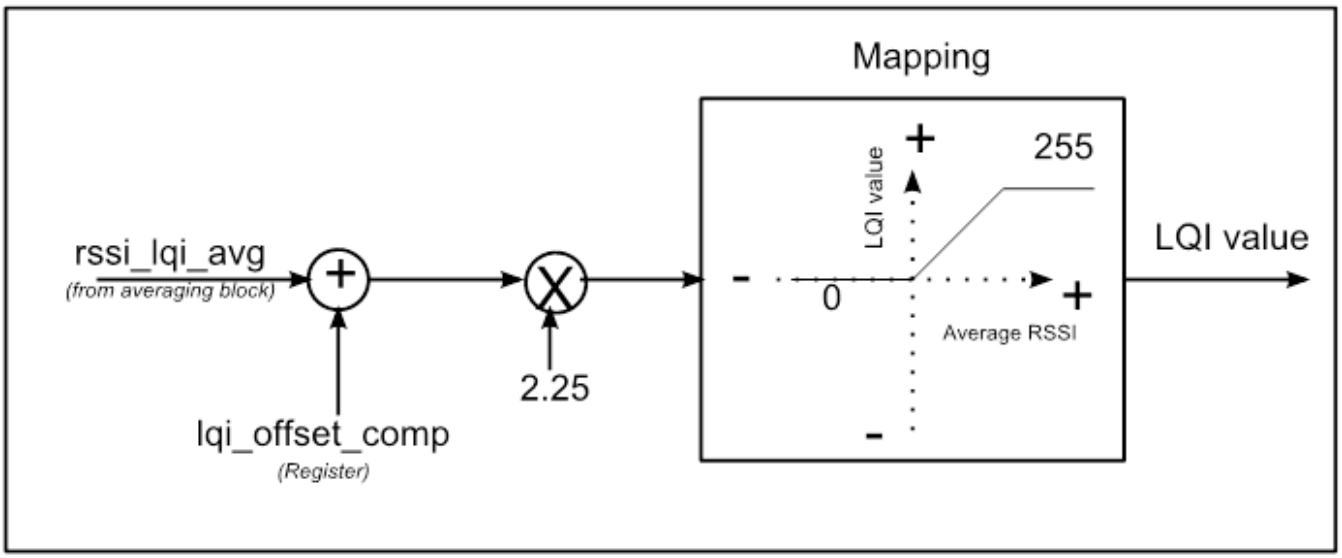


**Figure 64-158. LQI Computation**

The following picture shows an example of mapped LQI, when the register LQI_OFFSET_COMP is programmed to decimal value of 102.

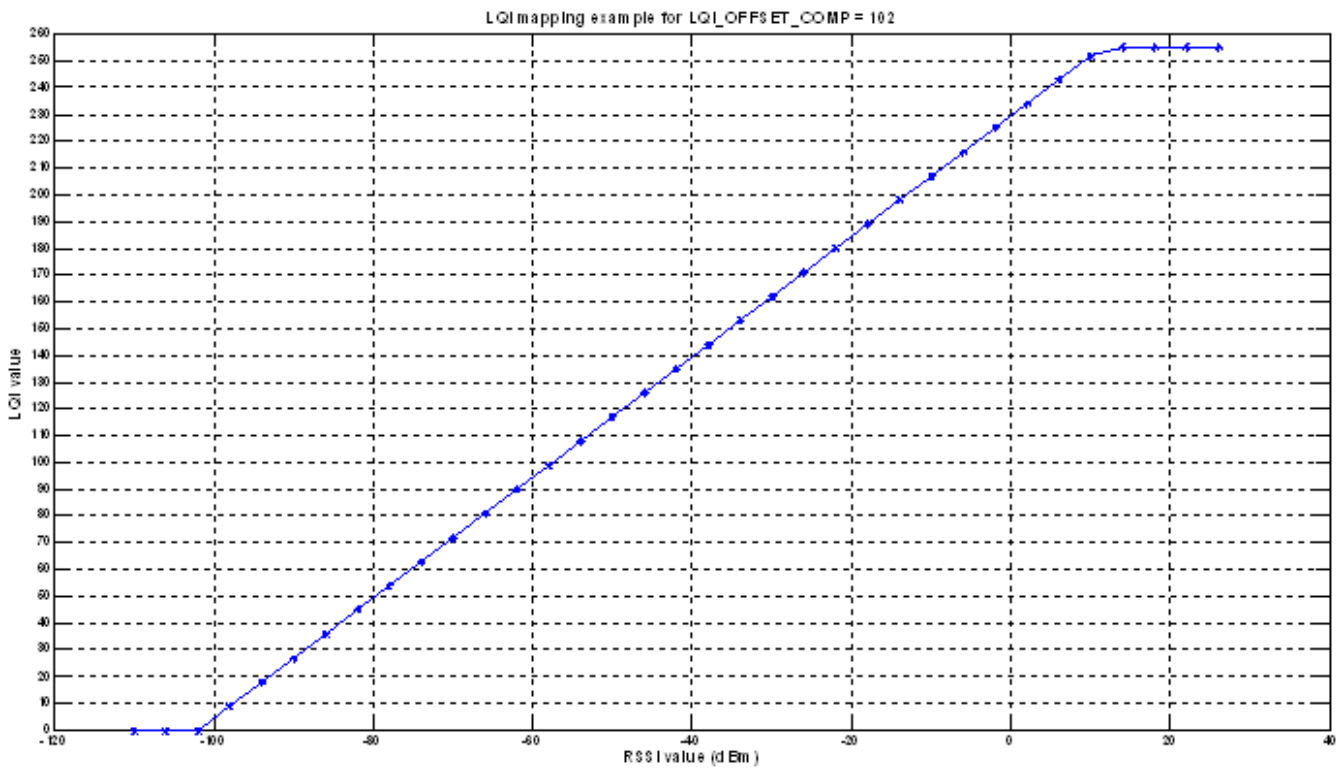

**Figure 64-159. Plot of LQI vs. RSSI**

#### *64.5.2.4.9.3.7 Clocks*

The CCA/ED/LQI module is a fully synchronous module. It has a single clock input **clk32m**. This clock input is driven by the RF Oscillator. The CCA/ED/LQI module has no asynchronous interfaces or clock domain crossings.

#### *64.5.2.4.9.3.8 Reset*

The CCA/ED/LQI module has a single, active-low, asynchronous reset input: **resetb** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

#### *64.5.2.4.9.3.9 Interrupts*

The CCA/ED/LQI module does not generate any interrupts.

### 64.5.2.4.10 Fast Antenna Diversity (FAD)

**FAD ALGORITHM**

The Fast Antenna Diversity (FAD) mode, when enabled, will allow the choice between two antennae to be selected during the preamble search. By continually monitoring the received signal the FAD block will select the first antenna on which the received signal has a correlation factor above a predefined, programmable, threshold. This threshold is register programmable. The FAD accomplishes the antenna selection by sequentially switching between the two antenna testing for the presence of a suitably strong s0 symbol, the first antenna to reach this condition is then selected for the reception of the packet.

The first antenna is monitored for a period equal to 1 symbol, $T_s$ = 16µs, then the antenna monitoring is switched to the second antenna, $T_a$ = 8µs. $T_a$ is required to allow for the external pin diodes to turn on/off to select the antenna. $T_s + T_a$ = 24µs which allows enough time to be able to test both antenna within the first 4 preamble symbols, $T_{fad} = 3 \times T_a + 2 \times T_s$ = 56µs, thus $T_{fad} < 4 \times T_s < 64$µs.

The FAD will continually switch between the two antenna until one is found which a sufficiently strong s0 detection. By virtue of the fact that the FAD operation covers less than four s0 symbols before the antenna is selected still allows the symbol demodulator to then detect at least four s0 symbols before declaring "Preamble Detect".

The symbol correlator runs during the $T_a$ period to calculate the max correlation factor for the antenna Cx. However since $T_c$ is not guaranteed to coincide with 1 unique symbol $T_s$ the correlation must be able to work across symbols. To accomplish this the correlator will rotate the s0 PN chip code through its 32 combinations in order to find the s0 symbol split across two adjacent symbols.

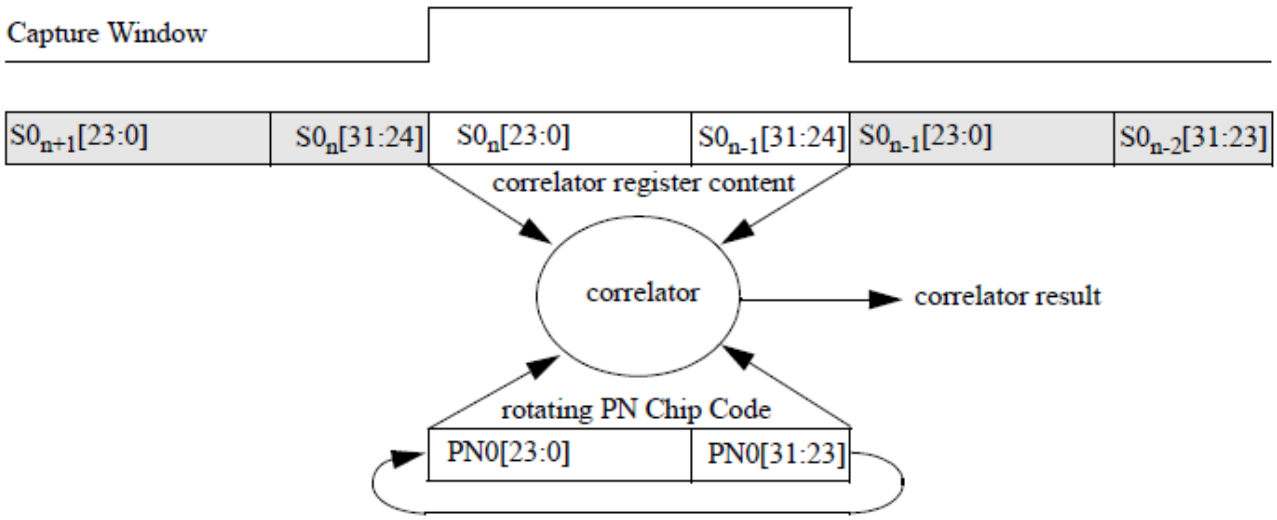

**Figure 64-160. S0 Symbol Search**

When the S0 PN Chip code becomes aligned to the Symbol data within the correlator register a correlation peak is produced that is used to determine the Antenna has a sufficiently strong signal to be selected.

It is not possible to choose between Antenna with the highest correlation factor, since indeed 1 antenna could receive no signal and thus is not distinguishable from a clear channel. This being the case, the first antenna that meets the requirements, correlation factor above the defined threshold, is selected.

When a correlator peak is detected, a second check is done ½ symbol later. A new peak should be detected with the rotation equal to ½ symbols ±2 chips. If it is the case the channel is validated and the classical *CORR_NVAL* consecutive S0 is used to certify a correct preamble, where *CORR_NVAL* is the programmable number of consecutive S0 symbols required to declare preamble detected.

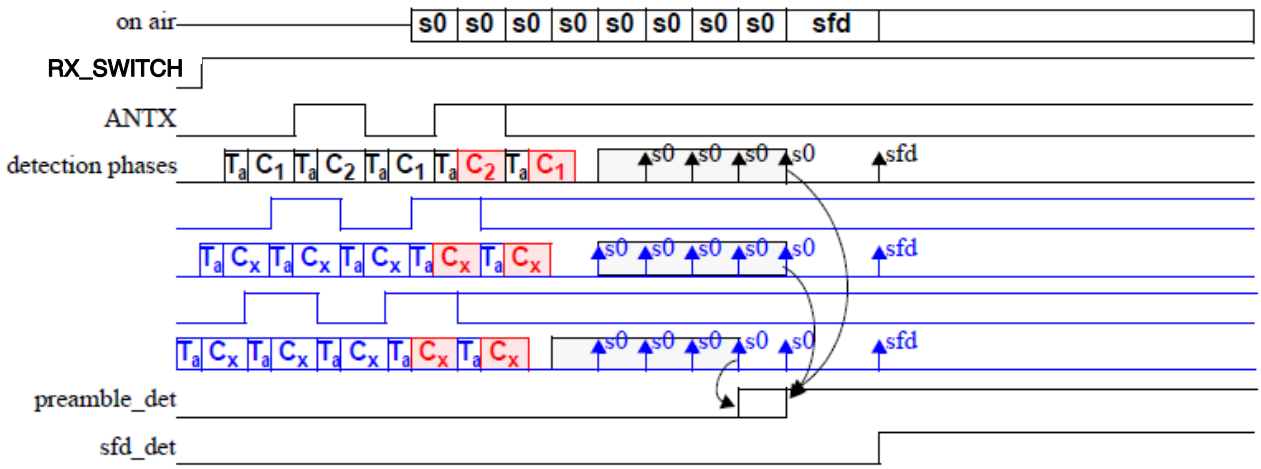

**Figure 64-161. FAD Switching**

y
s0_det?
n
ANT_B
n
s0_det?
y
n
preamble_detected?
y
sfd_detected?

The choice of the antenna is also used for the transmit. Since the antx_out value (the last antenna selected by the FAD algorithm) is kept after the end of the receive, the following TX will use the last best antenna found during the last receive. This is true also for any ensuing CCA or ED RX frame; the antenna selected will be the one selected by the FAD algorithm during the last successful preamble search. So a CCA will search for an empty channel on the best antenna chosen at the last RX. When FAD is enabled (FAD_CTRL[FAD_EN]=1), the state of the antenna can be ascertained at any time by reading the FAD_CTRL[ANTX] bit: 0 = ANT_A, 1 = ANT_B. When FAD_CTRL[FAD_EN]=0, antenna selection is placed under direct software control, and the value written to the FAD_CTRL[ANTX] bit becomes the selected antenna: 0 = ANT_A, 1 = ANT_B. The FAD_CTRL register resides in XCVR space.

**FAD PIN INTERFACE**

This content has been moved to: Chapter *Transceiver Sequence Manager*, Section *Fast Antenna Diversity (FAD)*

## 64.5.2.4.11 Interrupts

### 64.5.2.4.11.1 Introduction

This section describes the 802.15.4 Interrupt Architecture.

| Revision | Date | Author | Changes |
|---|---|---|---|
| 0.1 | 04-28-2014 | D. Brown | Copy-over from Coconino |
| 0.2 | 10-24-2015 | D. Brown | Updated for KW41 |

The 802.15.4 Link Layer has a single, active high, interrupt line (ipi_int_zigbee) to the MCU. Internally, the Link Layer has 13 interrupt sources, as shown in the following table:

| 802.15.4 Interrupt Sources |
|---|
| SEQIRQ |
| TXIRQ |
| RXIRQ |
| CCAIRQ |
| RXWTRMRKIRQ |
| FILTERFAIL_IRQ |
| PLL_UNLOCK_IRQ |
| TMR1IRQ |
| TMR2IRQ |
| TMR3IRQ |

*Table continues on the next page...*

| 802.15.4 Interrupt Sources |
|---|
| TMR4IRQ |
| WAKE_IRQ |
| TSM_IRQ |

Any or all of the interrupt sources, can be enabled to cause an assertion on ipi_int_zigbee. Each interrupt source has its own interrupt status bit in 802.15.4 register space. Each interrupt source is individually maskable (each has its own MASK bit), so that each interrupt source can be individual enabled to trigger an assertion on ipi_int_zigbee. There is also a global interrupt mask, TRCV_MSK, which can enable/disable all ipi_int_zigbee assertions by programming a single masking bit. All interrupt status bits (except TSM_IRQ) use a write-1-to-clear protocol. Interrupt status bits are not affected by reads. The ipi_int_zigbee pin is a level-sensitive interrupt indicator to the MCU; on an interrupt, ipi_int_zigbee will remain asserted until all active interrupt sources are cleared or masked.

#### *64.5.2.4.11.1.1 Features*

- 13 interrupt sources (interrupt status bits)
- each interrupt source individually maskable
- each interrupt source is individually write-1-to-clear.
- interrupts remain asserted until cleared.

### 64.5.2.4.11.2 Memory Map and register definition

Numerous register bits are provided to control 802.15.4 interrupt behaviour. The registers referred to below (IRQSTS1, IRQSTS2, IRQSTS3, PHY_CTRL2, PHY_CTRL3, and PHY_CTRL4) all reside in the 802.15.4 Address space.

| Field | R/W | Description | Default |
|---|---|---|---|
| SEQIRQ | r/w1tc | 1: A Sequencer Interrupt has occurred<br>0: A Sequencer Interrupt has not occurred | - |
| TXIRQ | r/w1tc | 1: A TX Interrupt has occurred<br>0: A TX Interrupt has not occurred | - |
| RXIRQ | r/w1tc | 1: A RX Interrupt has occurred<br>0: A RX Interrupt has not occurred | - |
| CCAIRQ | r/w1tc | 1: A CCA Interrupt has occurred<br>0: A CCA Interrupt has not occurred | - |
| RXWTRMRKIRQ | r/w1tc | 1: A RX Watermark Interrupt has occurred<br>0: A RX Watermark Interrupt has not occurred | - |
| FILTERFAIL_IRQ | r/w1tc | 1: A Filter Fail Interrupt has occurred | - |

*Table continues on the next page...*

| Field | R/W | Description | Default |
|---|---|---|---|
| | | 0: A Filter Fail Interrupt has not occurred | |
| PLL_UNLOCK_IRQ | r/w1tc | 1: A PLL Unlock Interrupt has occurred<br>0: A PLL Unlock Interrupt has not occurred | - |
| TMR1IRQ | r/w1tc | 1: A TMR1 Interrupt has occurred<br>0: A TMR1 Interrupt has not occurred | - |
| TMR2IRQ | r/w1tc | 1: A TMR2 Interrupt has occurred<br>0: A TMR2 Interrupt has not occurred | - |
| TMR3IRQ | r/w1tc | 1: A TMR3 Interrupt has occurred<br>0: A TMR3 Interrupt has not occurred | - |
| TMR4IRQ | r/w1tc | 1: A TMR4 Interrupt has occurred<br>0: A TMR4 Interrupt has not occurred | - |
| WAKE_IRQ | r | 1: A Wake Interrupt has occurred<br>0: A Wake Interrupt has not occurred | - |
| TSM_IRQ | r | 1: A TSM Interrupt has occurred<br>0: A TSM Interrupt has not occurred | - |
| TMR1MSK | rw | 1: Mask TMR1 Interrupt from asserting ipi_int_zigbee<br>0: Enable TMR1 Interrupt to assert ipi_int_zigbee | 1 |
| TMR2MSK | rw | 1: Mask TMR2 Interrupt from asserting ipi_int_zigbee<br>0: Enable TMR2 Interrupt to assert ipi_int_zigbee | 1 |
| TMR3MSK | rw | 1: Mask TMR3 Interrupt from asserting ipi_int_zigbee<br>0: Enable TMR3 Interrupt to assert ipi_int_zigbee | 1 |
| TMR4MSK | rw | 1: Mask TMR4 Interrupt from asserting ipi_int_zigbee<br>0: Enable TMR4 Interrupt to assert ipi_int_zigbee | 1 |
| SEQMSK | rw | 1: Mask Sequencer Interrupt from asserting ipi_int_zigbee<br>0: Enable Sequencer Interrupt to assert ipi_int_zigbee | 1 |
| TXMSK | rw | 1: Mask TX Interrupt from asserting ipi_int_zigbee<br>0: Enable TX Interrupt to assert ipi_int_zigbee | 1 |
| RXMSK | rw | 1: Mask RX Interrupt from asserting ipi_int_zigbee<br>0: Enable RX Interrupt to assert ipi_int_zigbee | 1 |
| CCAMSK | rw | 1: Mask CCA Interrupt from asserting ipi_int_zigbee<br>0: Enable CCA Interrupt to assert ipi_int_zigbee | 1 |
| RX_WMRK_MSK | rw | 1: Mask RX Watermark Interrupt from asserting ipi_int_zigbee<br>0: Enable RX Watermark Interrupt to assert ipi_int_zigbee | 1 |
| FILTERFAIL_MSK | rw | 1: Mask Filter Fail Interrupt from asserting ipi_int_zigbee<br>0: Enable Filter Fail Interrupt to assert ipi_int_zigbee | 1 |
| PLL_UNLOCK_MSK | rw | 1: Mask PLL Unlock Interrupt from asserting ipi_int_zigbee<br>0: Enable PLL Unlock Interrupt to assert ipi_int_zigbee | 1 |
| WAKE_MSK | rw | 1: Mask Wake Interrupt from asserting ipi_int_zigbee<br>0: Enable Wake Interrupt to assert ipi_int_zigbee | 1 |
| TSM_MSK | rw | 1: Mask TSM Interrupt from asserting ipi_int_zigbee | 1 |

*Table continues on the next page...*

| Field | R/W | Description | Default |
|---|---|---|---|
| | | 0: Enable TSM Interrupt to assert ipi_int_zigbee | |
| TRCV_MSK | rw | 1: Mask all Interrupts from asserting ipi_int_zigbee<br>0: Enable any Interrupt to assert ipi_int_zigbee | 0 |
| T1CMP[23:0] | rw | TMR1 compare value. If TMR1CMP_EN=1 and the Event Timer matches this value, TMR1IRQ is set. | 0xFFF |
| T2CMP[23:0] | rw | TMR2 compare value. If TMR2CMP_EN=1 and the Event Timer matches this value, TMR2IRQ is set. | 0xFFF |
| T2PRIMECMP[15:0] | rw | TMR2-prime compare value. If TMR2CMP_EN=1 and TC2PRIME_EN=1 and the lower 16 bits of Event Timer matches this value, TMR2IRQ is set. | 0xFF |
| T3CMP[23:0] | rw | TMR3 compare value. If TMR3CMP_EN=1 and the Event Timer matches this value, TMR3IRQ is set. | 0xFFF |
| T4CMP[23:0] | rw | TMR4 compare value. If TMR4CMP_EN=1 and the Event Timer matches this value, TMR4IRQ is set. | 0xFFF |
| TMR1CMP_EN | rw | 1: Allow an Event Timer Match to T1CMP to set TMR1IRQ<br>0: Don't allow an Event Timer Match to T1CMP to set TMR1IRQ | 0 |
| TMR2CMP_EN | rw | 1: Allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ<br>0: Don't allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ | 0 |
| TMR3CMP_EN | rw | 1: Allow an Event Timer Match to T3CMP to set TMR3IRQ<br>0: Don't allow an Event Timer Match to T3CMP to set TMR3IRQ | 0 |
| TMR4CMP_EN | rw | 1: Allow an Event Timer Match to T4CMP to set TMR4IRQ<br>0: Don't allow an Event Timer Match to T4CMP to set TMR4IRQ | 0 |
| TC2PRIME_EN | rw | 1: Allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ<br>0: Don't allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ | 0 |
| RX_WTR_MARK[7:0] | rw | Receive byte count (octets) needed to trigger a RXWTRMRKIRQ interrupt . A setting of 0 generates an interrupt at end of the Frame Length field (first byte after SFD). A setting of 1 generates an interrupt after the first byte of Frame Control Field, etc. | 0xFF |

## 64.5.2.4.11.3 Functional description

### *64.5.2.4.11.3.1 Interrupt Status Bit Structure*

The 802.15.4 Link Layer has 13 interrupt sources, each represented in the register map by an interrupt status bit. All interrupt status bits share a common, generic structure. If a particular interrupt source is enabled, a "TRIGGERING EVENT" for that interrupt source, will always set the status bit. A write-1-to-clear input from the IPS bus, will clear the status bit, but only if there is not a simultaneous triggering event. The triggering event prevails over a software clear attempt, if both events coincide. The clock gate guarantees that the status bit only sees a clock when either a triggering event occurs, or a write-1-to-

clear pulse arrives from the IPS bus. This reduces interrupt status bit power consumption to an absolute minimum. The common interrupt status bit structure is shown in the following diagram.

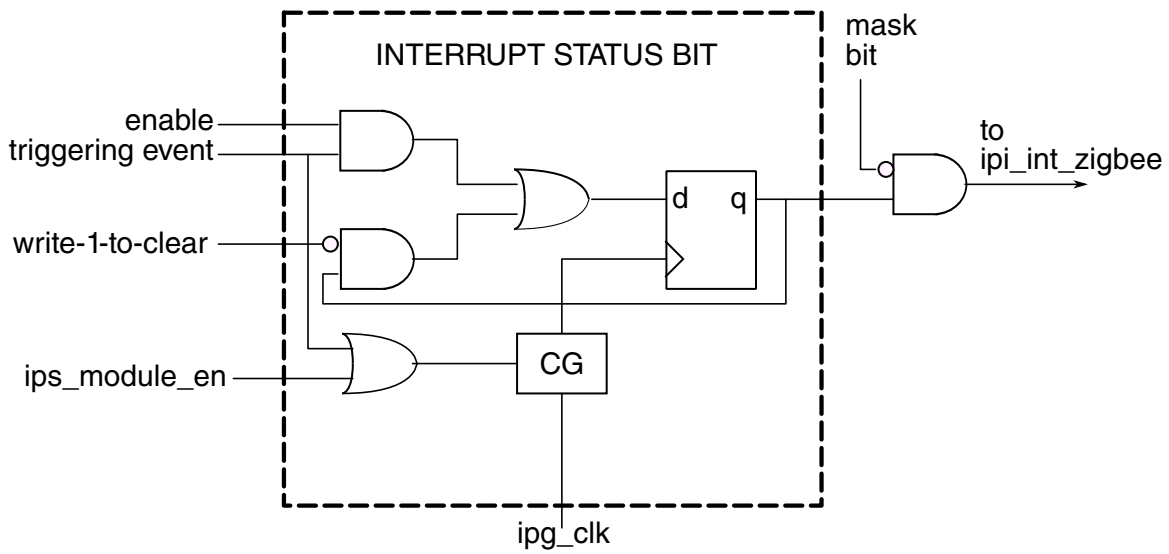

**Figure 64-163. Interrupt Status Bit**

Note that for any 802.15.4 interrupt source, if the triggering event occurs, the Interrupt Status Bit will be set regardless of the state of the corresponding MASK bit. If any of the 13 interrupts is to be ignored, software should set the corresponding MASK bit, and apply the appropriate bit mask when reading the IRQSTS1, IRQSTS2, or IRQSTS3 register, to mask out the unwanted status bit.

#### *64.5.2.4.11.3.2 802.15.4 Interrupt Architecture*

The 13 802.15.4 interrupt sources (status bits) are combined with their individual MASK bits, and then logically OR'ed together, in sum-of-products fashion, to generate single line to the MCU: ipi_int_zigbee. A global mask bit, TRCV_MSK, can enable or disable ipi_int_zigbee altogether. There is no prioritization of interrupt sources, they all have equal weight. The ipi_int_zigbee output is a level-sensitive indicator and will remain asserted until all interrupt status bits are cleared (or the corresponding mask bits set). The following diagram depicts the 802.15.4 Interrupt Architecture.

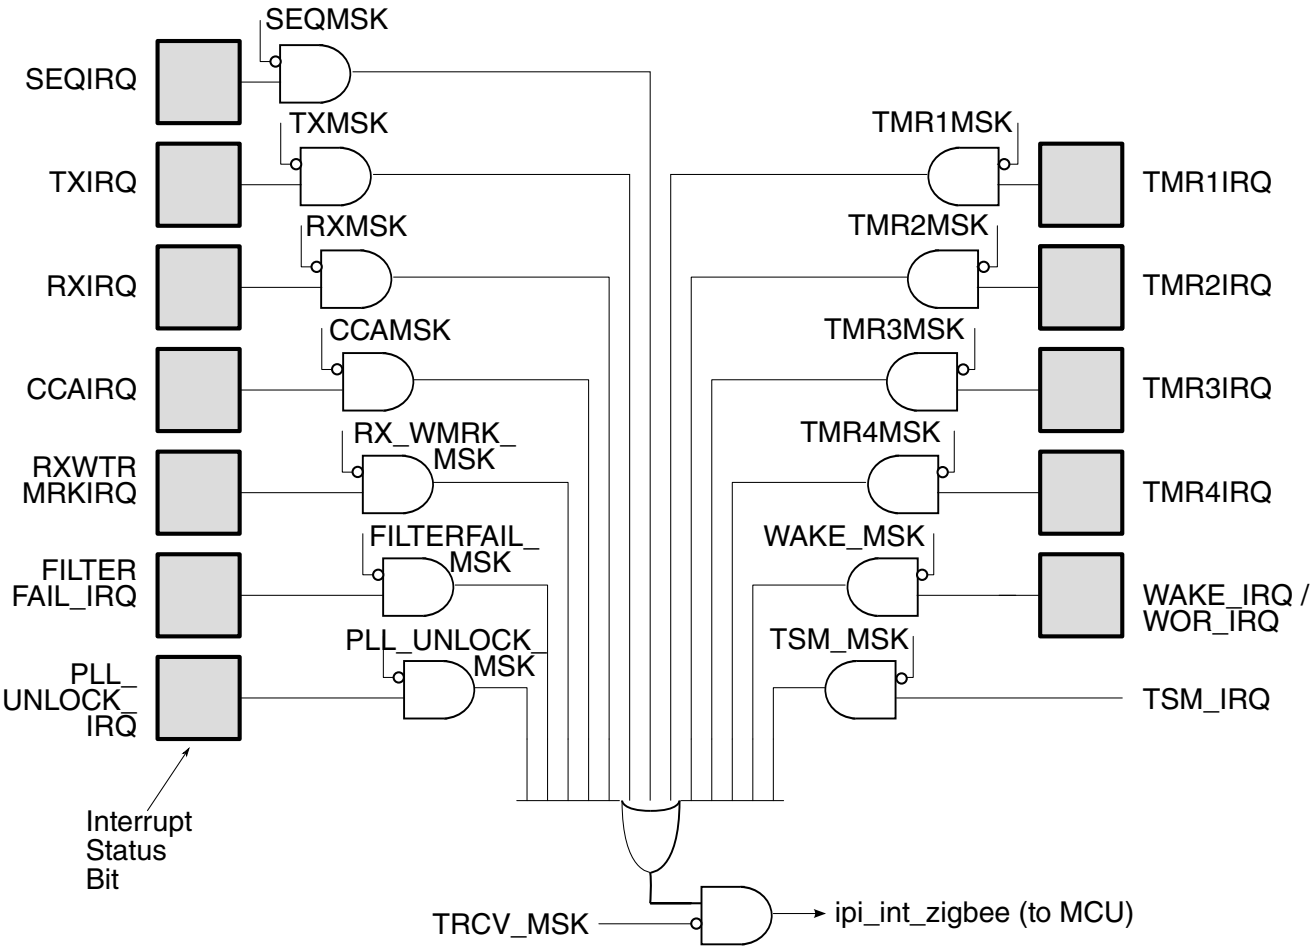

**Figure 64-164. 802.15.4 Interrupt Architecture**

#### *64.5.2.4.11.3.3 Clearing Interrupts*

All interrupt status bit use a write-1-to-clear protocol. Writing a ‘1’ to the interrupt status bit, in the IRQSTS1, IRQSTS2, or IRQSTS3 register, clears the offending interrupt. Writing a ‘0’ to an interrupt status bit has no effect on the bit. Interrupt status bits are not affected by reads.

**Note:** The TSM interrupt is an exception from the interrupt-clearing rules stated above. See Section TSM Interrupt below.

#### *64.5.2.4.11.3.4 Timer Interrupts*

The 802.15.4 Link Layer features a 24-bit Event Timer (see Section Event Timer). The Link Layer has 4 Timer interrupts (TMR1IRQ, TMR2IRQ, TMR3IRQ, and TMR4IRQ), each with its own 24-bit compare register (T1CMP, T2CMP, T3CMP, and T4CMP), and each with its own compare enable (TMR1CMP_EN, TMR2CMP_EN, TMR3CMP_EN, and TMR4CMP_EN). For each timer compare enable, if the bit is set, a match on the

respective 24-bit compare value to the Event Timer will cause the corresponding interrupt status bit to become set. If the compare enable is low, Event Timer matches won't cause the corresponding interrupt status bit to become set.

In addition, a 16-bit T2PRIMECMP compare value is provided, along with a compare-enable bit: TC2PRIME_EN. When TC2PRIME_EN is set (and TMR2CMP_EN is also set), a match on T2PRIMECMP with the *lower 16 bits of Event Timer*, will cause TMR2IRQ to become set, rather than a full 24-bit compare.

#### *64.5.2.4.11.3.5 PLL Unlock Interrupt*

When an PLL unlock event occurs during a 802.15.4 autosequence, the PLL_UNLOCK_IRQ status bit will become set. The ZSM Sequence Manager will begin monitoring for PLL unlock only after a complete transceiver warmup has occurred; unlocks which occur during warmup will not cause a PLL_UNLOCK_IRQ. A PLL unlock which occurs after the warmup period, can be enabled to cause a sequence abort. (See Section Sequence Aborting for more details).

#### *64.5.2.4.11.3.6 Filterfail Interrupt*

Filterfail interrupt will occur during packet reception, when a packet fails filtering rules. On a Filterfail interrupt, the FILTERFAIL_CODE register can be read to ascertain more information about the nature of the filter failure. Filterfail interrupt is not expected to be widely used in mission modes; it has been provided primarily for debug purposes.

#### *64.5.2.4.11.3.7 RX Watermark Interrupt*

RX Watermark interrupt will occur during packet reception, when the number of received bytes matches the contents of the RX_WTR_MARK register, minus 1. For the purpose of defining RX_WTR_MARK, the first byte received is the Frame Length field (PHR). The second byte received is the least-significant byte of Frame Control Field, etc. For example, to cause an RX Watermark Interrupt to occur after the 10th received byte, set RX_WTR_MARK=11.

#### *64.5.2.4.11.3.8 CCA Interrupt*

CCA interrupts occur at the end of CCA and ED measurement intervals. The presence, and timing, of CCA interrupts varies based on which autosequence is engaged. See Chapter ZSM Sequence Manager, Section Supported Sequences for more details on when to expect a CCAIRQ for each of the relevant autosequences (Sequences C, T, TR, and CCCA).

#### 64.5.2.4.11.3.9 RX Interrupt

RX interrupts occur at the end of an RX operation. An RX operation can be a standalone Sequence R, or the “R” portion of a Sequence TR. An RXIRQ, in combination with a SEQIRQ, is considered a “Data Indication”. RX interrupts are not generated on packets which fail FCS (CRC check), or fail packet filtering. Either of these two conditions results in an RX recycle back to the preamble-search state. To prevent RX recycling on packets which fail filtering or FCS, set the NO_RX_RECYCLE bit of the SEQ_MGR_CTRL register to 1. To receive a Data Indication (including RXIRQ) on packets which fail CRC, clear the CRC_MSK bit of the PHY_CTR2 register to 0. To inhibit packet filtering and enable Data Indication on packets which would otherwise fail packet filtering rules, set the PROMISCUOUS bit of the PHY_CTRL4 register to 1.

#### 64.5.2.4.11.3.10 TX Interrupt

TX interrupts occur at the end of a TX operation. An TX operation can be a standalone Sequence T, the “T” portion of a Sequence TR, or the auto-TXACK portion of a Sequence R with AUTOACK=1.

#### 64.5.2.4.11.3.11 Sequencer Interrupt

The Sequencer Interrupt (SEQIRQ), indicates that an autosequence has completed, and the 802.15.4 Sequence Manager has returned to its idle state. A SEQIRQ will *always* occur at the end of an autosequence, even if the autosequence terminated abnormally (such as a Software Abort, a TC3 Timeout, or a PLL Unlock Abort). **Note:** the ABORT_STS register can be read to determine which of these abnormal terminations occurred, if any. The SEQIRQ always occurs whenever the Sequence Manager transitions from non-idle to idle state. When SEQIRQ occurs, software can be sure that the Sequence Manager is in its idle state, and a new sequence can be programmed immediately.

#### 64.5.2.4.11.3.12 TSM Interrupt

TSM_IRQ is a debug feature, enabling the Transceiver Sequence Manager (TSM) to generate an interrupt at any point in a TX or RX Warmup. TSM is a multipurpose hardware resource shared by all of the protocol engines in the SoC. Thus, TSM does not have its own interrupts; its interrupts are assigned to whichever link layer controller is currently executing an RF operation. The 802.15.4 interrupt TSM_IRQ is asserted when the TSM interrupt is enabled in the transceiver's TSM_CTRL register, and the TSM interrupt asserts during an 802.15.4 TX or RX Warmup. The TSM Interrupt status bit in the IRQSTS register of 802.15.4 space is read-only. It is a logical OR of the 2 TSM_IRQ

interrupt status bits of the XCVR_STATUS register in XCVR address space. and the asserted status bit(s) should be cleared there. There is no intended mission-mode use for TSM_IRQ. See the TSM Chapter for more details.

#### *64.5.2.4.11.3.13 Wake Interrupt*

**For Manual DSM:** This is WAKE_IRQ. A WAKE_IRQ will be triggered when the 802.15.4 Link Layer Controller has awoken from a Manual DSM (Deep Sleep Mode) cycle. WAKE_IRQ indicates that the RF Oscillator has been restarted, and the 802.15.4 EVENT_TMR has resumed counting.

**For Wake-On-Radio:**: This is WOR_IRQ. This interrupt will become set when 802.15.4 has been assigned to Wake-On-Radio, and one or more of the following Wake-On-Radio conditions occurs:

1. A Wake-On-Radio slot of type "NO_RF" has completed, and MCU wakeup is requested in the descriptor
2. A Wake-On-Radio maximum slot count has been reached
3. A Wake-On-Radio Early Exit condition has been encountered

See Chapter *Wake-On-Radio* for more details

## 64.5.2.4.12 Bit Streaming Mode

### 64.5.2.4.12.1 Introduction

The 802.15.4 Link Layer features an optional Bit Streaming Mode. When activated, this feature allows all 802.15.4 packet data, received or transmitted, to be serialized and shifted out to external hardware for further processing.

#### *64.5.2.4.12.1.1 Overview*

Bit Streaming Mode (BSM), when activated, allows all 802.15.4 packet data, received or transmitted, to be serialized and shifted out to external hardware for further processing. A simple development system can be crafted to consume the BSM outputs and generate packet trace data for all 802.15.4 traffic appearing on a network, within range of the device. This enables PAN-level monitoring and debugging. BSM uses a simple, synchronous 3-wire interface, consisting of BSM_CLK, BSM_DATA, and BSM_FRAME outputs. Packet data is shifted out serially, at the 802.15.4 bit rate (250 kHz). Signalling is provided on BSM_FRAME to indicate start-of-packet and end-of-packet conditions, and to distinguish between TX and RX packet types. BSM_DATA and BSM_FRAME are synchronous to BSM_CLK. BSM_DATA and BSM_FRAME are shifted out on falling BSM_CLK, and are intended to be captured on rising BSM_CLK. A single control bit activates or deactivates BSM. Aside from controlling this bit, BSM

requires no software support, and there is no software insight into BSM status while the mode is engaged. The BSM outputs are multiplexed with GPIO, so that the pins are available for general purpose use when BSM is disabled. BSM does not interfere with 802.15.4 packet processing, or transmit data handling, in any way; it is merely a passive monitoring and debugging tool. BSM, when engaged, will not measurably increase current consumption, since the BSM module operates at a 500 kHz clock rate.

#### *64.5.2.4.12.1.2 Features*

BSM includes the following features:

- Enables monitoring and debugging of all network traffic within range of the device
- Simple, synchronous 3-wire interface facilitates external hardware development
- Low power consumption
- Non-intrusive design.
- Minimal software support required

#### *64.5.2.4.12.1.3 Block Diagram*

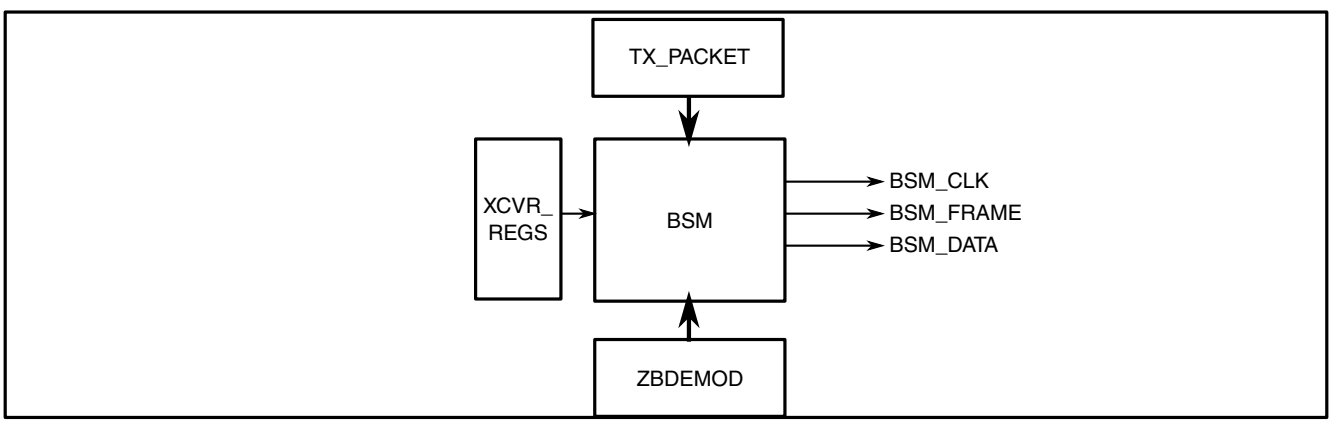

**Figure 64-165. Block diagram**

### 64.5.2.4.12.2 Memory Map and register definition

A single control bit, BSM_EN activates and deactivates BSM.

The control bit BSM_EN, is in the BSM Control Register (BSM_CTRL), which resides in 802.15.4 address space.

BSM_EN activates Bit Streaming Mode. Default is disabled. BSM mode, when enabled, allows all TX and RX packet data to appear on the 3-wire BSM interface as described in the following section.

### 64.5.2.4.12.3 Functional description

Bit Streaming Mode is enabled by setting BSM_EN=1 in the BSM_CTRL register. Once engaged, BSM will begin tracking sequence manager state, to determine when a packet is to be transmitted or received. If there is no sequence underway, or the sequence manager is in a state that does not involve transmission or reception (e.g., CCA), there will be no activity on the BSM outputs; they will be held low by hardware. Once a packet transmission or reception begins, the interface will automatically activate. The BSM_CLK will start and a single high pulse (1 BSM_CLK long) on BSM_FRAME, with BSM_DATA also high, will indicate a start-of-packet condition. The state of BSM_DATA, following the BSM_FRAME assertion, will indicate whether the packet which follows, is a TX or RX packet (1=TX, 0 = RX). The packet contents follow, starting with the next BSM_CLK period. The 802.15.4 preamble and SFD (start-of-frame delimiter), are not shifted out on BSM, since they are the same for every packet. A start-of-packet condition implies that preamble and SFD have been transmitted (for TX packets), or correctly received (for RX packets). After the start-of-packet bit and the TX/RX indicator bit, BSM packet shifting begins with the Frame Length byte (802.15.4 PHR), followed by the packet payload (802.15.4 PSDU). The MAC frame structure is shown here for reference.

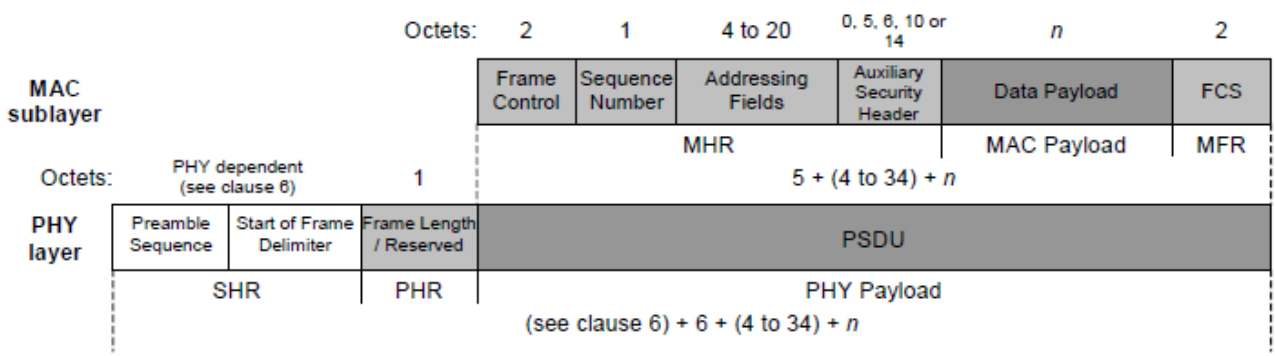

**Figure 64-166. MAC Frame Structure**

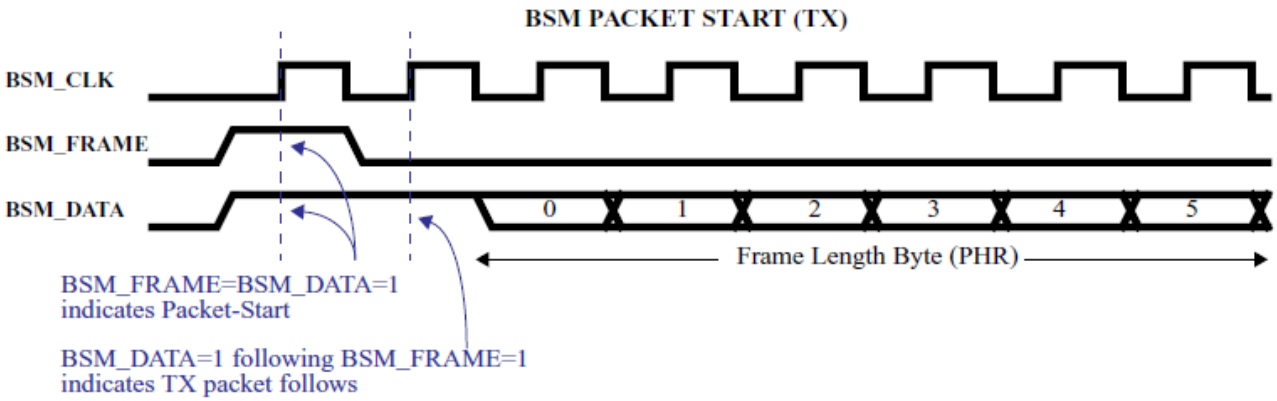
#### *64.5.2.4.12.3.1 Functional timing*

**BSM Packet Start (TX)**

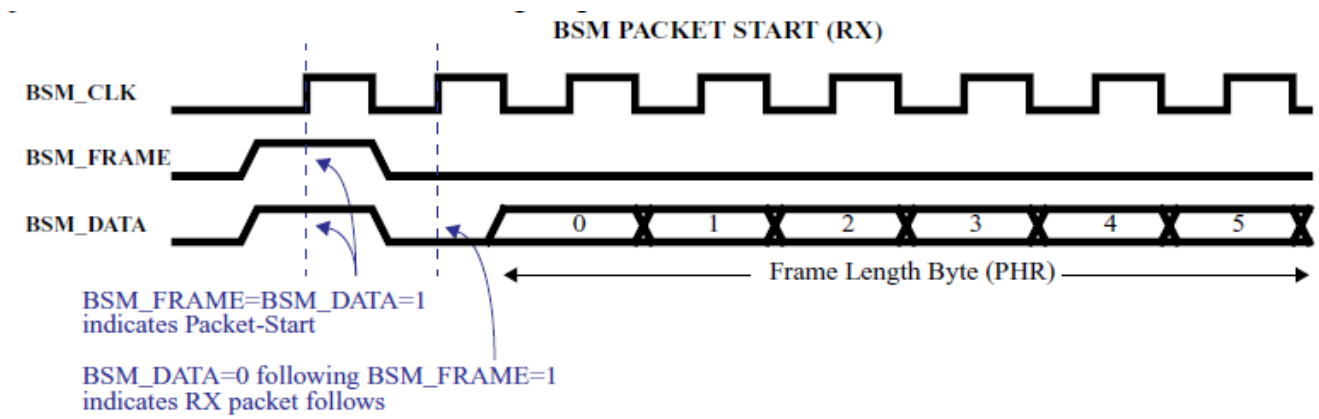
A simple protocol on BSM_FRAME and BSM_DATA are used to indicate a BSM Packet Start. If BSM_FRAME and BSM_DATA are both high at rising edge of BSM_CLK, this indicates a Packet Start condition. The state of BSM_DATA during the

bit period following the BSM_FRAME assertion, is used to indicate whether the ensuing packet is TX or RX. If BSM_DATA is high during this bit period, a TX packet follows, as shown in the following diagram.



## BSM Packet Start (RX)

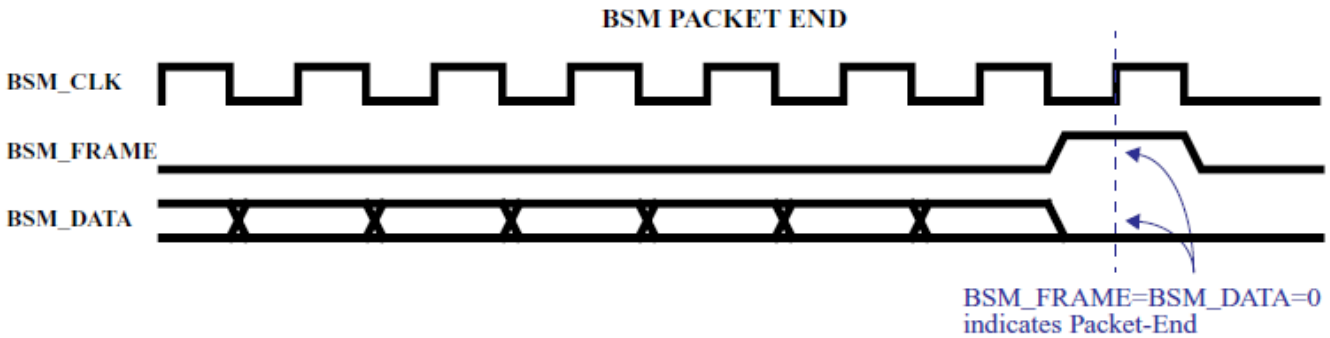
A simple protocol on BSM_FRAME and BSM_DATA is used to indicate a BSM Packet Start. If BSM_FRAME and BSM_DATA are both high at rising edge of BSM_CLK, this indicates a Packet Start condition. The state of BSM_DATA during the bit period following the BSM_FRAME assertion, is used to indicate whether the ensuing packet is TX or RX. If BSM_DATA is low during this bit period, an RX packet follows, as shown in the following diagram.



## BSM Packet End

A simple protocol on BSM_FRAME and BSM_DATA is used to indicate a BSM Packet End. If BSM_FRAME is high and BSM_DATA is low at the rising edge of BSM_SCLK, this indicates a Packet End condition. Nominally, external hardware can predict the point at which the packet should end, based on the Frame Length (first BSM byte shifted out).

However, because a TX or RX sequence could end abnormally, (e.g., a software abort or a hardware timeout), this BSM packet end indicator is provided to convey that information to the external development system. How the external hardware opts to handle an abnormally-terminated sequence, is beyond the scope of this document.



#### *64.5.2.4.12.3.2 Clocks*

BSM is a fully synchronous module. It has a single clock input **bsm_500khz_clk**. This clock is generated in the CGM (Clock Generation Module), and is only active when BSM is enabled. This input clock is divided by 2 to generate the BSM output BSM_CLK, whenever an active TX or RX operation is in progress. BSM has no asynchronous interfaces.

#### *64.5.2.4.12.3.3 Reset*

The BSM module has a single, active-low, asynchronous reset input: **rb** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

#### *64.5.2.4.12.3.4 Interrupts*

BSM generates no interrupts.

### 64.5.2.4.13 Wifi Coexistence

Provisions have been made to allow for the 2.4GHz transceiver to coexist in the same space as a WiFi transceiver IC, which shares the same frequency band. The coexistence scheme designates the WiFi transceiver as the master, and the 2.4GHz transceiver as the

slave. The objective of the coexistence strategy is to prevent both the WiFi and 2.4GHz transceivers transmitting simultaneously; a configuration option exists to also prevent the 2.4GHz transceiver from receiving when the WiFi transceiver owns the RF channel.

A very basic mechanism is used in cases where 2.4GHz radio does not generate requests, but instead defers to the WiFi transceiver to grant permission to use the medium. The WiFi IC generates a signal, RF_NOT_ALLOWED. If this signal is asserted, then 2.4GHz radio does not perform any communication. When this signal is de-asserted, then 2.4GHz radio is free to perform communications. In case the signal RF_NOT_ALLOWED is de-asserted when 2.4GHz radio has already initiated the transmission/reception of a packet then the 2.4GHz radio must stop its activity immediately .

When RF_NOT_ALLOWED aborting is enabled, the 802.15.4 Link Layer hardware must respond to RF_NOT_ALLOWED assertions, by aborting any autosequence which is currently underway, and Link Layer software must not initiate any new autosequences until RF_NOT_ALLOWED has been deasserted. The hardware response must be handled autonomously by the Link Layer, with no MCU intervention required, because the RF_NOT_ALLOWED assertions can occur during a Wake-On-Radio timeslot which has been designated as "no-MCU-wakeup" in the slot's descriptor. In this scenario, the aborting of the autosequence occurs without any assistance from, or notification of, the MCU.

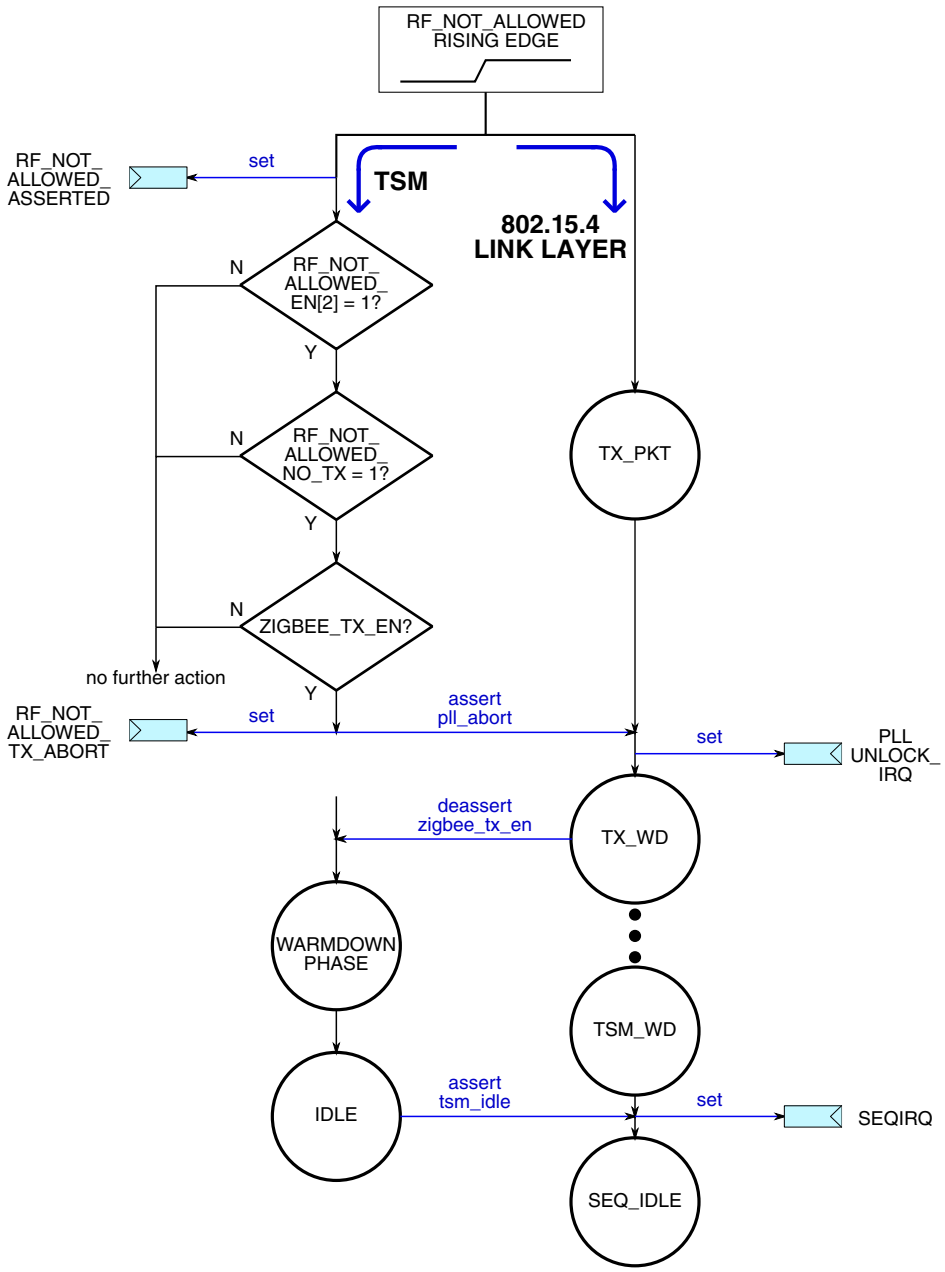
In the multi-protocol 2.4GHz radio, RF_NOT_ALLOWED aborting can be individually enabled/disabled for each protocol engine. For 802.15.4, RF_NOT_ALLOWED_EN[2] is the associated enable control bit. This bit resides in the COEX_CTRL register in XCVR address space. When this bit is 0, transitions on RF_NOT_ALLOWED are ignored by the 802.15.4 Link Layer hardware; when this bit is 1, the 802.15.4 Link Layer hardware will monitor RF_NOT_ALLOWED at all times, and abort any active autosequence which is underway when an assertion on the pin occurs. The complete hardware response to RF_NOT_ALLOWED assertions is described below.

Additional control over RF_NOT_ALLOWED aborting is provided by the RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits. If RF_NOT_ALLOWED_NO_TX=1, then an RF_NOT_ALLOWED abort will occur only if an 802.15.4 autosequence is active, and currently executing a TX operation (zigbee_tx_en=1); 802.15.4 autosequence TX operations will not be aborted if RF_NOT_ALLOWED_NO_TX=0. If RF_NOT_ALLOWED_NO_RX=1, then an

RF_NOT_ALLOWED abort will occur only if an 802.15.4 autosequence is active, and currently executing an RX operation (zigbee_rx_en=1); 802.15.4 autosequence RX operatons will not be aborted if RF_NOT_ALLOWED_NO_RX=0. The RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits reside in the COEX_CTRL register.

For the purposes of triggering a hardware abort, the *pll_abort* input to the 802.15.4 Sequence Manager (ZSM) is used. This is because the hardware response to the RF_NOT_ALLOWED assertion is identical to that of a PLL unlock event. This also means that, when RF_NOT_ALLOWED aborting is enabled for 802.15.4, the PLL_UNLOCK_IRQ interrupt status bit, will be dual purpose: it will not only indicate a PLL unlock condition, but also a RF_NOT_ALLOWED abort. PLL aborting and RF_NOT_ALLOWED aborting are enabled separately, with the COEX_CTRL register maintaining the control bits required for the latter. The status bits for RF_NOT_ALLOWED aborting are also available in COEX_CTRL, so that software will be able to distinguish the source of the PLL_UNLOCK_IRQ, in case both PLL and RF_NOT_ALLOWED aborting are enabled.

The sequence of events which results in a hardware abort of an 802.15.4 TX operation triggered by an assertion on RF_NOT_ALLOWED, is a collaboration between the TSM (Transceiver Sequence Manager) and the 802.15.4 Sequence Manager (ZSM), as shown in the following diagram.



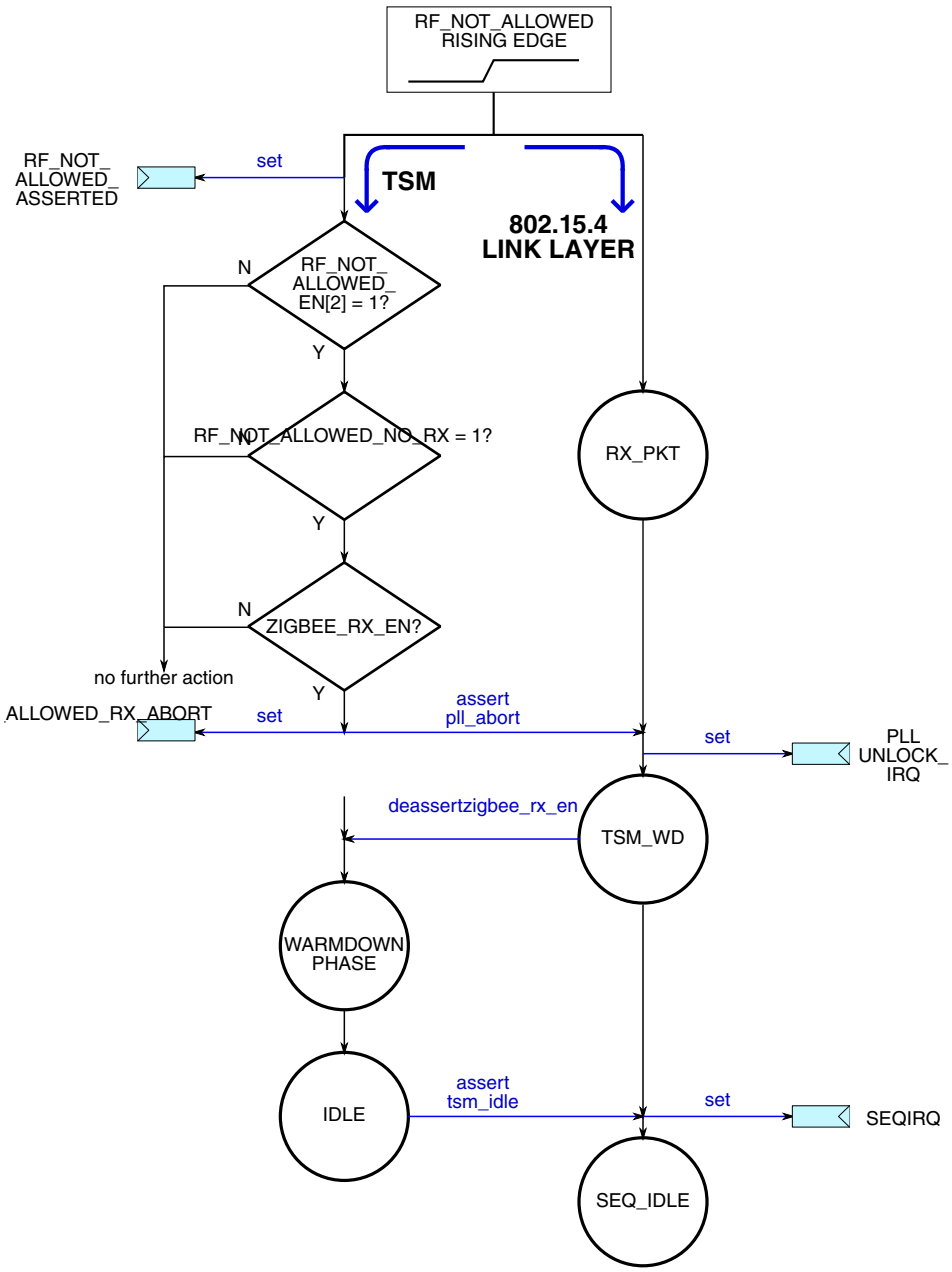
Upon assertion on RF_NOT_ALLOWED, the TSM sets the RF_NOT_ALLOWED_ASSERTED status bit in COEX_CTRL, then checks that the conditions for a hardware abort are all met:

- RF_NOT_ALLOWED_EN[2] = 1, which enables 802.15.4 to respond to RF_NOT_ALLOWED events
- RF_NOT_ALLOWED_NO_TX = 1, which enables TX operations to be aborted
- zigbee_tx_en = 1, TX request to TSM from 802.15.4 ZSM, indicating TX operation in progress

If all conditions are not met, no further action is taken. Otherwise, the TSM sets COEX_CTRL[RF_NOT_ALLOWED_TX_ABORT], and also asserts *pll_unlock* to the 802.15.4 ZSM Sequence Manager. The ZSM responds by asserting IRQSTS1[PLL_UNLOCK_IRQ] in 802.15.4 space. ZSM enters TX_WD state, which deasserts zigbee_tx_en to the TSM. This initiates the TSM TX warmdown, while the ZSM simultaneously steps through its TX warmdown sequence of states. ZSM enters TSM_WD to wait for TSM to return to idle. Once this occurs, ZSM asserts IRQSTS1[SEQIRQ] and returns to its SEQ_IDLE state. Three status bits are now set to indicate to software that the source of the abort was an RF_NOT_ALLOWED assertion:

- IRQSTS1[PLL_UNLOCK_IRQ]
- COEX_CTRL[RF_NOT_ALLOWED_ASSERTED]
- COEX_CTRL[RF_NOT_ALLOWED_TX_ABORT]

The sequence of events which results in a hardware abort of an 802.15.4 RX operation triggered by an assertion on RF_NOT_ALLOWED, is shown in the following diagram.



Upon assertion on RF_NOT_ALLOWED, the TSM sets the RF_NOT_ALLOWED_ASSERTED status bit in COEX_CTRL, then checks that the conditions for a hardware abort are all met:

- RF_NOT_ALLOWED_EN[2] = 1, which enables 802.15.4 to respond to RF_NOT_ALLOWED events
- RF_NOT_ALLOWED_NO_RX = 1, which enables RX operations to be aborted
- zigbee_rx_en = 1, RX request to TSM from 802.15.4 ZSM, indicating RX operation in progress

If all conditions are not met, no further action is taken. Otherwise, the TSM sets COEX_CTRL[RF_NOT_ALLOWED_RX_ABORT], and also asserts *pll_unlock* to the 802.15.4 ZSM Sequence Manager. The ZSM responds by asserting IRQSTS1[PLL_UNLOCK_IRQ] in 802.15.4 space. ZSM enters TSM_WD state, which deasserts zigbee_rx_en to the TSM. This initiates the TSM RX warmdown. ZSM waits in the TSM_WD to wait for TSM to return to idle. Once this occurs, ZSM asserts IRQSTS1[SEQIRQ] and returns to its SEQ_IDLE state. Three status bits are now set to indicate to software that the source of the abort was an RF_NOT_ALLOWED assertion:

- IRQSTS1[PLL_UNLOCK_IRQ]
- COEX_CTRL[RF_NOT_ALLOWED_ASSERTED]
- COEX_CTRL[RF_NOT_ALLOWED_RX_ABORT]

The complete set of control and status bits in the COEX_CTRL register is described in the following table:

| Field | R/W | Description |
|---|---|---|
| RF_NOT_ALLOWED_EN | RW | The coexistence input RF_NOT_ALLOWED can be enabled to selectively abort TX or RX sequences, with individual enables for each supported protocol, subject also to the state of the RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits, according to the following table:<br>**xxx1**: RF_NOT_ALLOWED assertions are enabled to abort BLE TX and RX sequences<br>**xxx0**: RF_NOT_ALLOWED assertions are not enabled to abort BLE TX and RX sequences<br>**x1xx**: RF_NOT_ALLOWED assertions are enabled to abort 802.15.4 TX and RX sequences<br>**x0xx**: RF_NOT_ALLOWED assertions are not enabled to abort 802.15.4 TX and RX sequences<br>**1xxx**: RF_NOT_ALLOWED assertions are enabled to abort GENERIC_FSK TX and RX sequences<br>**0xxx**: RF_NOT_ALLOWED assertions are not enabled to abort GENERIC_FSK TX and RX sequences |
| RF_NOT_ALLOWED_NO_TX | RW | TX Sequences will be aborted by RF_NOT_ALLOWED assertions, if the appropriate RF_NOT_ALLOWED_EN[x] bit is set. |
| RF_NOT_ALLOWED_NO_RX | RW | RX Sequences will be aborted by RF_NOT_ALLOWED assertions, if the appropriate RF_NOT_ALLOWED_EN[x] bit is set. |
| RF_NOT_ALLOWED_ASSERTED | R/W1TC | RF_NOT_ALLOWED has gone from not asserted, to asserted, since the last time this bit was cleared |
| RF_NOT_ALLOWED_TX_ABORT | R/W1TC | An TX sequence has been aborted since the last time this bit was cleared |
| RF_NOT_ALLOWED_TX_ABORT | R/W1TC | An TX sequence has been aborted since the last time this bit was cleared |
| RF_NOT_ALLOWED | R | Reflects the instantaneous state of the RF_NOT_ALLOWED pin, |

# 64.5.2.5 ZLL register descriptions

## 64.5.2.5.1 ZLL register descriptions

### 64.5.2.5.1.1 ZLL Memory map

ZLL base address: 4103_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | INTERRUPT REQUEST STATUS (IRQSTS) | 32 | RW | See description. |

## 64.5.2.5.1.2 INTERRUPT REQUEST STATUS (IRQSTS)

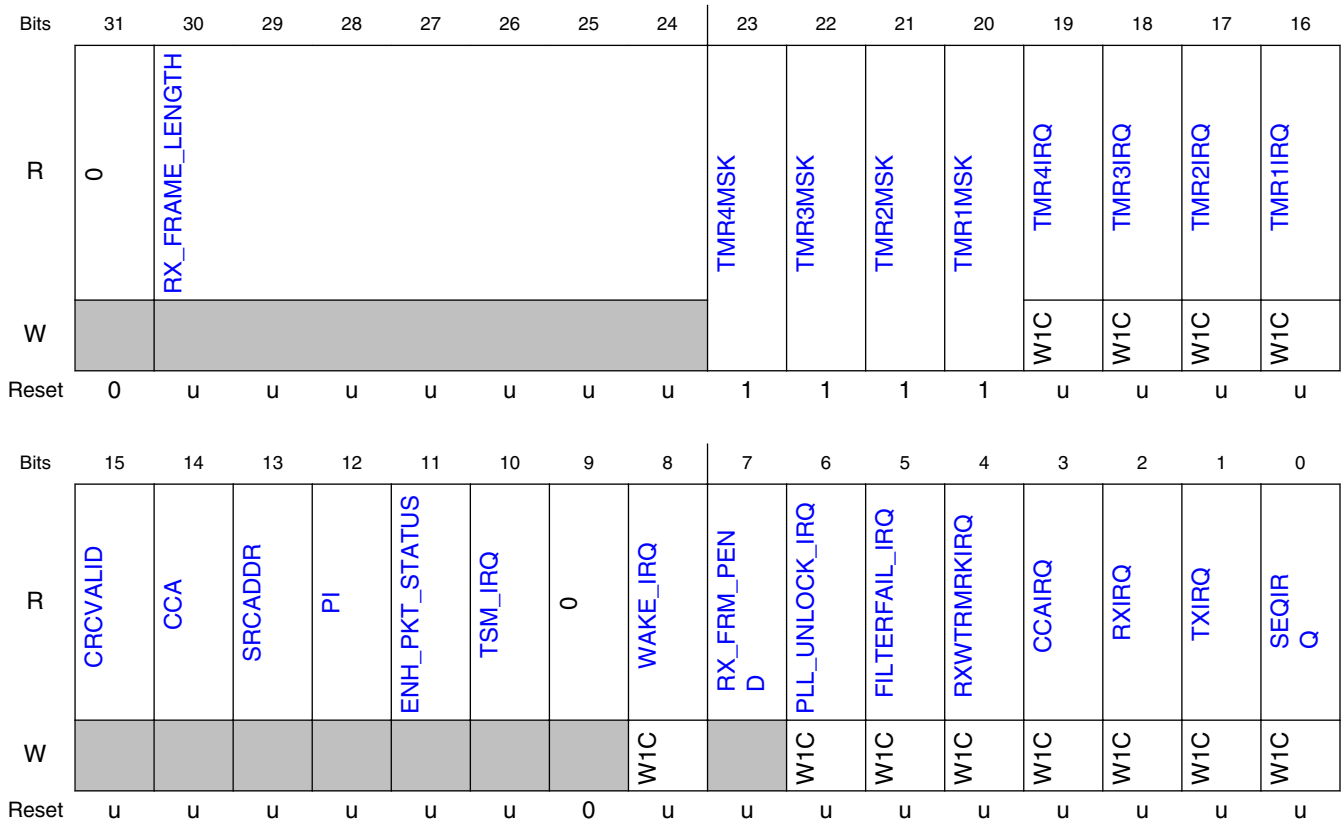
### *64.5.2.5.1.2.1 Offset*

| Register | Offset |
|---|---|
| IRQSTS | 0h |

### *64.5.2.5.1.2.2 Function*

The IRQSTS register indicates the status of interrupt requests in the 802.15.4 module.

### 64.5.2.5.1.2.3 Diagram



### 64.5.2.5.1.2.4 Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved. |
| 30-24<br>RX_FRAME_LENGTH | Receive Frame Length<br>Contents of the PHR (PHY header), or FrameLength field, of the most recently received packet. Read-only. |
| 23<br>TMR4MSK | Timer Comperator 4 Interrupt Mask bit<br>0b - allows interrupt when comparator matches event timer count<br>1b - Interrupt generation is disabled, but a TMR4IRQ flag can be set |
| 22<br>TMR3MSK | Timer Comperator 3 Interrupt Mask bit<br>0b - allows interrupt when comparator matches event timer count<br>1b - Interrupt generation is disabled, but a TMR3IRQ flag can be set |
| 21<br>TMR2MSK | Timer Comperator 2 Interrupt Mask bit<br>0b - allows interrupt when comparator matches event timer count<br>1b - Interrupt generation is disabled, but a TMR2IRQ flag can be set |
| 20<br>TMR1MSK | Timer Comperator 1 Interrupt Mask bit<br>0b - allows interrupt when comparator matches event timer count<br>1b - Interrupt generation is disabled, but a TMR1IRQ flag can be set |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 19<br>TMR4IRQ | Timer 4 IRQ<br>Timer Comparator 4 Interrupt Status bit: Indiates T4CMP comparator value matched event timer counter. This is write '1' to clear bit |
| 18<br>TMR3IRQ | Timer 3 IRQ<br>Timer Comparator 3 Interrupt Status bit: Indiates T3CMP comparator value matched event timer counter. This is write '1' to clear bit |
| 17<br>TMR2IRQ | Timer 2 IRQ<br>Timer Comparator 2 Interrupt Status bit: Indiates comparator value matched event timer counter. This flag is shared between the T2CMP (24-bit) and T2PRIMECMP (16-bit) compare registers. This is write '1' to clear bit |
| 16<br>TMR1IRQ | Timer 1 IRQ<br>Timer Comparator 1 Interrupt Status bit: Indiates T1CMP comparator value matched event timer counter. This is write '1' to clear bit |
| 15<br>CRCVALID | CRC Valid Status<br>Code Redundancy Check Valid: This flag indicates the compare result between the FCS field, in the most-recently received frame, and the internally calculated CRC value. This flag is cleared at next receiver warm up.<br>0b - Rx FCS != calculated CRC (incorrect)<br>1b - Rx FCS = calculated CRC (correct) |
| 14<br>CCA | CCA Status<br>Channel IDLE/BUSY indicator. This indicator is valid at CCAIRQ and also at SEQIRQ. This flag is cleared at next receiver warm up.<br>0b - IDLE<br>1b - BUSY |
| 13<br>SRCADDR | Source Address Match Status<br>If Source Address Management is engaged, meaning at least one of the following bits is set:<br>SAP0_EN<br>SAA0_EN<br>SAP1_EN<br>SAA1_EN<br><br>Then SRCADDR will be set to 1 if the packet just received is a poll request (PI=1), *and* at least one of the following conditions is met:<br>SAP0_EN and SAP0_ADDR_PRESENT<br>SAA0_EN and SAA0_ADDR_ABSENT<br>SAP1_EN and SAP1_ADDR_PRESENT<br>SAA1_EN and SAA1_ADDR_ABSENT<br><br>If SRCADDR=1, this indicates to SW that the Packet Processor has determined that an auto-TxACK frame must be transmitted with the FramePending subfield of the FrameControlField set to 1. HW will assemble and transmit this Ack packet. If the above conditions are not met, SRCADDR will be cleared to 0. |
| 12<br>PI | Poll Indication<br>0b - the received packet was not a data request<br>1b - the received packet was a data request, regardless of whether a Source Address table match occurred, or whether Source Address Management is enabled or not |
| 11<br>ENH_PKT_STATUS | Enhanced Packet Status<br>0b - The last packet received was neither 4e- nor 2015-compliant<br>1b - The last packet received was 4e- or 2015-compliant (RX_FRAME_FILTER register should be queried for additional status bits) |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 10<br>TSM_IRQ | TSM IRQ<br>TSM Interrupt Request<br>0b - A TSM Interrupt has not occurred<br>1b - A TSM Interrupt has occurred |
| 9<br>— | Reserved. |
| 8<br>WAKE_IRQ | WAKE Interrupt Request<br>Wake Interrrupt. The RSIM SLEEP_TMR has matched the RSIM ZIGBEE_WAKE register, and DSM has exited. The 802.15.4 EVENT_TMR has resumed counting.<br>0b - A Wake Interrupt has not occurred<br>1b - A Wake Interrupt has occurred |
| 7<br>RX_FRM_PEND | RX Frame Pending<br>Status of the frame pending bit of the frame control field for the most-recently received packet. Read-only. |
| 6<br>PLL_UNLOCK_IRQ | PLL Unlock IRQ<br>PLL Un-lock Interrupt Status bit. A '1' indicates an unlock event has occurred in the PLL. This is write a '1' to clear bit.<br>0b - A PLL Unlock Interrupt has not occurred<br>1b - A PLL Unlock Interrupt has occurred |
| 5<br>FILTERFAIL_IRQ | Filter Fail IRQ<br>Receiver Packet Filter Fail Interrupt Status bit. A '1' indicates that the most-recently received packet has been rejected due to elements within the packet. This is write a '1' to clear bit.<br>In Dual PAN mode, FILTERFAIL_IRQ applies to either or both networks, as follows:<br>**A:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=0, FILTERFAIL_IRQ applies to PAN0.<br>**B:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=1, FILTERFAIL_IRQ applies to PAN1.<br>**C:** If PAN0 and PAN1 occupy the same channel, FILTERFAIL_IRQ is the logical 'AND' of the individual PANs' Filter Fail status.<br>0b - A Filter Fail Interrupt has not occurred<br>1b - A Filter Fail Interrupt has occurred |
| 4<br>RXWTRMRKIRQ | Receive Watermark IRQ<br>Receiver Byte Count Water Mark Interrupt Status bit. A '1' indicates that the number of bytes specified in the RX_WTR_MARK register has been reached. This is write a '1' to clear bit.<br>0b - A Receive Watermark Interrupt has not occurred<br>1b - A Receive Watermark Interrupt has occurred |
| 3<br>CCAIRQ | CCA IRQ<br>Clear Channel Assessment Interrupt Status bit. A '1' indicates completion of CCA operation. This is write '1' to clear bit.<br>0b - A CCA Interrupt has not occurred<br>1b - A CCA Interrupt has occurred |
| 2<br>RXIRQ | RX IRQ<br>Receiver Interrupt Status bit. A '1' indicates the completion of a receive operation. This is write a '1' to clear bit.<br>0b - A RX Interrupt has not occurred<br>1b - A RX Interrupt has occurred |
| 1 | TX IRQ |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TXIRQ | Transmitter Interrupt Status bit. A '1' indicates the completion of a transmit operation. This is write a '1' to clear bit.<br>0b - A TX Interrupt has not occurred<br>1b - A TX Interrupt has occurred |
| 0<br>SEQIRQ | Sequencer IRQ<br>Sequence-end Interrupt Status bit. A '1' indicates the completion of an autosequence. This interrupt will assert whenever the Sequence Manager transitions from non-idle to idle state, for any reason. This is write a '1' to clear bit.<br>0b - A Sequencer Interrupt has not occurred<br>1b - A Sequencer Interrupt has occurred |

## 64.5.2.5.1.3 PHY CONTROL (PHY_CTRL)

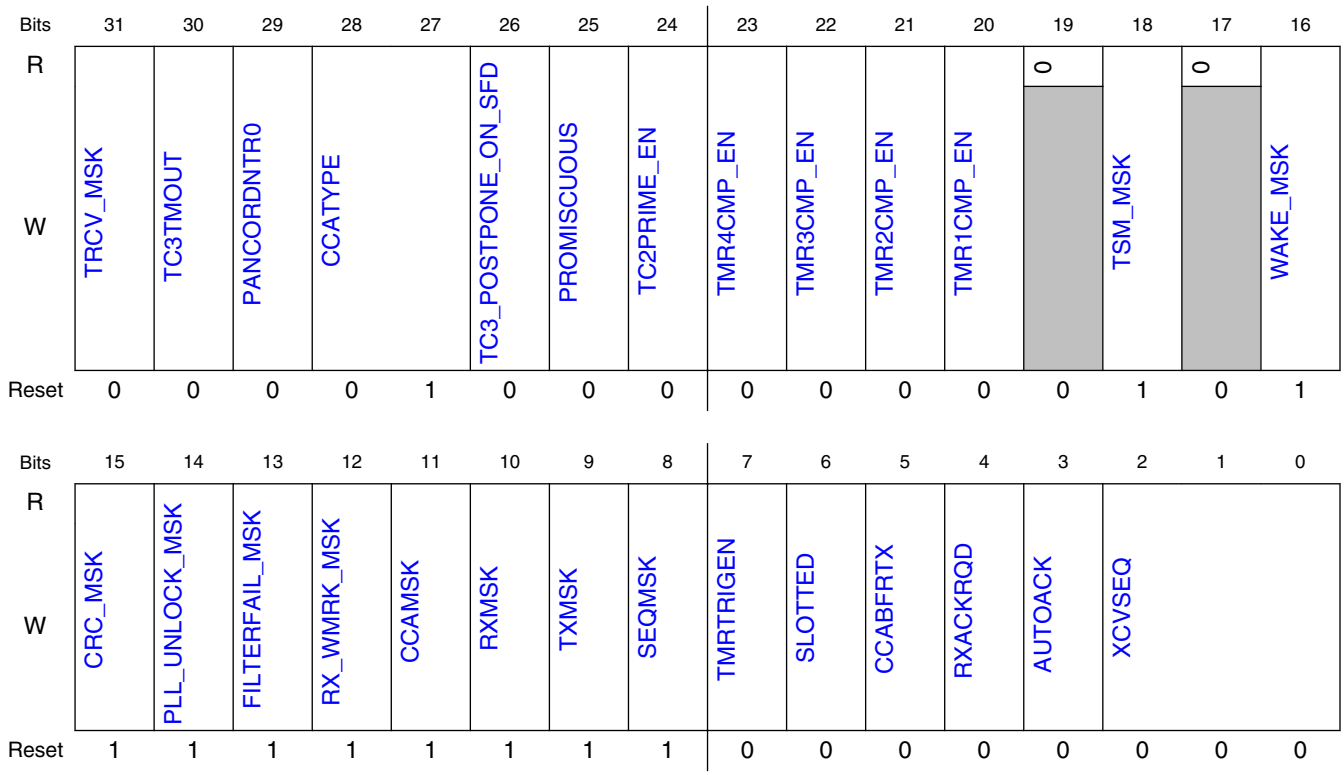
### *64.5.2.5.1.3.1 Offset*

| Register | Offset |
|---|---|
| PHY_CTRL | 4h |

### *64.5.2.5.1.3.2 Function*

PHY Control Register

### 64.5.2.5.1.3.3 Diagram



### 64.5.2.5.1.3.4 Fields

| Field | Function |
|---|---|
| 31<br>TRCV_MSK | Transceiver Global Interrupt Mask<br>Transceiver Global Interrupt Mask<br>0b - Enable any unmasked interrupt source to assert zigbee interrupt<br>1b - Mask all interrupt sources from asserting zigbee interrupt |
| 30<br>TC3TMOUT | TMR3 Timeout Enable<br>TMR3 Timeout Enable<br>0b - TMR3 is a software timer only<br>1b - Enable TMR3 to abort Rx or CCCA operations. |
| 29<br>PANCORDNTR0 | Device is a PAN Coordinator on PAN0<br>Device is a PAN Coordinator on PAN0. Allows device to receive packets with no destination address, if Source PAN ID matches. |
| 28-27<br>CCATYPE | Clear Channel Assessment Type<br>Clear Channel Assessment Type. Selects one of four possible functions for CCA or Energy Detect, per below.<br>00b - ENERGY DETECT<br>01b - CCA MODE 1<br>10b - CCA MODE 2<br>11b - CCA MODE 3 |
| 26 | Postpone TC3 Timeout On SFD Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TC3_POSTPONE_ON_SFD | If this bit is set, if a TMR3 timeout occurs while a packet is being received (*rx_sfd_detect* = 1), the timeout-related abort will be deferred untl the packet reception is completed. If the packet is good, HW will signal Data Indication; otherwise the 802.15.4 ZSM (Sequence Manager) will return to SEQ_IDLE and await further commanding.<br>0b - TC3 Abort will occur on TMR3 timeout, regardless of rx_sfd_detect<br>1b - TC3 Abort will be deferred on TMR3 timeout if rx_sfd_detect is asserted; otherwise the TC3 Abort will occur immediately |
| 25<br>PROMISCUOUS | Promiscuous Mode Enable<br>Bypasses most packet filtering.<br>0b - normal mode<br>1b - all packet filtering except frame length checking (FrameLength>=5 and FrameLength<=127) is bypassed. |
| 24<br>TC2PRIME_EN | Timer 2 Prime Compare Enable<br>0b - Don't allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ<br>1b - Allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ |
| 23<br>TMR4CMP_EN | Timer 4 Compare Enable<br>0b - Don't allow an Event Timer Match to T4CMP to set TMR4IRQ<br>1b - Allow an Event Timer Match to T4CMP to set TMR4IRQ |
| 22<br>TMR3CMP_EN | Timer 3 Compare Enable<br>0b - Don't allow an Event Timer Match to T3CMP to set TMR3IRQ<br>1b - Allow an Event Timer Match to T3CMP to set TMR3IRQ |
| 21<br>TMR2CMP_EN | Timer 2 Compare Enable<br>0b - Don't allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ<br>1b - Allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ |
| 20<br>TMR1CMP_EN | Timer 1 Compare Enable<br>0b - Don't allow an Event Timer Match to T1CMP to set TMR1IRQ<br>1b - Allow an Event Timer Match to T1CMP to set TMR1IRQ |
| 19<br>— | Reserved. |
| 18<br>TSM_MSK | Reserved.<br>0b - allows assertion of a TSM interrupt to generate a zigbee interrupt<br>1b - Assertion of a TSM interrupt will set the TSM_IRQ status bit, but a zigbee interrupt is not generated |
| 17<br>— | Reserved. |
| 16<br>WAKE_MSK | Reserved.<br>0b - Allows a wakeup from DSM to generate a zigbee interrupt<br>1b - Wakeup from DSM will set the WAKE_IRQ status bit, but a zigbee interrupt is not generated |
| 15<br>CRC_MSK | CRC Mask<br>CRC Mask<br>0b - sequence manager ignores CRCVALID and considers the receive operation complete after the last octet of the frame has been received.<br>1b - sequence manager requires CRCVALID=1 at the end of the received frame in order for the receive operation to complete successfully; if CRCVALID=0, sequence manager will return to preamble-detect mode after the last octet of the frame has been received. |
| 14<br>PLL_UNLOCK_MSK | PLL Unlock Interrupt Mask<br>0b - allows PLL unlock event to generate a zigbee interrupt<br>1b - A PLL unlock event will set the PLL_UNLOCK_IRQ status bit, but a zigbee interrupt is not generated |
| 13 | FilterFail Interrupt Mask |

*Table continues on the next page...*

| Field | Function |
|---|---|
| FILTERFAIL_MSK | FilterFail Interrupt Mask<br>0b - allows Packet Processor Filtering Failure to generate a zigbee interrupt<br>1b - A Packet Processor Filtering Failure will set the FILTERFAIL_IRQ status bit, but a zigbee interrupt is not generated |
| 12<br>RX_WMRK_MSK | RX Watermark Interrupt Mask<br>RX Watermark Interrupt Mask<br>0b - allows a Received Byte Count match to the RX_WTR_MARK threshold register to generate a zigbee interrupt<br>1b - A Received Byte Count match to the RX_WTR_MARK threshold register will set the RXWTRMRKIRQ status bit, but a zigbee interrupt is not generated |
| 11<br>CCAMSK | CCA Interrupt Mask<br>CCA Interrupt Mask<br>0b - allows completion of a CCA operation to generate a zigbee interrupt<br>1b - Completion of a CCA operation will set the CCA status bit, but a zigbee interrupt is not generated |
| 10<br>RXMSK | RX Interrupt Mask<br>0b - allows completion of a RX operation to generate a zigbee interrupt<br>1b - Completion of a RX operation will set the RXIRQ status bit, but a zigbee interrupt is not generated |
| 9<br>TXMSK | TX Interrupt Mask<br>0b - allows completion of a TX operation to generate a zigbee interrupt<br>1b - Completion of a TX operation will set the TXIRQ status bit, but a zigbee interrupt is not generated |
| 8<br>SEQMSK | Sequencer Interrupt Mask<br>0b - allows completion of an autosequence to generate a zigbee interrupt<br>1b - Completion of an autosequence will set the SEQIRQ status bit, but a zigbee interrupt is not generated |
| 7<br>TMRTRIGEN | Timer2 Trigger Enable<br>0b - programmed sequence initiates immediately upon write to XCVSEQ.<br>1b - allow timer TC2 (or TC2') to initiate a preprogrammed sequence (see XCVSEQ register). |
| 6<br>SLOTTED | Slotted Mode<br>Slotted Mode, for beacon-enabled networks. Applies only to Sequences T, TR, and R, ignored during all other sequences. Used, in concert with CCABFRTX, to determine how many CCA measurements are required prior to a transmit operation. Also used during R sequence to determine whether the ensuing transmit acknowledge frame (if any) needs to be synchronized to a backoff slot boundary. |
| 5<br>CCABFRTX | CCA Before TX<br>Applies only to Sequences T and TR, ignored during all other sequences.<br>0b - no CCA required, transmit operation begins immediately.<br>1b - at least one CCA measurement is required prior to the transmit operation (see also SLOTTED). |
| 4<br>RXACKRQD | Receive Acknowledge Frame required<br>Applies only to Sequence TR, ignored during all other sequences.<br>0b - An ordinary receive frame (any type of frame) follows the transmit frame.<br>1b - A receive Ack frame is expected to follow the transmit frame (non-Ack frames are rejected). |
| 3<br>AUTOACK | Auto Acknowledge Enable<br>Applies only to Sequence R and Sequence TR, ignored during other sequences<br>0b - sequence manager will not follow a receive frame with a Tx Ack frame, under any conditions; the autosequence will terminate after the receive frame.<br>1b - sequence manager will follow a receive frame with an automatic hardware-generated Tx Ack frame, assuming other necessary conditions are met. |

*Table continues on the next page...*

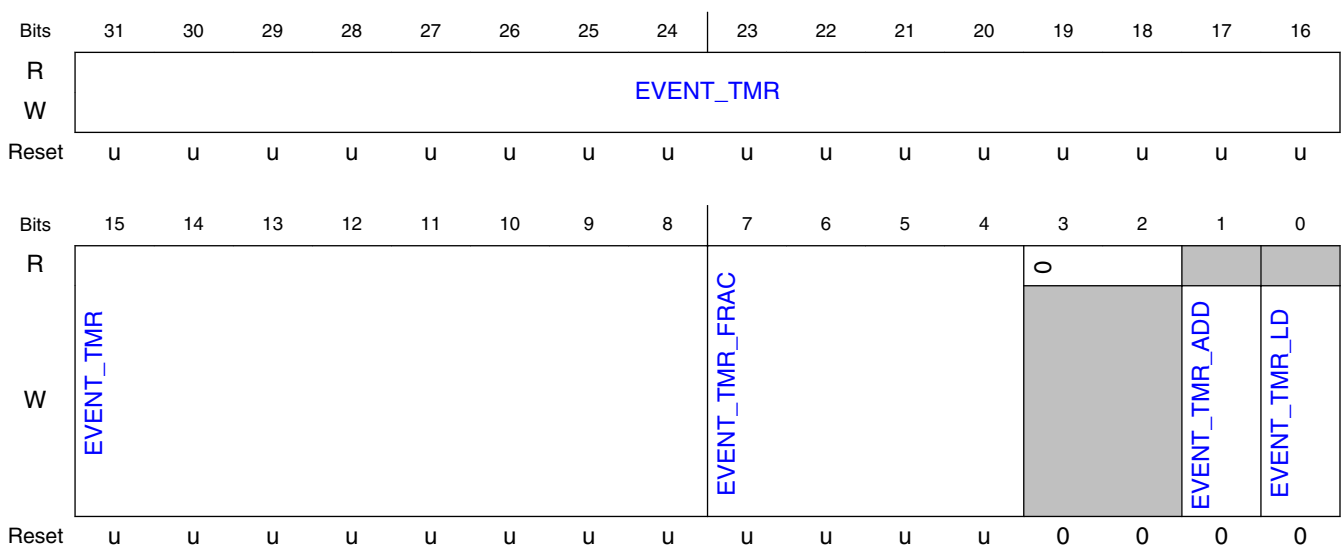
| Field | Function |
|---|---|
| 2-0<br>XCVSEQ | 802.15.4 Transceiver Sequence Selector<br>The Transceiver Sequence Selector register selects an autosequence for the sequence manager to execute. Sequence initiation can be immediate, or scheduled (see TMRTRIGEN). A write of XCVSEQ=IDLE will abort any ongoing sequence. A write of XCVSEQ=IDLE must always be performed after a sequence is complete, and before a new sequence is programmed. Any write to XCVSEQ other than XCVSEQ=IDLE during an ongoing sequence, shall be ignored. The mapping of XCVSEQ to sequence types is as follows:<br>000b - I (IDLE)<br>001b - R (RECEIVE)<br>010b - T (TRANSMIT)<br>011b - C (CCA)<br>100b - TR (TRANSMIT/RECEIVE)<br>101b - CCCA (CONTINUOUS CCA)<br>110b - Reserved<br>111b - Reserved |

## 64.5.2.5.1.4 EVENT TIMER (EVENT_TMR)

### *64.5.2.5.1.4.1 Offset*

| Register | Offset |
|---|---|
| EVENT_TMR | 8h |

### *64.5.2.5.1.4.2 Diagram*



#### *64.5.2.5.1.4.3 Fields*

| Field | Function |
|---|---|
| 31-8<br>EVENT_TMR | Event Timer Integer Component<br>The EVENT_TMR represents a 28-bit number with 24 Integer bits and 4 Fractional bits. This field is the integer component, which appears to the left of the decimal point. Most 802.15.4 operations which relate to the Event Timer require only the integer component. |
| 7-4<br>EVENT_TMR_FRAC | Event Timer Fractional Component<br>The EVENT_TMR represents a 28-bit number with 24 Integer bits and 4 Fractional bits. This field is the fractional component, which appears to the right of the decimal point. The fractional component can be ignored for most 802.15.4 operations which relate to the Event Timer; it has been provided only to allow for microsecond accuracy when software updates the Event Timer after a long period of DSM (sleep) mode |
| 3-2<br>— | Reserved. |
| 1<br>EVENT_TMR_ADD | Event Timer Add Enable<br>Increments the Event Timer by the values written to the EVENT_TMR[23:0] and EVENT_TMR_FRAC[3:0] fields of this register. |
| 0<br>EVENT_TMR_LD | Event Timer Load Enable<br>Loads the Event Timer with the values written to the EVENT_TMR[23:0] and EVENT_TMR_FRAC[3:0] fields of this register. |

## 64.5.2.5.1.25 DUAL PAN CONTROL (DUAL_PAN_CTRL)

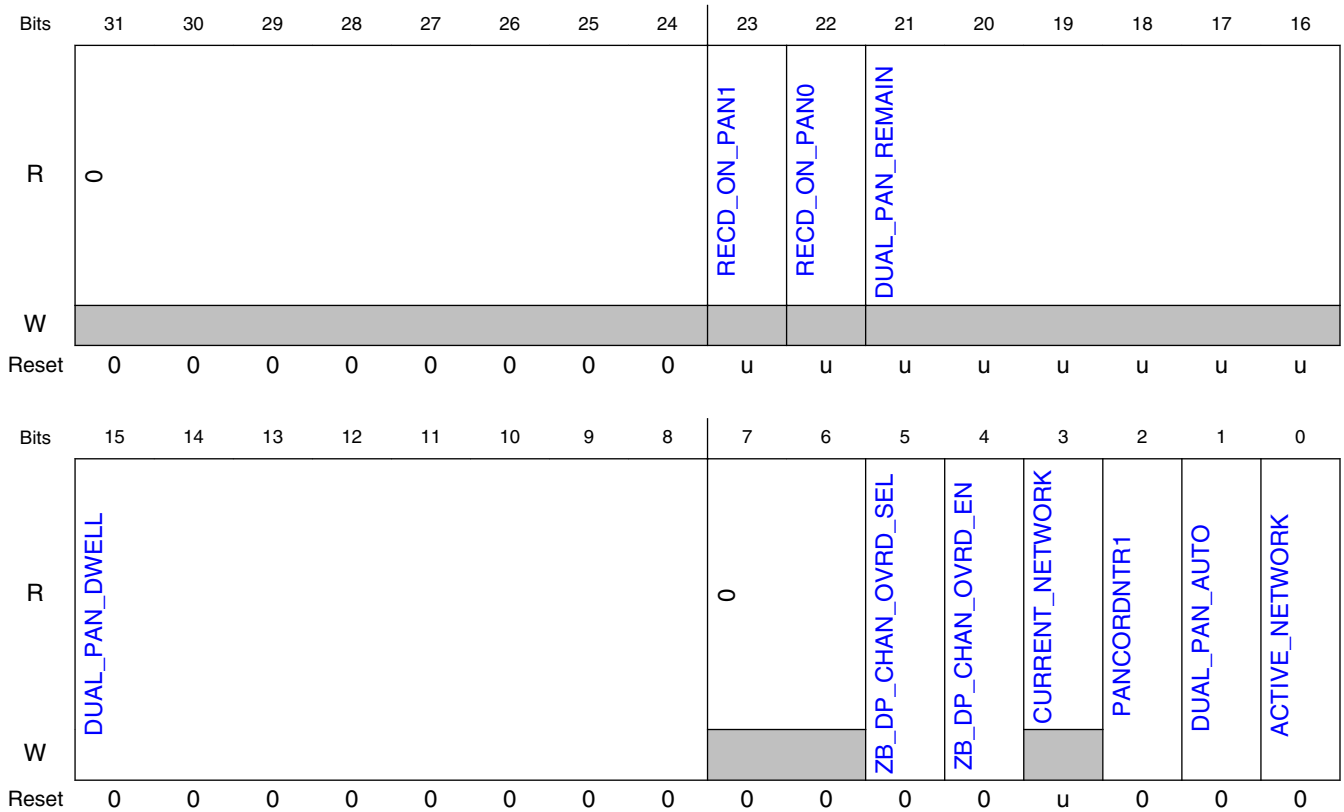
#### 64.5.2.5.1.25.1 Offset

| Register | Offset |
|---|---|
| DUAL_PAN_CTRL | 60h |

#### 64.5.2.5.1.25.2 Function

Dual PAN Control Register

### 64.5.2.5.1.25.3 Diagram



### 64.5.2.5.1.25.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved. |
| 23<br>RECD_ON_PAN1 | Last Packet was Received on PAN1<br>Indicates the packet which was just received, was received on PAN1. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN1 will be set if CURRENT_NETWORK=1 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN1 will be set only if a valid packet was received on PAN1 (PAN1's FILTERFAIL_FLAG is deasserted). RECD_ON_PAN1 remains valid until the start of the next autoseqeuence. |
| 22<br>RECD_ON_PAN0 | Last Packet was Received on PAN0<br>Indicates the packet which was just received, was received on PAN0. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN0 will be set if CURRENT_NETWORK=0 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN0 will be set only if a valid packet was received on PAN0 (PAN0's FILTERFAIL_FLAG is deasserted). RECD_ON_PAN0 remains valid until the start of the next autoseqeuence. |
| 21-16 | Time Remaining before next PAN switch in auto Dual PAN mode |

*Table continues on the next page...*

| Field | Function |
|---|---|
| DUAL_PAN_REMAIN | This read-only register indicates time remaining before next PAN switch in auto Dual PAN mode. The units for this register, depend on the PRESCALER setting (bits [1:0]) in the DUAL_PAN_DWELL register. Tthe units are the same as the TIMEBASE determined by the prescaler, as per the following table:<br><br>DUAL_PAN_DWELL[1:0]=0b00 (TIMEBASE=0.5ms) DUAL_PAN_REMAIN UNITS=0.5ms<br>DUAL_PAN_DWELL[1:0]=0b01 (TIMEBASE=2.5ms) DUAL_PAN_REMAIN UNITS=2.5ms<br>DUAL_PAN_DWELL[1:0]=0b10 (TIMEBASE=10ms) DUAL_PAN_REMAIN UNITS=10ms<br>DUAL_PAN_DWELL[1:0]=0b11 (TIMEBASE=50ms) DUAL_PAN_REMAIN UNITS=50ms<br><br>The readback value indicates that between N-1 and N timebase units remain until the next PAN switch. For example, a DUAL_PAN_REMAIN readback value of 3, with a DUAL_PAN_DWELL PRESCALER setting of 2 (10ms), indicates that between 20ms (2*10ms) and 30ms (3*10ms), remain until the next automatic PAN switch. |
| 15-8<br><br>DUAL_PAN_DWELL | Dual PAN Channel Frequency Dwell Time<br><br>Channel Frequency Dwell Time. In Auto Dual PAN mode, hardware will toggle the PAN, after dwelling on the current PAN for the interval described below (assuming Preamble/SFD not detected). A write to DUAL_PAN_DWELL, always re-initilizes the DWELL TIMER to the programmed value. If a write to DUAL_PAN_DWELL occurs during an autosequence, the DWELL TIMER will begin counting down immediately. If a write to DUAL_PAN_DWELL occurs when there is no autosequence underway, the DWELL TIMER will not begin counting until the next autosequence begins; it will begin counting at the start of the sequence warmup.<br><br>DUAL_PAN_DWELL[1:0] select the timebase for the dwell time. There are 4 options:<br><br>DUAL_PAN_DWELL[1:0]=0b00 --> TIMEBASE=0.5ms<br>DUAL_PAN_DWELL[1:0]=0b01 --> TIMEBASE=2.5ms<br>DUAL_PAN_DWELL[1:0]=0b10 --> TIMEBASE=10ms<br>DUAL_PAN_DWELL[1:0]=0b11 --> TIMEBASE=50ms<br><br>DUAL_PAN_DWELL[7:2] select how many multiples of the time base to use, from 1 (DUAL_PAN_DWELL[7:2]=0) to 64 (DUAL_PAN_DWELL[7:2]=63). Given those definitions, the table below specifies the minimum and maximum dwell times for each TIMEBASE option:<br><br>DUAL_PAN_DWELL[1:0]=0b00 --> MIN_DWELL=0.5ms MAX_DWELL=32ms<br>DUAL_PAN_DWELL[1:0]=0b01 --> MIN_DWELL=2.5ms MAX_DWELL=160ms<br>DUAL_PAN_DWELL[1:0]=0b10 --> MIN_DWELL=10ms MAX_DWELL=640ms<br>DUAL_PAN_DWELL[1:0]=0b11 --> MIN_DWELL=50ms MAX_DWELL=3.2seconds<br><br>A write to DUAL_PAN_DWELL also causes the value of ACTIVE_NETWORK to get latched into the hardware. This latched value will be the starting point for the automatic dual-pan mode (i.e., start on PAN0 or on PAN1). The starting value takes effect immediately (if sequence is underway and DUAL_PAN_AUTO=1), or is otherwise delayed until sequence starts and DUAL_PAN_AUTO=1. |
| 7-6<br><br>— | Reserved. |
| 5<br><br>ZB_DP_CHAN_OVRD_SEL | Dual PAN Channel Override Selector<br><br>This bit works with **ZB_DP_CHAN_OVRD_EN** to allow one of the two Dual PAN channels to use Direct Frequency programming. See description for **ZB_DP_CHAN_OVRD_EN**. |
| 4<br><br>ZB_DP_CHAN_OVRD_EN | Dual PAN Channel Override Enable<br><br>In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to accomplish that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | the direct frequency-programming registers -- integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the Zigbee mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1.<br><br>Two bits have been provided in 802.15.4 space to realize this feature: ZB_DP_CHAN_OVRD_SEL and ZB_DP_CHAN_OVRD_EN. When ZB_DP_CHAN_OVRD_EN=1, this enables one of the Dual PAN channels to use the direct frequency programming. The ZB_DP_CHAN_OVRD_SEL bit determines which channel uses the direct programming, according to the following:<br><br>If ZB_DP_CHAN_OVRD_EN=0, then PAN0 frequency is determined by register CHANNEL_NUM0[6:0] and PAN1 frequency is determined by register CHANNEL_NUM1[6:0].<br><br>If ZB_DP_CHAN_OVRD_EN=1 and ZB_DP_CHAN_OVRD_SEL=0, then PAN0 frequency is determined by DIRECT FREQUENCY PROGRAMMING and PAN1 frequency is determined by register CHANNEL_NUM1[6:0].<br><br>If ZB_DP_CHAN_OVRD_EN=1 and ZB_DP_CHAN_OVRD_SEL=1, then PAN0 frequency is determined by register CHANNEL_NUM0[6:0] and PAN1 frequency is determined by DIRECT FREQUENCY PROGRAMMING.<br><br>**NOTE:** Direct Frequency Programming is accomplished by setting the PLL's Integer, Numerator, and Denominator registers to the appropriate values for the desired RF frequency. |
| 3<br><br>CURRENT_NETWORK | Indicates which PAN is currently selected by hardware<br><br>This read-only bit indicates which PAN is currently selected by hardware in automatic Dual PAN mode<br>0b - PAN0 is selected<br>1b - PAN1 is selected |
| 2<br><br>PANCORDNTR1 | Device is a PAN Coordinator on PAN1<br><br>Device is a PAN Coordinator on PAN1. Allows device to receive packets with no destination address, if Source PAN ID matches. |
| 1<br><br>DUAL_PAN_AUTO | Activates automatic Dual PAN operating mode<br><br>Activates automatic Dual PAN operating mode. In this mode, PAN-switching is controlled by hardware at a pre-programmed rate, determined by DUAL_PAN_DWELL.<br>0: Manual Dual PAN mode (or Single PAN mode).<br>1: Auto Dual PAN Mode<br><br>Whenever DUAL_PAN_AUTO=0, CURRENT_NETWORK=ACTIVE_NETWORK at all times. In other words, software directly controls which PAN is selected. Whenever DUAL_PAN_AUTO=1, CURRENT_NETWORK is controlled by hardware. |
| 0<br><br>ACTIVE_NETWORK | Active Network Selector<br><br>Selects the PAN on which to transceive, by activating a PAN parameter set (PAN0 or PAN1). In Manual Dual PAN mode (or Single PAN mode), this bit selects the active PAN parameter set (channel and addressing parameters) which governs all autosequences. In Auto Dual PAN mode, this bit selects the PAN on which to begin transceiving, latched at the point at which DUAL_PAN_DWELL register is written.<br>0b - Select PAN0<br>1b - Select PAN1 |

| Field | Function |
|---|---|
| 31-28<br>— | Reserved. |
| 27<br>EXT_ABORTED | Autosequence has terminated due to a Wake-On-Radio command<br>when asserted, indicates that the autosequence has terminated due to an external event, such as a Wake-On-Radio stop command. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| 26<br>PLL_ABORTED | Autosequence has terminated due to an PLL unlock event<br>when asserted, indicates that the autosequence has terminated due to an PLL unlock event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| 25<br>TC3_ABORTED | autosequence has terminated due to an TMR3 timeout<br>when asserted, indicates that the autosequence has terminated due to an TC3 (TMR3) timeout during a receive operation. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| 24<br>SW_ABORTED | Autosequence has terminated due to a Software abort. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | when asserted, indicates that the autosequence has terminated due to an Software abort. Software can abort any programmed autosequence by writing Sequence I to XCVSEQ. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| 23-22<br>— | Reserved. |
| 21-16<br>SEQ_T_STATUS | Status of the just-completed or ongoing Sequence T or Sequence TR<br>Status of the just-completed (or ongoing) Sequence T or Sequence TR autosequence. This register is valid at all times during, and after, the Sequence T or Sequence TR. Not valid for other types of autosequences. This is a read-only register. The bits of this register map to status, according to the following table:<br>[0] 1st CCA complete (CCABFRTX=1)<br>[1] 2nd CCA complete (SLOTTED=1)<br>[2] Tx operation complete<br>[3] Rx Recycle occurred (Sequence TR only)<br>[4] Rx operation complete (Sequence TR only)<br>[5] TxAck operation complete(Sequence TR only) |
| 15<br>TMR2_SEQ_TRIG_ARMED | indicates that TMR2 has been programmed and is armed to trigger a new autosequence<br>when asserted, indicates that TMR2 has been programmed and is "armed" to trigger a new autosequence, when Zigbee Sequence Manager timer-triggering mode is selected (i.e., TMRTRIGEN=1). When timer-triggering mode is selected, TMR2 must be re-programmed (using either T2CMP or T2PRIMECMP), in advance of each new sequence. Once TMR2 is programmed, this bit will be asserted, and will remain asserted until the new sequence commences (at TMR2 match). Hardware will deassert this bit when the new sequence starts. When TMRTRIGEN=0, this bit should be ignored. Read-only bit. |
| 14<br>RX_MODE | RX Operation in Progress<br>when asserted, this Sequence Manager Output indicates that an RX operation is in progress. An RX operation can be part of a complex transmit autosequence such as a Sequence TR. CCA and ED operations are considered RX operations, during which rx_mode is asserted. Read-only bit. |
| 13<br>RX_TIMEOUT_PENDING | Indicates a TMR3 RX Timeout is Pending<br>when asserted, indicates that a TMR3 timeout (RX timeout) flag has been set by Hardware, but the Sequence Manager has not yet aborted because an RX operation is not currently underway. This would be the case, for example, during a Sequence TR, if a TMR3 timeout were to occur during the transmit operation of this sequence; the sequence would not be aborted by Hardware until the receive operation begins. This bit will always be 0 if TC3TMOUT=0. Read-only bit. |
| 12<br>NEW_SEQ_INHIBIT | New Sequence Inhibit<br>When asserted, indicates that a new programmed autosequence has commenced (TMR2 match has occurred if TMRTRIGEN=1). Once this bit is asserted, software is blocked from commanding any "new" autosequences (other than Sequence I to abort the current sequence), until the current sequence completes. Hardware will ignore a sequence-change command from software while this bit is asserted. Hardware will automatically deassert this bit once the sequence completes. Read-only bit. |
| 11<br>SEQ_IDLE | ZSM Sequence Idle Indicator |
| 10-8<br>XCVSEQ_ACTUAL | Indicates the programmed sequence that has been recognized by the ZSM Sequence Manager<br>Reflects the programmed sequence that has been recognized by the Zigbee Sequence Manager. Takes into account the fact that sequence-change commands from software are ignored while a sequence is underway (see NEW_SEQ_INHIBIT). Read-only bits. |
| 7 | Enable Continuous TX or RX Mode |

*Table continues on the next page...*

| Field | Function |
|---|---|
| CONTINUOUS_EN | Continuous Mode Enable (Continuous TX or RX).<br>**Note:** Dual PAN mode should not be engaged in Continuous TX or RX modes.<br>0b - normal operation<br>1b - Continuous TX or RX mode is enabled (depending on XCVSEQ setting). |
| 6<br>FORCE_CRC_ERROR | Induce a CRC Error in Transmitted Packets<br>0b - normal operation<br>1b - Force the next transmitted packet to have a CRC error |
| 5<br>NO_RX_RECYCLE | Disable Automatic RX Sequence Recycling<br>when asserted, prevents the Zigbee Sequence Manager (ZSM) from automatically re-starting (recycling) the receiver when a packet is received which results in a FilterFail or CRC failure. Normally, on a RX recycle, the ZSM returns to the RX_WU (warmup) state, and then resumes from there with a new, foreshortened, Rx warmup, in search of a new preamble. When this bit is set, the Sequence Manager will instead return to idle state, and issue a SEQIRQ, after a FilterFail or CRC failure. |
| 4<br>LATCH_PREAMBLE | Stickiness Control for Preamble Detection<br>0b - Don't make PREAMBLE_DET and SFD_DET bits of PHY_STS (SEQ_STATE) Register "sticky", i.e, these status bits reflect the realtime, dynamic state of preamble_detect and sfd_detect<br>1b - Make PREAMBLE_DET and SFD_DET bits of PHY_STS (SEQ_STATE) Register "sticky", i.e.,occurrences of preamble and SFD detection are latched and held until the start of the next autosequence |
| 3<br>EVENT_TMR_DO_NOT_LATCH | Overrides the automatic hardware latching of the Event Timer<br>when asserted, overrides the automatic hardware latching of the Event Timer that prevents the timer from updating while software reads the 3 Event Timer bytes. This allows the Event Timer LS byte to continue to update without reading the upper 2 bytes. Overriding the automatic latching of the Event Timer should be used with caution, as it can allow the Event Timer lower bytes to get out-of-sync with the upper bytes. However, it can be useful when polling the Event Timer LS byte for a value that is just a few counts in the future. |
| 2<br>CLR_NEW_SEQ_INHIBIT | Overrides the automatic hardware locking of the programmed XCVSEQ while an autosequence is underway<br>when asserted, overrides the automatic hardware locking of the programmed XCVSEQ while an autosequence is underway. Asserting this feature will allow software to change the programmed autosequence "on-the-fly", without aborting and returning to idle between sequences. Overriding the hardware lockout of XCVSEQ should be used with caution, since the Sequence Manager is not designed (or verified) for manual state transitions between one type of autosequence and other (i.e., Sequence T -> Sequence R). |
| 1<br>FORCE_CLK_ON | Force On 802.15.4 phy_gck<br>Force On 802.15.4 phy_gck<br>0b - Allow TSM to control 802.15.4 phy_gck, for minimum power consumption (default)<br>1b - Force on 802.15.4 phy_gclk at all times, for debug purposes only |

| 7-0<br>SLOT_PRELOAD | Slotted Mode Preload<br>This register represents the number that gets loaded into the slot_timer at SFD detect, which ultimately determines when the next slot boundary will occur. Due to processing delays within the analog front-end and digital modem, the point at which SFD is detected by the modem, is delayed relative to over-the-air timing. This register setting compensates for that delay. This timing parameter is critical for the Sequence R autosequence in slotted mode, when an automatic TxAck is required. |

| Field | Function |
|---|---|
| 31-30<br>— | Reserved. |
| 29-24<br>CCCA_BUSY_CNT | Number of CCA Measurements resulting in Busy Channel<br>For Sequence CCCA mode only, this register indicates the number of "busy" CCA attempts which occurred during the autosequence, before the channel was detected to be idle. This register can also be read in real-time (during the autosequence) to determine how many busy CCA attempts have occurred to that point. The register saturates at 63 (i.e, if there are more than 63 busy attempts, the register will continue to read 63). This register is automatically cleared to zero by hardware when the next autosequence commences. Read-only register. |
| 23-16<br>RX_BYTE_COUNT | Realtime Received Byte Count<br>During packet reception, this read-only register is a real-time indicator of the number of bytes that have been received. This register will read 0 until SFD and PHR have been received. It will read 1 after the first byte of Frame Control Field has been received, etc. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 15-14<br>— | Reserved. |
| 13<br>PLL_ABORTED | Autosequence has terminated due to an PLL unlock event<br>when asserted, indicates that the autosequence has terminated due to an PLL unlock event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. This bit is a read-only mirror of the register bit of the same name in the ABORT_STS (SEQ_CTRL_STS) register. |
| 12<br>PLL_ABORT | Raw PLL Abort Signal<br>This bit reflects the instantaneous, consolidated status of the PLL unlock detection circuits; if asserted high, indicates that at least one of the three PLL unlock detect mechanisms is currently reporting an unlocked condition. |
| 11<br>CRCVALID | CRC Valid Indicator<br>Cyclic Redundancy Check Valid: This flag indicates the compare result between the FCS field, in the most-recently received frame, and the internally calculated CRC value. This flag is cleared at next receiver warm up.<br>0b - Rx FCS != calculated CRC (incorrect)<br>1b - Rx FCS = calculated CRC (correct) |
| 10<br>FILTERFAIL_FLAG_SEL | Consolidated Filter Fail Flag<br>0: The incoming, or just-received packet, passed packet filtering rules.<br>1: The incoming, or just-received packet, failed packet filtering rules<br>When FILTERFAIL_FLAG_SEL=1, a non-zero FILTERFAIL_CODE is present (see FILTERFAIL_CODE registers).<br>In Dual PAN mode, FILTERFAIL_FLAG_SEL applies to either or both networks, as follows:<br>**A:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=0, FILTERFAIL_FLAG_SEL applies to PAN0.<br>**B:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=1, FILTERFAIL_FLAG_SEL applies to PAN1.<br>**C:** If PAN0 and PAN1 occupy the same channel, FILTERFAIL_FLAG_SEL is the logical 'AND' of the individual PANs' FILTERFAIL_FLAG bits. |
| 9<br>SFD_DET | SFD Detected<br>0: an 802.15.4 preamble-and-SFD have not been detected.<br>1: An 802.15.4 preamble-and-SFD have been detected.<br>The function of this read-only bit depends on the setting of the LATCH_PREAMBLE bit of the SEQ_MGR_CTRL register. If LATCH_PREAMBLE=1, any preamble-and-SFD detection during a Sequence R (even false detections), will set this bit, and it will remain set (sticky) until the start of the next autosequence. If LATCH_PREAMBLE=0, this bit is not sticky, and reflects the instantaneous state of the SFD-detection circuit; for false SFD, the bit will clear when the false nature of the SFD is recognized (i.e., an RX recycle). When LATCH_PREAMBLE=0, SFD_DET should be considered valid only while an autosequence is underway. |
| 8<br>PREAMBLE_DET | Preamble Detected<br>0: an 802.15.4 preamble has not been detected.<br>1: An 802.15.4 preamble has been detected.<br>The function of this read-only bit depends on the setting of the LATCH_PREAMBLE bit of the SEQ_MGR_CTRL register. If LATCH_PREAMBLE=1, any preamble detection during a Sequence R (even false detections), will set this bit, and it will remain set (sticky) until the start of the next autosequence. ## 64.5.3 Generic_FSK Link Layer Controller

### 64.5.3.1 Introduction

The Generic FSK protocol enables radio operation using a custom GFSK/GMSK or MSK modulation format achieved by programming a set of PHY variables such as BT product, modulation index and modulation filter co-efficients (such that max frequency deviation <= 500kHz). Generic FSK mode also offers a highly configurable packet structure, variable bit rate transmission and reception, some limited packet (header) processing, and interface to a RAM-based Packet Buffer.

#### 64.5.3.1.1 Overview

The Generic FSK Link Layer Controller provides the interface between Generic FSK software, and the 2.4GHz transceiver hardware. The interface consists of an IP bus-based set of registers, which provide command, control, and status to Generic FSK software. The Link Layer controller features programmability that allows for a highly configurable packet structure, defining the lengths, bit ordering, and contents of individual packet fields, defining the start and end points for whitening, CRC, and Manchester encoding/decoding, and providing for some primitive parsing of the packet header. The controller

provides multiple options for bitrate, for both TX and RX. The Link Layer Controller implements a Sequence Command Set consisting of 12 commands; a command decoder to interpret the commands in realtime as they are received from Generic FSK software, and to provide the necessary control signals to the radio's Transceiver Sequence Manager (TSM); a high-precision timebase based on an external crystal-based oscillator; an Interrupt Control Unit; finite state machines to control the transmission and reception of Generic FSK packets; controls for CRC generation (TX) and verification (RX); controls for data whitening; Manchester encoding; interface to RAM-based Packet Buffer for packet storage; and provisions for entering and exiting low-power Deep Sleep Mode.

#### 64.5.3.1.2 Features

- Highly configurable packet structure
- Optimized 12-entry Sequence Command Set
- High-precision timebase to maintain network timing
- Two timer-compare mechanisms for Interrupt Generation and Sequence Launching
- Hardware automation for packet transmit and receive, CRC, Whitening, and Manchester encoding
- Up to 4 Network Addresses to synchronize to, each can be 8-bit, 16-bit or 32-bit
- Packet Lengths up to 2047 Bytes
- Deep Sleep Mode support
- Highly configurable packet structure
- Optimized 12-entry Sequence Command Set

| 10-0<br>PB_PARTITION | Packet Buffer Partition Point<br>The Packet Buffer Partition Point defines the starting point for the RX segment of the Packet Buffer. The partitioning of the consolidated RAM between TX and RX is controlled by this configurable TX/RX Partition Point. PB_PARTITION can be programmed with any value between 0 (base of RAM0) and 1088 (after the last address of RAM1). The consolidated RAM is partitioned such that the TX buffer resides before the Partition Point (RAM entries 0 to (PB_PARTITION-1)), and the RX buffer resides after it (RAM |

| Field | Function |
|---|---|
| | entries PB_PARTITION to 1087). Programming the Partition Point register to 0 dedicates the entire consolidated RAM to RX; programming the Partition Point register to 1088 dedicates the entire consolidated RAM to TX; programming the Partition Point register to any value between 1 and 1087 yields a split TX/RX buffer. The TX segment (if any) is always first in the Packet Buffer, starting at Packet RAM address 0 of RAM0. Since the Packet Buffer RAM word-width is 2 bytes, the units for PB_PARTITION is "words". (Multiply by 2 to convert to byte addressing) |

## 64.5.3.2.1.32 PACKET BUFFER (PACKET_BUFFER_0 - PACKET_BUFFER_1087)

### *64.5.3.2.1.32.1 Offset*

For a = 0 to 1087:

| Register | Offset |
|---|---|
| PACKET_BUFFER_a | 700h + (a × 2h) |

## 64.5.3.2.2 Register Summary

## 64.5.3.2.3 Register Descriptions

| Field | R/W | Description |
|---|---|---|
| SEQCMD[3:0] | w | Sequence Command Register. See Section Sequence Commands and Status for details |
| SEQSTS[12:0] | r | Sequence Status Register. See Section Sequence Commands and Status for details |
| CMDDEC_CS[2:0] | r | Current State of the Command Decoder FSM (debug only) |
| TX_WHITEN_DIS | rw | Disable all whitening on TX packets |
| RX_DEWHITEN_DIS | rw | Disable all de-whitening on RX packets |
| SW_CRC_EN | rw | SW override of the HW-computed CRC for TX. SW must include CRC in the Packet Buffer TX buffer |
| CRC_VALID | r | CRC Valid indicator for RX packets.<br>1: good CRC<br>0: bad CRC |
| TX_WARMUP[7:0] | r | TX warmup time, in microseconds, provided to Link Layer SW |
| RX_WARMUP[7:0] | r | RX warmup time, in microseconds, provided to Link Layer SW |
| CHANNEL_NUM[6:0] | rw | RF Channel Select: 0 <= CHANNEL_NUM <= 127;<br>Formula: F = (2360 + CHANNEL_NUM) [in MHz] |
| TX_POWER[5:0] | rw | PA Power Level. Refer Data Sheet for mapping to dBm. |
| RSSI[7:0] | r | Received Signal Stength Indicator, signed value |
| LQI[7:0] | r | Link Quality Indicator, signed value |
| PREAMBLE_SZ[2:0] | rw | Number of Octets = PREAMBLE_SZ + 1,<br>where 0 <= PREAMBLE_SZ <= 7 |
| BYTE_COUNTER[12:0] | r | Signed value, reflects the current Byte Count, for TX and RX.<br>< 0: Preamble byte(s), TX only<br>0: First Byte of Network Address;<br>1: Second Byte of Network Address<br>… |
| XCVR_BUSY | r | For multi-protocol arbitration, XCVR_BUSY=1 indicates an RF channel access is underway (TSM is busy) |
| EVENT_TMR[23:0] | r +load + add | Event Timer can be read in these byte locations.<br>To update the Event Timer, either:<br>1. Write the desired EVENT_TMR to these bytes and set EVENT_TMR_LD=1, or,<br>2. Write the desired EVENT_TMR *increment* amount to these bytes and set EVENT_TMR_ADD=1<br>Note for EVENT_TMR_ADD, EVENT_TMR[23:0] is a signed value. |
| EVENT_TMR_LD | w | A write access with this bit sets loads EVENT_TMR with the contents of EVENT_TMR[23:0] |
| EVENT_TMR_ADD | w | A write access with this bit sets increments EVENT_TMR by the contents of EVENT_TMR[23:0]. This is a signed addition. |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| TIMESTAMP[23:0] | r | Received Packet Timestamp, Captured from EVENT_TMR at NTW_ADR_IRQ. |
| T1_CMP[23:0] | rw | Timer1 (T1) Compare Value. Can be used to generate T1_IRQ and/or launch Sequence Commands |
| T2_CMP[23:0] | rw | Timer2 (T2) Compare Value. Can be used to generate T2_IRQ and/or launch Sequence Commands |
| T1_CMP_EN | rw | Enable Timer Compare #1 (T1_CMP) to generate T1_IRQ and/or launch Sequence Commands |
| T2_CMP_EN | rw | Enable Timer Compare #2 (T2_CMP) to generate T2_IRQ and/or launch Sequence Commands |
| NTW_ADR_MCH[3:0] | r | Indicates which of the 4 Network Addresses has matched in the PHY. Valid during a RX sequence at the point of match, and remains valid until either:<br>1. The next RX sequence begins (if the current packet passed CRC and header filtering), or,<br>2. An RX recycle to Network Address search (if the current packet failed CRC or header filtering) |
| NTW_ADR0[31:0] | rw | Network Address 0, to PHY for correlation |
| NTW_ADR1[31:0] | rw | Network Address 1, to PHY for correlation |
| NTW_ADR2[31:0] | rw | Network Address 2, to PHY for correlation |
| NTW_ADR3[31:0] | rw | Network Address 3, to PHY for correlation |
| NTW_ADR_EN[3:0] | rw | Enable Network Address N for PHY correlation, where 0 <= N <= 3. Any bit combination can be set. |
| NTW_ADR0_SZ[1:0] | rw | 3: Network Address 0 requires a 32-bit correlation<br>2: Network Address 0 requires a 24-bit correlation<br>1: Network Address 0 requires a 16-bit correlation<br>0: Network Address 0 requires a 8-bit correlation |
| NTW_ADR1_SZ[1:0] | rw | 3: Network Address 1 requires a 32-bit correlation<br>2: Network Address 1 requires a 24-bit correlation<br>1: Network Address 1 requires a 16-bit correlation<br>0: Network Address 1 requires a 8-bit correlation |
| NTW_ADR2_SZ[1:0] | rw | 3: Network Address 2 requires a 32-bit correlation<br>2: Network Address 2 requires a 24-bit correlation<br>1: Network Address 2 requires a 16-bit correlation<br>0: Network Address 2 requires a 8-bit correlation |
| NTW_ADR3_SZ[1:0] | rw | 3: Network Address 3 requires a 32-bit correlation<br>2: Network Address 3 requires a 24-bit correlation<br>1: Network Address 3 requires a 16-bit correlation<br>0: Network Address 3 requires a 8-bit correlation |
| NTW_ADR_THR0[2:0] | rw | Number of Tolerated bit errors for Network Address 0 |
| NTW_ADR_THR1[2:0] | rw | Number of Tolerated bit errors for Network Address 1 |
| NTW_ADR_THR2[2:0] | rw | Number of Tolerated bit errors for Network Address 2 |
| NTW_ADR_THR3[2:0] | rw | Number of Tolerated bit errors for Network Address 3 |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| RX_WATERMARK_IRQ | r / w1tc | Asserts when Byte Counter == RX_WATERMARK[12:0] |
| NTW_ADR_IRQ | r / w1tc | Network Address Match Interrupt. A NA Match has occurred |
| TX_IRQ | r / w1tc | TX Interrupt. The TX sequence has completed with a successful packet transmission. |
| RX_IRQ | r / w1tc | RX Interrupt. The RX sequence has completed with a successful packet reception. |
| PLL_UNLOCK_IRQ | r / w1tc | PLL Unlock Interrupt. An unlock event has occurred. |
| SEQ_END_IRQ | r / w1tc | Sequence End Interrupt. Will assert when any TX or RX sequence ends for any reason. |
| T1_IRQ | r / w1tc | Timer Compare #1 (T1) Interrupt |
| T2_IRQ | r / w1tc | Timer Compare #2 (T2) Interrupt |
| WAKE_IRQ | r / w1tc | **For Manual DSM:** This is WAKE_IRQ. A WAKE_IRQ will be triggered when the GENERIC_FSK Link Layer Controller has awoken from a Manual DSM (Deep Sleep Mode) cycle. WAKE_IRQ indicates that the RF Oscillator has been restarted, and the GENERIC_FSK EVENT_TMR has resumed counting.<br><br>**For Wake-On-Radio:** This is WOR_IRQ. See Section Wake-On-Radio |
| TSM_IRQ | r | TSM Interrupt. Indicates TSM0_IRQ or TSM1_IRQ is set in XCVR_STATUS. For debug purposes. |
| RX_WATERMARK_IRQ_EN | rw | Enable for RX_WATERMARK_IRQ |
| NTW_ADR_IRQ_EN | rw | Enable for NTW_ADR_IRQ |
| TX_IRQ_EN | rw | Enable for TX_IRQ |
| RX_IRQ_EN | rw | Enable for RX_IRQ |
| PLL_UNLOCK_IRQ_EN | rw | Enable for PLL_UNLOCK_IRQ |
| SEQ_END_IRQ_EN | rw | Enable for SEQ_END_IRQ |
| T1_IRQ_EN | rw | Enable for T1_IRQ |
| T2_IRQ_EN | rw | Enable for T2_IRQ |
| WAKE_IRQ_EN | rw | Enable for WAKE_IRQ |
| TSM_IRQ_EN | rw | Enable for TSM_IRQ |
| GENERIC_FSK_IRQ_EN | rw | Master enable for the GENERIC_FSK_IRQ interrupt line to the MCU. |
| CRC_IGNORE | rw | If set, assert RX_IRQ even for a received packet which fails CRC verification, and do not recycle. |
| RX_WATERMARK[12:0] | rw | Sets the trigger for RX_WATERMARK_IRQ.<br>Trigger the RX_WATERMARK_IRQ when:<br>RX Byte Counter == RX_WATERMARK[12:0] |
| GEN_SLEEP_REQUEST | w | Enable a match on MAN_SLEEP[23:0] to DSM_TIMER[23:0], to enter Deep Sleep Mode |
| DSM_TIMER[23:0] | r | Current State of the 32 KHz Sleep Timer<br>**NOTE:** This register resides in RSIM Address Space |
| PART_ID[7:0] | r | Part ID to identify HW revision |
| SYNC_ADDR_SZ[1:0] | rw | Number of Octets = SYNC_ADDR_SZ + 1, 0 <= SYNC_ADDR_SZ <= 3. Applies to TX only. |
| H0_SZ[4:0] | rw | Size of H0 in bits; 0 <= H0_SZ <= 16 |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| H0_MASK[15:0] | rw | For each bit that is set to 1, the received H0 field must match the corresponding bit of H0_MATCH[15:0], else the received packet is rejected. |
| H0_MATCH[15:0] | rw | For each bit of H0_MASK[15:0] that is set to 1, the received H0 field must match this register, else the received packet is rejected. |
| LENGTH_SZ[4:0] | rw | Size of Packet Length in bits; 0 <= LENGTH_SZ <= 16 |
| LENGTH_BIT_ORD | rw | Bit order for the LENGTH field<br>0: LS Bit First;<br>1: MS Bit First |
| LENGTH_ADJ[7:0] | rw | Signed Adjustment to the LENGTH field for TX and RX. A value of 0 (default) means LENGTH is interpreted as PAYLOAD + CRC |
| LENGTH_ADJ_UNSIGNED | rw | Length Adjustment Unsigned Enabled<br>0: Hardware interprets LENGTH_ADJ as a signed integer (default)<br>1: Hardware interprets LENGTH_ADJ as a unsigned integer |
| LENGTH_MAX[6:0] | rw | Sets the Maximum Length Packet that can be received, in multiples of 16 bytes. LENGTH_MAX is compared directly against the extracted LENGTH field of the header (not the adjusted length). LENGTH_MAX=0 (default) is a special case that implies no limit. |
| REC_BAD_PKT | rw | 1: packets which fail H0, H1, or LENGTH_MAX are received in their entirety<br>0: packets which fail H0, H1, or LENGTH_MAX result in a recycle after the header is fully received |
| LENGTH_FAIL | r | For packets received with REC_BAD_PKT=1, LENGTH_FAIL indicates the extracted LENGTH header field exceeded LENGTH_MAX |
| H0_FAIL | r | For packets received with REC_BAD_PKT=1, H0_FAIL indicates the received H0 header field violates the H0_MASK/H0_MATCH pattern |
| H1_FAIL | r | For packets received with REC_BAD_PKT=1, H1_FAIL indicates the received H1 header field violates the H1_MASK/H1_MATCH pattern |
| H1_SZ[4:0] | rw | Length of H1 in bits; 0 <= H1_SZ <= 16 |
| H1_MASK[15:0] | rw | For each bit that is set to 1, the received H1 field must match the corresponding bit of H1_MATCH[15:0], else the received packet is rejected. |
| H1_MATCH[15:0] | rw | For each bit of H1_MASK[15:0] that is set to 1, the received H1 field must match this register, else the received packet is rejected. |
| CRC_SZ[2:0] | rw | Number of CRC Octets = CRC_SZ, 0 <= CRC_SZ <= 4. |
| CRC_POLY[31:0] | rw | CRC Polynomial.<br>1: XOR exists in the bit's feedback path;<br>0: no XOR in the bit's feedback path |
| CRC_SEED[31:0] | rw | CRC Seed Value |
| CRC_START_BYTE[3:0] | rw | Start CRC with this byte position. Byte #0 is the first byte of Sync Address |
| CRC_BYTE_ORD | rw | 0: LS Byte First<br>1: MS Byte First |
| CRC_REF_IN | rw | 0: do not manipulate input data stream; |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | 1: reflect each byte in the input stream bitwise |
| CRC_REF_OUT | rw | 0: do not manipulate CRC result;<br>1: CRC result is to be reflected bitwise (operated on entire word) |
| CRC_XOR_OUT[31:0] | rw | XOR mask for CRC result (for no mask, should be 0) |
| WHITEN_B4_CRC | rw | Order of Bit Stream Processing for TX and RX:<br>1: Whiten/de-whiten before CRC<br>0: CRC before whiten/de-whiten |
| WHITEN_SEED[8:0] | rw | Initialization Value for Whitening/De-whitening |
| WHITEN_ POLY[8:0] | rw | Polynomial Value for Whitening/De-whitening |
| WHITEN_POLY_TYPE | rw | Whiten polynomial type. A Fibonacci type LFSR is used with the whiten polynomial if this bit is asserted. Otherwise, a Galois type LFSR is used. |
| WHITEN_SIZE[3:0] | rw | Whitener Length |
| WHITEN_REF_IN | rw | The input data stream is reflected, bit-wise, per byte, if this bit is asserted. Bit 7 becomes bit 0, bit 6 becomes bit 1, etc. This bit will only cause the reflection of the payload data bits as they are used in the whiten calculation and will not cause any change in the output bit order |
| WHITEN_START[1:0] | rw | 0: no whiten;<br>1: start whiten @ start-of-H0;<br>2: start whiten @ start-of-H1 but only if LENGTH > WHITEN_SZ_THR<br>3: start whiten @ start-of-payload but only if LENGTH > WHITEN_SZ_THR |
| WHITEN_END | rw | 0: end whiten at end-of-payload<br>1: end whiten at end-of-crc |
| WHITEN_PAYLOAD_REINIT | rw | 1: re-assert whiten_init at start-of-payload<br>0 = don't re-assert whiten_init |
| WHITEN_SZ_THR[11:0] | rw | Minimum Packet Length (extracted LENGTH field) required to enable whiten. Requires WHITEN_START=2 or 3 |
| BITRATE[1:0] | rw | 0: 1 Mbs<br>1: 500 Kbs<br>2: 250 Kbs<br>3: 2 Mbs |
| MANCHESTER_EN | rw | 1: Enable Manchester encoding (TX) and decoding (RX)<br>0: Disable Manchester Encoding and Decoding |
| MANCHESTER_INV | rw | 0: Manchester coding as per 802.3<br>1: Manchester coding as per 802.3 but with the encoding signal inverted |
| MANCHESTER_START | rw | 0: Start Manchester coding @ start-of-payload<br>1: Start Manchester coding @ start-of-header |

## 64.5.3.3 Functional Description

### 64.5.3.3.1 Packet Configuration

The Generic FSK Link Layer Controller provides the capability to configure the over-the-air packet structure by way of a set of programmable registers. The Generic FSK packet has a consistent structure, which consists of various elements which are transmitted and received in fixed order. Most of the packet elements have associated configurability, which allows software to pre-configure, for example, the size of the element (in number of bits, or octets), or bit ordering of the element. Other configuration options apply to the entire packet, such as bitrate. In addition, the generic structure defines a variable-length header, for which some (optional) primitive parsing is provided, allowing hardware to differentiate packets based on header-bit settings, into compliant and non-compliant packets. Data Indication is provided on compliant packets only. Non-complaint packets are discarded. For transmitting and receiving, multiple bitrate options are provided. By default, all packet elements are transmitted and received LSB-first.

The Generic FSK Link Layer Controller supports a packet structure based on the following template:

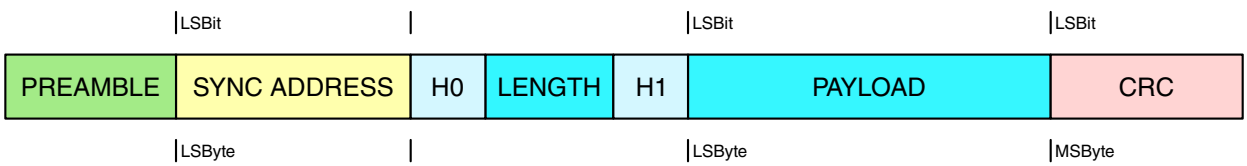

**Figure 64-167. GENERIC_FSK Packet Structure**

The Generic_FSK Link Layer controller transmits and receives packets which conform to the format shown above. The elements of the packet are transmitted in received in the order shown, although some of the packet elements may be optionally skipped, depending on the configuration options chosen.

The following diagram depicts the register configurability associated with the Preamble, Sync Address, H0, Length, and H1 elements of the packet structure.

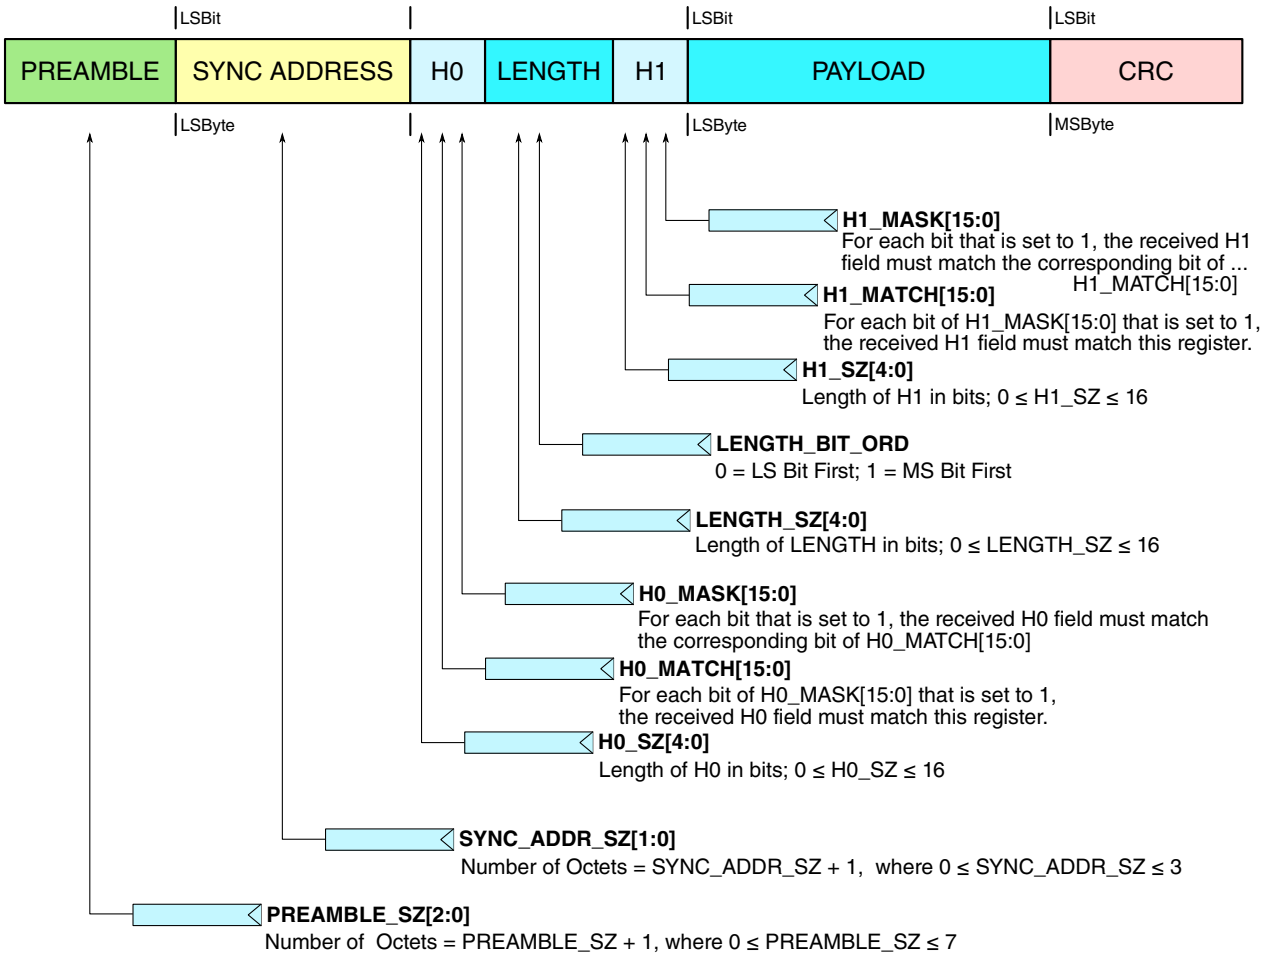

**Figure 64-168. Packet Structure Definitions (Part 1)**

The following diagram depicts the register configurability associated with the Payload and CRC elements of the packet structure.

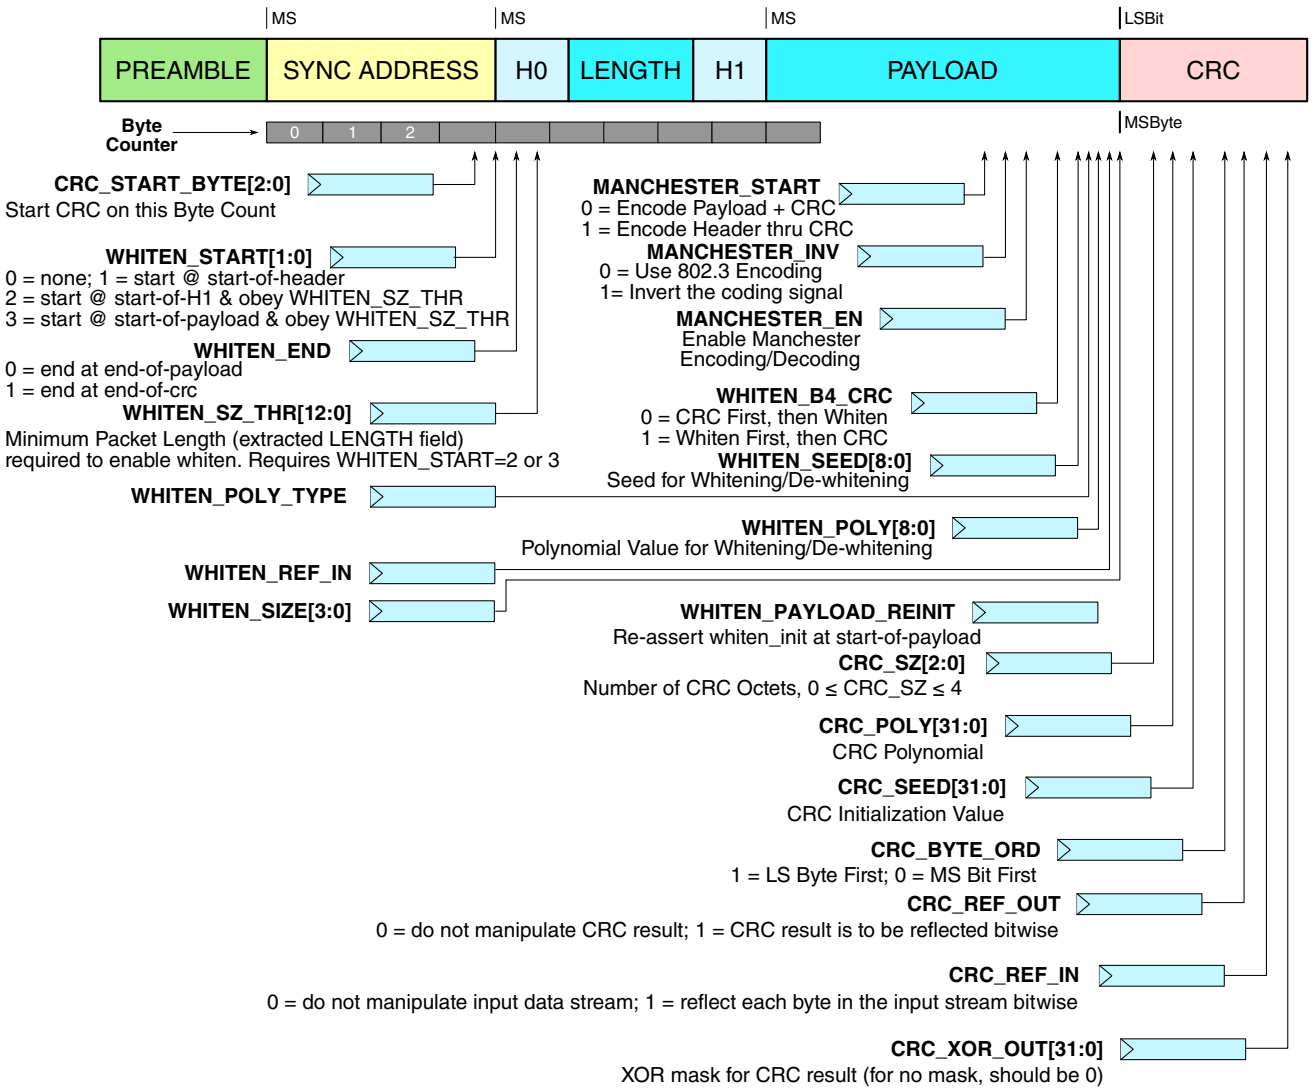

**Figure 64-169. Packet Structure Definitions (Part 2)**

The following subsections describe each of the packet elements, and the configurability associated with each.

## PREAMBLE

The preamble pattern is 0x55 or 0xAA. Like all packet elements, preamble is transmitted LSB first. The Sync Address, which immediately follows the preamble, determines which of the 2 preamble options is selected by hardware: the controller hardware selects the preamble pattern based on the first transmitted bit of Network Address, such that the last bit of preamble is the opposite polarity from the first bit of Network Address, forcing a bit transition at this boundary. The number of octets of preamble is programmable, via the PREAMBLE_SZ[2:0] register, with a range from 1 to 8 octets. A setting of PREAMBLE_SZ=0 yields a single preamble octet, whereas a setting of PREAMBLE_SZ=7 yields 8 octets. For transmission, the Generic FSK

BYTE_COUNTER will be negative during preamble transmission. If PREAMBLE_SZ=0 (1 preamble octet), BYTE_COUNTER will be -1 while the single preamble octet is being transmitted. If PREAMBLE_SZ=7 (8 octets), BYTE_COUNTER will be -8 during the first preamble octet, -7 during the next, and so on and so forth, until the eighth and final octet, during which the BYTE_COUNTER will be -1. Unlike most packet elements, the preamble is generated and shifted out by hardware (only preamble and CRC are hardware-generated); there is no software setup required, and preamble does not appear in the Packet Buffer TX buffer. During reception, the Link Layer controller does not receive preamble, since preamble detection is performed by the PHY; preamble does not appear in the Packet Buffer RX buffer.

## SYNC (NETWORK) ADDRESS

Sync Address, known synonymously as Network Address or Access Address depending on the protocol in use, is the second packet element transmitted by the Link Layer controller, and the first element received. In a network of associated devices, all devices generally share a common Network Address. The first bit of Network Address determines the preamble selection for transmission, as noted above. For TX, Network Address is the first packet element programmed into the Packet Buffer TX buffer, in LSB-first format. For RX, Network Address is also the first element stored into the Packet Buffer RX buffer, in LSB-first format. The register NTW_ADRx_SZ[1:0] determines the length, in octets, of the Network Address field in the packet structure. A setting of NTW_ADRx_SZ=0 yields a single-octet Network Address, whereas a setting of NTW_ADRx_SZ=3 yields 4 octets. For reception, up to four unique Network Addresses are supported. Any combination of the 4 can be simultaneously searched for. Network Address correlation is performed in the PHY. Multiple Network Address capability allows GENERIC_FSK devices to be associated to more than one network simultaneously, if the network topology supports it; this feature also enables multi-protocol operation. Each of the 4 Network Address options has its own enable bit, NTW_ADR_EN[x]; when the enable bit for a Network Address is set to 1, the PHY is instructed to search for that Network Address pattern in the demodulated data, and when the enable bit is set to 0, the PHY will disregard that pattern. Each of the 4 Network Address options has its own NTW_ADRx_SZ register, to program its octet size during reception. Additionally, each of the 4 Network Address options has a register, NTW_ADR_THRx[2:0], which determine the number of bit errors that can be tolerated by the PHY during Network Address correlation to the respective Network Address option. Finally, when the PHY detects a match to one of the 4 Network Address options, with a number of bit errors less than or equal to the threshold programmed into NTW_ADR_THRx, a read only status bit, NTW_ADR_MCH[x] becomes set, indicating which of the 4 patterns matched. After a match has been detected, the PHY shall hold NTW_ADR_MCH[x] valid (sticky), until the next receiver warmup, or the next RX recycle. (Specifically, the TSM output rx_init clears the NTW_ADR_MCH[x] bits; TSM

will assert this signal during either an RX warmup or a recycle). A table listing the registers which apply to Network Address Management, for each of the 4 Network Address options, is shown below.

| NTW_ADR PATTERN REGISTER | NTW_ADR ENABLE BIT | NTW_ADR SIZE REGISTER | NTW_ADR THRESHOLD REGISTER | NTW_ADR PATTERN-MATCH STATUS BIT |
|---|---|---|---|---|
| NTW_ADR_0[31:0] | NTW_ADR_EN[0] | NTW_ADR0_SZ[1:0] | NTW_ADR_THR0[2:0] | NTW_ADR_MCH[0] |
| NTW_ADR_1[31:0] | NTW_ADR_EN[1] | NTW_ADR0_SZ[1:0] | NTW_ADR_THR1[2:0] | NTW_ADR_MCH[1] |
| NTW_ADR_2[31:0] | NTW_ADR_EN[2] | NTW_ADR2_SZ[1:0] | NTW_ADR_THR2[2:0] | NTW_ADR_MCH[2] |
| NTW_ADR_3[31:0] | NTW_ADR_EN[3] | NTW_ADR3_SZ[1:0] | NTW_ADR_THR3[2:0] | NTW_ADR_MCH[3] |

For Network Addresses of size less than 4 octets, the PHY expects the desired pattern to occupy the least-significant byte positions of the NTW_ADR_x register. Unused byte positions may be filled with any value.

**NOTE**

When programming the NTW_ADR_x, NTW_ADR_EN[x], NTW_ADRx_SZ, and NTW_ADR_THRx for any RX operation, the following software restrictions apply:

1. All NTW_ADR_x patterns which are enabled by their respective NTW_ADR_EN[x]=1 must be unique (disabled NTW_ADR_x registers need not follow this restriction).
2. Given restriction #1 above, not only must the patterns be unique, but the bit patterns of NTW_ADR_x and NTW_ADR_y must differ by an amount greater than the sum of the bit-error thresholds for each pattern, i.e., NTW_ADR_THRx + NTW_ADR_THRy.
3. Given all combinations of NTW_ADR_x and NTW_ADR_y, where (x != y) and both Network Addresses are enabled by NTW_ADR_EN[x]=NTW_ADR_EN[y]=1, if the sizes of the Network Address patterns differ because NTW_ADRx_SZ != NTW_ADRy_SZ, then the “matching portion” of NTW_ADR_x and NTW_ADR_y, that is, the octets of the pattern which the PHY is instructed to correlate to for each pattern, programmed into the lower byte positions of NTW_ADR_x or NTW_ADR_y for patterns of size less than 4 octets, must be unique.
4. Given restriction #3 above, not only must the “matching portion” of the patterns be unique, but bit patterns of the matching portions of NTW_ADR_x and NTW_ADR_y must differ by greater than the sum of the bit-error thresholds for each pattern, i.e., NTW_ADR_THRx + NTW_ADR_THRy.

These restrictions are designed to preclude multiple, simultaneous pattern matches during a pattern search. Results are indeterminate if the restrictions are violated.

When the PHY detects a pattern match on any enabled NTW_ADR_x during reception, and asserts NTW_ADR_MCH[x], the GENERIC_FSK Link Layer Controller shall assert NTW_ADR_IRQ. The NTW_ADR_IRQ is the Link Layer's first indication that a packet is being received. After any NTW_ADR_IRQ assertion, a packet will be received and stored into the Packet Buffer RX buffer.

## HEADER

The packet header is comprised of H0, LENGTH, and H1, in that order. Each of the 3 fields of the header has programmable length, from 0 to 16 bits. A size of zero for any of the header components infers that that component is skipped in the packet structure. Although the size of the individual H0, LENGTH, and H1 components need not be aligned to a byte boundary, the overall header must be byte-aligned. That is, the sum of the sizes (in bits) of H0, LENGTH, and H1, must be a integer multiple of 8 bits. This is a software restriction, a violation of which may result in indeterminate behavior.

For GENERIC_FSK protocol, the purpose of the header is twofold:

1. To frame the LENGTH field, so that LENGTH can be extracted and interpreted by the GENERIC_FSK packet processor, so as to determine how and when perform the required bit-stream processing on the data. In most wireless protocols with regular structures, the LENGTH field is embedded within the packet header, but its positioning, number of LENGTH bits, bit ordering, and interpretation can differ. The GENERIC_FSK configurability thus provides support for a wide range of header formats, yielding a high likelihood that most current and future packet formats and LENGTH fields will be parsable by the GENERIC_FSK Link Layer controller.
2. To provide rudimentary packet filtering on the non-LENGTH header bits, namely H0 and H1. Screening of packets based on H0 and/or H1 bit comparisons can reduce power consumption, by avoiding notification to the host processor on received packets that do not comply with pre-configured H0 and/or H1 bitmasks, enabling longer MCU sleep durations.

The header components, and their configurability options, are further described below.

### H0

H0 is an optional header packet element. Its length in bits is determined by register H0_SZ[4:0]. Legal values for H0_SZ are:

0 <= H0_SZ <= 16

If H0 is present (non-zero size), it can be filtered-on by the GENERIC_FSK packet processor; each bit of H0 can be forced to match a programmable bitmask, or ignored. Every bit of H0 that is forced to match the bitmask, must match; otherwise, the packet is rejected. The registers H0_MATCH[15:0] and H0_MASK[15:0] control H0 filtering. For every bit of H0_MASK that is set to one, the received bit in the H0 portion of the header

must match the corresponding bit of H0_MATCH. Bits of H0_MASK which are cleared, do not require a match of received data bits to H0_MATCH bits. If any bit of received data which is qualified with H0_MASK[x]=1 fails to match its corresponding H0_MATCH[x] bit, the H0_FAIL register status bit will be set, an RX recycle will occur, and the host processor will not be notified. (The recycle operation will self-clear the H0_FAIL bit). For debug purposes, the control bit REC_BAD_PKT has been provided. If REC_BAD_PKT=1 and a H0-mismatch occurs, the RX recycle is prevented, the full packet is received, the MCU is notified, and the H0_FAIL flag stays asserted. In this case, the H0-fail flag will stay asserted until the next RX warmup (specifically, rx_init clears the bit).

The equation for H0_FAIL is thus:

$H0_FAIL = [H0_{received} \text{\^{}} H0_MATCH[15:0]) \ \& \ H0_MASK > 0$

## LENGTH

LENGTH is an optional header packet element. Its length in bits is determined by the register LENGTH_SZ[4:0]. Legal values for LENGTH_SZ are:

0 <= LENGTH_SZ <= 16

If LENGTH is present (non-zero size), its value determines the number of octets remaining in the packet after the header is complete, that is, PAYLOAD octets plus CRC octets, as depicted below.

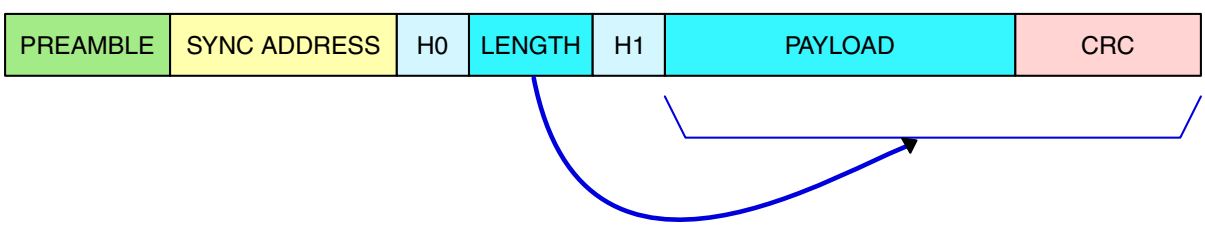

**Figure 64-170. LENGTH Field Interpretation with No LENGTH_ADJ**

For example, if the payload consists of 16 octets, and CRC is 4 octets, the LENGTH field of the header should be set to 20. The packet processor will extract the packet length from the LENGTH field of the header, and use this information to determine the timing of the CRC, Whitening, and Manchester control signals, as well as end-of-packet interrupt triggering.

In case a protocol exists for which the LENGTH field is to be interpreted differently, a configurability option has been provided to compensate for this. Hypothetically, this could happen, for example, in a proprietary packet structure, in which LENGTH is to be

defined to represent PAYLOAD only, excluding CRC. The register LENGTH_ADJ, allows a fixed offset to be applied to the extracted LENGTH field, such that the sum of LENGTH + LENGTH_ADJ represents the number of PAYLOAD + CRC octets, as depicted below:

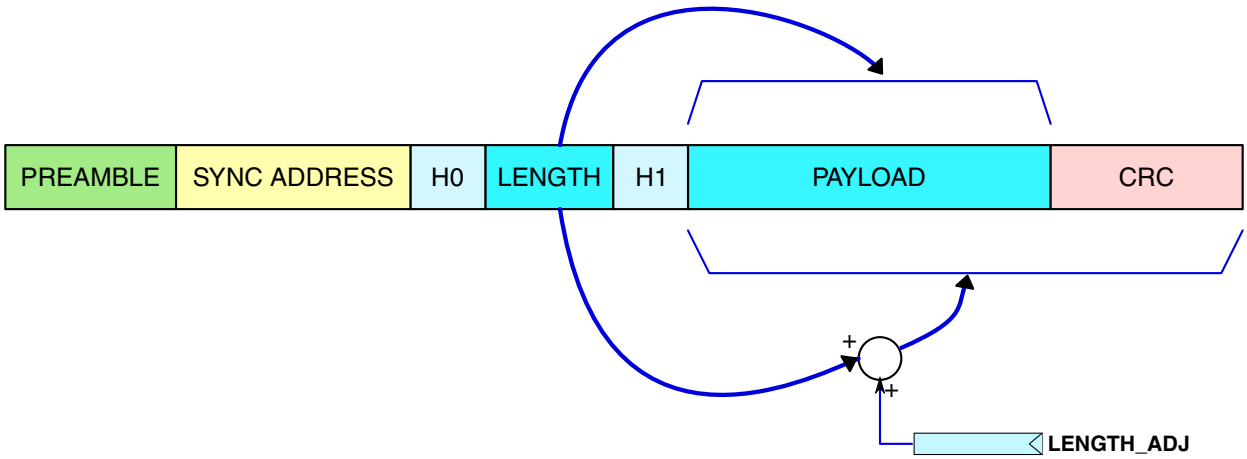

**Figure 64-171. LENGTH Field Interpretation with LENGTH_ADJ**

Applying the previous example, if, using a proprietary format, LENGTH were to be defined as payload-length only, LENGTH would be set to 16. In order for the packet processor to correctly time the CRC and Whitening control signals, etc., the LENGTH_ADJ register should be programmed to 4 in this case, so that the packet processor would operate on a 20-octet “PAYLOAD + CRC” PDU. The LENGTH_ADJ register represents a signed value, so that negative offsets can be applied. The legal range for LENGTH_ADJ is:

-31 <= LENGTH_ADJ <= 31

The LENGTH field could be ordered MSB first or LSB first. The packet processor must be able to accommodate either case, in order to extract the LENGTH field properly from the header, so a configurability option has been provided. The register bit LENGTH_BIT_ORD specifies the bit order. If LENGTH_BIT_ORD=0, ordering is LSB-first, as shown below.

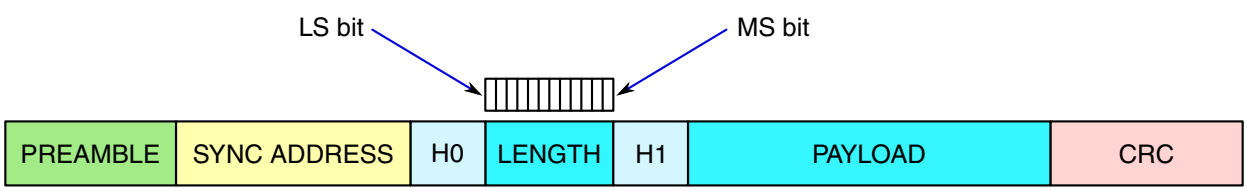

**Figure 64-172. LENGTH Bit Ordering (LSB First)**

If LENGTH_BIT_ORD=1, ordering is MSB-first, as shown below.

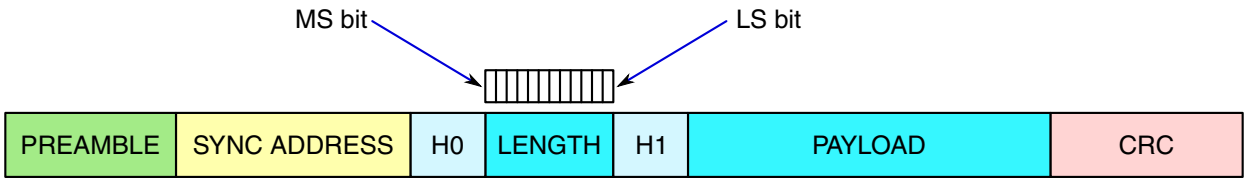

**Figure 64-173. LENGTH Bit Ordering (MSB First)**

If LENGTH_SZ=0, then LENGTH is not present in the header. The packet processor interprets this as LENGTH=0. If, in this case, LENGTH_ADJ=0 also, the packet processor interprets this to mean that the packet ends with the last bit of H1, and there are no PAYLOAD or CRC octets (CRC_SZ should be programmed to 0 in this case). There is no CRC verification in this scenario. If, in this case, LENGTH_SZ=0, meaning an empty payload field, but a CRC check is desired, CRC_SZ should be programmed to the desired number of CRC octets, and LENGTH_ADJ should be programmed to the same value: LENGTH_ADJ = CRC_SZ.

For GENERIC_FSK, valid payload lengths are from 0 to 2047 octets, i.e.,

0 <= LENGTH <= 2047

If LENGTH_ADJ is non-zero, then the maximum limit of 2047 applies to the sum of LENGTH and LENGTH_ADJ, i.e.,

0 <= (LENGTH + LENGTH_ADJ) <= 2047

A restriction on LENGTH_ADJ follows:

If the packet ends immediately after the LENGTH field of the header, i.e., H1_SZ=0 and there is neither payload nor CRC, then LENGTH_ADJ must be set to 0.

Although the LENGTH field has a maximum size of 16 bits, since the maximum receivable packet size is 2047 bytes, any received LENGTH bits above bit [10] are ignored by the packet processor, which effectively clamps LENGTH at 2047 bytes. There may be cases where it is desirable to limit the maximum received packet length to values less than 2047, so that received packets whose extracted LENGTH field indicates to be larger than a pre-set limit, are rejected by the packet processor. A configurability option has been provided for this, the register LENGTH_MAX[6:0]. The LENGTH_MAX setting configures a pre-set limit on the extracted LENGTH field, in multiples of 16 octets. A special case exists for LENGTH_MAX=0 (the register default), which implies no hardware-limiting; this setting should be used to allow reception of full-length 2047-octet packets. If LENGTH_MAX=1, packets with LENGTH >= 16 octets are rejected. If LENGTH_MAX=2, packets with LENGTH >= 32 octets are rejected. If LENGTH_MAX=127 (the maximum setting) packets with LENGTH >= 2032 octets are rejected. To determine compliance with LENGTH_MAX, the packet processor compares

the LENGTH_MAX register with the extracted LENGTH field directly, not the adjusted length (LENGTH + LENGTH_ADJ). If a packet is received during which the extracted LENGTH field exceeds the LENGTH_MAX setting, the LENGTH_FAIL register status bit will be set, an RX recycle will occur, and the host processor will not be notified. (The recycle will self-clear the LENGTH_FAIL bit). For debug purposes, the control bit REC_BAD_PKT has been provided. If REC_BAD_PKT=1 and a LENGTH_MAX violation occurs, the RX recycle is prevented, the full packet is received, the MCU is notified, and the LENGTH_FAIL flag stays asserted. In this case, the LENGTH_FAIL flag will stay asserted until the next RX warmup (specifically, rx_init clears the bit).

### H1

H1 is an optional header packet element. Its length in bits is determined by register H1_SZ[4:0]. Legal values for H1_SZ are $0 \leq H1_SZ \leq 16$. If H1 is present (non-zero size), it can be filtered-on by the GENERIC_FSK packet processor; each bit of H1 can be forced to match a programmable bitmask, or ignored. Every bit of H1 that is forced to match the bitmask, must match; otherwise, the packet is rejected. The registers H1_MATCH[15:0] and H1_MASK[15:0] control H1 filtering. For every bit of H1_MASK that is set to one, the received bit in the H1 portion of the header must match the corresponding bit of H1_MATCH. Bits of H1_MASK which are cleared, do not require a match of received data bits to H1_MATCH bits. If any bit of received data which is qualified with H1_MASK[x]=1 fails to match its corresponding H1_MATCH[x] bit, the H1_FAIL register status bit will be set, an RX recycle will occur, and the host processor will not be notified. (The recycle will self-clear the H1_FAIL bit). For debug purposes, the control bit REC_BAD_PKT has been provided. If REC_BAD_PKT=1 and a H1-mismatch occurs, the RX recycle is prevented, the full packet is received, the MCU is notified, and the H1_FAIL flag stays asserted. In this case, the H1-fail flag will stay asserted until the next RX warmup (specifically, rx_init clears the bit).

The equation for H1_FAIL is thus:

$H1_FAIL = [H1_{received} \text{^} H1_MATCH[15:0]) \ \& \ H1_MASK > 0$

### PAYLOAD

In the GENERIC_FSK packet structure, the payload directly followed the header. For transmission, payload bytes are serialized, and transmitted, LSB first, in order, as they are received from the Packet Buffer interface. During reception, payload bytes are received LSB first, undergo serial-to-parallel conversion to octets, 4 octets are packed into a 32-bit word, and the word is transferred to memory via Packet Buffer. For both TX and RX, since the packet processor interprets the extracted LENGTH to represent the number of Payload + CRC octets, the actual number of payload octets is computed from the following equation:

$Number_of_Payload_Octets = (LENGTH_{extracted} + LENGTH_ADJ - CRC_SZ)$

For TX, payload bytes are subjected to whitening or Manchester encoding. They are also shifted through CRC to compute a CRC checksum value. Whitening, encoding, and CRC computing are all optional. Whitening and Manchester encoding are mutually exclusive. For RX, payload bytes are subjected to de-whitening, Manchester decoding, and CRC verification. De-whitening, Manchester decoding, and CRC verification are all optional. De-whitening and Manchester decoding are mutually exclusive. For both TX and RX, (de-)whitening can precede CRC, or follow it. Manchester encoding always operates on post-CRC bitstream for transmission, and Manchester decoding always precedes CRC verification for reception. For more details on CRC, whitening, and Manchester encoding, see Section Bitstream Processing.

### CRC

In the GENERIC_FSK packet structure, the CRC field directly followed the payload. The size of the CRC field, in octets, is set by the CRC_SZ register. The valid range for CRC_SZ is:

0 <= CRC_SZ <= 4

For both TX and RX, the portion of the packet which are subjected to CRC is programmable, via the register CRC_START_BYTE[3:0]. The register CRC_START_BYTE programs the absolute byte count of the first byte for which CRC shifting is desired. The CRC_START_BYTE value is referenced to the GENERIC_FSK Byte Counter. The Byte Counter starts at 0 for the first octet of Sync Address, and increments octet-for-octet henceforth, until the last octet of CRC is transmitted or received. An example of CRC_START_BYTE programming is shown below.

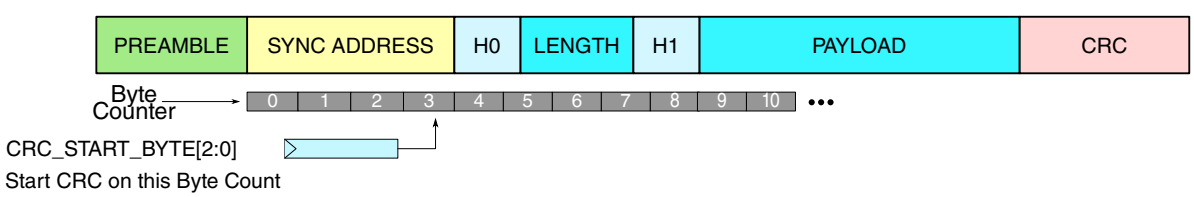

**Figure 64-174. CRC Start Byte**

In this example

SYNC_ADDR_SZ = 4

Header Size = 4 i.e. (H0_SZ + LENGTH_SZ +H1_SZ)/8 = 4

To initiate CRC shifting at the start of Sync Address, program CRC_START_BYTE = 0

To initiate CRC shifting at the start of Header, program CRC_START_BYTE = 4

To initiate CRC shifting at the start of Payload, program CRC_START_BYTE = 9

The CRC_START_BYTE should not be programmed so large as to exceed the length of the PDU; that is, larger than extracted LENGTH – CRC_SZ. If CRC_SZ=0, program CRC_START_BYTE=0.

For more details on how the GENERIC_FSK packet processor controls the CRC generation and verification processes, see Section Bitstream Processing.

## EXAMPLE

A real-world example follows, describing how the GENERIC_FSK Link Layer packet configuration can be applied to transmit and receive packets which conform to IEEE 802.15.4g . For this example, please refer to IEEE Std 802.15.4g™-2012, Part 15.4: Low-Rate Wireless Personal Area Networks (LR-WPANs), Amendment 3: Physical Layer (PHY) Specifications for Low-Data-Rate, Wireless, Smart Metering Utility Networks.

Section 18.1.1.3 of 802.15.4g describes the packet header (PHR), which is replicated below as it appears in that standard:

**Table 64-48. Format of the PHR(without mode switching) for MR-FSK**

| Bit string index | 0 | 1-2 | 3 | 4 | 5-15 |
|---|---|---|---|---|---|
| Bit mapping | MS | $R_1$-$R_0$ | FCS | DW | $L_{10}$-$L_0$ |
| Field Name | Mode Switch | Reserved | FCS Type | Data Whitening | Frame Length |

The GENERIC_FSK Link Layer controller supports such a header format, and can be programmed to transmit and receive packets which conform to it. To correctly size and order the GENERIC_FSK header elements so as to conform with this header format:

1. The LENGTH field ends the header, so there is no H1 (H1_SZ=H1_MASK=0)
2. The 5 bits which precede LENGTH in the header, are grouped into H0 (H0_SZ=5)
3. The size of the LENGTH field is 11 bits (LENGTH_SZ=11)
4. The LENGTH is specified as MSB-first (LENGTH_BIT_ORD=1)

For this example, we would like to leverage the H0-filtering capability built into the GENERIC_FSK Link Layer to screen the 802.15.4g header, to require that the bit fields in the received packet comply with the following conditions:

1. MS (Mode Switch, bit [0] of header) = 0
2. DW (Data Whitening, bit [4]) = 1
3. FCS (FCS Type, bit [3]) = 1 (Four-octet FCS)
4. Bits [1] and [2] are marked as Reserved, to be ignored on reception

Given these parameters, the following diagram shows how we would program the GENERIC_FSK Link Layer controller to accept this packet configuration, and then screen H0 accordingly:

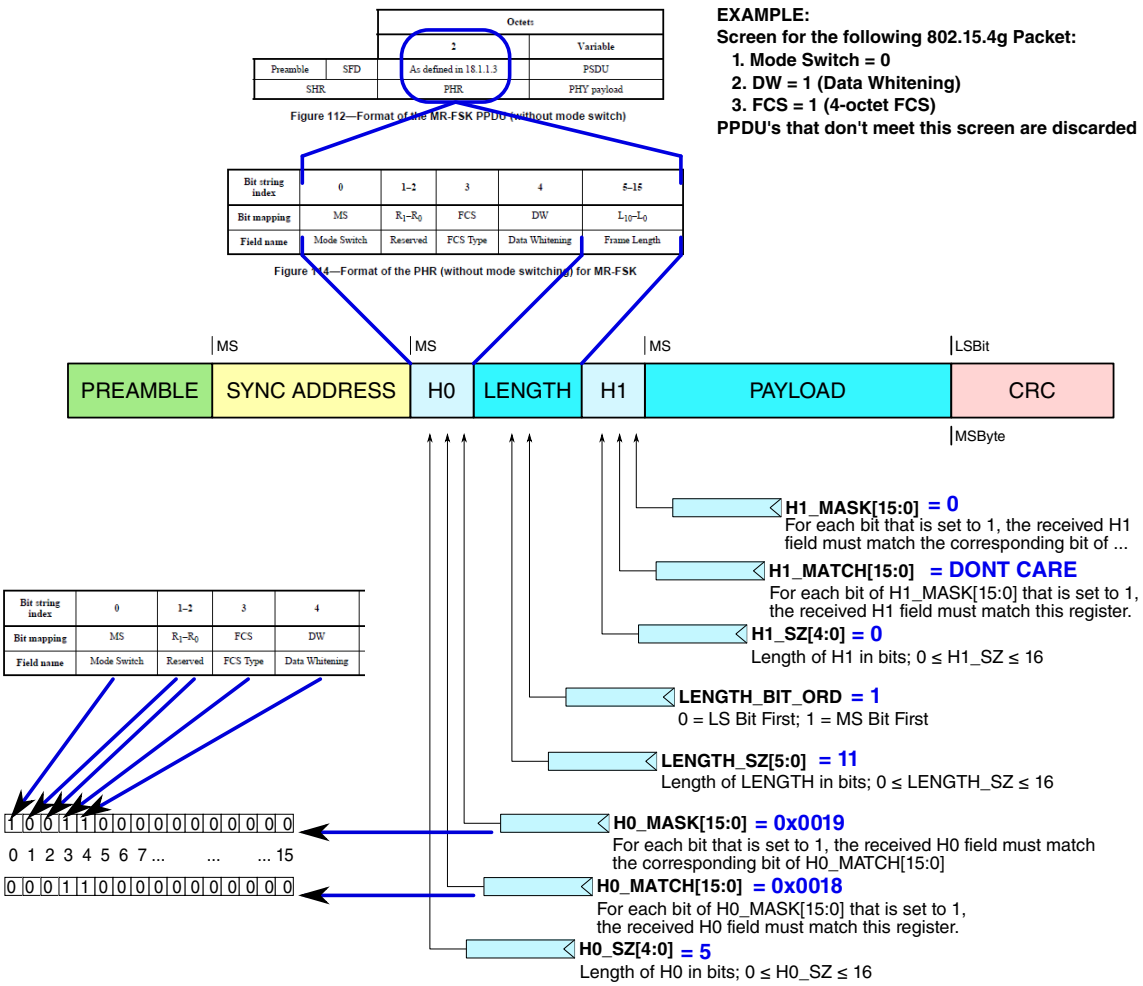

**Figure 64-175. GENERIC FSK PACKET STRUCTURE AS APPLIED TO 802.15.4g PHR**

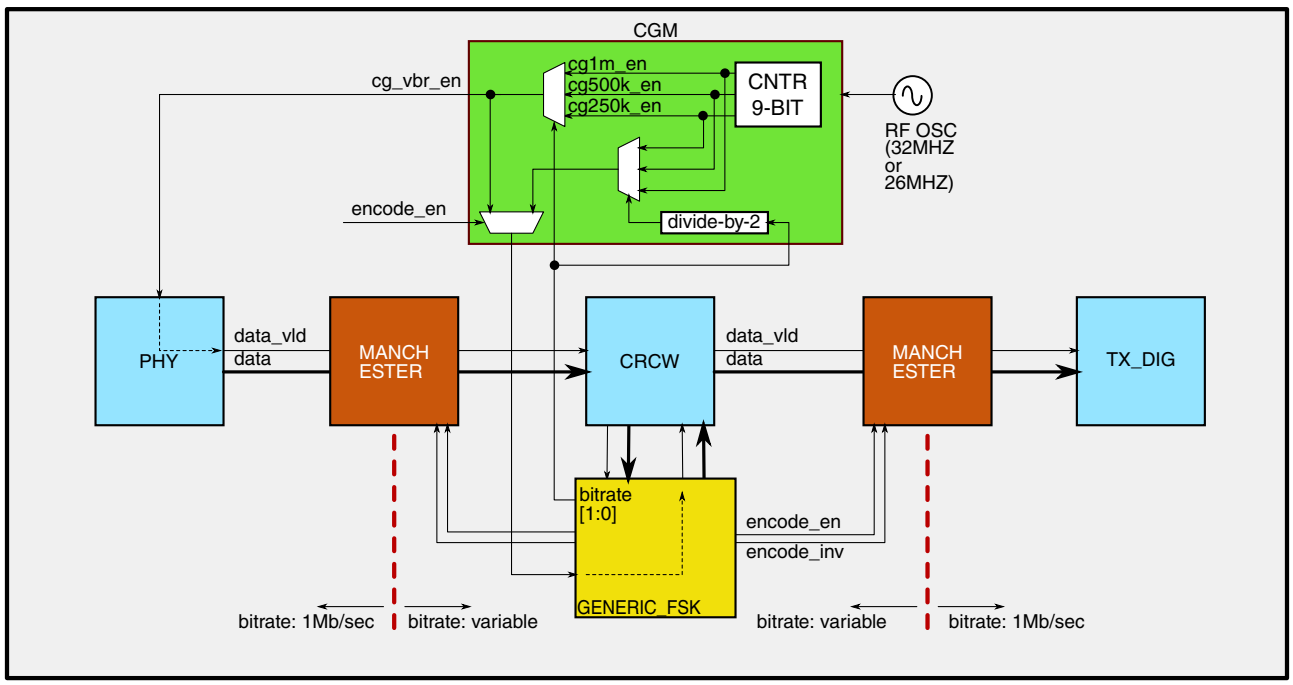
Received packets which meet the H0 filtering screen are fully received, and Data Indication is provided to the host processor. Packets which fail the screen result in an RX recycle, and no notification to the host.

## 64.5.3.3.2 Bitstream Processing

The GENERIC_FSK Link Layer controller provides a number of options to allow for control and modification of the serial bitstream as the packet is being transmitted and received. From a high-level point-of-view, these 4 options are provided:

1. CRC generation (TX) and CRC verification (RX)
2. Data Whitening (TX) and De-whitening (RX)
3. Manchester Encoding (TX) and Decoding (RX)
4. Variable Bit Rate

The following diagram provides another perspective of bitstream processing.



**BITSTREAM PROCESSING WITH MANCHESTER ENCODING**

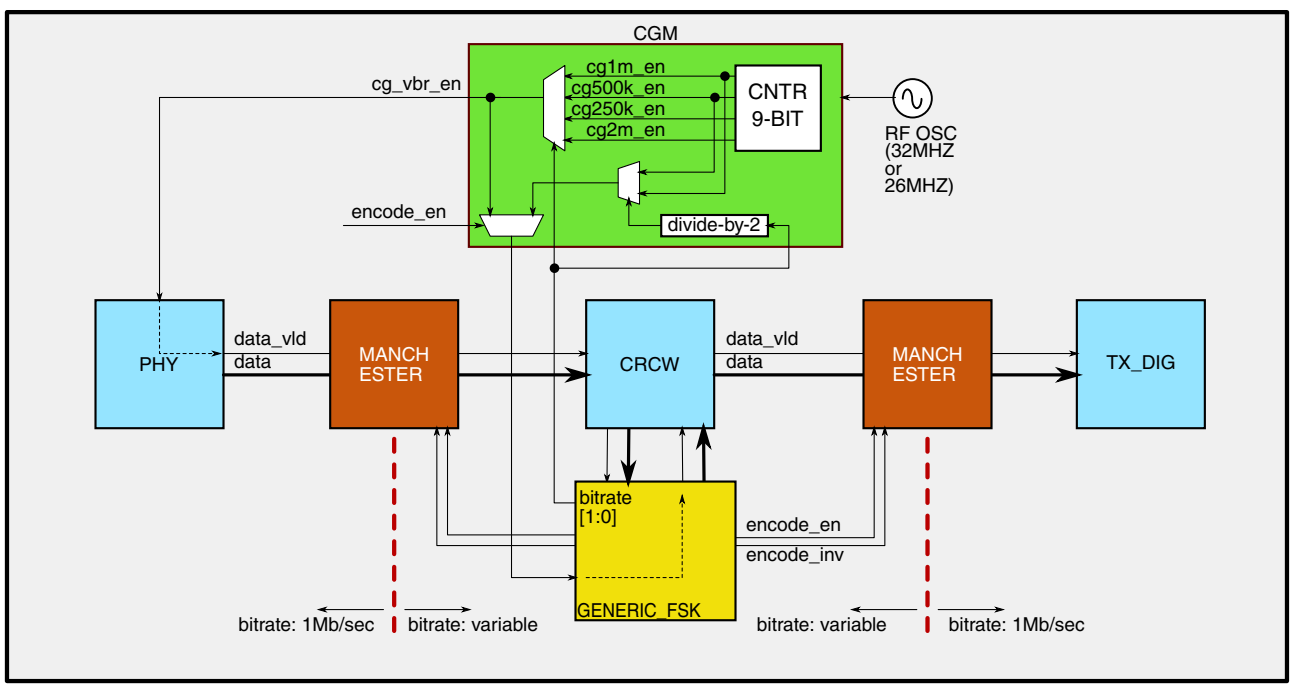


**Figure 64-176. BITSTREAM PROCESSING WITH MANCHESTER ENCODING**

For GENERIC_FSK, CRC and Whitening are somewhat consolidated, and are performed in a separate module external to the Link Layer Controller. The CRC/Whitener block performs these functions. Manchester encoding is also performed externally, and is described later in this section. Bitrate configurability is managed jointly by the

GENERIC_FSK Link Layer controller and the 2.4GHz Radio's Clock Generation Module (CGM). The following sections provide more detail on how CRC, whitening, Manchester encoding, and bitrate, are controlled by the GENERIC_FSK Link Layer, and describes the configuration options associated with each.

## CRC & WHITENING

The GENERIC_FSK Link Layer controller dynamically manages the CRC generation process (for TX), and CRC verification process (for RX), by way of 3 timing signals that it asserts to the CRC/Whitener module.

For GENERIC_FSK, the CRC engine in the CRC/Whitener block shall only shift incoming bits (data_in) through its LFSR when all the following conditions are met:

1. crcw_init=0
2. crc_en=1
3. tx_data_in_vld=1 (signal is data_in_vld at the CRC/Whitener)

The CRC/Whitener shall only shift bits out of its CRC LFSR, to the TX digital block, when all the following conditions are met:

1. crcw_init=0
2. crc_comp=1
3. tx_data_in_vld=1 (signal is data_in_vld at the CRC/Whitener)

The packet processor uses the extracted LENGTH field of the packet, as well as the registers which control the size of the individual packet elements, in order to determine when to assert the CRC-related control signals, **crc_en** and **crc_comp**. This is true for both transmission and reception. The calculations used by the packet processor to determine when to assert the CRC-related control signals are summarized in the following diagram.

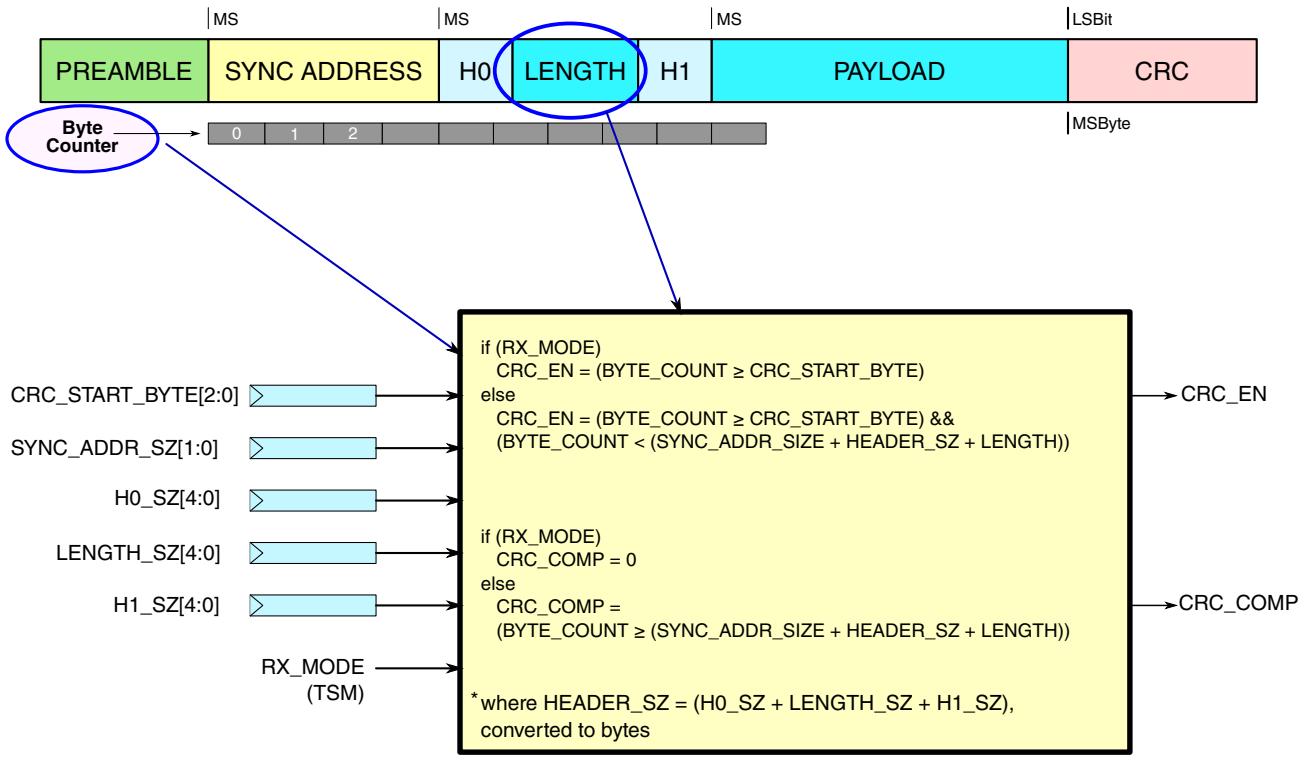

**Figure 64-177. GENERIC FSK: CONTROL OF CRC**

Likewise, the GENERIC_FSK Link Layer controller optionally enables whitening and de-whitening of the packet bitstream, and controls the portions of the packet which are subjected to whitening. For both TX and RX, the portion of the packet which are subjected to whitening/de-whitening is programmable; the following table describes the 3 registers which determine which elements of the packet bitstream are whitened/de-whitened.

| REGISTER NAME | FUNCTIONAL DESCRIPTION |
|---|---|
| WHITEN_START[1:0] | **0**: No whitening/de-whitening<br>**1**: Begin whitening/de-whitening at the start of the header (H0) field, regardless of packet length.<br>**2**: Begin whitening/de-whitening at the start of the header H1 field, but only if the extracted length field meets or exceeds WHITEN_SZ_THR, i.e.,<br>($LENGTH_{extracted}$ >= WHITEN_SZ);<br>otherwise, there is no whitening/de-whitening of the bitstream<br>**3**: Begin whitening/de-whitening at the start of the PAYLOAD, but only if the extracted length field meets or exceeds WHITEN_SZ_THR, i.e.,<br>($LENGTH_{extracted}$ >= WHITEN_SZ);<br>otherwise, there is no whitening/de-whitening of the bitstream |

*Table continues on the next page...*

| REGISTER NAME | FUNCTIONAL DESCRIPTION |
|---|---|
| WHITEN_END | **0**: Whitening/de-whitening ends with the last bit of the last PAYLOAD byte<br>**1**: Whitening/de-whitening ends with the last bit of the last CRC byte |
| WHITEN_SZ_THR[12:0] | If WHITEN_START=2 or WHITEN_START=3, apply whitening/de-whitening at the point determined by WHITEN_START, but only if the extracted LENGTH field of the packet meets or exceeds this WHITEN_SZ_THR threshold; if LENGTHextracted < WHITEN_SZ_THR, there is no whitening/de-whitening of the bitstream. If WHITEN_START < 2, this register has no effect. |

The GENERIC_FSK Link Layer controller dynamically manages the data whitening process (for TX), and de-whitening (for RX), via 2 timing signals that it asserts to the CRC/Whitener module.

For GENERIC_FSK, the Whitening/de-whitening engine in the CRC/Whitener block shall only shift incoming bits (data_in) through its LFSR when all the following conditions are met:

1. crcw_init=0
2. whiten_en=1
3. tx_data_in_vld=1 (signal is data_in_vld at the CRC/Whitener)

The packet processor uses the extracted LENGTH field of the packet, as well as the registers which control the size of the individual packet elements, in order to determine when to assert the whitening-related control signal, whiten_en. This is true for both transmission and reception. The calculations used by the packet processor to determine when to assert whiten_en control signals are summarized in the following diagram.

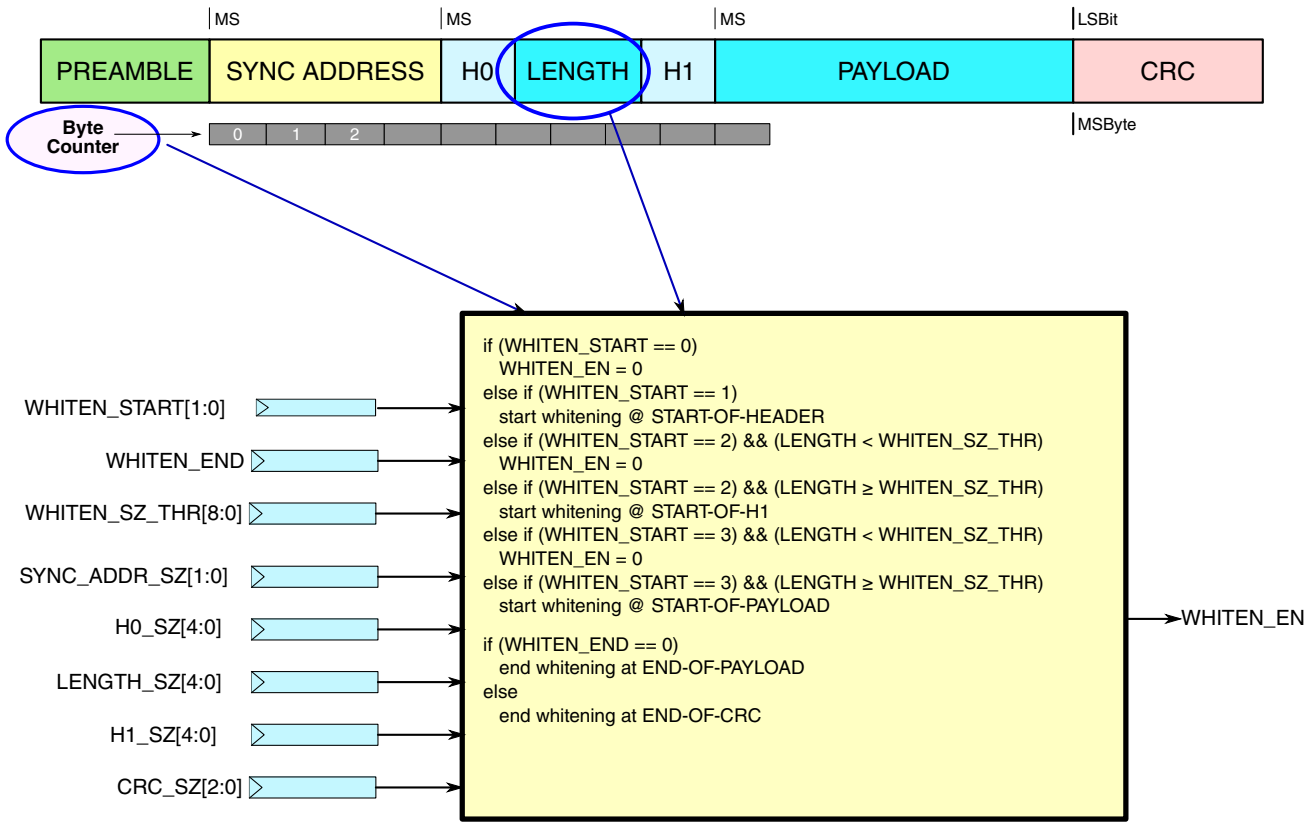

**Figure 64-178. GENERIC FSK: CONTROL OF WHITENING**

The order in which CRC and whitening are performed, is configurable, via the static register bit WHITEN_B4_CRC. This bit is programmed in the GENERIC_FSK Link Layer, and sent to the CRC/Whitening engine to control the ordering. The following table describes how the bitstream is processed for both settings of WHITEN_B4_CRC, for both TX and RX.

| | TX | RX |
|---|---|---|
| WHITEN_B4_CRC=1 | In the CRC/Whitener, the CRC engine shifts in data bits which have been whitened first through the whitener LSFR. The entire post-whitened bitstream is then transmitted to the TX Digital. | Since the entire bitstream, including CRC, has been pre-whitened, the incoming bitstream from the PHY is shifted directly through the CRC LFSR to verify the checksum. The entire bitstream is simultaneously de-whitened by the whitener LFSR and shifted out to the Link Layer. |
| WHITEN_B4_CRC=0 | In the CRC/Whitener, the CRC engine shifts in data bits which have not been whitened. Whitening is performed on the CRC LFSR output. The entire post-whitened bitstream is then transmitted to the TX Digital. | The entire bitstream is de-whitened first by the whitener LFSR, and then shifted through the CRC LFSR to verify the checksum. The entire de-whitened bitstream is simultaneously shifted out to the Link Layer. |

A diagram depicting an example of bitstream processing flow during packet transmission, with WHITEN_B4_CRC=1 (the register default), is shown below.

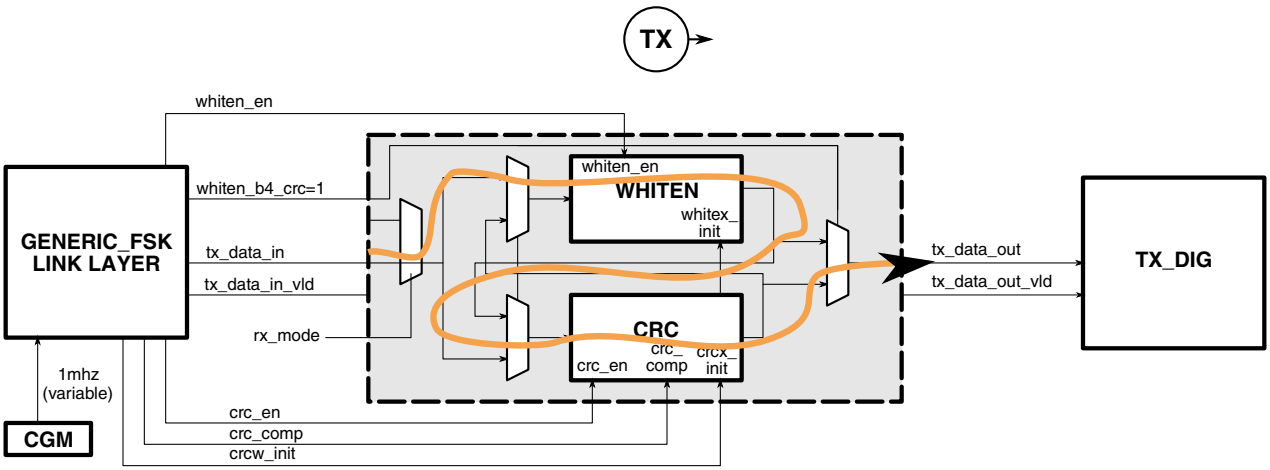

**Figure 64-179. Whitening Before CRC (TX)**

A diagram depicting an example of bitstream processing flow during packet reception, with WHITEN_B4_CRC=1, is shown below.

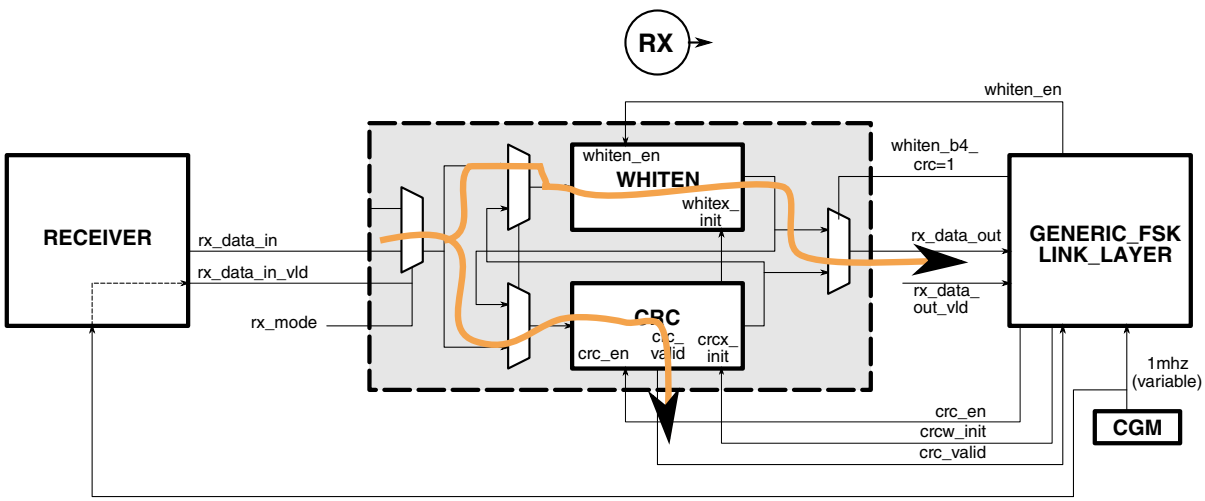

**Figure 64-180. Whitening Before CRC (RX)**

A timing diagram depicting a real-world example of TX bitstream processing timing is shown below. In this example, the desired start point for CRC shifting is the start of Network Address, so CRC_START_BYTE=0. The desired start point for whitening is the start of the header (H0), so WHITEN_START=1. It is also desired to stop whitening after the last bit of the last PAYLOAD byte, so WHITEN_END=0.

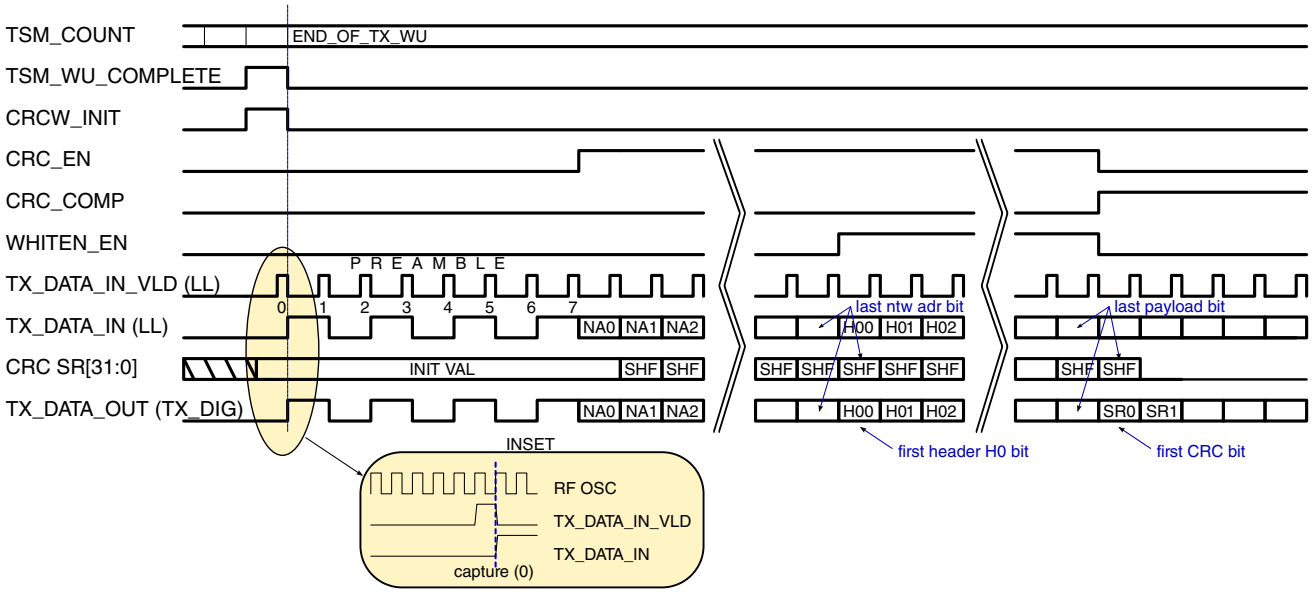

**Figure 64-181. BIT STREAM PROCESSING CRC AND WHITENING TX TIMING**

The bitstream depicted in the previous timing diagram, with CRC and whitening applied, is shifted out to the TX digital block, and transmitted over the air. A receiving device, will receive and process this same bitstream, by applying de-whitening, and verifying CRC on the de-whitened bitstream. The CRC and whitening parameters (registers) would be programmed to the receiving device, identically to how they are programmed for the transmitting device, specifically:

CRC_START_BYTE=0

WHITEN_START=1

WHITEN_END=0

A similar timing diagram depicting this RX bitstream processing timing, is shown below.

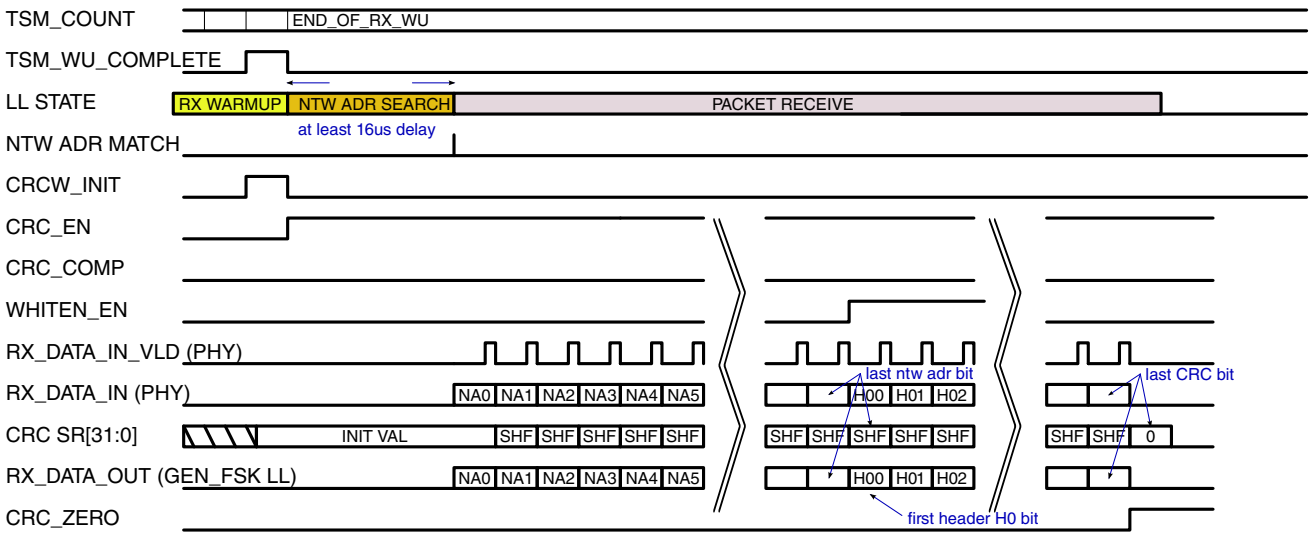

**Figure 64-182. BIT STREAM PROCESSING CRC AND WHITENING RX TIMING**

The GENERIC_FSK Link Layer controller provides a special whitening option, that causes the whitening LFSR to be re-initialized at the start of the PAYLOAD. The register bit WHITEN_PAYLOAD_REINIT, when 1, will result in the LFSR being re-initialized to its programmed initial state, determined by WHITEN_SEED[8:0], coincident with the first bit of the first byte of PAYLOAD. This applies to both TX and RX. When WHITEN_PAYLOAD_REINIT=0, there is no such re-initialization. This feature is only relevant when whitening/de-whitening is programmed to start before the PAYLOAD, i.e., WHITEN_START=1 or WHITEN_START=2.

The GENERIC_FSK Link Layer controller provides a number of other configurability options, which affect the internal operation of the CRC engine, and not the Link Layer controller itself. A listing of these registers which affect CRC internal operation, appears in the table below. For more details on how these registers affect CRC operation, see the CRC/Whitener Chapter.

| CRC-related Register | Brief Description |
|---|---|
| CRC_POLY[31:0] | CRC Polynomial<br>1: XOR exists in the bit's feedback path<br>0: no XOR in the bit's feedback path |
| CRC_SEED[31:0] | CRC Initialization Value |
| CRC_BYTE_ORD | 0: LS Byte First<br>1: MS Byte First |
| CRC_REF_IN | 0: do not manipulate input data stream<br>1: reflect each byte in the input stream bitwise |
| CRC_REF_OUT | 0: do not manipulate CRC result |

*Table continues on the next page...*

| CRC-related Register | Brief Description |
|---|---|
| | 1: CRC result is to be reflected bitwise (operated on entire word) |
| CRC_XOR_OUT[31:0] | XOR mask for CRC result (for no mask, should be 0) |

Similarly, there are a number of configurable whitening options provided by the Link Layer controller, which affect the internal operation of the whitening engine, and not the Link Layer controller itself. A listing of these registers which affect whitener internal operation, appears in the table below. For more details on how these registers affect whitener operation, see the CRC/Whitener Chapter.

| Whitener-related Register | Brief Description |
|---|---|
| WHITEN_ POLY[8:0] | Polynomial Value for Whitening/De-whitening |
| WHITEN_POLY_TYPE | Whiten polynomial type. A Fibonacci type LFSR is used with the whiten polynomial if this bit is asserted. Otherwise, a Galois type LFSR is used. |
| WHITEN_SEED[31:0] | Initialization Value for Whitening/De-whitening |
| WHITEN_SIZE[3:0] | Whitener Length |
| WHITEN_REF_IN | The input data stream is reflected, bit-wise, per byte, if this bit is asserted. Bit 7 becomes bit 0, bit 6 becomes bit 1, etc. This bit will only cause the reflection of the payload data bits as they are used in the whiten calculation and will not cause any change in the output bit order. |

## BITRATE

The GENERIC_FSK Link Layer controller provides multiple bitrate options. The register BITRATE[1:0] selects the bitrate, according to the following table.

| BITRATE[1:0] Register | BITRATE |
|---|---|
| 0 | 1 Mbit/sec |
| 1 | 500 Kbit/sec |
| 2 | 250 Kbit/sec |
| 3 | 2 Mbit/sec |

For transmission, BITRATE affects the rate at which the Link Layer controller shifts out bits, through the CRC/Whitener, and ultimately to the TX Digital Block. For reception, BITRATE affects the rate at which the PHY shifts out bits, through the CRC/Whitener, and ultimately to the Link Layer controller, which receives and processes the bitstream. The Link Layer is the originator of the packet bitstream for transmission; the PHY is the originator of the bitstream for reception. The Link Layer controller determines the bitrate by sending the **bitrate[1:0]** signal to the CGM (Clock Generation Module). The CGM decodes this signal and adjusts the rate at which pulses appear on **cg_vbr_en** to track the

programmed BITRATE. (Note: the 'vbr' in **cg_vbr_en** is an acronym for ‘variable bit rate’.) The CGM divides down the reference oscillator frequency to generate the frequency of the desired BITRATE, and then sends out pulses on cg_vbr_en which are one reference oscillator clock wide, at that rate. The **cg_vbr_en** shall be used as a gating signal (clock gating and/or data gating) inside the blocks which originate the bitstream (Link Layer, PHY), and those that consume it (CRC/Whitener, TX digital). The timing on cg_vbr_en manifests itself on the respective *_data_in_vld and *_data_out_vld signals to and from the 4 blocks that operate on the bitstream. This way, all 4 blocks operate in unison at all times at a single, desired bitrate.

The following diagram depicts how bitrate is controlled by the Link Layer and CGM, and how the respective blocks involved in bitstream processing stay in sync using **cg_vbr_en**.

**BITSTREAM PROCESSING WITH VARIABLE BIT RATE**

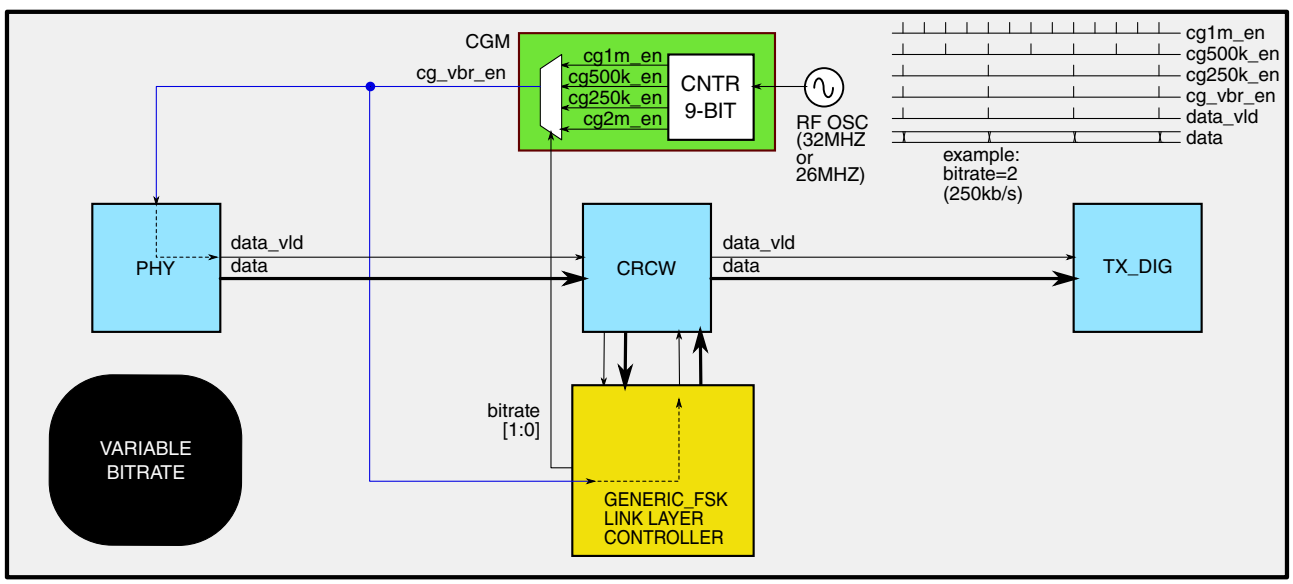

**Figure 64-183. BITSTREAM PROCESSING WITH VARIABLE BIT RATE**

## MANCHESTER ENCODING AND DECODING

The GENERIC_FSK Link Layer controller allows the packet bitstream to be Manchester-encoded for transmission, and decoded for reception. The Manchester encoding used by the controller conforms to IEEE 802.3, which is shown in the following diagram.

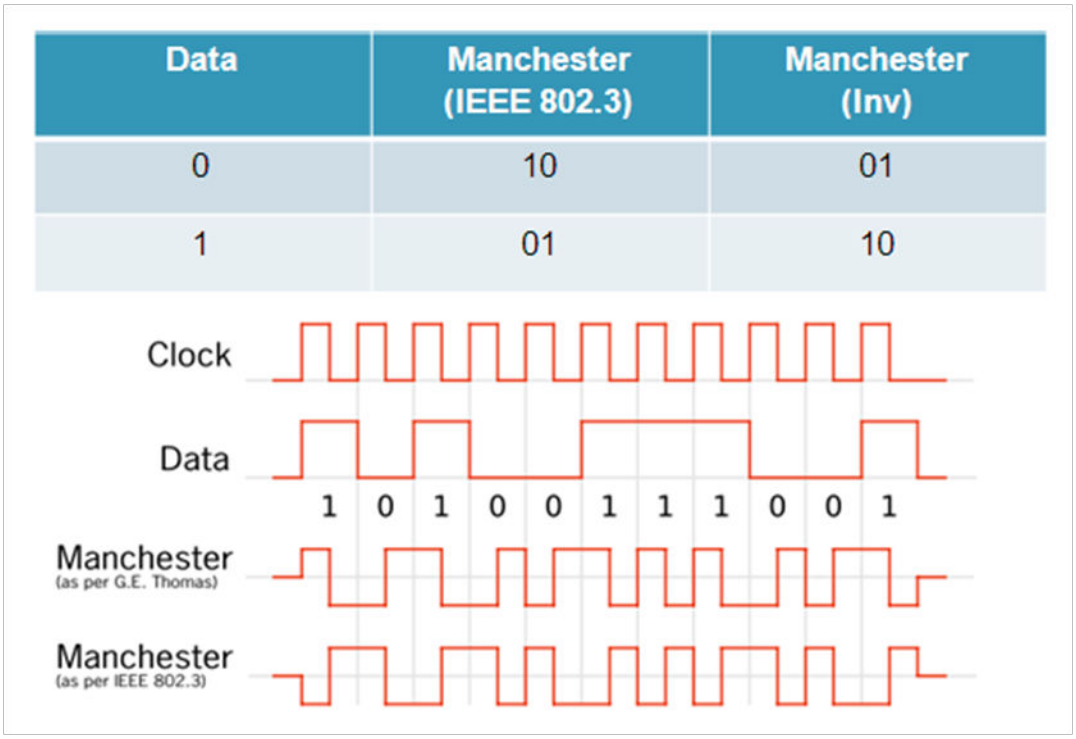

**Figure 64-184. Manchester Encoding**

Three programmable registers enable and control Manchester encoding and decoding, as described in the following table.

| | TX | RX |
|---|---|---|
| MANCHESTER_EN | 1: the entire packet bitstream, including CRC, is Manchester-encoded as it is transmitted to the TX digital block. CRC operates on the original, non-encoded bitstream.<br>0: No encoding applied | 1: the entire packet bitstream, including CRC, is Manchester-decoded, and the output of the decoder is transmitted simultaneous to the CRC engine and the Link Layer.<br>0: No decoding applied |
| MANCHESTER_INV | 1: Encoding is per 802.3, but with the coding signal inverted<br>0: Encoding is as per 802.3 | 1: Decoding is per 802.3, but with the coding signal inverted<br>0: Decoding is as per 802.3 |
| MANCHESTER_START | 1: Begin encoding at start-of-header<br>0: Begin encoding at start-of-payload | 1: Begin decoding at start-of-header<br>0: Begin decoding at start-of-payload |

As the encoding diagram implies, the post-encoded process bitstream has a bitrate of twice that of the pre-encoded data. The over-the-air bitrate must, of course, be constant. Thus, for transmission, the source of the bitstream data, i.e., the GENERIC_FSK Link Layer controller, must halve its bitrate whenever Manchester encoding is engaged. Since the CRC engine is also upstream of the encoder, it will also see the half bitrate. The output of the Manchester encoder, which feeds the TX digital block, will see the full bitrate. For reception, the source of the bitstream data, i.e, the PHY, will see the full

bitrate. After the PHY feeds the Manchester decoder with the full-rate data, the blocks downstream of the decoder, i.e., the Link Layer controller and the CRC engine, will need to operate at half bitrate. When Manchester encoding is used, the over-the-air bitrate, that is, the bitrate programmed via the BITRATE register, is restricted to either 1Mbit/sec (BITRATE=0), or 500Kbit/sec (BITRATE=1); other BITRATE options are not supported with Manchester. The following table summarizes the supported over-the-air bitrates, and specifies the effective bit rates seen by the 4 blocks involved in bitstream processing while Manchester is engaged.

| | PHY | GENERIC_FSK Link Layer | CRC LFSR | TX Digital |
|---|---|---|---|---|
| BITRATE=0 (ota bitrate = 1 Mbit/sec) | 1 Mbit/sec | 500 Kbit/sec | 500 Kbit/sec | 1 Mbit/sec |
| BITRATE=1 (ota bitrate = 500Kbit/sec) | 500 Kbit/sec | 250 Kbit/sec | 250 Kbit/sec | 500 Kbit/sec |

Because the Manchester encoding and decoding is not performed over the entire packet, e.g., the Network Address is never encoded, the Link Layer controller must switch its bitrate *dynamically*, reducing its own bitrate by half whenever Manchester is engaged, and restoring full bitrate when Manchester is disengaged. Since the PHY and TX digital must process bits at the full rate at all times, the bitstream-pacing signal, **cg_vbr_en**, must be split, such that the PHY and TX digital get the full rate gating signal, and the Link Layer and CRC get the variable rate gating signal. The following diagram describes how the CGM generates a special half-rate rendition of **cg_vbr_en** when Manchester is engaged (**encode_en**=1), and feeds this to the Link Layer (and indirectly, the CRC engine). The diagram assumes the default setting of BITRATE=0 (over-the-air rate is 1Mb/sec).

## BITSTREAM PROCESSING WITH MANCHESTER ENCODING

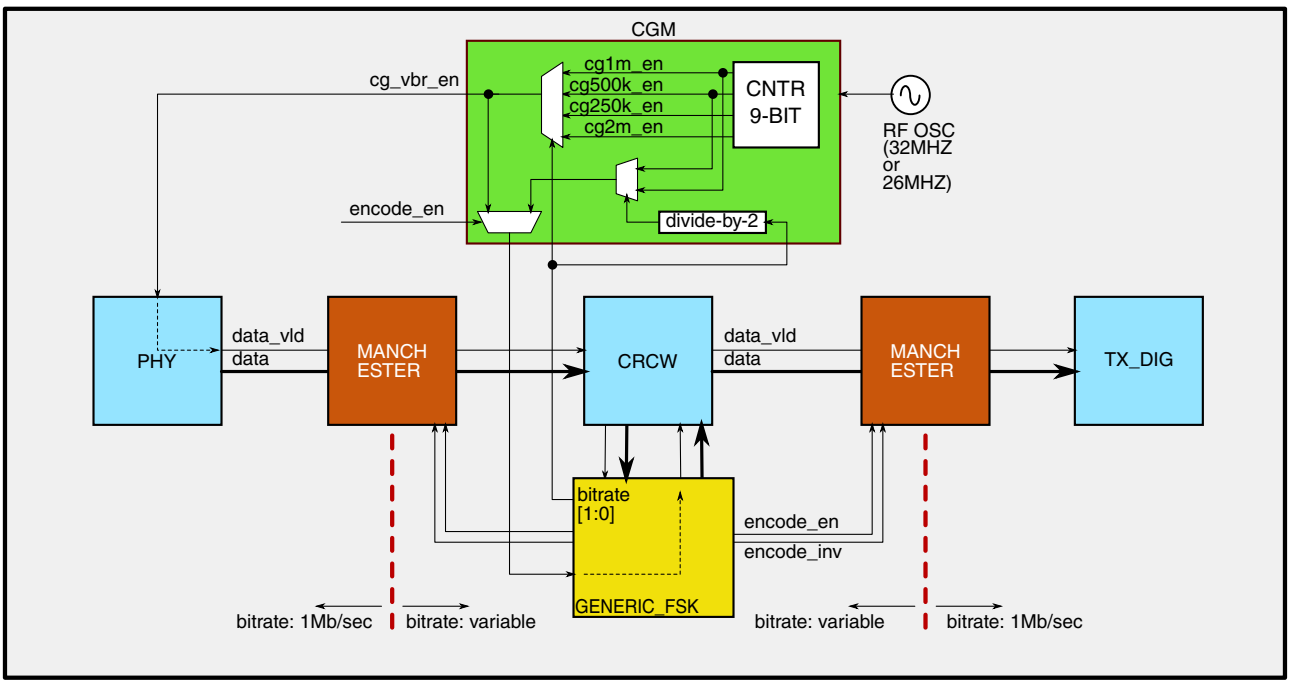

**Figure 64-185. BITSTREAM PROCESSING WITH MANCHESTER ENCODING**

A timing diagram depicting an example of bitstream processing, including Manchester encoding, for a packet transmission, is included below. The diagram shows the mid-packet switching of the encoding-enable signal, encode_en, and the halving of the bitrate as seen by the Link Layer controller. This example uses MANCHESTER_START=0, to initiate encoding at the start-of-payload.

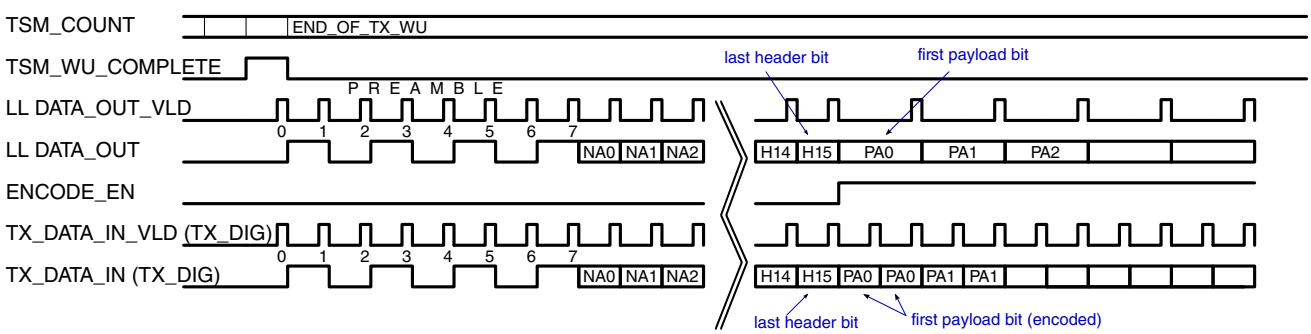

**Figure 64-186. BIT STREAM PROCESSING (WITH MANCHESTER) TX TIMING -- 1MBIT/SEC OTA**

An example of bitstream processing, including Manchester encoding, for a packet reception, is included below. The diagram shows the mid-packet switching of the decoding-enable signal, encode_en, and the halving of the bitrate as seen by the Link Layer controller. This example uses MANCHESTER_START=0, to initiate encoding at the start-of-payload.

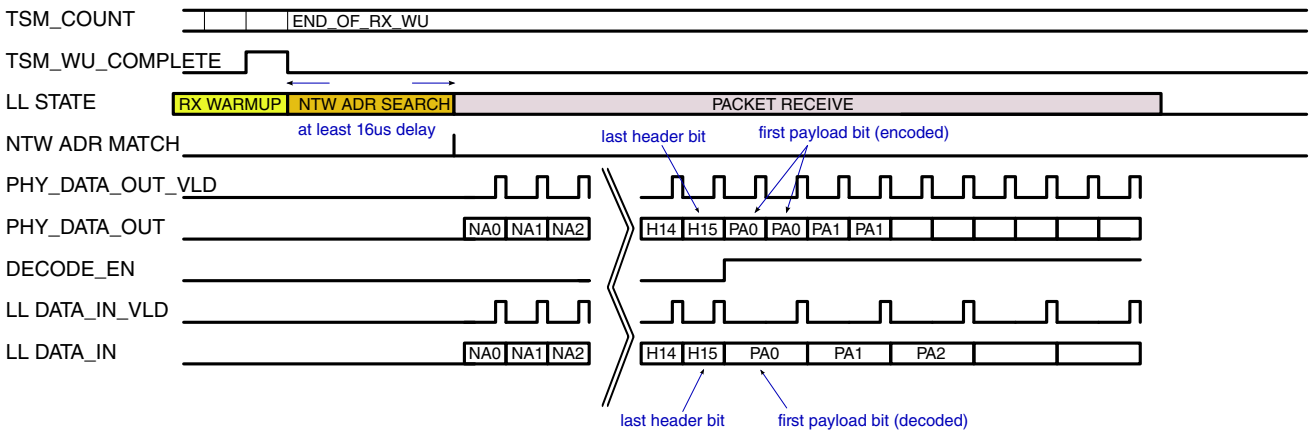

**Figure 64-187. BIT STREAM PROCESSING (WITH MANCHESTER) RX TIMING -- 1MBIT/SEC OTA**

**NOTE**

Whitening and Manchester encoding are mutually exclusive, and must not be enabled simultaneously. This is a software restriction on the setting of the register bits WHITEN_START and MANCHESTER_EN. Both may not be simultaneously non-zero. Failure to heed this restriction may lead to indeterminate behavior.

### 64.5.3.3.3 Fixed Packet Length

The GENERIC_FSK Link Layer controller expects a stream of consecutive bits specifying the length of the packet, to be transmitted and received over-the-air, as part of the packet bitstream, with the length specification typically encoded into the packet header, as shown below.

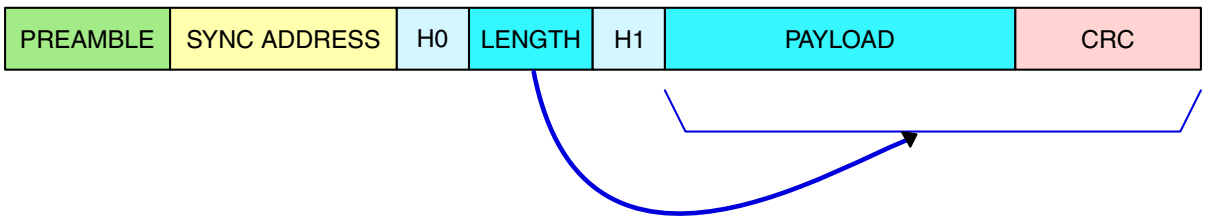

**Figure 64-188. PACKET STRUCTURE WITH LENGTH FIELD IN HEADER**

Some protocols don't include any length instructions in the packet header, as shown below.

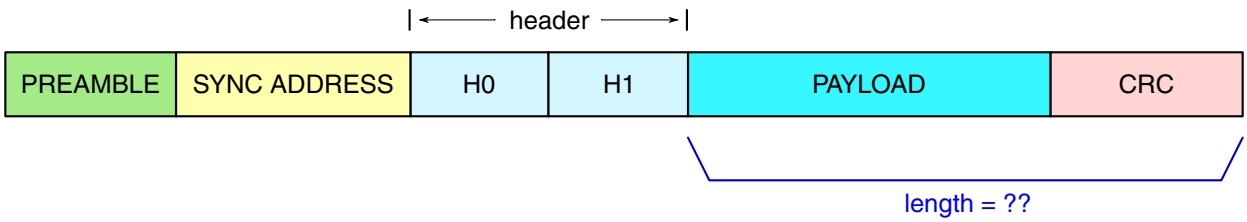

**Figure 64-189. PACKET STRUCTURE WITH NO LENGTH FIELD IN HEADER**

And, some protocols may not include a header at all.

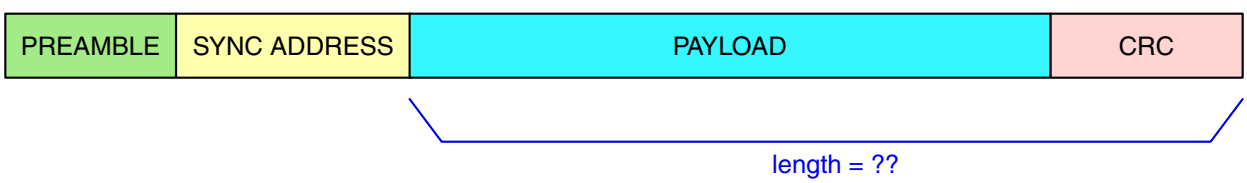

**Figure 64-190. PACKET STRUCTURE WITH NO HEADER**

In the aforementioned cases, another method of specifying length to the GENERIC_FSK Link Layer hardware must be employed. In both cases, if the length is not specified as part of the over-the-air bitstream, then GENERIC_FSK software must know the length in advance of the TX or RX operation, or know how to calculate it. So GENERIC_FSK software will provide this information to the hardware, in advance of the TX or RX operation, by programming the following registers:

- PACKET_CFG[LENGTH_SZ] = 0 : instructs the hardware that there is no LENGTH info in the packet header, and thus forces the hardware to use LENGTH_ADJ for packet length
- PACKET_CFG[LENGTH_ADJ] = ??? : program the desired (known) length of PAYLOAD + CRC

- PACKET_CFG[LENGTH_ADJ_UNSIGNED] = 1 : allows programmed length up to 255 octets
- CRC_CFG[CRC_SZ] = ??? : program the desired number of CRC octets

As an example, a packet is to be transmitted or received using the GENERIC_FSK Link Layer hardware. The packet has no header, but the length of the payload is known in advance to be 57 octets, and the number of CRC octets is 3. In this case, LENGTH_ADJ is programmed to 60 (57 + 3) and CRC_SZ is programmed to 3, as shown below.

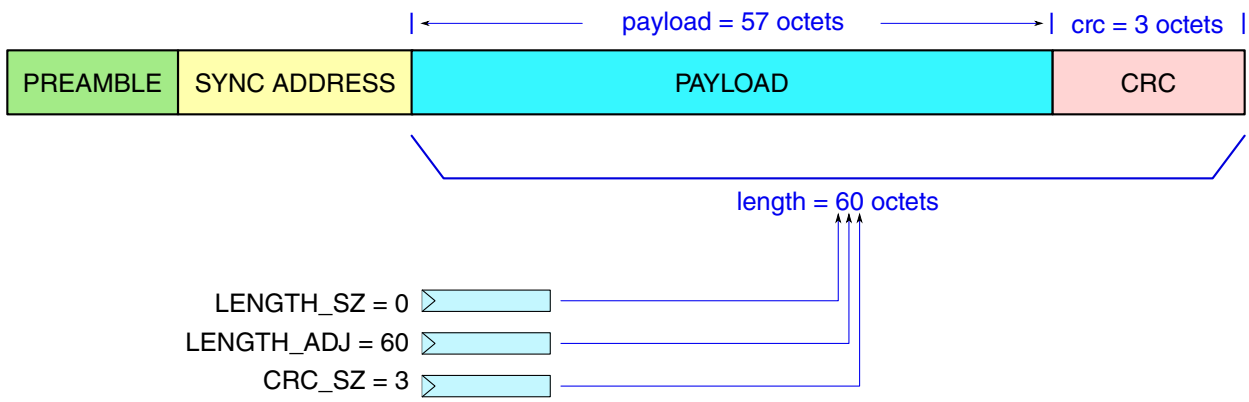

**Figure 64-191. PACKET STRUCTURE WITH NO HEADER AND FIXED PACKET LENGTH**

### 64.5.3.3.4 Packet Storage

The GENERIC_FSK Link Layer has access to a Packet Buffer (also known as Packet RAM), to store data to be transmitted, and to receive incoming packet data. The GENERIC_FSK Link Layer software prepares data to be transmitted, by loading the octets, in order, into the Packet Buffer. After reception, the octets received over the air are stored into the Packet Buffer, in the order they are received. The Packet Buffer contains separate spaces for TX and RX data, so incoming receive octets don't overwrite previously-loaded content intended for transmission. The Packet Buffer is large enough to accommodate the longest GENERIC_FSK packet, 2047 octets, plus header and CRC octets, for either transmit or receive.

The GENERIC_FSK Packet Buffer is contained within the multi-protocol Packet RAM. When operating in GENERIC_FSK mode, the entire Packet RAM is allocated to the GENERIC_FSK packet buffer. Because of the potentially large size of the GENERIC_FSK packets, and taking into account the high likelihood of asymmetry between the required lengths of packets for TX and RX, the 2 normally-separated RAM components of the Packet RAM are adjoined sequentially to form a double-depth (1088-entry) single storage space, still 16-bits wide. In addition, the consolidated RAM can be dedicated entirely to TX, entirely to RX, or split between TX and RX. The partitioning of the consolidated RAM between TX and RX is controlled by a configurable TX/RX

Partition Point. A Partition Point register, PB_PARTITION[10:0], has been provided. The Register can be programmed with any value between 0 and 1087. The consolidated RAM is partitioned such that the TX buffer resides before the Partition Point (RAM entries 0 -> (Partition_Point-1)), and the RX buffer resides after it (RAM entries Partition_Point -> 1087). Programming the Partition Point register to 0 dedicates the entire consolidated RAM to RX; programming the Partition Point register to 1088 dedicates the entire consolidated RAM to TX; programming the Partition Point register to any value between 1 and 1087 yields a split TX/RX buffer. Separate TX and RX buffers within the consolidated RAM means that incoming RX packets don't overwrite TX packet data. Because the Packet RAM is 16 bits wide, the GENERIC_FSK Link Layer controller hardware will address the consolidated RAM in an interleaved fashion as it stores octets to, or fetches octets from, the RAM-based packet buffer.

The partitioning of the consolidated RAM between transmit and receive sections for GENERIC_FSK is shown in the diagram below:

1. RAM0 and RAM1 abutted sequentially to form 1 contiguous space from Entry #0 - #1087
2. A Programmable Partition Point is defined: TX data before the partition, RX data after
3. The partition point can be programmed to any value from Entry #0 - #1087
4. Full 2 KB packet can be stored, for TX or RX
5. TX and RX packets are separated (RX does not overwrite TX)
6. Host access restricted to 16-bit

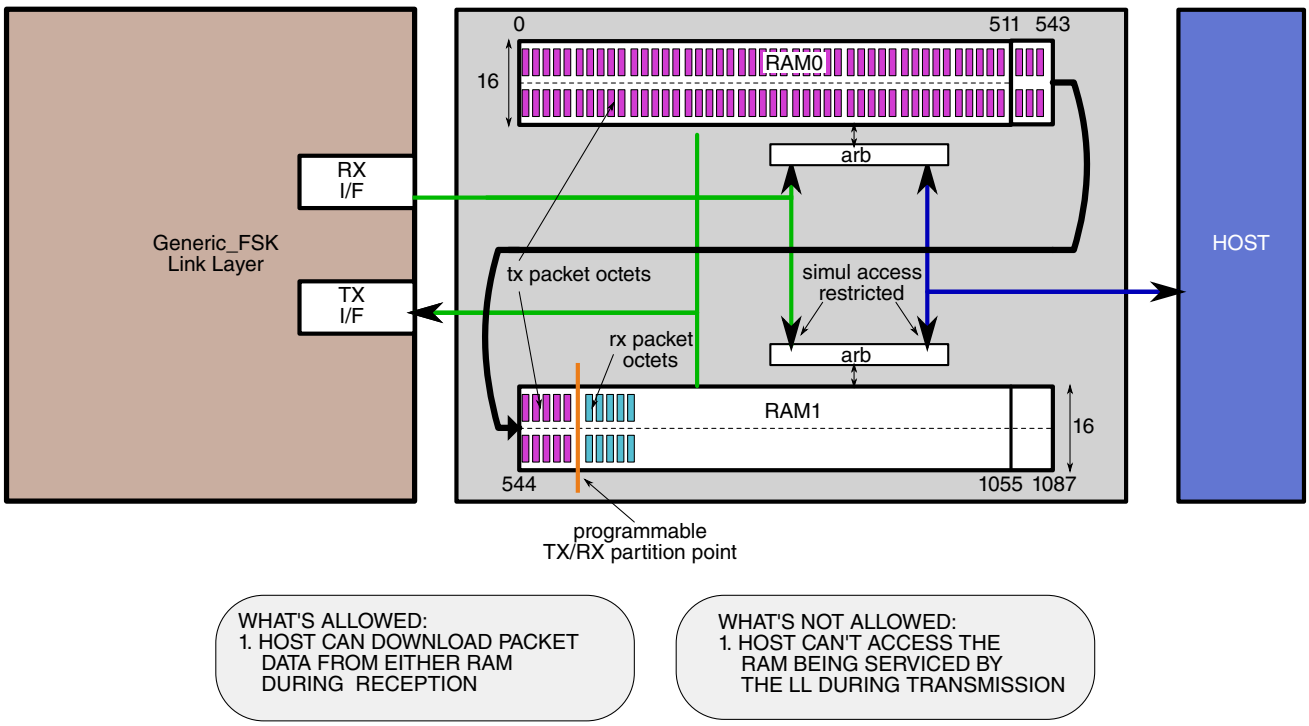

**Figure 64-192. RAM ALLOCATIONS FOR GENERIC_FSK**

During packet reception, the MCU is allowed to access the RX packet buffer of the consolidated RAM, in order to download the packet while it's being received, if so desired. In cases where both the MCU and the GENERIC_FSK Link Layer controller attempt to simultaneously access the RAM during reception, internal hardware arbitration is provided to delay the MCU access until the GENERIC_FSK Link Layer completes its access to the RAM. Link Layer accesses complete in a single reference oscillator clock period, so one and only 1 wait state shall be inserted on the IPS bus whenever access attempts coincide.

During packet transmission, MCU access to the consolidated RAM is not allowed. The GENERIC_FSK software must program the TX buffer before commanding a TX operation, and must not access the RAM during the transmission.

As mentioned previously, incoming receive data lands in the RX section of the Packet Buffer. Nominally, a newly received packet will overwrite the contents of the previously received packet (the TX section of the Packet Buffer remains intact). Software can inhibit receive-packet overwriting of the RX section of the Packet Buffer contents by setting the PB_PROTECT bit in the PACKET_RAM_CTRL register, in XCVR address space. When this bit is set, incoming receive data will be blocked from overwriting the existing contents of the RX section of the Packet Buffer. This will block RX packet overwriting, but will not inhibit TX content loading of the TX section of the Packet Buffer.

In the 2.4GHz Radio, the GENERIC_FSK Link Layer is the controlling Link Layer whenever the XCVR_CTRL[PROTOCOL] register is set to 8, 9, or 10. GENERIC_FSK software must not attempt to access the Packet RAM unless XCVR_CTRL[PROTOCOL] is set to 8, 9, or 10. When XCVR_CTRL[PROTOCOL] is set to one of the following: {0, 1, 2, 3, 4, or 5}, another Protocol Engine besides GENERIC_FSK, has exclusive access to the Packet RAM. That also means that the IPS bus assigned to that Protocol Engine, is the only IPS bus allowed to access the Packet RAM. If the GENERIC_FSK Link Layer software attempts to access the Packet RAM via the GENERIC_FSK IPS bus, when XCVR_CTRL[PROTOCOL] is set to one of the above settings, the access attempt will fail, as described below:

1. RAM contents shall not be altered on a GENERIC_FSK write attempt
2. Readback data on a GENERIC_FSK read attempt shall be indeterminate
3. The **ips_xfr_err** shall be asserted on the GENERIC_FSK IPS bus

If XCVR_CTRL[PROTOCOL] is set to neither {8, 9, or 10}, nor {0, 1, 2, 3, 4, or 5}, this means no Protocol Engine has exclusive access to the Packet RAM. GENERIC_FSK software should not attempt to access the Packet RAM under such conditions; results are indeterminate.

#### 64.5.3.3.5 Timebase

The GENERIC_FSK Link Layer includes a dedicated, 24-bit multi-purpose Event Timer (EVENT_TMR), that is updated at a 1 MHz rate. The EVENT_TMR maintains the timebase for all GENERIC_FSK-related activities, except during intervals of Deep Sleep Mode. The clock source for the EVENT_TMR is a high-precision, crystal-referenced RF Oscillator, which can be either 32MHz or 26MHz. The RF Oscillator is divided down to 1MHz for GENERIC_FSK in the Clocks Generation Module (CGM). To reduce power consumption to a minimum, most of the GENERIC_FSK Link Layer Controller runs off this 1MHz clock. The exceptions are the Register IP bus interface, Command Decoder, and Interrupt Control Unit, parts of which must run at the IP bus frequency.

The 24-bit EVENT_TMR running at 1 MHz rolls over (wraps around) approximately every 16.8 seconds.

The EVENT_TMR count can be read at any time, via the register of the same name. A 32-bit read is recommended to ensure coherency of the 3 bytes that make up the counter. No synchronization to the IP bus is required.

If the EVENT_TMR needs to be updated (changed), this can be done by writing the new, desired EVENT_TMR value to the register of the same name, and setting the EVENT_TMR_LD bit to 1. The update to EVENT_TMR will take effect at the next

1MHz clock edge. The EVENT_TMR[23:0] and EVENT_TMR_LD are all part of the same 32-bit register, and loading of the EVENT_TMR using this method should be performed as an atomic, 32-bit write.

If it is desired to increment the EVENT_TMR by a known amount, this can be done by writing the desired increment value to the EVENT_TMR register, and setting the EVENT_TMR_ADD bit to 1. The increment value is 24-bit signed, thus enabling a decrement function as well. The update to EVENT_TMR will take effect immediately. The EVENT_TMR_ADD avoids the necessity to perform an read-modify-write operation to the EVENT_TMR to adjust its value; this facilitates accurate restoration of the EVENT_TMR state after a period of Deep Sleep Mode. The EVENT_TMR[23:0] and EVENT_TMR_ADD are all part of the same 32-bit register, and incrementing of the EVENT_TMR using this method should be performed as an atomic, 32-bit write.

Two 24-bit timer-compare registers are provided, T1_CMP and T2_CMP.

GENERIC_FSK software may load T1_CMP with a future EVENT_TMR count value. When EVENT_TMR reaches the T1_CMP value, either (or both) of the following events can be triggered:

1. T1_IRQ (Interrupt)
2. Sequence Command Trigger (can automatically launch or stop a transceiver operation)

Similarly, GENERIC_FSK software may load T2_CMP with a future EVENT_TMR count value. When EVENT_TMR reaches the T2_CMP value, either (or both) of the following events can be triggered:

1. T2_IRQ(Interrupt)
2. Sequence Command Trigger (can automatically launch or stop a transceiver operation)

For either type of T1-triggered events to be enabled, i.e., interrupt or sequence-launch, set T1_CMP_EN=1 after loading T1_CMP with the desired value. If T1_CMP_EN=1, the T1_IRQ interrupt status bit will always become set on a T1 timer match. (Whether or not T1_IRQ generates an GENERIC_FSK Interrupt to the MCU depends on the settings of T1_IRQ_EN and GENERIC_FSK_IRQ_EN, see section: Interrupts). If T1_CMP_EN=0, neither an interrupt nor a sequence command can be triggered by a T1 match.

For either T2-triggered events to be enabled, i.e., interrupt or sequence launch, set T2_CMP_EN=1 after loading T2_CMP with the desired value. If T2_CMP_EN=1, the T2_IRQ interrupt status bit will always become set on a T2 timer match. (Whether or not T2_IRQ generates a GENERIC_FSK Interrupt to the MCU depends on the settings of T2_IRQ_EN and GENERIC_FSK_IRQ_EN, see Section: Interrupts). If T2_CMP_EN=0, neither an interrupt nor a sequence command can be triggered by a T2 match.

See Section Interrupts for a description of how the Link Layer Controller manages the T1 and T2 interrupts, and how software can clear them.

See Section Sequence Commands and Status for a description on how to launch and stop sequences on T1 and T2 timer matches.

### 64.5.3.3.6 Sequence Commands and Status

The GENERIC_FSK Link Layer Controller provides a command set of 12 transceiver commands, which can be used to launch and stop sequences. GENERIC_FSK software can issue sequence commands by writing to the SEQCMD[3:0] field of the XCVR_CTRL register. The SEQCMD field always reads back what was previously written by software, enabling software to quickly recall the last command written. The sequence commands are as listed in the table below:

| SEQCMD[3:0] | COMMAND | DESCRIPTION |
|---|---|---|
| 0x0 | NULL | No Action |
| 0x1 | TX_START_NOW | TX Start Now |
| 0x2 | TX_START_T1 | TX Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP) |
| 0x3 | TX_START_T2 | TX Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP) |
| 0x4 | TX_CANCEL | TX Cancel -- Cancels pending TX events but do not abort TX-in-progress[1] |
| 0x5 | RX_START_NOW | RX Start Now |
| 0x6 | RX_START_T1 | RX Start @ T1 Timer Compare Match (EVENT_TMR = T1_CMP) |
| 0x7 | RX_START_T2 | RX Start @ T2 Timer Compare Match (EVENT_TMR = T2_CMP) |
| 0x8 | RX_STOP_T1 | RX Stop @ T1 Timer Compare Match (EVENT_TMR = T1_CMP) |
| 0x9 | RX_STOP_T2 | RX Stop @ T2 Timer Compare Match (EVENT_TMR = T2_CMP) |
| 0xA | RX_CANCEL | RX Cancel -- Cancels pending RX events but do not abort RX-in-progress[2] |
| 0xB | ABORT | Abort All - Cancels all pending events and abort any sequence-in-progress |

1. TX-in-progress implies TX Warmup is complete, and packet transmission is underway (i.e., command decoder state = IN_TX)
2. RX-in-progress implies RX Warmup is complete, and Network Address search or packet reception is underway (i.e., command decoder state = IN_RX)

As described above, sequences can be launched immediately (actually on the next 1MHz clock edge) by issuing one of the following commands:

- TX_START_NOW
- RX_START_NOW

Alternatively, sequences can be scheduled to launch (or stop) in the future on a T1 timer compare, by loading T1_CMP with the desired launch time (relative to the EVENT_TMR), setting T1_CMP_EN=1, and then issuing one of the following commands:

- TX_START_T1
- RX_START_T1
- RX_STOP_T1

Similarly, sequences can be scheduled to launch (or stop) in the future on a T2 timer compare, by loading T2_CMP with the desired launch time (relative to the EVENT_TMR), setting T2_CMP_EN=1, and then issuing one of the following commands:

- TX_START_T2
- RX_START_T2
- RX_STOP_T2

Any transceiver sequence that has been launched, either immediately (by way of the *_NOW commands), or in the future (by way of the *_T1 or *_T2 commands), can be terminated immediately by issuing the ABORT command. This is true whether or not the sequence has actually begun, or is merely pending because the T1- (or T2-) match has not yet occurred. In either case, this is called a software abort. The ABORT command will terminate any active sequence and cancel any pending events.

Regarding the issuance of sequence commands, both immediate and timer-triggered, GENERIC_FSK software should be mindful of the following Guidelines and Restrictions:

| PROGRAMING GUIDELINES AND RESTRICTIONS | |
|---|---|
| 1 | T1 can only be assigned to 1 function at a time {TX_START, RX_START, RX_STOP}.<br>Once assigned to a function, attempts to change the assignment will be ignored |
| 2 | T2 can only be assigned to 1 function at a time {TX_START, RX_START, RX_STOP}.<br>Once assigned to a function, attempts to change the assignment will be ignored |
| 3 | To change a T1- or T2- assignment, do one of the following first:<br>**a.** issue an ABORT command<br>**b.** issue an TX_CANCEL command if T1 (or T2) is already assigned to TX_START, and the sequence has not yet started<br>**c.** issue an RX_CANCEL command if T1 (or T2) is already assigned to RX_START or RX_STOP, and the sequence has not yet started |
| 4 | T1 and T2 should not be assigned to the same function (results are indeterminate) |
| 5 | If T1 and T2 are both assigned to functions, then T1_CMP shall not be equal to T2_CMP (results are indeterminate) |

*Table continues on the next page...*

| PROGRAMING GUIDELINES AND RESTRICTIONS | |
|---|---|
| 6 | If any TX or RX sequence is underway (e.g., TSM not idle), the ongoing sequence will not be interrupted or perturbed by any of the following:<br>**a.** a T1 timer-match with T1 assigned to a function. The sequence trigger will be ignored, but the associated "pending" status bit will be cleared.<br>**b.** a T2 timer-match with T2 assigned to a function. The sequence trigger will be ignored, but the associated "pending" status bit will be cleared.<br>**c.** a TX_START_NOW or RX_START_NOW command. Both commands will be ignored |

To perform operations on an RF channel, the GENERIC_FSK Link Layer Controller interacts with the Transceiver Sequence Manager (TSM), which is responsible for the low-level signaling required to activate the individual RF blocks. To do this, the Link Layer Controller includes a Command Decoder. The Command Decoder translates sequence commands (e.g., TX_START_NOW, RX_STOP_T1) into TSM inputs required to start and stop sequences. Then, the TSM executes the warmup, TX, RX, and warmdown functions on the channel. The GENERIC_FSK Command Decoder sends 2 signals (mutually exclusive) to the TSM:

- generic_fsk_tx_en
- generic_fsk_rx_en

Upon receiving an assertion on either of these signals, TSM will launch into warmup on either a TX or RX sequence. When the TSM completes its warmup, it asserts the signal **tsm_wu_complete** back to the Command Decoder, which uses that signal to transition into full-on packet transmit or packet receive. When the packet transmission or reception is complete, the Command Decoder will deassert **generic_fsk_tx_en** (or **generic_fsk_rx_en**), and wait for the TSM to assert **tsm_idle**. At that point, the Command Decoder will return to its IDLE state.

To implement these functions, the Command Decoder includes a small (6-state) finite state machine. The state diagram is shown below, including the TSM interactions.

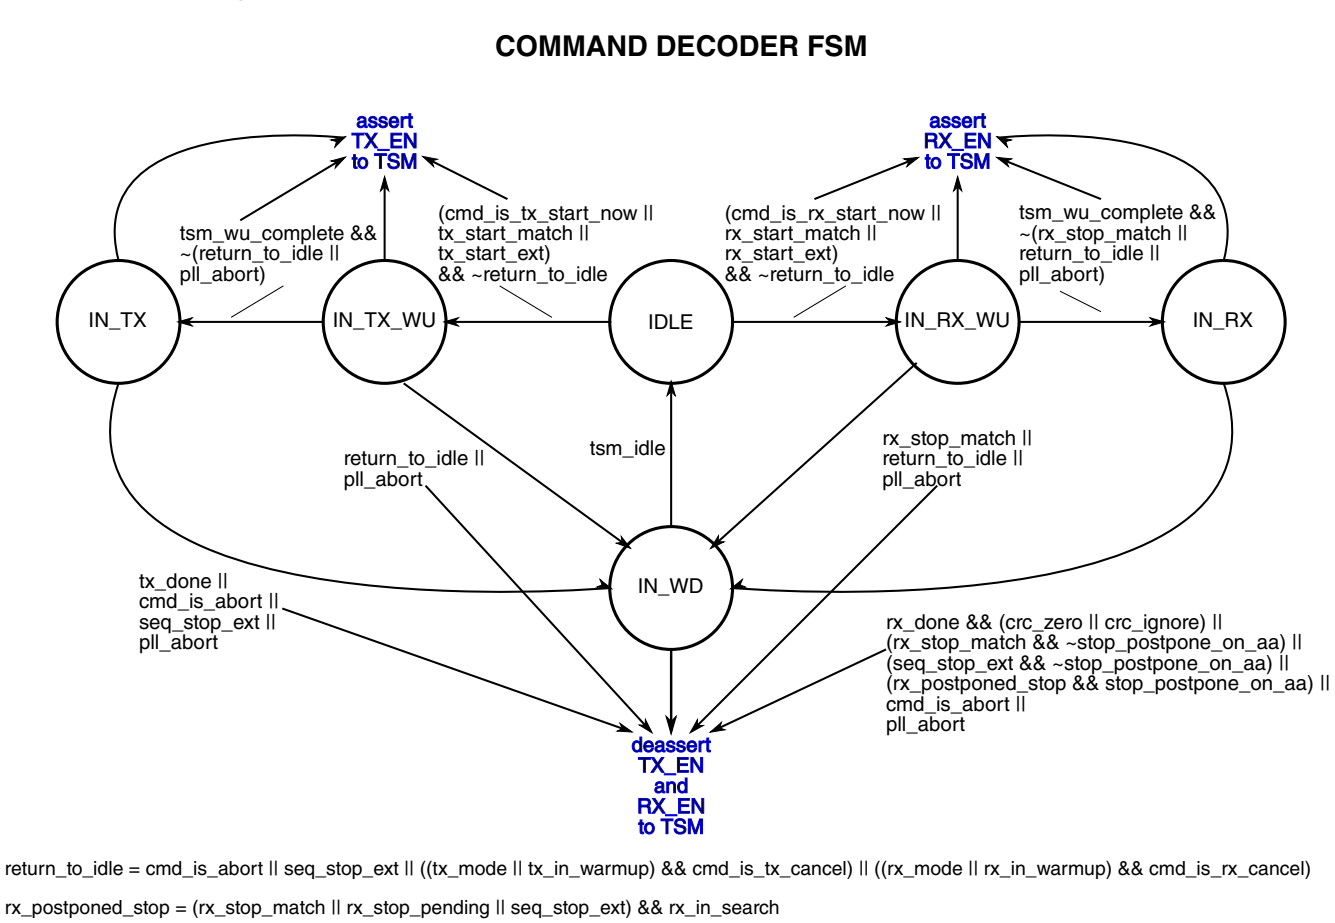

**Figure 64-193. GENERIC_FSK COMMAND DECODER FSM**

The state of the Command Decoder is carried by the state vector CMDDEC_CS[2:0]. The state can be monitored at all times by reading the CMDDEC_CS field of the XCVR_STATUS register, or via DTEST. The mapping of states to state vector is shown in the table below.

| CMDDEC_CS[2:0] | STATE NAME |
|---|---|
| 0b000 | IDLE |
| 0b001 | IN_TX_WU |
| 0b011 | IN_TX |
| 0b101 | IN_RX_WU |
| 0b111 | IN_RX |
| 0b010 | IN_WD |

The Command Decoder also maintains an set of 13 status bits, that make it easy for Link Layer software to track, not only state, but pending events; that is, timer-linked events scheduled for future triggering. These status bits reside in the XCVR_STS register. A description of these bits is provided in the table below.

| SEQSTS[12:0] | BIT | DESCRIPTION |
|---|---|---|
| TX_START_T1_PEND | [0] | TX Sequence will start @ next T1 Match |
| TX_START_T2_PEND | [1] | TX Sequence will start @ next T2 Match |
| TX_IN_WARMUP | [2] | TX Sequence in TSM Warmup |
| TX_IN_PROGRESS | [3] | TX Packet Transmission Currently Underway |
| TX_IN_WARMDN | [4] | TX Sequence in TSM Warmdown |
| RX_START_T1_PEND | [5] | RX Sequence will start @ next T1 Match |
| RX_START_T2_PEND | [6] | RX Sequence will start @ next T2 Match |
| RX_STOP_T1_PEND | [7] | RX Sequence will stop @ next T1 Match |
| RX_STOP_T2_PEND | [8] | RX Sequence will stop @ next T2 Match |
| RX_IN_WARMUP | [9] | RX Sequence in TSM Warmup |
| RX_IN_SEARCH | [10] | RX Sequence in Network Address Search |
| RX_IN_PROGRESS | [11] | RX Packet Reception Currently Underway |
| RX_IN_WARMDN | [12] | RX Sequence in TSM Warmdown |

### 64.5.3.3.7 Interrupts

Interrupt Status Bit Structure

The Generic FSK Link Layer Controller has 10 interrupt sources, each represented in the register map by an interrupt status bit. All interrupt status bits share a common, generic structure. If a particular interrupt source is enabled, a “TRIGGERING EVENT” for that interrupt source, will always set the status bit. A write-1-to-clear input from the IPS bus, will clear the status bit, but only if there is not a simultaneous triggering event. The triggering event prevails over a software clear attempt, if both events coincide. An integrated clock gate guarantees that the status bit only sees a clock when either a triggering event occurs, or a write-1-to-clear pulse arrives from the IPS bus. This reduces interrupt status bit power consumption to an absolute minimum. (Note: the TSM_IRQ does not have an associated status bit in the Link Layer Controller; its status bit resides in the Transceiver Sequence Manager, or TSM).

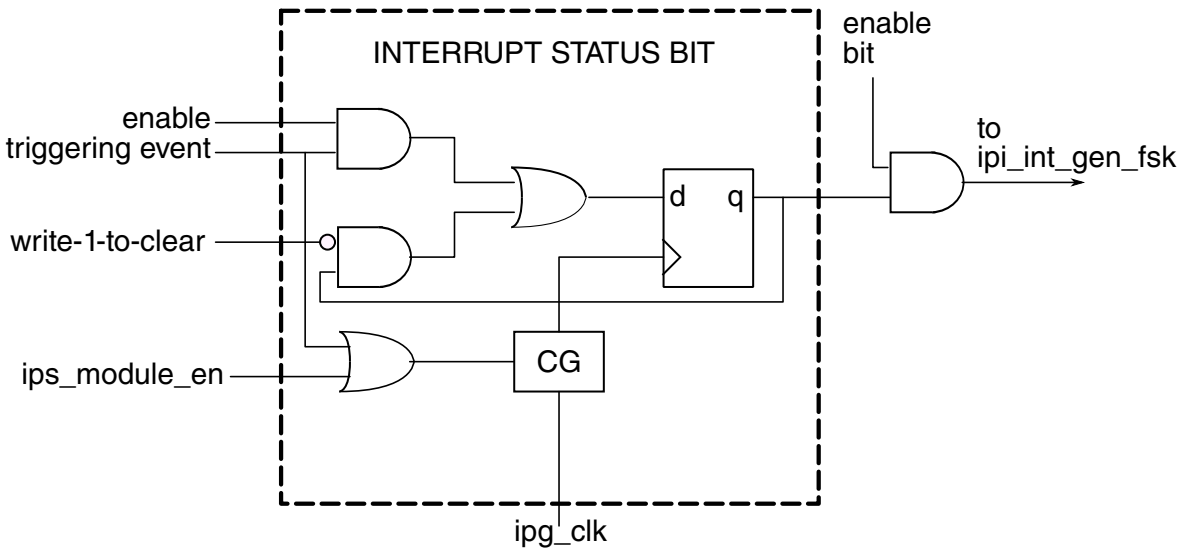

**Figure 64-194. Interrupt Status Bit**

Each GENERIC_FSK interrupt status bit, has an ENABLE bit associated with it. The name of the enable bit tracks the name of the interrupt source, with the string "_EN" appended at the end. Note that for any GENERIC_FSK interrupt source, if the triggering event occurs, the Interrupt Status Bit will be set regardless of the state of the corresponding ENABLE bit. If any of the 10 interrupts is to be ignored, software should clear the corresponding ENABLE bit, and apply the appropriate bit mask when reading the IRQ_CTRL register, to mask out the unwanted status bit.

GENERIC_FSK Interrupt Architecture

The 10 interrupt sources (status bits) are combined with their individual ENABLE bits, and then logically OR'ed together, in sum-of-products fashion, to generate single interrupt line to the MCU: **ipi_int_gen_fsk**. A global mask bit, GENERIC_FSK_IRQ_EN, can enable or disable **ipi_int_gen_fsk** altogether. There is no prioritization of interrupt sources; they have equal weight. The **ipi_int_gen_fsk** output is a level-sensitive indicator and will remain asserted until all interrupt status bits are cleared (or the corresponding ENABLE bits cleared). The following diagram depicts the GENERIC_FSK Interrupt Architecture.

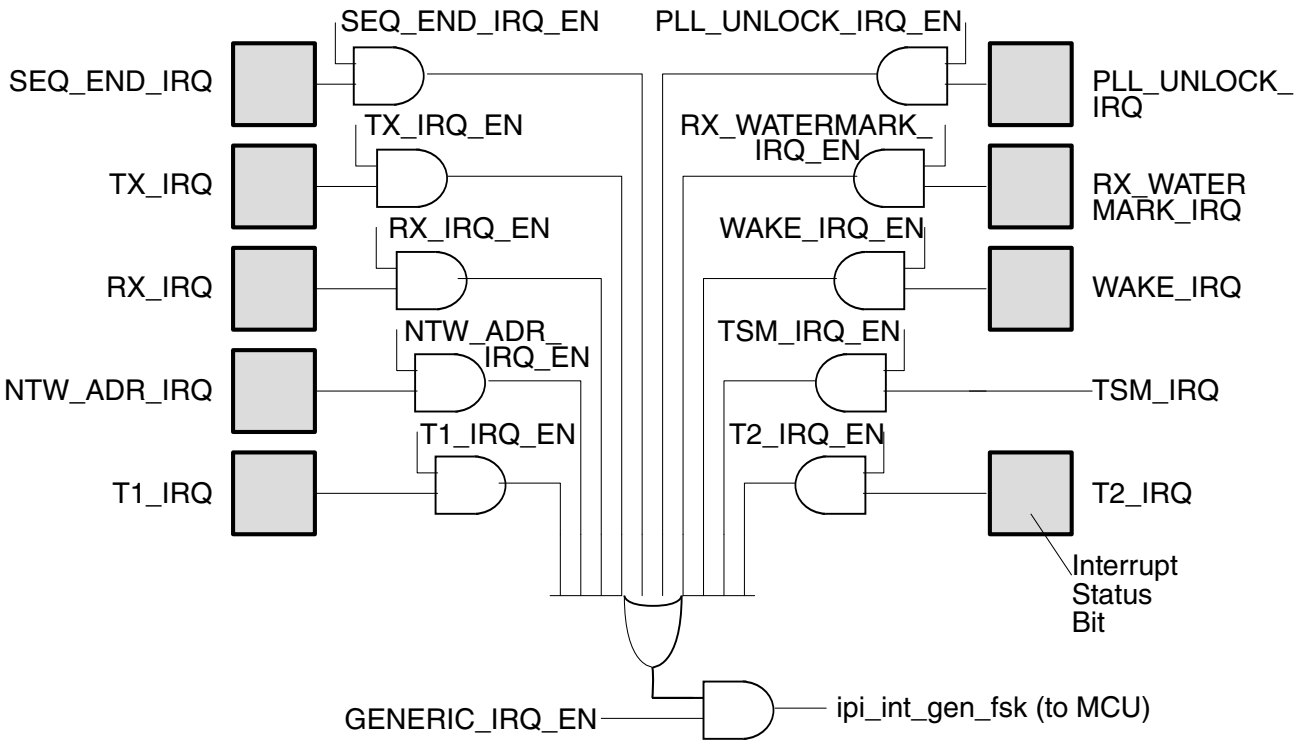

**Figure 64-195. GENERIC_FSK Interrupt Architecture**

## Clearing Interrupts

All interrupt status bit use a write-1-to-clear protocol. Writing a '1' to the interrupt status bit, in the IRQ_CTRL register, clears the offending interrupt. Writing a '0' to an interrupt status bit has no effect on the bit. Interrupt status bits are not affected by reads.

## GENERIC FSK Interrupt Sources

The following table describes the 10 GENERIC_FSK Interrupt Sources

| Interrupt | Description |
|---|---|
| T1_IRQ, T2_IRQ | The GENERIC_FSK Link Layer features a 24-bit Event Timer, which runs at a rate of 1MHz. The Link Layer has 2 Timer interrupts (T1_IRQ, T2_IRQ), each with its own 24-bit compare register (T1_CMP, T2_CMP), and each with its own compare enable (T1_CMP_EN, T2_CMP_EN). For each timer compare enable, if the bit is set, a match on the respective 24-bit compare value to the Event Timer will cause the corresponding interrupt status bit to become set. If the compare enable is not set, Event Timer matches won't cause the corresponding interrupt status bit to become set. |
| TX_IRQ | TX interrupt occurs at the end of a TX operation. |
| RX_IRQ | RX interrupt occurs at the end of a successful RX packet reception. A successful packet reception implies CRC was verified to be good, H0 matching passed, H1 matching passed, and received packet length did not violate pre-set |

*Table continues on the next page...*

| Interrupt | Description |
|---|---|
| | limits. Nominally, RX interrupts are not generated on packets which fail CRC check, or which failure the H0, H1 or LENGTH limits. A received packet with a failed CRC check or a H0, H1, or LENGTH violation, results in an RX recycle back to the Network Address Search state. To receive a Data Indication (RX_IRQ) on packets which fail CRC, set the bit CRC_IGNORE=1. H0 and H1 matching, and LENGTH limiting, are under SW control. |
| NTW_ADR_IRQ | A Network Address Match has occurred on an enabled Network Address. At NTW_ADR_IRQ, a timestamp is captured by transferring the current contents of the EVENT_TMR into the TIMESTAMP register. Software can determined which Network Address matched by querying the NTW_ADR_MCH[3:0] field of the NTW_ADR_CTRL register. |
| SEQ_END_IRQ | The Sequence End Interrupt (SEQ_END_IRQ), indicates that a transceiver operation (TX or RX) has completed, and the Command Decoder State Machine, and the Transceiver Sequence Manager (TSM), have returned to their respective IDLE states. A SEQ_END_IRQ will always occur at the end of a sequence, even if the sequence terminated abnormally (such as a Software Abort, or a PLL Unlock Abort). A SEQ_END_IRQ always occurs whenever the Command Decoder FSM transitions from any non-idle to IDLE state. When SEQ_END_IRQ occurs, software can be sure that the Command Decoder and TSM are in their idle state, and a new sequence can be programmed. |
| RX_WATERMARK_IRQ | RX Watermark interrupt will occur during packet reception, when the number of received bytes, as indicated by the read-only BYTE_COUNTER register, matches the contents of the RX_WATERMARK register. For the purpose of defining RX_WTR_MARK, the first byte received (BYTE_COUNTER = 0) is the first byte of Network Address; the second byte received (BYTE_COUNTER = 1) is the second byte of Network Address, etc. To cause an RX Watermark Interrupt to occur after a 2-byte Network Address has been received, set RX_WTR_MARK=1. By default, RX_WATERMARK is set to a value larger than the longest supported GENERIC_FSK packet length, so an RX_WATERMARK_IRQ won't be triggered under these conditions. |
| PLL_UNLOCK_IRQ | When an PLL unlock event occurs during an transceiver operation, and the transceiver has been configured to automatically abort sequences on PLL unlock events, the PLL_UNLOCK_IRQ status bit will become set. The Transceiver Sequence Manager (TSM) will begin monitoring for PLL unlock only after the PLL has been given sufficient time to achieve lock; A PLL unlock which occurs after the warmup period, can be enabled to cause a sequence abort. Individual enables are provided for TX and RX sequences. (See the TSM Chapter for more details). |
| WAKE_IRQ | **For Manual DSM:** This is WAKE_IRQ. A WAKE_IRQ will be triggered when the GENERIC_FSK Link Layer Controller has awoken from a Manual DSM (Deep Sleep Mode) cycle. WAKE_IRQ indicates that the RF Oscillator has been restarted, and the GENERIC_FSK EVENT_TMR has resumed counting. |

*Table continues on the next page...*

| Interrupt | Description |
|---|---|
| | **For Wake-On-Radio:**: This is WOR_IRQ. See Section Wake-On-Radio |
| TSM_IRQ | TSM_IRQ is a debug feature, enabling the Transceiver Sequence Manager (TSM) to generate an interrupt at any point in a TX or RX Warmup. TSM is a multipurpose hardware resource shared by all of the protocol engines in the SoC. Thus, TSM does not have its own interrupts; its interrupts are assigned to whichever link layer controller is currently executing an RF operation. TSM Interrupt Status bits reside in Transceiver (XCVR) Address Space, and can be cleared there. There is no intended mission-mode use for TSM_IRQ. See the TSM Chapter for more details. |

#### 64.5.3.3.8 Memory Mapping

In the SoC memory map, space has been allocated to GENERIC_FSK. Within the SoC, peripherals are allocated memory space in 4KB blocks, called IPS slots. GENERIC_FSK occupies one such slot. GENERIC_FSK address space consists of the GENERIC_FSK registers. The partitioning of address space for GENERIC_FSK is shown in the diagram below.

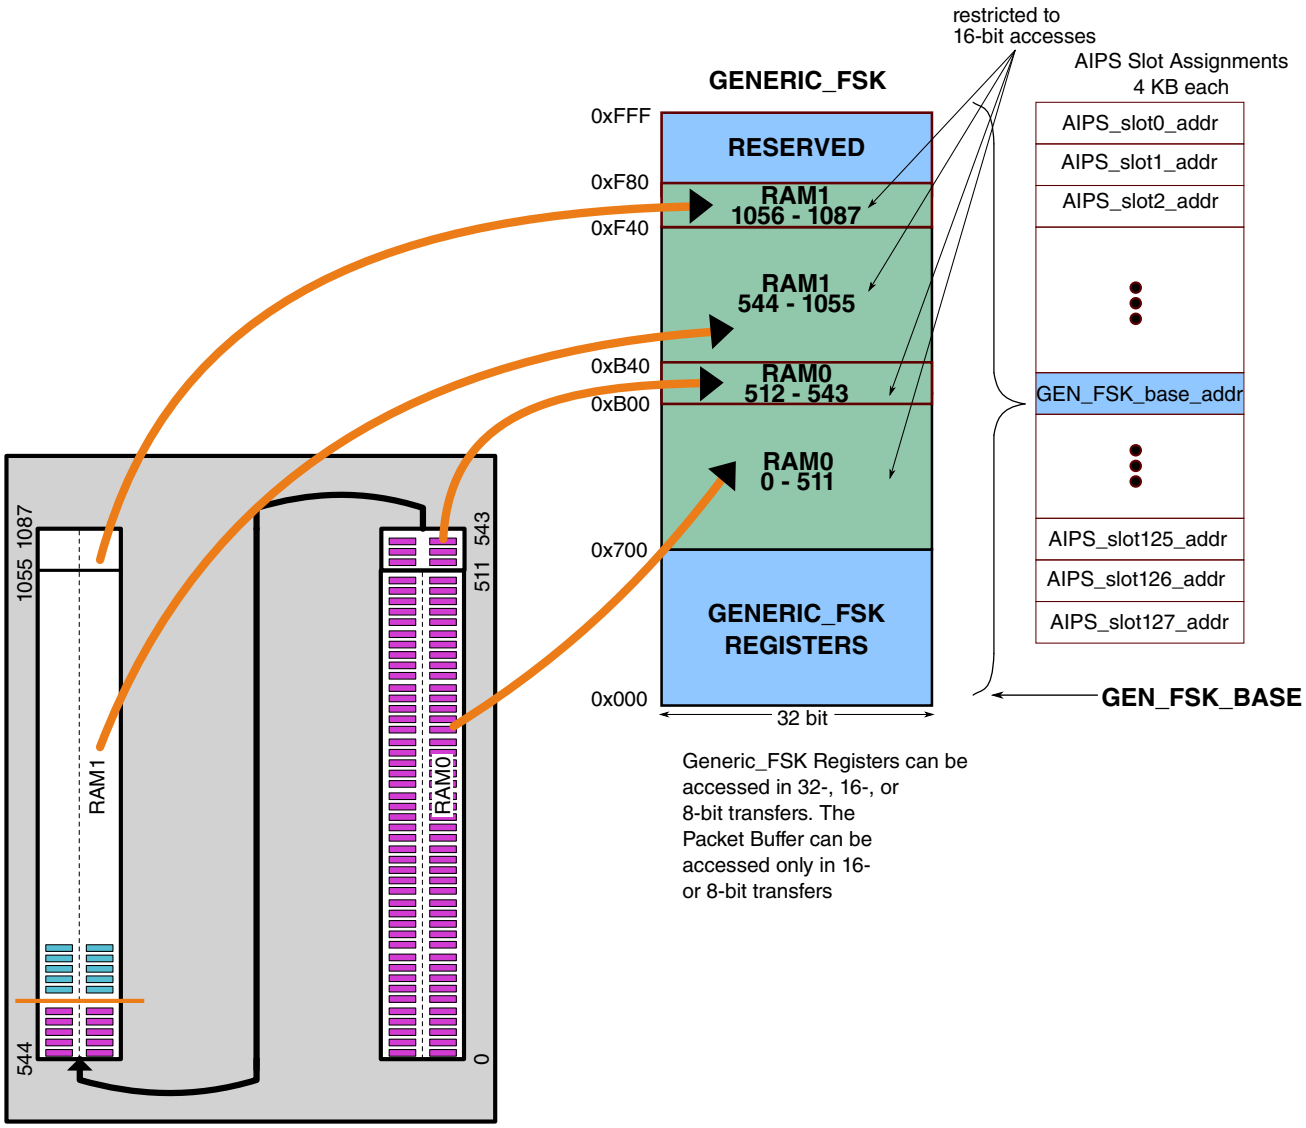

**Figure 64-196. GENERIC_FSK MEMORY MAPPING**

**NOTE**

See AIPS Memory Map for specific memory assignments details.

All registers within GENERIC_FSK memory space, are accessible by the MCU in 8-, 16-, or 32-bit accesses. For efficiency, 32-bit accesses are recommended.

### 64.5.3.3.9 Sequence Timing Diagrams

The following timing diagram depicts an example of GENERIC_FSK packet transmission, highlighting the following events:

1. Software stores packet octets into Packet Buffer, to be transmitted

2. Software loads T1_CMP with desired TX start time, sets T1_CMP_EN=1
3. Software schedules TX sequence with TX_START_T1 command
4. EVENT_TMR matches T1_CMP, TX sequence starts automatically
5. Generic_FSK Link Layer reads octets from Packet Buffer. Packet is transmitted
6. TX_IRQ asserts after last bit of packet transmitted
7. SEQ_END_IRQ asserts after TSM returns to IDLE (TX warmdown complete)

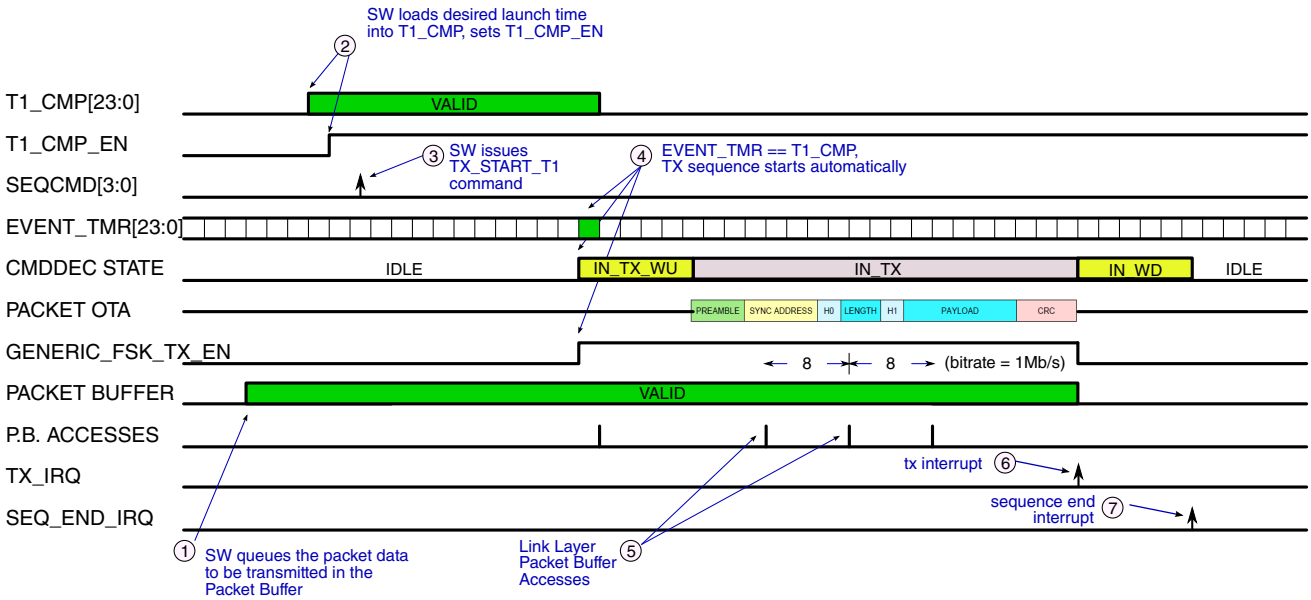

**Figure 64-197. GENERIC FSK TX SEQUENCE: LAUNCH VIA T1 TIMER**

The following timing diagram depicts an example of GENERIC_FSK “good” packet reception, highlighting the following events:

1. Software loads T2_CMP with desired RX start time, sets T2_CMP_EN=1
2. Software schedules RX sequence with RX_START_T2 command
3. EVENT_TMR matches T2_CMP, RX sequence starts automatically
4. Network Address search, followed by NTW_ADR_IRQ interrupt, TIMESTAMP capture
5. Packet reception, Generic_FSK LL write octets to Packet Buffer
6. CRC verification passes, and no H0, H1, or LENGTH_MAX violations, RX_IRQ asserted, Packet RX Buffer valid, RSSI valid
7. SEQ_END_IRQ asserts after TSM returns to IDLE (RX warmdown complete)

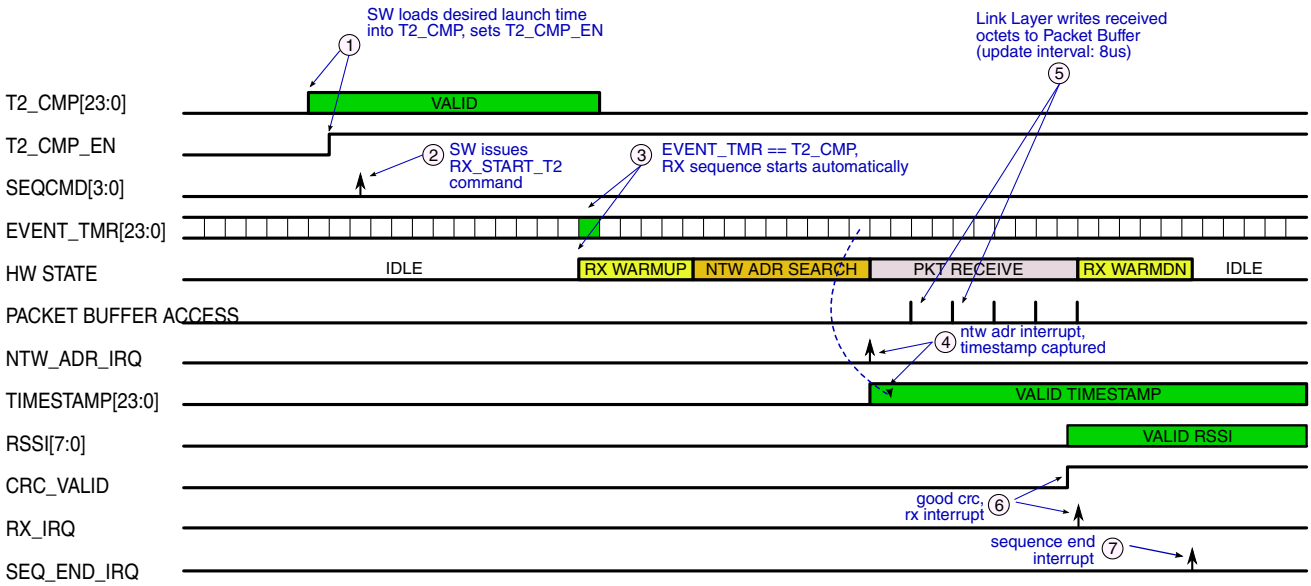

**Figure 64-198. GENERIC FSK RX SEQUENCE: LAUNCH VIA T2 TIMER, GOOD PACKET**

The following timing diagram depicts an example of GENERIC_FSK “bad” packet reception, highlighting the following events:

1. Software loads T2_CMP with desired RX start time, sets T2_CMP_EN=1
2. Software schedules RX sequence with RX_START_T2 command
3. EVENT_TMR matches T2_CMP, RX sequence starts automatically
4. Network Address search, followed by NTW_ADR_IRQ interrupt, TIMESTAMP capture
5. Packet reception, Generic_FSK LL write octets to Packet Buffer
6. CRC verification fails, no CRC_VALID, no RX_IRQ, RX Recycle
7. No SEQ_END_IRQ, return to Network Address Search

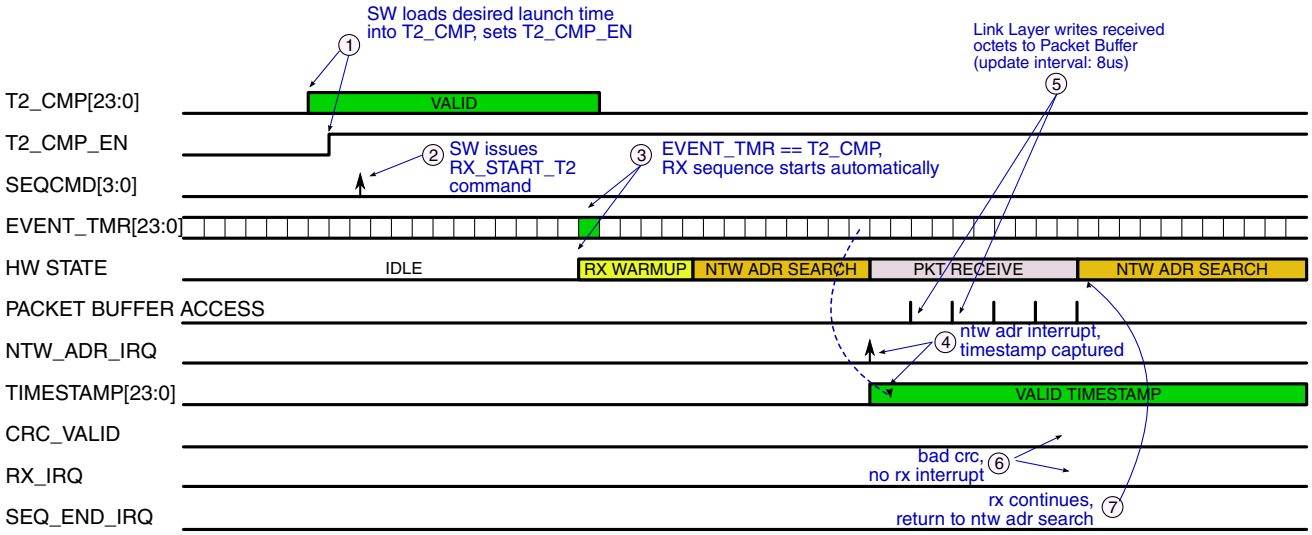

**Figure 64-199. GENERIC FSK RX SEQUENCE: LAUNCH VIA T2 TIMER, BAD PACKET, RX RECYCLE**

The following timing diagram depicts a GENERIC_FSK RX search operation, which fails to detect a Network Address before timing out. The following events are highlighted:

1. Software loads T1_CMP with desired RX start time, sets T1_CMP_EN=1
2. Software loads T2_CMP with desired RX stop time, sets T2_CMP_EN=1
3. Software schedules RX sequence start with RX_START_T1 command
4. Software schedules RX sequence end with RX_START_T2 command
5. EVENT_TMR matches T1_CMP, RX sequence starts automatically
6. EVENT_TMR matches T2_CMP, RX sequence goes into warmdown automatically
7. SEQ_END_IRQ asserts to indicate TSM has returned to IDLE. No NTW_ADR_IRQ, No RX_IRQ.

## 64.5.3.3.10 Manual DSM

When the GENERIC_FSK Link Layer anticipates long periods of inactivity, the Link Layer controller can be put into a Deep Sleep Mode (DSM), where all of its clocks are turned off. In addition, the GENERIC_FSK Link Layer can be configured to optionally turn off the RF Oscillator, if it is not otherwise needed by the SoC. Deep Sleep Mode results in dramatic power savings. The procedure described below, is called Manual DSM.

To make Manual DSM possible, the transceiver incorporates a low-frequency, high-precision Deep Sleep Timer, DSM_TIMER. This timer is clocked by a crystal-referenced 32.768KHz oscillator. The timer is 24-bit wide, yielding a 8.5 minute rollover (the maximum length of a deep sleep period).

The hardware to implement DSM within the SoC, is partitioned across several modules, and several power domains. This is to allow the maximum achievable power savings, by retaining full voltage for only those modules which need to be active in DSM, and placing the remaining modules in “state retention” mode. The diagram below depicts the partitioning of DSM hardware across the various modules, including the GENERIC_FSK Link Layer Controller.

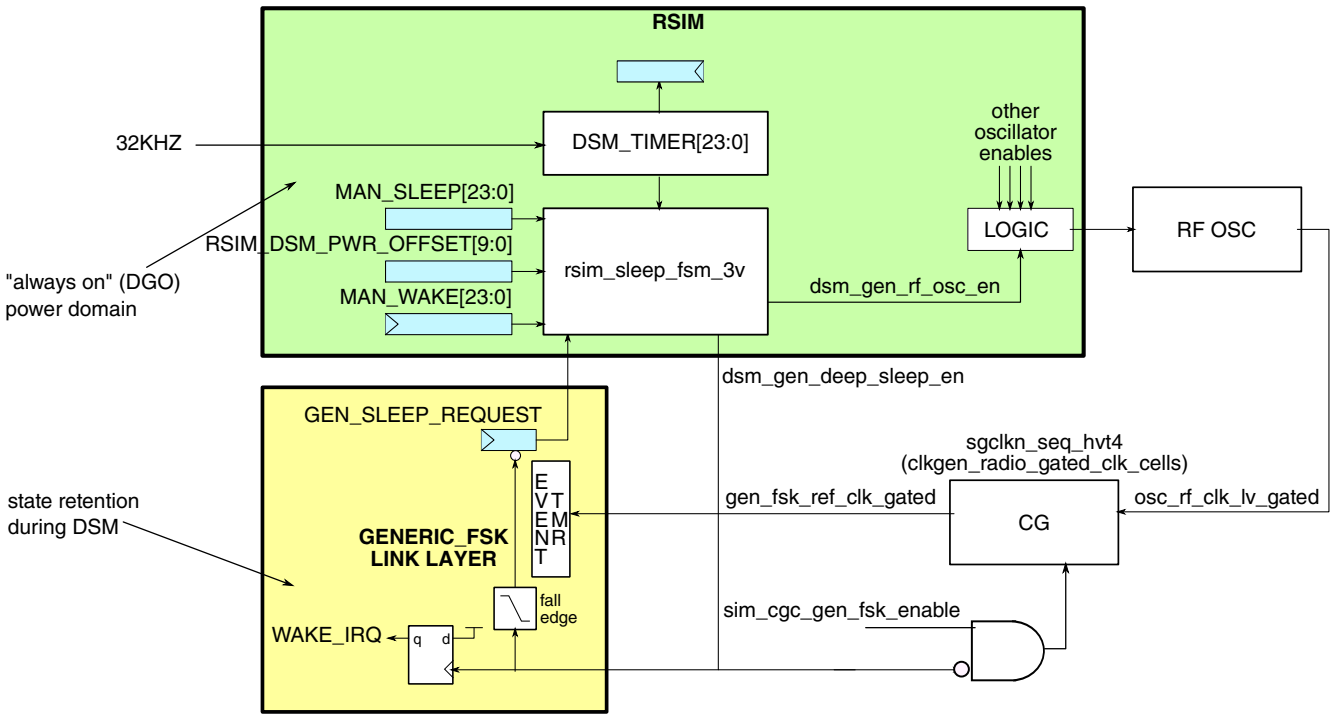

**Figure 64-201. MANUAL DSM BLOCK DIAGRAM**

The concept behind Manual DSM, as it is implemented for GENERIC_FSK, is to allow the GENERIC_FSK timebase to be maintained for a period of time, while the RF Oscillator is turned off and much of the SoC is placed in state-retention. During DSM, the timebase management is temporarily transferred from the GENERIC_FSK EVENT_TMR to the low-power DSM_TIMER, and after DSM exit, timebase management is transferred back to the EVENT_TMR, under software control. During DSM, the EVENT_TMR is frozen. The total time spent in DSM is known to software, so that upon exiting DSM, the EVENT_TMR can be updated to correct for the precise amount of time it was frozen.

DSM entry and exit, and RF Oscillator re-start during Manual DSM, are governed by 5 registers, as described in the table below.

| Field | R/W | Description |
|---|---|---|
| MAN_SLEEP[23:0] | rw | If GEN_SLEEP_REQUEST=1, enter DSM & freeze EVENT_TMR when MAN_SLEEP matches DSM_TIMER.<br>**NOTE:** This register resides in RSIM Address Space |
| RSIM_DSM_PWR_OFFSET[9:0] | rw | Determines the power and RF oscillator re-start times relative to MAN_WAKE<br>**NOTE:** This register resides in RSIM Address Space |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| MAN_WAKE[23:0] | rw | Exit Deep Sleep Mode, and resume EVENT_TMR, when MAN_WAKE matches DSM_TIMER<br>**NOTE:** This register resides in RSIM Address Space |
| GEN_SLEEP_REQUEST | w | Enable a match on MAN_SLEEP[23:0] to DSM_TIMER[23:0], to enter Deep Sleep Mode, by writing a 1 to this bit. Cancel a pending sleep request by writing a 0 to it, if already set, at least 2 32.768KHz clock cycles prior to MAN_SLEEP[23:0] |
| DSM_TIMER[23:0] | r | Current State of the 32KHz Sleep Timer<br>**NOTE:** This register resides in RSIM Address Space |

## Procedure

The procedure to schedule a Manual DSM cycle (entry/exit) as well as to program the desired RF Oscillator re-start time, and the calculation to restore the GENERIC_FSK EVENT_TMR after a DSM cycle, is described below.

1. Software determines the future time at which it would like to enter DSM, by reading the DSM_TIMER, computing the number of 32KHz clock cycles remaining until the desired DSM start-time, and writing this value into MAN_SLEEP register. The value programmed into MAN_SLEEP should be no fewer than 4 clocks greater (in the future) than the current time as read from DSM_TIMER.
2. Software determines the future time at which it would like to exit DSM, by computing the number of 32KHz clock cycles remaining until the desired DSM exit-time, and writing this value into MAN_WAKE register.
3. Software writes a 1 to DSM_CTRL[GEN_SLEEP_REQUEST]. This bit resides in GENERIC_FSK address space. Writing this bit to 1 enables a DSM cycle to commence using the values programmed into MAN_SLEEP and MAN_WAKE.
4. MCU can go into a low power state (e.g., STOP, VLPS, or VLLSx)
5. When DSM_TIMER = MAN_SLEEP, the EVENT_TMR will be clock-gated so that it will remain frozen at its current count. The RF Oscillator will be turned off (unless overridden due to a non-Generic-related SoC requirement)
6. All hardware not in the low-voltage domain will be placed into state-retention, or other low-power state.
7. When DSM_TIMER = MAN_WAKE, clocking of the GENERIC_FSK Link Layer Controller will resume and the EVENT_TMR will be ungated (allowed to resume counting).
8. Software computes the time that the SoC was in DSM (and hence the time the EVENT_TMR was frozen), in microseconds, with the equation:

   **(MAN_WAKE – MAN_SLEEP) / 32768 * 1000000**

9. Software increments the GENERIC_FSK EVENT_TMR by this amount, by writing this value to EVENT_TMR[23:0] register with EVENT_TMR_ADD=1.
10. On the next 1MHz clock edge, the EVENT_TMR has been restored to where it would have been, had no DSM occurred, with 1.0-microsecond accuracy.

Note that the 1.0-microsecond accuracy quoted above, assumes an ideal 32.768KHz source. Any ppm error in the 32.768KHz source will degrade the microsecond accuracy proportionally to the magnitude of the error.

Once GEN_SLEEP_REQUEST has been set to 1 to request Manual DSM, the request can be cancelled by writing a 0 to the bit. The cancellation must be performed at least 2 32.768KHz before the MAN_SLEEP[23:0] match to DSM_TIMER[23:0] to avoid a race condition to enter DSM.

The following timing diagram depicts an GENERIC_FSK-driven DSM entry/exit cycle.

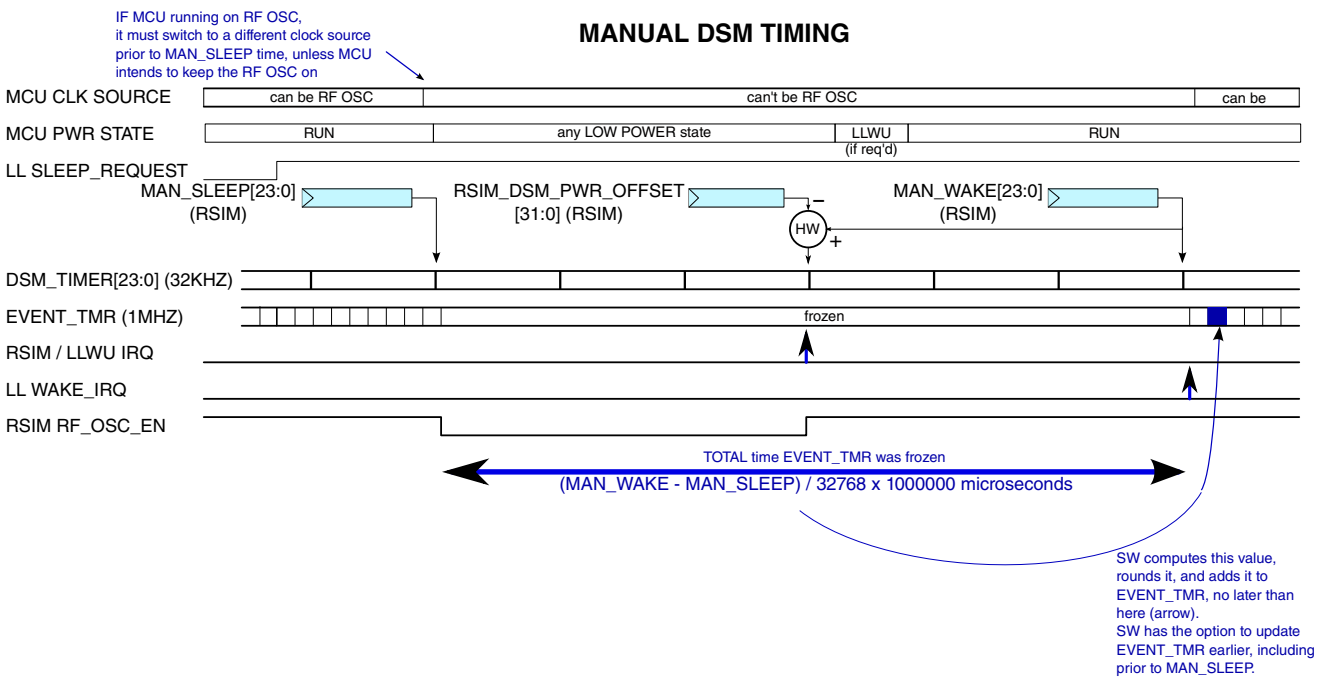

**Figure 64-202. GENERIC_FSK DEEP SLEEP TIMING**

## DSM Early Exit

Circumstances may arise where the Manual DSM cycle may occasionally need to be cut short, due to circumstances beyond the control of the radio. When this happens, the SoC, starting with the MCU, is awakened out of its low power state, long before the RSIM DSM_TIMER reaches MAN_WAKE. Therefore, software handling the event which triggered the wakeup, will determine if the radio needs to be awakened as well. If this is the case, software will advance the MAN_WAKE setting to a point in the near future, but no fewer than 4 32KHz clock cycles beyond the current time ascertained by reading

DSM_TIMER. So, to execute a Manual DSM Early Exit, software shall read DSM_TIMER, add +4 to the value, and write the sum to the RSIM MAN_WAKE regiter. Software shall then wait for the GENERIC_FSK WAKE_IRQ interrupt, which will assert once the full radio wakeup from the low power state has completed. Software should then take whatever steps are necessary to configure the radio to respond to the conditions which triggered the early exit. Servicing of a DSM early exit interrupt is beyond the scope of this document.

#### 64.5.3.3.11 Wake-On-Radio

The GENERIC_FSK Link Layer can take advantage of the automated sequence- and DSM-scheduling provided by Wake-On-Radio. Wake-On-Radio is one of two DSM control schemes that can be selected for GENERIC_FSK, as an alternative to Manual DSM. See Chapter *Wake-On-Radio*.

Several changes to the GENERIC_FSK Link Layer Controller have been made to support Wake-On-Radio.

Interrupt WAKE_IRQ has been made dual-purpose. If Wake-On-Radio is disabled, i.e., WOR_CTRL[WOR_EN]=0, or Wake-On-Radio not assigned to GENERIC_FSK, WAKE_IRQ performs its legacy function for Manual DSM. (See Section Manual DSM). If Wake-On-Radio is enabled, i.e., WOR_EN=1, and assigned to GENERIC_FSK, this interrupt becomes WOR_IRQ, and has new functionality specific to Wake-On-Radio. See Chapter *Wake-On-Radio*, Section *Interrupt Management*, for more details on the meaning, and handling of WOR_IRQ. The Interrupts section of this chapter describes the dual-purpose nature of WAKE_IRQ / WOR_IRQ.

In addition to WOR_IRQ, numerous interface changes have been made to support Wake-On-Radio. The changes allow, for example, WOR to manage GENERIC_FSK's RF interrupts, inhibit timestamp updates, etc. The added port signals are listed in the table below, along with a description or each:

| WAKE-ON-RADIO INTERFACE SIGNAL | DIRECTION | DESCRIPTION |
|---|---|---|
| wor_event_tmr_add[23:0] | WOR -> GENERIC_FSK | The Event Timer "Addback" value computed by WOR to compensate for the amount of time Event Timer was frozen during DSM |
| wor_addback | WOR -> GENERIC_FSK | A 1µs-long pulse commanding the GENERIC_FSK Event Timer to auto-increment by the the amount appearing on wor_event_tmr_add[23:0] |
| wor_force_wake_irq | WOR -> GENERIC_FSK | Force WOR_IRQ to assert, due to an occurrence of one of the 3 WOR_IRQ interrupt triggers |

*Table continues on the next page...*

| WAKE-ON-RADIO INTERFACE SIGNAL | DIRECTION | DESCRIPTION |
|---|---|---|
| wor_block_wake_irq | WOR -> GENERIC_FSK | Inhibit the legacy WAKE_IRQ assertion when WOR_EN=1 (this interrupt becomes WOR_IRQ) |
| tx_start_ext | WOR -> GENERIC_FSK | A 1µs-long pulse to the GENERIC_FSK command decoder to initiate a WOR-driven TX sequence |
| rx_start_ext | WOR -> GENERIC_FSK | A 1µs-long pulse to the GENERIC_FSK command decoder to initiate a WOR-driven RX sequence |
| seq_stop_ext | WOR -> GENERIC_FSK | A 1µs-long pulse to the GENERIC_FSK command decoder to stop (abort) a WOR-driven RX sequence |
| wor_allow_irq | WOR -> GENERIC_FSK | Inhibits RF interrupts, so that interrupt assertions can be managed based on WOR descriptor settings. Controlled dynamically by the WOR state machine. |
| timestamp_inhibit | WOR -> GENERIC_FSK | In Wake-On-Radio, the legacy GENERIC_FSK TIMESTAMP register becomes WOR TIMESTAMP0 (timestamp for SLOT0). This signal blocks this register from updating on SLOTS 1-3 |
| wake_irq_trig | WOR <- GENERIC_FSK | WOR uses this signal to cancel GEN_SLEEP_REQUEST and transition from IN_DSM -> COMP_ADDBACK state |
| event_tmr[23:0] | WOR <- GENERIC_FSK | GENERIC_FSK Event Timer, used by WOR for timestamp capture |
| event_tmr_plus_1[23:0] | WOR <- GENERIC_FSK | GENERIC_FSK Event Timer + 1, used by WOR to schedule RF operation starts and stops |
| tx_irq_trig | WOR <- GENERIC_FSK | TXIRQ trigger, indicates the completion of a packet transmission, used by WOR to transition out of WAKE_SEQ_END state |
| rx_irq_trig | WOR <- GENERIC_FSK | RXIRQ trigger, indicates the completion of a good packet reception, used by WOR to transition out of WAKE_SEQ_END state |
| rx_status_for_wor[2:0] | WOR <- GENERIC_FSK | Internal RX status signals used by WOR to formulate TIMESTAMPx_STS[2:0].<br>**NOTE:** See Section Timestamp Status for Wake-On-Radio following this table |
| timestamp_clk_en | WOR <- CGM <- GENERIC_FSK | Timestamp clock gate enable, the resultant clock is used by WOR to update the TIMESTAMP1,2, and 3 registers |

# Timestamp Status for Wake-On-Radio

The GENERIC_FSK Link Layer has 3 methods for filtering and screening packets as they are being received:

H0 filtering
H1 filtering
LENGTH_MAX filtering

In Normal operation, when one or more of the filtering rules are violated, an RX recycle will occur immediately after the header, and the cause of the filtering violation (status bit) will not be preserved. In addition, the final CRC status can't be known at the point of recycle. In Wake-On-Radio operation, The TIMESTAMPx_STS[1] bit reflects CRC status, and TIMESTAMPx_STS[2] bit reflects Packet Filter status. For an RX recycle at the end of the packet header, the GENERIC_FSK Link Layer won't be able to provide the necessary signalling to Wake-On-Radio in order to properly set those 2 bits of each TIMESTAMPx_STS register, so these bits should be considered invalid. To render them valid, set the GENERIC_FSK PACKET_CFG[REC_BAD_PKT]=1, which will force reception of the entire packet, including CRC, before recycling. This will allow the Wake-On-Radio TIMESTAMPx_STS[2:1] bits to yield valid information.

#### 64.5.3.3.12 Multi-protocol Arbitration

The GENERIC_FSK Link Layer controller may be included in an SoC that includes similar controllers for other protocols (e.g., Bluetooth Low Energy). GENERIC_FSK may be required to operate simultaneously with other protocols on the SoC, and there are scenarios where both protocol engines require access to the RF channel at the same time.

To assist in software arbitration between GENERIC_FSK and other protocols, the read-only status but XCVR_BUSY has been included in the XCVR_STS register. When this bit is set, this indicates that the RF channel is currently in use (TSM is busy), by one of the Radio’s four link layer controllers. When this bit it clear, the RF channel is available to GENERIC_FSK (TSM is idle).

#### 64.5.3.3.13 Wifi Coexistence

Provisions have been made to allow for the 2.4GHz transceiver to coexist in the same space as a WiFi transceiver IC, which shares the same frequency band. The coexistence scheme designates the WiFi transceiver as the master, and the 2.4GHz transceiver as the slave. The objective of the coexistence strategy is to prevent both the WiFi and 2.4GHz transceivers transmitting simultaneously; a configuration option exists to also prevent the 2.4GHz transceiver from receiving when the WiFi transceiver owns the RF channel.

A very basic mechanism is used in cases where 2.4GHz radio does not generate requests, but instead defers to the WiFi transceiver to grant permission to use the medium. The WiFi IC generates a signal, RF_NOT_ALLOWED. If this signal is asserted, then 2.4GHz radio does not perform any communication. When this signal is de-asserted, then 2.4GHz radio is free to perform communications. In case the signal RF_NOT_ALLOWED is de-asserted when 2.4GHz radio has already initiated the transmission/reception of a packet then the 2.4GHz radio must stop its activity immediately .

When RF_NOT_ALLOWED aborting is enabled, the GENERIC_FSK Link Layer hardware must respond to RF_NOT_ALLOWED assertions, by aborting any TX or RX sequence which is currently underway, and Link Layer software must not initiate any new sequences until RF_NOT_ALLOWED has been deasserted. The hardware response must be handled autonomously by the Link Layer, with no MCU intervention required. This is because the RF_NOT_ALLOWED assertions can occur during a Wake-On-Radio timeslot which has been designated as "no-MCU-wakeup" in the slot's descriptor. In this scenario, the aborting of the sequence occurs without any assistance from, or notification of, the MCU.

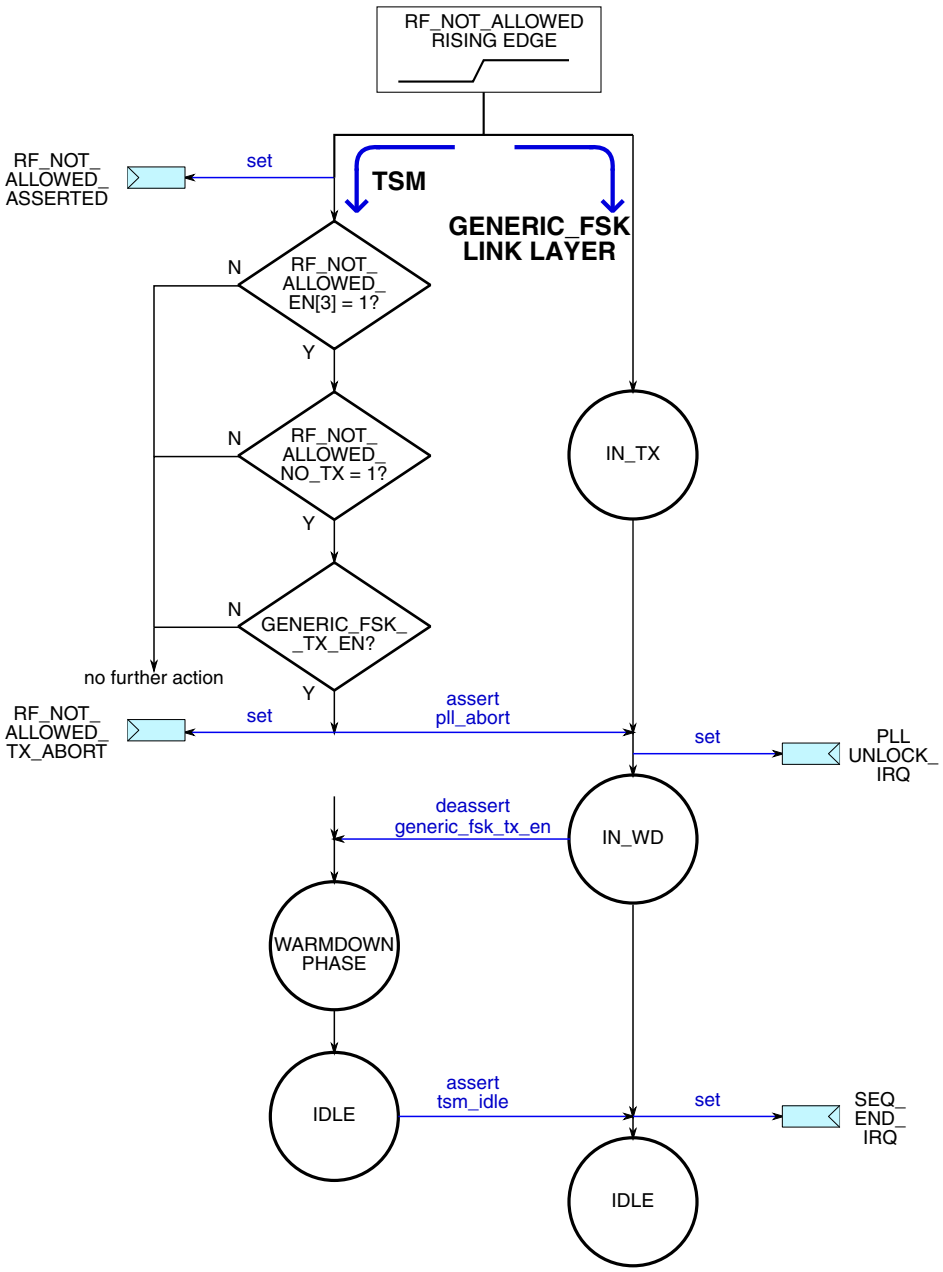
In the multi-protocol 2.4GHz radio, RF_NOT_ALLOWED aborting can be individually enabled/disabled for each protocol engine. For GENERIC_FSK, RF_NOT_ALLOWED_EN[3] is the associated enable control bit. This bit resides in the COEX_CTRL register in XCVR address space. When this bit is 0, transitions on RF_NOT_ALLOWED are ignored by the GENERIC_FSK Link Layer hardware; when this bit is 1, the GENERIC_FSK Link Layer hardware will monitor RF_NOT_ALLOWED at all times, and abort any active sequence which is underway when an assertion on the pin occurs. The complete hardware response to RF_NOT_ALLOWED assertions is described below.

Additional control over RF_NOT_ALLOWED aborting is provided by the RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits. If RF_NOT_ALLOWED_NO_TX=1, then an RF_NOT_ALLOWED abort will occur only if a GENERIC_FSK TX sequence is underway (generic_fsk_tx_en=1). GENERIC_FSK TX sequences will not be aborted if RF_NOT_ALLOWED_NO_TX=0. If RF_NOT_ALLOWED_NO_RX=1, then an RF_NOT_ALLOWED abort will occur only if GENERIC_FSK RX sequence is underway (generic_fsk_rx_en=1). GENERIC_FSK

RX sequences will not be aborted if RF_NOT_ALLOWED_NO_RX=0. The RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits reside in the COEX_CTRL register.

For the purposes of triggering a hardware abort, the *pll_abort* input to the GENERIC_FSK Link Layer hardware is used. This is because the hardware response to the RF_NOT_ALLOWED assertion is identical to that of a PLL unlock event. This also means that, when RF_NOT_ALLOWED aborting is enabled for GENERIC_FSK the PLL_UNLOCK_IRQ interrupt status bit, will be dual purpose: it will not only indicate a PLL unlock condition, but also a RF_NOT_ALLOWED abort. PLL aborting and RF_NOT_ALLOWED aborting are enabled separately, with the COEX_CTRL register maintaining the control bits required for the latter. The status bits for RF_NOT_ALLOWED aborting are also available in COEX_CTRL, so that software will be able to distinguish the source of the PLL_UNLOCK_IRQ, in case both PLL and RF_NOT_ALLOWED aborting are enabled.

The sequence of events which results in a hardware abort of an GENERIC_FSK TX operation triggered by an assertion on RF_NOT_ALLOWED, is a collaboration between the TSM (Transceiver Sequence Manager) and the GENERIC_FSK Link Layer hardware, as shown in the following diagram.



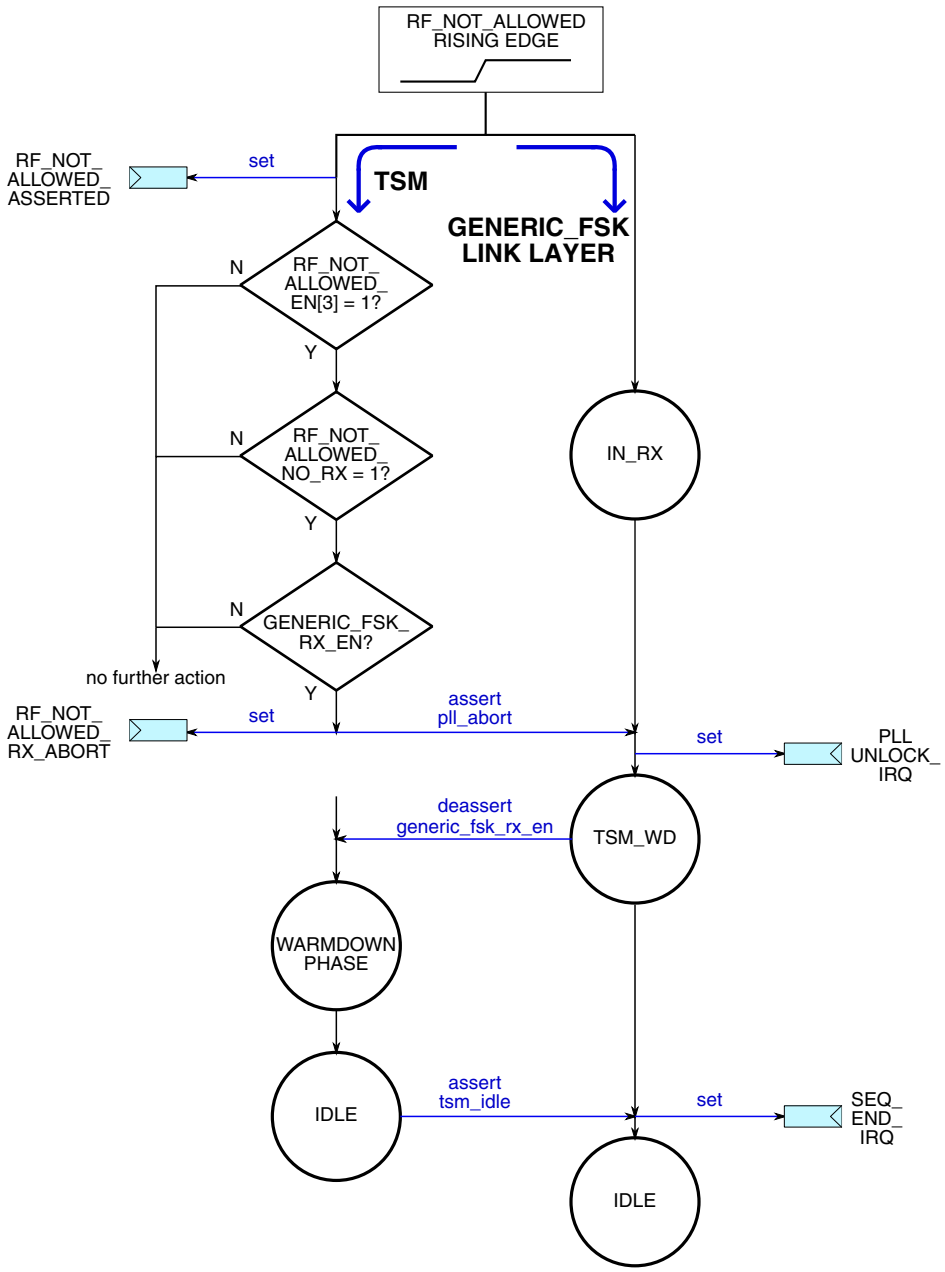
Upon assertion on RF_NOT_ALLOWED, the TSM sets the RF_NOT_ALLOWED_ASSERTED status bit in COEX_CTRL, then checks that the conditions for a hardware abort are all met:

- RF_NOT_ALLOWED_EN[3] = 1, which enables GENERIC_FSK to respond to RF_NOT_ALLOWED events
- RF_NOT_ALLOWED_NO_TX = 1, which enables TX operations to be aborted
- generic_fsk_tx_en = 1, TX request to TSM from GENERIC_FSK, indicating TX operation in progress

If all conditions are not met, no further action is taken. Otherwise, the TSM sets COEX_CTRL[RF_NOT_ALLOWED_TX_ABORT], and also asserts *pll_unlock* to the GENERIC_FSK Link Layer hardware. GENERIC_FSK responds by asserting IRQ_CTRL[PLL_UNLOCK_IRQ] in GENERIC_FSK address space. GENERIC_FSK enters IN_WD state, which deasserts generic_fsk_tx_en to the TSM. This initiates the TSM TX warmdown. GENERIC_FSK holds in IN_WD to wait for TSM to return to idle. Once this occurs, GENERIC_FSK asserts IRQ_CTRL[SEQ_END_IRQ] and returns to its IDLE state. Three status bits are now set to indicate to software that the source of the abort was an RF_NOT_ALLOWED assertion:

- IRQ_CTRL[PLL_UNLOCK_IRQ]
- COEX_CTRL[RF_NOT_ALLOWED_ASSERTED]
- COEX_CTRL[RF_NOT_ALLOWED_TX_ABORT]

The sequence of events which results in a hardware abort of an GENERIC_FSK RX sequence triggered by an assertion on RF_NOT_ALLOWED, is shown in the following diagram.



Upon assertion on RF_NOT_ALLOWED, the TSM sets the RF_NOT_ALLOWED_ASSERTED status bit in COEX_CTRL, then checks that the conditions for a hardware abort are all met:

- RF_NOT_ALLOWED_EN[3] = 1, which enables GENERIC_FSK to respond to RF_NOT_ALLOWED events
- RF_NOT_ALLOWED_NO_RX = 1, which enables RX operations to be aborted
- generic_fsk_rx_en = 1, RX request to TSM from GENERIC_FSK, indicating RX operation in progress

If all conditions are not met, no further action is taken. Otherwise, the TSM sets COEX_CTRL[RF_NOT_ALLOWED_RX_ABORT], and also asserts *pll_unlock* to the GENERIC_FSK Link Layer hardware. GENERIC_FSK responds by asserting IRQ_CTRL[PLL_UNLOCK_IRQ] in GENERIC_FSK address space. GENERIC_FSK enters IN_WD state, which deasserts generic_fsk_rx_en to the TSM. This initiates the TSM TX warmdown. GENERIC_FSK holds in IN_WD to wait for TSM to return to idle. Once this occurs, GENERIC_FSK asserts IRQ_CTRL[SEQ_END_IRQ] and returns to its IDLE state. Three status bits are now set to indicate to software that the source of the abort was an RF_NOT_ALLOWED assertion:

- IRQSTS1[PLL_UNLOCK_IRQ]
- COEX_CTRL[RF_NOT_ALLOWED_ASSERTED]
- COEX_CTRL[RF_NOT_ALLOWED_RX_ABORT]

The complete set of control and status bits in the COEX_CTRL register is described in the following table:

| Field | R/W | Description |
|---|---|---|
| RF_NOT_ALLOWED_EN | RW | The coexistence input RF_NOT_ALLOWED can be enabled to selectively abort TX or RX sequences, with individual enables for each supported protocol, subject also to the state of the RF_NOT_ALLOWED_NO_TX and RF_NOT_ALLOWED_NO_RX control bits, according to the table below.<br>**xxx1**: RF_NOT_ALLOWED assertions are enabled to abort BLE TX and RX sequences<br>**xxx0**: RF_NOT_ALLOWED assertions are not enabled to abort BLE TX and RX sequences<br>**x1xx**: RF_NOT_ALLOWED assertions are enabled to abort 802.15.4 TX and RX sequences<br>**x0xx**: RF_NOT_ALLOWED assertions are not enabled to abort 802.15.4 TX and RX sequences<br>**1xxx**: RF_NOT_ALLOWED assertions are enabled to abort GENERIC_FSK TX and RX sequences<br>**0xxx**: RF_NOT_ALLOWED assertions are not enabled to abort GENERIC_FSK TX and RX sequences |
| RF_NOT_ALLOWED_NO_TX | RW | TX Sequences will be aborted by RF_NOT_ALLOWED assertions, if the appropriate RF_NOT_ALLOWED_EN[x] bit is set. |
| RF_NOT_ALLOWED_NO_RX | RW | RX Sequences will be aborted by RF_NOT_ALLOWED assertions, if the appropriate RF_NOT_ALLOWED_EN[x] bit is set. |
| RF_NOT_ALLOWED_ASSERTED | R/W1TC | RF_NOT_ALLOWED has gone from not asserted, to asserted, since the last time this bit was cleared |
| RF_NOT_ALLOWED_TX_ABORT | R/W1TC | An TX sequence has been aborted since the last time this bit was cleared |
| RF_NOT_ALLOWED_TX_ABORT | R/W1TC | An TX sequence has been aborted since the last time this bit was cleared |
| RF_NOT_ALLOWED | R | Reflects the instantaneous state of the RF_NOT_ALLOWED pin, |

|---|---|
| 15<br>IPP_OBE_RF_ACTIVE | IPP_OBE_RF_ACTIVE<br>This bit enables the Output Driver (OBE) on the SoC port that provides the RF Active signal as a pin interface option. |
| 14<br>IPP_OBE_BLE_EARLY_WARNING | IPP_OBE_BLE_EARLY_WARNING<br>This bit enables the Output Driver (OBE) on the SoC port that provides the BLE Early Warning signal as a pin interface option. |
| 13<br>RADIO_GASKET_BYPASS_OVRD | Radio Gasket Bypass Override<br>This bit directly controls the SoC platform asynchronous gasket bypass signal when the Gasket Bypass Override is enabled.The default behavior of the SoC Asynchronous Gasket is Not Bypassed, which means the Radio registers are accessed using the RF Ref Osc clock. The Radio sends the RF Ref Osc to the asynchronous gasket which then uses that clock for SoC register accesses of the Radio registers. This requires the RF Ref Osc to be Enabled and Ready. If the RF Ref Osc is not Enabled and Ready, then the IPS Gasket can be overridden to be in Bypass Mode, which forces the use of the SoC IPG clock as the register access clock. If the RF Ref Osc Is Enabled and Ready, then the IPS Gasket can be overridden to be in Bypass Mode, but this is an ILLEGAL ACCESS if the Radio is operational, DO NOT write Radio registers with the Asynchronous Gasket Bypassed when the Radio is Operating. Test mode access is allowed but glitches may occur. The intent of Bypass Mode is to allow software to configure the Radio before the RF Ref Osc is Enabled and Ready. Note that the BLE Link Layer registers can only be accessed when the RF Ref Osc is Enabled and Ready.<br>0b - XCVR and Link Layer Register Clock is the RF Ref Osc Clock<br>1b - XCVR and Link Layer Register Clock is the SoC IPG Clock |
| 12<br>RADIO_GASKET_BYPASS_OVRD_EN | Radio Gasket Bypass Override Enable<br>The SoC platform has an asynchronous gasket that allows register access for the Radio registers in all SoC clocking modes. This bit allows software to directly control the SoC platform asynchronous gasket bypass signal. |
| 11-9<br>— | Reserved |
| 8<br>RF_OSC_EN | RF Ref Osc Enable<br>The RF Reference Oscillator can be enabled by a Radio link layer (Including the Link Layer use of Deep Sleep Modes), by an internal SoC clock mode, by an External Pin request, or by this bit.<br>If this bit is 0, then in Radio Run Mode, the RF Ref Osc can be turned on by the SoC, or by a Radio link layer using RRun Mode (Including the Link Layer use of Deep Sleep Modes), or by an External Pin request. Warning: The RF Ref Osc can not be enabled by the SoC until the Radio has entered RRun Mode.<br>If this bit is 0, then in Radio Stop Modes, the RF Ref Osc will be off (except that the external pin request can turn the RF Osc on even if the RF Power is off). Warning: Radio will not go into Stop mode while the RF Ref Osc is being used by the SoC, or by a Radio link layer unless the Link Layer is using a Deep Sleep State Machine.<br>If this bit is 1, then the RF Ref Osc will be on in Radio Run Mode. Warning: The RF Ref Osc can not be enabled until the Radio has entered RRun Mode.<br>If this bit is 1, then the RF Ref Osc will be off in Radio Stop Modes (except that the external pin request can turn the RF Osc on even if the RF Power is off). Warning: Radio will not go into Stop mode while the RF Ref Osc is On. |
| 7-6<br>— | Reserved |
| 5 | BLE RF Power Request Interrupt Flag<br>This bit is the BLE_RF_POWER_REQ_INT interrupt flag. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| BLE_RF_POWER_REQ_INT | This interrupt flag is cleared by writing a 1 to it. |
| 4<br>BLE_RF_POWER_REQ_INT_EN | BLE RF Power Request Interrupt Enable<br>This bit enables an interrupt request, that is also added to the RSIM Asynchronous MCU Wakeup signal, when the WAKEUP_INTERRUPT_SOURCE selected version of the BLE RF Power Request is asserted high. |
| 3-2<br>— | Reserved |
| 1<br>BLE_RF_POWER_REQ_STAT | BLE RF Power Request Status<br>This bit indicates the current status of the BLE link layer request to turn on the RF Power. |
| 0<br>BLE_RF_POWER_REQ_EN | BLE RF Power Request Enable<br>This bit resets on POR only.<br>If this bit is cleared (the default state), then all BLE link layer requests to turn on the RF Power will be blocked and ignored.<br>In BLE protocols the BLE link layer will always restart when exiting reset by first Requesting the RF Power, this bit blocks that behavior until software configures the Radio and enables the requests. |

| 11<br>RSIM_STOP_REQ_OVRD_EN | Radio Stop Request Override Enable<br>This bit enables the Radio Stop Request Override bit. |
| 10<br>RSIM_STOP_REQ_OVRD | Radio Stop Request Override<br>This bit directly controls the Radio Stop Request signal when the Radio Stop Request Override is enabled. |
| 9<br>RADIO_STOP_REQ_STAT | Radio Stop Request Status<br>This is the value of the Radio Stop Request signal being sent to the SPM module, including any overrides. |
| 8<br>RADIO_STOP_ACK_STAT | Radio Stop Acknowledge Status<br>This is the status of the Stop request Acknowledge signal being used by the Radio, including any override of the SPM module signal. |
| 7<br>RADIO_STOP_MODE_OVRD_EN | Radio Stop Mode Override Enable<br>This bit enables the Radio Stop Mode Override bit. |
| 6-4<br>RADIO_STOP_MODE_OVRD | Radio Stop Mode Override<br>This bit directly controls the Radio Stop Mode signal when the Radio Stop Mode Override is enabled. |
| 3<br>SPM_STOP_ACK_STAT | SPM Stop Acknowledge Status<br>This is the status of the Stop request Acknowledge signal received from the SPM module. |
| 2-0<br>RADIO_STOP_MODE_STAT | Radio Stop Mode Status<br>This is the value of the Radio Stop Mode bus that is sent to the SPM module. |

## A.1.1.5 Radio Software Configuration (SW_CONFIG)

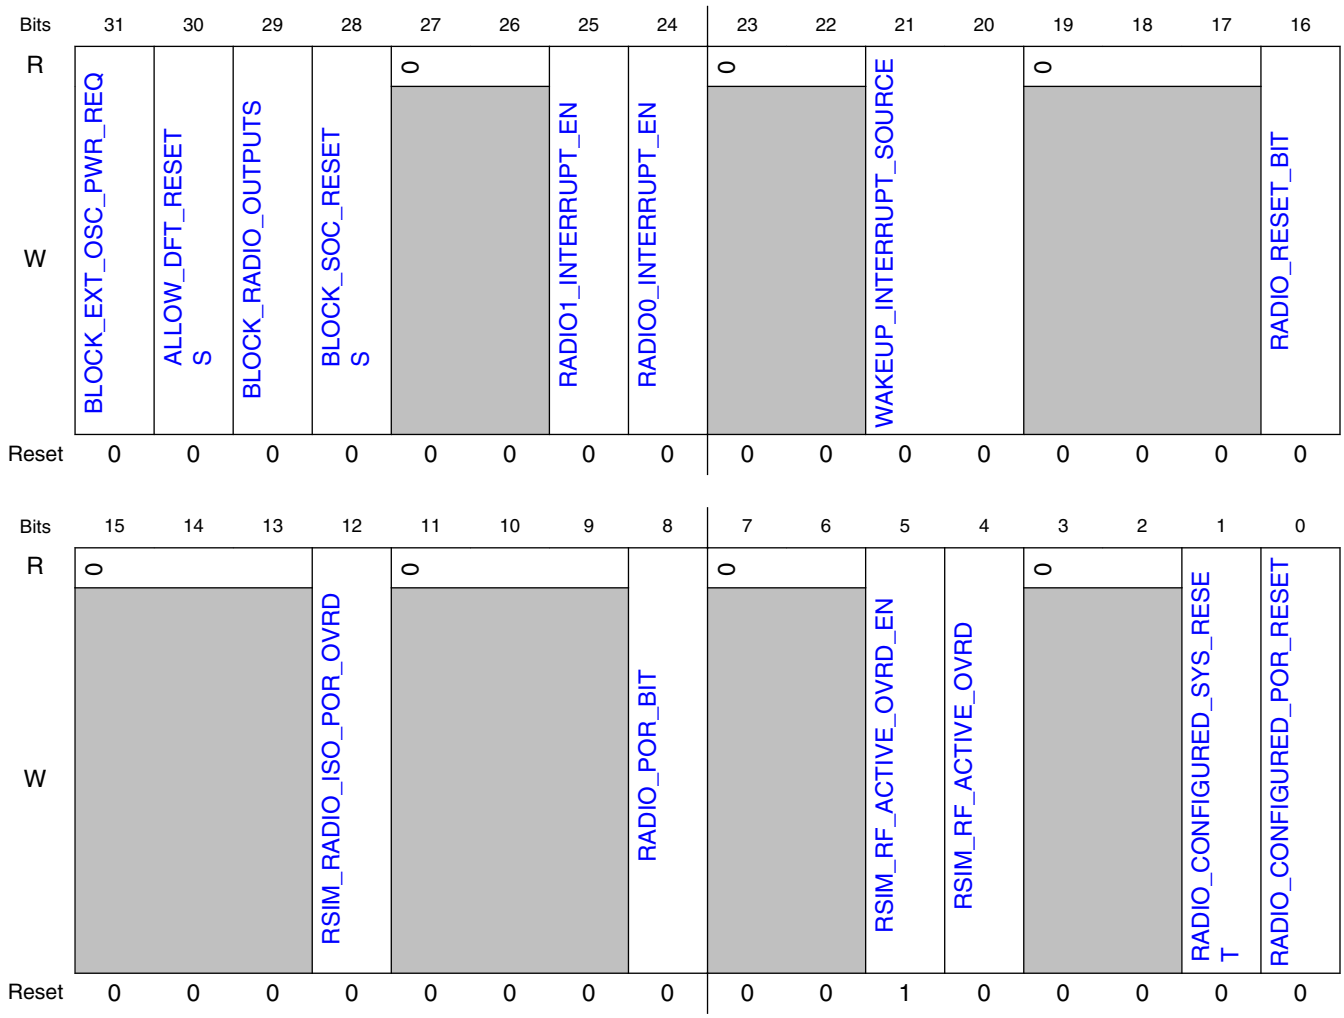
### A.1.1.5.1 Offset

| Register | Offset |
|---|---|
| SW_CONFIG | 18h |

### A.1.1.5.2 Function

This register contains the software configuration and control bits.

### A.1.1.5.3 Diagram



### A.1.1.5.4 Fields

| Field | Function |
|---|---|
| 31<br>BLOCK_EXT_OSC_PWR_REQ | Block External Requests for RF OSC from starting a Radio Power Wakeup Sequence<br>If this bit is set then any External request for the OSC will not start a Radio Power Wakeup Sequence, otherwise any such request does request full Run Regulation mode. |
| 30<br>ALLOW_DFT_RESETS | Allow the DFT Reset Pin to Reset the Radio<br>The Radio provides a port that can be connected to a test mode pin in order to provide a method of resetting the Radio independently from SoC resets. This bit enables that DFT functionality. |
| 29<br>BLOCK_RADIO_OUTPUTS | Block Radio Outputs<br>This bit resets on POR only. This bit is intended to allow the SoC to perform concurrent testing of various SoC logic while the Radio is operating independently. Any Radio output signals that go to the SoC will be blocked so as to not affect the SoC testing when this bit is set. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 28<br>BLOCK_SOC_RESETS | Block SoC Resets of the Radio, cleared by Radio System Reset<br>Most SoC System or Power On Resets will be blocked and the Radio will not be affected by them when this bit is set.<br>The Radio Power Mode logic is not blocked by this bit and will reset on any SoC Power On Reset. |
| 27-26<br>— | Reserved |
| 25<br>RADIO1_INTERRUPT_EN | Radio1 Interrupt Enable<br>This bit enables the Radio1 interrupt source, as selected by the Radio1 IRQ Select bits, to be added to the interrupt sources that are used to generate the RSIM Asynchronous MCU Wakeup signal (typically connected to the MCU LLWU). |
| 24<br>RADIO0_INTERRUPT_EN | Radio0 Interrupt Enable<br>This bit enables the Radio0 interrupt source, as selected by the Radio0 IRQ Select bits, to be added to the interrupt sources that are used to generate the RSIM Asynchronous MCU Wakeup signal (typically connected to the MCU LLWU). |
| 23-22<br>— | Reserved |
| 21-20<br>WAKEUP_INTERRUPT_SOURCE | RSIM Wakeup Interrupt Source Selector<br>The Radio Power-On Sequence can generate an interrupt at three times in the sequence, these bits make that selection.<br>00b - No Radio Power-On Sequence interrupt will be generated.<br>01b - A Power-On Sequence interrupt will be generated when the RF Power Request occurs, including unblocked requests from an external source to use the RF OSC.<br>10b - A Power-On Sequence interrupt will be generated when the RF OSC Request occurs, but not if the RF OSC request was from an external source.<br>11b - A Power-On Sequence interrupt will be generated when the RSIM RF Active Warning occurs |
| 19-17<br>— | Reserved |
| 16<br>RADIO_RESET_BIT | Software System Reset for the Radio<br>This bit only clears if there is an SoC Power On Reset.<br>Setting this bit will reset the Global Radio and RSIM logic, including all Link Layer logic.<br>The logic will stay in reset until this bit is cleared.<br>This bit will not reset the Power Mode logic or the Deep Sleep Mode related logic. |
| 15-13<br>— | Reserved |
| 12<br>RSIM_RADIO_ISO_POR_OVRD | RSIM ISO_POR Override<br>This bit directly controls the Radio ISO_POR signal when the RSIM_ISO_OVRD_EN bit is set. |
| 11-9<br>— | Reserved |
| 8<br>RADIO_POR_BIT | Software Power On Reset for the Radio<br>This bit only clears if there is an SoC Power On Reset.<br>Setting this bit will reset all the radio logic that uses the Radio Power On Reset or Radio VLLS Reset signal, it will be held in reset until this bit is cleared. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 7-6<br>— | Reserved |
| 5<br>RSIM_RF_ACTIVE_OVRD_EN | RF Active Internal Override Enable<br>This bit enables the RF Active Internal Override bit. |
| 4<br>RSIM_RF_ACTIVE_OVRD | RF Active Internal Override<br>If the RSIM_RF_ACTIVE_OVRD_EN bit is set, then this bit controls the Internal version of RF Active instead of the Link Layers. The Internal version of RF Active whether overridden or not has a lower priority and can always be overridden by software using the SW_RF_ACTIVE_BIT or the TSM Spare 1 bit if it is selected using the WIFI_COEXIST_1 select bit. |
| 3-2<br>— | Reserved |
| 1<br>RADIO_CONFIGURED_SYS_RESET | Radio Configuration Bit, cleared by Radio System Reset<br>This is a bit software can write when it wants to be able to check if a Radio System Reset occurs. |
| 0<br>RADIO_CONFIGURED_POR_RESET | Radio Configuration Bit, cleared by Radio Power On Reset<br>This is a bit software can write when it wants to be able to check if a Radio Power On Reset occurs. |

| 17-16<br>GFSK_MI | GFSK Modulation Index<br>This register selects the GFSK Modulation Index which, together with the GFSK Symbol Rate, determines the Peak Modulation frequency.<br>The formula used for the Peak Modulation is { Symbol Rate / (2 x 1/Modulation Index) }<br>00b - 0.32<br>01b - 0.50<br>10b - 0.70<br>11b - 1.00 |
| 15-0<br>GFSK_MULTIPLY_TABLE_MANUAL | Manual GFSK Multiply Lookup Table Value<br>The GFSK Modulator Multiplier uses a lookup table to select the multiplicand representing the { Frequency Deviation divided by the Low Port Sigma Delta LSB resolution in Hz } for the Modulation requested based on the Modulation Index, the Symbol Rate, and the Reference Clock Frequency.<br>The lookup table value is overridden by this register if GFSK_MLD is set, and these bits should then contain a number that represents { FDev/SD_LSB integer[11:0] + FDev/SD_LSB fraction[3:0] } |

## A.2.1.5 TX GFSK Filter Coefficients 2 (GFSK_COEFF2)

### A.2.1.5.1 Offset

| Register | Offset |
|---|---|
| GFSK_COEFF2 | Ch |

### A.2.1.5.2 Function

The two registers TX_GFSK_COEFF1 and TX_GFSK_COEFF2 form a 64-bit little endian register that is memory mapped internally as shown to override the GFSK Filter Coefficients.

In 64-bit they combine as {TX_GFSK_COEFF2[31:0],TX_GFSK_COEFF1[31:0]}

The resulting 64-bit value is the GFSK Manual Filter Coefficient [63:0]

### A.2.1.5.3 Diagram

| GFSK_COEFF1 | 10h |

### A.2.1.6.2 Function

The two registers TX_GFSK_COEFF1 and TX_GFSK_COEFF2 form a 64-bit little endian register that is memory mapped internally as shown to override the GFSK Filter Coefficients.

In 64-bit they combine as {TX_GFSK_COEFF2[31:0],TX_GFSK_COEFF1[31:0]}

The resulting 64-bit value is the GFSK Manual Filter Coefficient [63:0]

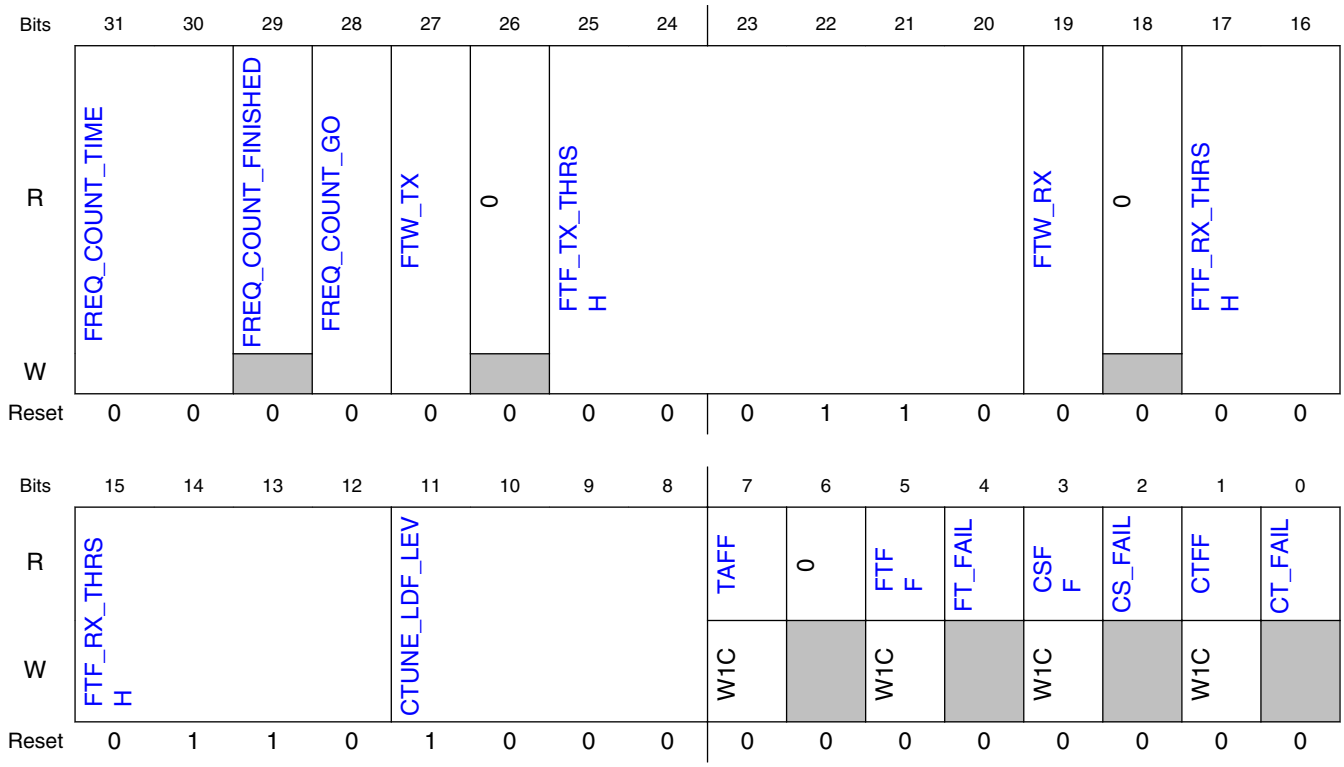
## A.2.2.5 PLL Lock Detect Control (LOCK_DETECT)

### A.2.2.5.1 Offset

| Register | Offset |
|---|---|
| LOCK_DETECT | Ch |

## A.2.2.5.2 Diagram



## A.2.2.5.3 Fields

| Field | Function |
|---|---|
| 31-30<br>FREQ_COUNT_TIME | Frequency Meter Count Time<br>This is the length of time that the Frequency Meter will count VCO clocks.<br>00b - 800 us<br>01b - 25 us<br>10b - 50 us<br>11b - 100 us |
| 29<br>FREQ_COUNT_FINISHED | Frequency Meter has finished the Count Time<br>This bit is set when the FREQ_COUNT_TIME value is reached, it is cleared when FREQ_COUNT_GO is cleared. |
| 28<br>FREQ_COUNT_GO | Start the Frequency Meter<br>The Frequency Meter starts when this bit is set and runs until the FREQ_COUNT_TIME value is reached. The bit should not be cleared until after the counting is finished.<br>After the Counting Time finishes, the FREQ_COUNT_FINISHED bit will read as a one. Then the measured frequency can be calculated by reading the frequency counts in the DFT_FREQ_COUNTER register (in the XCVR_ANALOG register space) and dividing by the FREQ_COUNT_TIME.<br>Note that the counting is done at the VCO frequency which is 2X the Carrier Frequency |
| 27<br>FTW_TX | TX Frequency Target Window time select<br>In Radio Transmit Mode, this bit selects the length of time to count for the estimation of PLL lock frequency, which is compared with the Frequency Target Window, set by FTF_TX. |

*Table continues on the next page...*

| Field | Function |
|---|---|

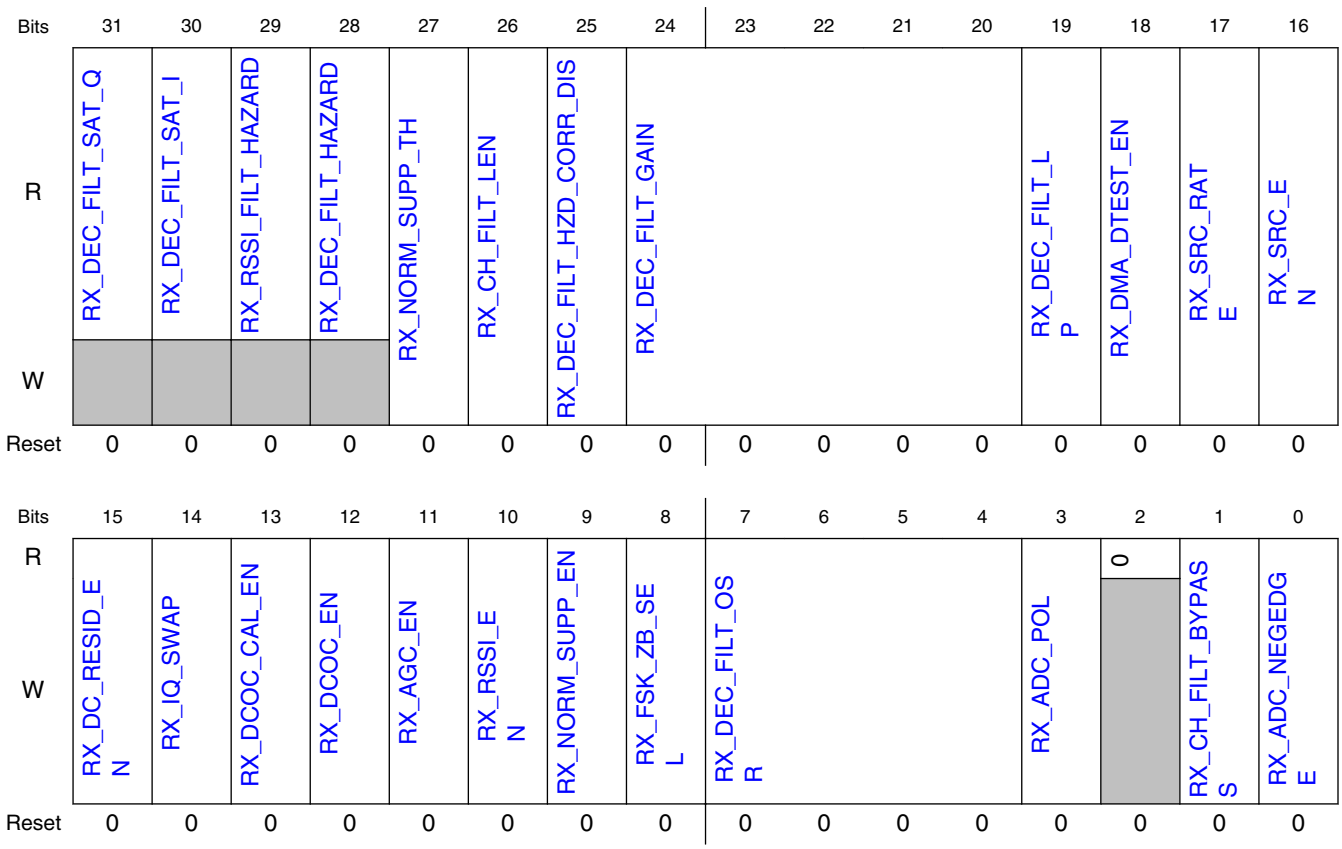
## A.2.3.2 RX Digital Control (RX_DIG_CTRL)

### A.2.3.2.1 Offset

| Register | Offset |
|---|---|
| RX_DIG_CTRL | 0h |

### A.2.3.2.2 Diagram



### A.2.3.2.3 Fields

| Field | Function |
|---|---|
| 31<br>RX_DEC_FILT_SAT_Q | Decimator output, saturation detected for Q channel<br>This bit will be set if a saturation condition is detected in the decimator filter Q channel. This bit is cleared by tsm_rx_dcoc_init and rx_init.<br>0b - A saturation condition has not occurred.<br>1b - A saturation condition has occurred. |
| 30<br>RX_DEC_FILT_SAT_I | Decimator output, saturation detected for I channel<br>This bit will be set if a saturation condition is detected in the decimator filter I channel. This bit is cleared by tsm_rx_dcoc_init and rx_init.<br>0b - A saturation condition has not occurred. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - A saturation condition has occurred. |
| 29<br>RX_RSSI_FILT_HAZARD | Decimator output for RSSI, hazard condition detected<br>This bit will be set if a hazard condition is detected in either the I or Q decimator filter related to the wideband RSSI measurement. This does not indicate that a data corruption has occurred, only that the conditions associated with data corruption were detected. This bit is cleared by rx_init.<br>0b - A hazard condition has not been detected<br>1b - A hazard condition has been detected |
| 28<br>RX_DEC_FILT_HAZARD | Decimator output, hazard condition detected<br>This bit will be set if a hazard condition is detected in either the I or Q decimator filter. This does not indicate that a data corruption has occurred, only that the conditions associated with data corruption were detected. This bit is cleared by rx_init.<br>0b - A hazard condition has not been detected<br>1b - A hazard condition has been detected |
| 27<br>RX_NORM_SUPP_TH | Normalizer Suppression Threshold<br>Configures the threshold for suppressing the normalizer's phase output when RX_NORM_SUPP_EN is set.<br>0b - Normalizer suppression threshold is 12'd7.<br>1b - Normalizer suppression threshold is 12'd15. |
| 26<br>RX_CH_FILT_LEN | RX Channel Filter Length<br>0b - Channel filter length is 24.<br>1b - Channel filter length is 16. Only RX_CHF_COEF_4 - RX_CHF_COEF_11 are used in this mode. |
| 25<br>RX_DEC_FILT_HZD_CORR_DIS | Decimator filter hazard correction disable<br>The decimator uses an asynchronous FIFO between the data coming out of the ADC (in the ADC clock domain) and the decimator output (in the ref osc clock domain, with the rest of the radio digital logic). The hazard detection logic checks for a hazard condition when the ADC clock domain logic may be about to write into the same FIFO location where the ref osc clock domain logic is about to read. If hazard correction is not disabled, the FIFO pointers will be adjusted on detection of a hazard condition.<br>0b - Hazard correction is enabled<br>1b - Hazard correction is disabled |
| 24-20<br>RX_DEC_FILT_GAIN | Decimation Filter Fractional Gain<br>Defines the fractional gain which is applied at the decimator output. The format is u0.5. The gain applied is 1 + RX_DEC_FILT_GAIN/32, so e.g. if RX_DEC_FILT_GAIN is 5'b10110=5'd22, the gain is 1+22/32=1.6875. The nominal gain through the ADC is 2048codes/1.7V; the combined gain through the ADC and decimator would therefore be 2048codes/1.7e3mV*1.6875=2.03codes/mV for the example RX_DEC_FILT_GAIN=5'b10110. |
| 19<br>RX_DEC_FILT_LP | RX Decimator Low Power<br>This bit can be set to reduce the power in the decimator.<br>0b - Decimator operates in normal mode.<br>1b - Decimator operates in low power mode. |
| 18<br>RX_DMA_DTEST_EN | RX DMA and DTEST enable<br>This bit should be set to ensure that all of the rx_dig outputs related to DMA or DTEST are enabled. In mission mode this bit is intended to be cleared to reduce switching power. |
| 17<br>RX_SRC_RATE | RX Sample Rate Converter Rate Selections<br>0b - SRC is configured for a First Order Hold rate of 8/13.<br>1b - SRC is configured for a Zero Order Hold rate of 12/13. |
| 16<br>RX_SRC_EN | RX Sample Rate Converter Enable<br>0b - SRC is disabled.<br>1b - SRC is enabled. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 15<br>RX_DC_RESID_EN | DC Residual Enable<br>Enables DC Residual block<br>0b - DC Residual block is disabled.<br>1b - DC Residual block is enabled. |
| 14<br>RX_IQ_SWAP | RX IQ Swap<br>Enable swap of I/Q channels (does not affect ADC raw mode).<br>0b - IQ swap is disabled.<br>1b - IQ swap is enabled. |
| 13<br>RX_DCOC_CAL_EN | DCOC Calibration Enable<br>Enable DCOC warm-up calibration in receiver.<br>0b - DCOC calibration is disabled.<br>1b - DCOC calibration is enabled. |
| 12<br>RX_DCOC_EN | DCOC Enable<br>Enables DCO calculation and application of corrections.<br>0b - DCOC is disabled.<br>1b - DCOC is enabled. |

## A.2.3.3.3 Fields

| Field | Function |
|---|---|
| 31-24<br>AGC_DOWN_RSSI_THRESH | AGC DOWN RSSI Threshold<br>ADC RSSI threshold to take downward step (AGC slow). If the ADC RSSI measurment is higher than this threshold, a downward gain step can be taken. The ADC RSSI is measured directly from the ADC input and does not have any adjustment applied for gain settings, etc. In other words, it is a measurement of how saturated the digital bus is, similar to a dBFS measurement. |
| 23-16<br>AGC_UP_RSSI_THRESH | AGC UP RSSI Threshold<br>ADC RSSI threshold to take upward step (AGC slow). If the ADC RSSI measurment is below this threshold, an upward gain step can be taken. The ADC RSSI is measured directly from the ADC input and does not have any adjustment applied for gain settings, etc. In other words, it is a measurement of how saturated the digital bus is, similar to a dBFS measurement. |
| 15-12<br>AGC_DOWN_LNA_STEP_SZ | AGC_DOWN_LNA_STEP_SZ<br>Number of table steps for downward step (LNA) in AGC fast. |
| 11-8<br>AGC_DOWN_BBA_STEP_SZ | AGC_DOWN_BBA_STEP_SZ<br>Number of table steps for downward step (BBA) in AGC fast. |
| 7<br>AGC_UP_SRC | AGC Up Source<br>Criterion to use for upward AGC steps in SLOW state. For pdet_lo, a timing window is observed for no assertions of the LO peak detectors and then an upward step is made. If RSSI is selected, the current RSSI measurement is compared with the UP threshold to determine if an upward step is due.<br>0b - PDET LO<br>1b - RSSI |
| 6<br>AGC_UP_EN | AGC Up Enable<br>Allow AGC to take upward steps in the gain table in slow mode. |
| 5-4<br>AGC_FREEZE_SRC | AGC Freeze Source Selection<br>Select trigger source for entering freeze AGC (HOLD state).<br>00b - Access Address match (for active protocol)<br>01b - Preamble Detect (for active protocol)<br>10b - PD confirmation / Access Address match (for active protocol) |
| 3<br>AGC_FREEZE_EN | AGC Freeze Enable<br>Allow AGC to freeze (ie enter HOLD state). AGC can still go to hold mode if timer expires (same as fast expire) from slow mode. |
| 2-1<br>SLOW_AGC_SRC | Slow AGC Source Selection<br>Select trigger source for entering slow AGC. For address match and preamble detect, the trigger is generated by the PHY. If the Fast AGC expire timer is selected, when the timer expires, the AGC state machine will transition into SLOW.<br>00b - Access Address match (for active protocol)<br>01b - Preamble Detect (for active protocol)<br>10b - Fast AGC expire timer<br>11b - Reserved |
| 0<br>SLOW_AGC_EN | Slow AGC Enable<br>Allow AGC to enter into slow mode. |

| 15-12<br>LNA_USER_GAIN | LNA_USER_GAIN<br>User defined LNA gain index if user_lna_gain_en =1. |
| 11-8<br>— | Reserved. |
| 7-4<br>PRESLOW_DOWN_THRESH | PRESLOW_DOWN_THRESH<br>ADC RSSI threshold to take downward step in (AGC PRESLOW state). The actual threshold is computed as the programmed value minus 10, so the threshold assumes values in the range [-10,5]. If the ADC RSSI measurment is above this threshold, a downward gain step of 1 is taken. The ADC RSSI is measured directly from the ADC input and does not have any adjustment applied for gain settings, etc. In other words, it is a measurement of how saturated the digital bus is, similar to a dBFS measurement. |
| 3-0<br>PRESLOW_UP_THRESH | PRESLOW_UP_THRESH<br>ADC RSSI threshold to take upward step in (AGC PRESLOW state). The actual threshold is computed as the programmed value minus 15, so the threshold assumes values in the range [-15,0]. If the ADC RSSI measurment is below this threshold, an upward gain step of 1 is taken. The ADC RSSI is measured directly from the ADC input and does not have any adjustment applied for gain settings, etc. In other words, it is a measurement of how saturated the digital bus is, similar to a dBFS measurement. |

## A.2.3.40 DCOC Offset (DCOC_OFFSET_0 - DCOC_OFFSET_26)

### A.2.3.40.1 Offset

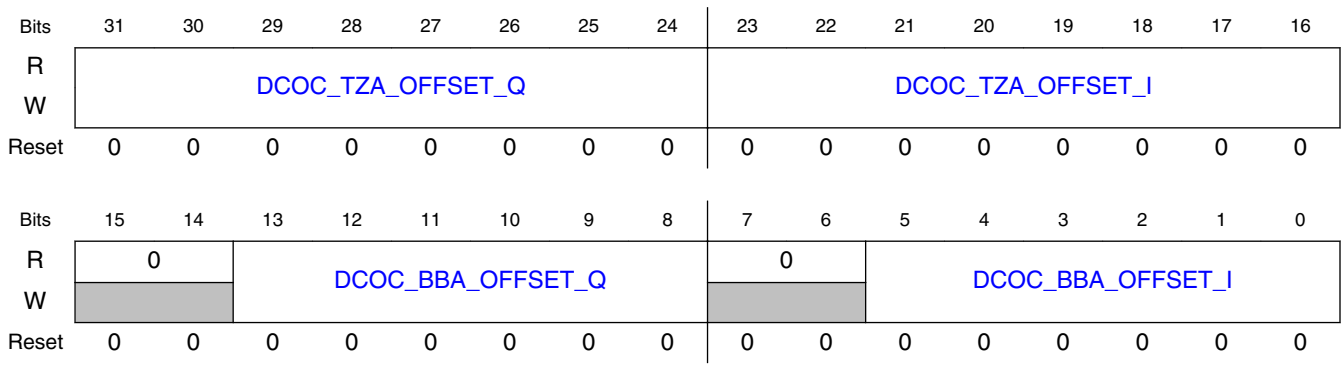
For a = 0 to 26:

| Register | Offset |
|---|---|
| DCOC_OFFSET_a | A0h + (a × 4h) |

### A.2.3.40.2 Function

DCOC Offset Registers. These registers can only be accessed when the radio oscillator clock is active.

### A.2.3.40.3 Diagram



### A.2.3.40.4 Fields

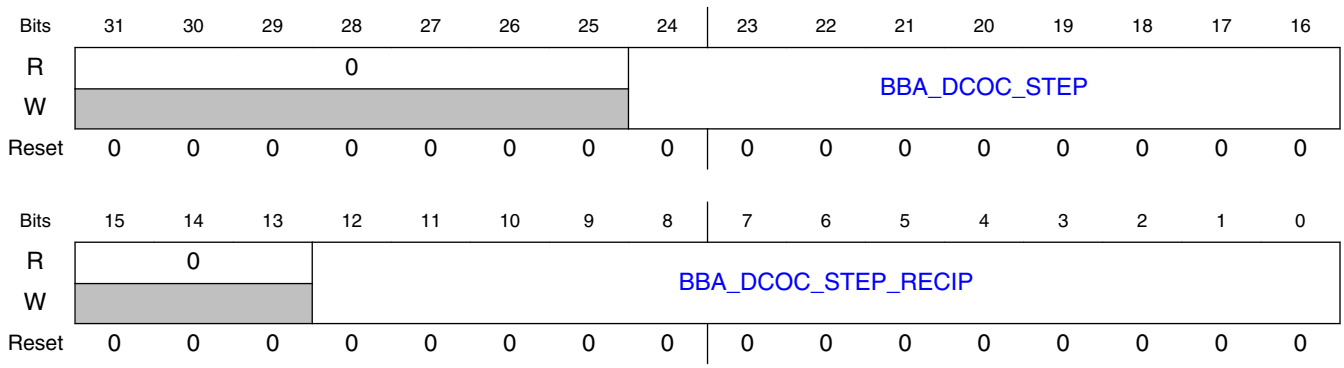
| Field | Function |
|---|---|
| 31-24<br>DCOC_TZA_OFFSET_Q | DCOC TZA Q-channel offset<br>DCOC TZA Q-channel offset. When RX_DCOC_CAL_EN=1, this table is generated by the DCOC during calibration. When RX_DCOC_CAL_EN=0, this table may optionally be written by software. |
| 23-16<br>DCOC_TZA_OFFSET_I | DCOC TZA I-channel offset<br>DCOC TZA I-channel offset. When RX_DCOC_CAL_EN=1, this table is generated by the DCOC during calibration. When RX_DCOC_CAL_EN=0, this table may optionally be written by software. |
| 15-14<br>— | Reserved. |
| 13-8<br>DCOC_BBA_OFFSET_Q | DCOC BBA Q-channel offset<br>DCOC BBA Q-channel offset. When RX_DCOC_CAL_EN=1, this table is generated by the DCOC during calibration. When RX_DCOC_CAL_EN=0, this table may optionally be written by software. |
| 7-6<br>— | Reserved. |
| 5-0<br>DCOC_BBA_OFFSET_I | DCOC BBA I-channel offset<br>DCOC BBA I-channel offset. When RX_DCOC_CAL_EN=1, this table is generated by the DCOC during calibration. When RX_DCOC_CAL_EN=0, this table may optionally be written by software. |

# A.2.3.41 DCOC BBA DAC Step (DCOC_BBA_STEP)

## A.2.3.41.1 Offset

| Register | Offset |
|---|---|
| DCOC_BBA_STEP | 10Ch |

## A.2.3.41.2 Diagram



## A.2.3.41.3 Fields

| Field | Function |
|---|---|
| 31-25<br>— | Reserved. |
| 24-16<br>BBA_DCOC_STEP | DCOC BBA Step Size<br>DCOC BBA Step Size (format: u6.3). This is the BBA DAC resolution in mV (1.2e3/32*63.44/120 = 19.83mV) times the ADC/decimator gain. This value is stored in the register with 3 fractional bits. |
| 15-13<br>— | Reserved. |
| 12-0<br>BBA_DCOC_STEP_RECIP | DCOC BBA Reciprocal of Step Size<br>DCOC BBA Reciprocal of Step Size (format: u.[00]13). This the reciprocal of the BBA DCOC STEP value. This value is stored as a 15 bit fraction (though only 13 bits are programmed). |

# A.2.3.42 DCOC TZA DAC Step 0 (DCOC_TZA_STEP_0)

## A.2.3.42.1 Offset

| Register | Offset |
|---|---|
| DCOC_TZA_STEP_0 | 110h |

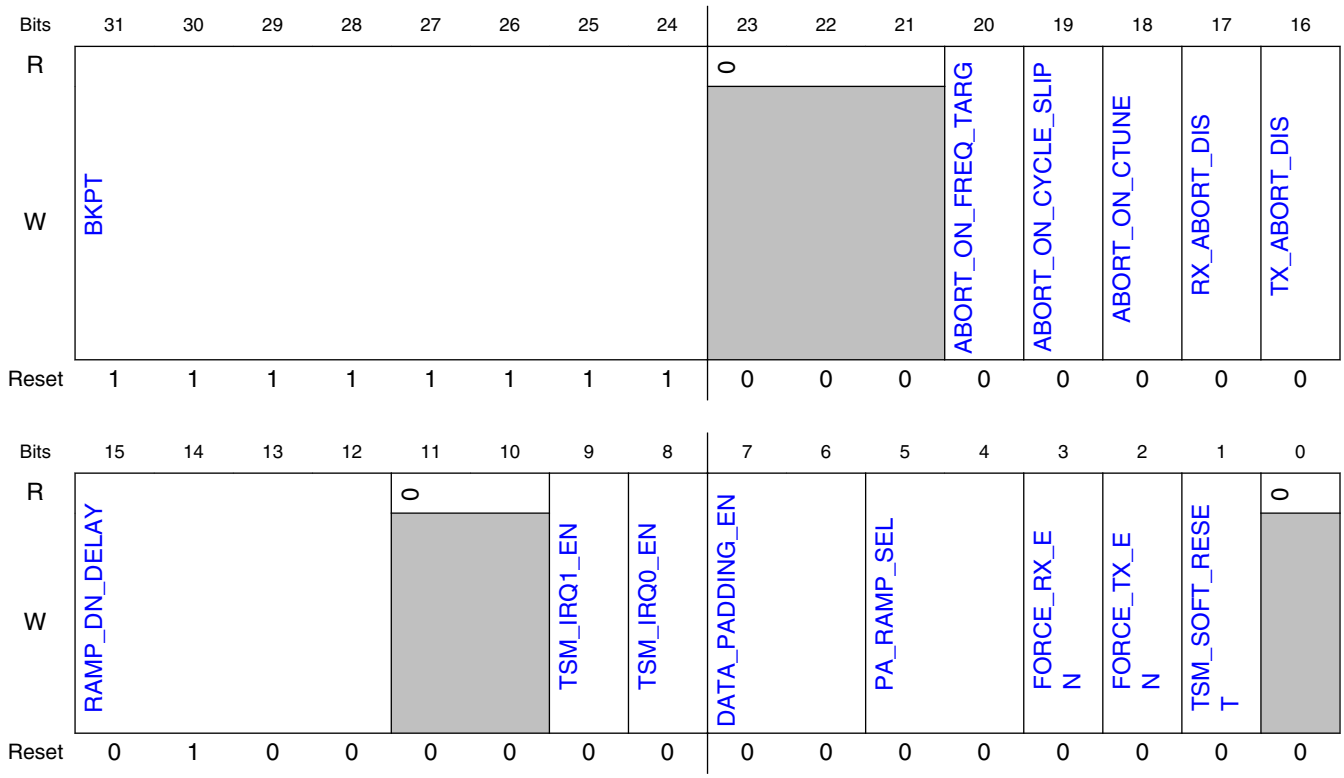
## A.2.4.2 TSM CONTROL (CTRL)

### A.2.4.2.1 Offset

| Register | Offset |
|---|---|
| CTRL | 0h |

### A.2.4.2.2 Diagram



### A.2.4.2.3 Fields

| Field | Function |
|---|---|
| 31-24<br>BKPT | TSM Breakpoint<br>Temporarily halt a TSM sequence during the warmup or warmdown phase. When the TSM counter matches the value of BKPT[7:0], breakpoint will take effect and the TSM counter will stop and hold its count. Breakpoint will remain in effect as long as BKPT[7:0] matches the TSM counter value. The TSM Breakpoint can be lifted by modifying the contents of this register. The default value of this register, 0xFF, is greater than the length of the longest possible sequence, so a breakpoint will never be triggered unless BKPT[7:0] is programmed to a value less than the length of sequence. |
| 23-21<br>— | Reserved |
| 20<br>ABORT_ON_FREQ_TARG | Abort On Frequency Target Lock Detect Failure<br>0b - don't allow TSM abort on Frequency Target Unlock Detect<br>1b - allow TSM abort on Frequency Target Unlock Detect |

### A.2.4.9.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-16<br>RECYCLE_COUNT2 | TSM RX Recycle Count 2<br>The RECYCLE_COUNT2[7:0] register determines the TSM count value to which the TSM "recycles" when, in LPPS mode, an LPPS power save cycle completes and the receiver is switched back on, necessitating a foreshortened RX warmup. The intention is for this register to be programmed to a TSM count value that is just prior to the assertion of rx_lna_en, but there are no restrictions on programming this register. An LPPS recycle is a command from the LPPS state machine to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there. |
| 15-8<br>RECYCLE_COUNT1 | TSM RX Recycle Count 1<br>The RECYCLE_COUNT1[7:0] register determines the TSM count value to which the TSM "recycles" when the 802.15.4 Sequence Manager (ZSM) state "RX_PAN1" is reached and the ZSM asserts tsm_recycle[1] to TSM. The intention is for this register to be programmed to a TSM count value such that |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | the TSM de-asserts, and then re-asserts its "pll_dig_en" output, to effectuate a Dual PAN on-the-fly channel change, but there are no restrictions on programming this register. An RX recycle is a command from ZSM to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there. A recycle will result from the expiration of the Dual PAN Dwell Timer, at which point an RF-channel change is required. This necessitates the desassertion and reassertion of pll_dig_en, hence the return to the WARMUP phase at the appropriate point. |
| 7-0<br>RECYCLE_COUNT0 | TSM RX Recycle Count 0<br>The RECYCLE_COUNT0[7:0] register determines the TSM count value to which the TSM "recycles" when the 802.15.4 Sequence Manager (ZSM) state "RX_CYC" is reached and the ZSM asserts tsm_recycle[0] to TSM. This register also determines the TSM count value to which the TSM recycles when the ZSM state RX_CCCA is reached because tsm_recycle[0] is also asserted in this state. This register also determines the TSM count value to which the TSM recycles when theGeneric_FSK Link Layer asserts a tsm_recycle to TSM. The intention is for this register to be programmed to a TSM count value such that the TSM re-asserts its "rx_init" output, but there are no restrictions on programming this register. An RX recycle is a command from any protocol engine to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there. A recycle will result from the reception of a packet with bad CRC or one which fails packet-filtering rules, or the end of a CCA operation in Continuous CCA mode which results in a channel indicating "busy". |

## A.2.4.10 TSM FAST WARMUP CONTROL 1 (FAST_CTRL1)

### A.2.4.10.1 Offset

| Register | Offset |
|---|---|
| FAST_CTRL1 | 28h |

### A.2.4.10.2 Function

This register provides enabling and control for Fast TSM Mode

### A.2.4.11.4 Fields

| Field | Function |
|---|---|
| 31-24<br>FAST_DEST_RX | Fast TSM RX "Jump-to" Point<br>During a Fast RX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, FAST_START_RX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump.<br>Example:<br>FAST_START_RX = 10<br>FAST_DEST_RX = 15 |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | The TSM will count as follows: … 7,8,9,15,16,17 … |
| 23-16<br>FAST_START_RX | Fast TSM RX "Jump-from" Point<br>During a Fast RX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_RX[7:0], thereby executing the jump. |
| 15-8<br>FAST_DEST_TX | Fast TSM TX "Jump-to" Point<br>During a Fast TX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, FAST_START_TX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump.<br>Example:<br>FAST_START_TX = 10<br>FAST_DEST_TX = 15<br>The TSM will count as follows: … 7,8,9,15,16,17 … |
| 7-0<br>FAST_START_TX | Fast TSM TX "Jump-from" Point<br>During a Fast TX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_TX[7:0], thereby executing the jump. |

## A.2.4.12 TSM_TIMING00 (TIMING00)

### A.2.4.12.1 Offset

| Register | Offset |
|---|---|
| TIMING00 | 30h |

### A.2.4.12.2 Function

This register contains the timing values to control the assertion and deassertion times for both TX and RX sequences for the BB_LDO_HF_EN TSM signal or signal group.

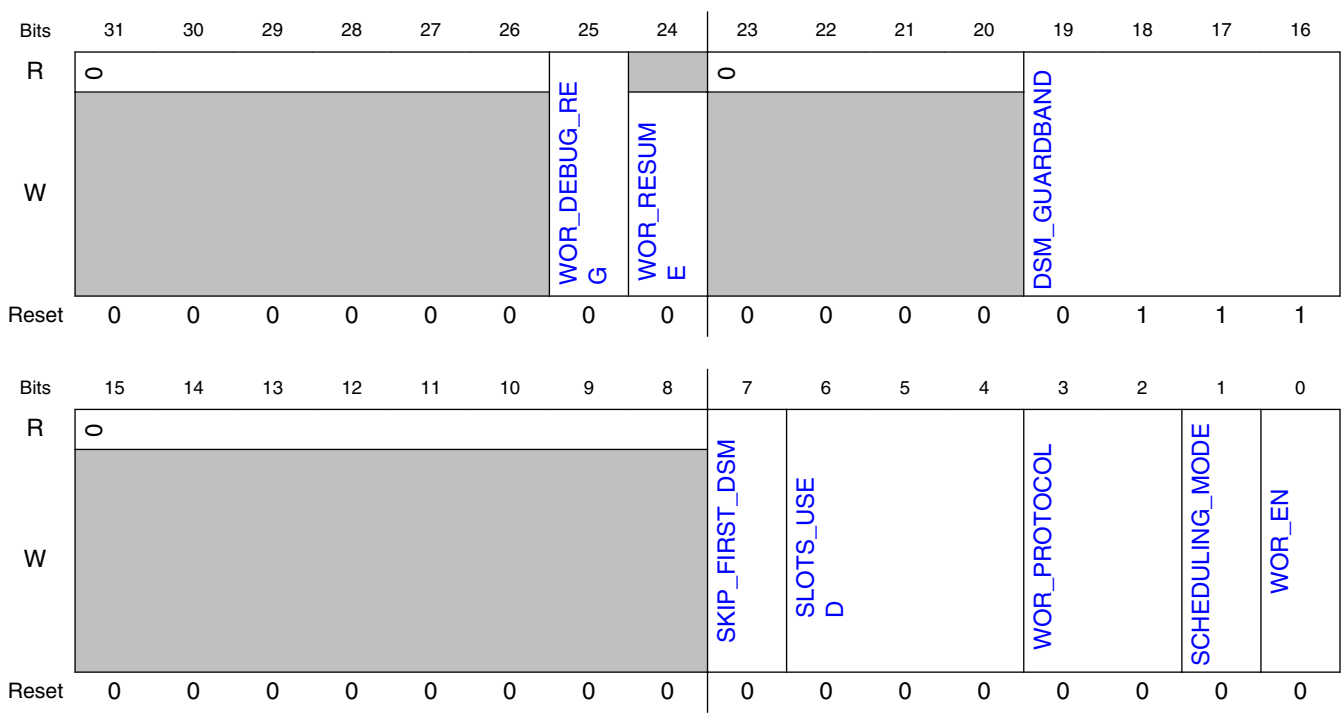
| 3Ch | SLOT 3 DESCRIPTOR (MSB) (SLOT3_DESC1) | 32 | RW | 0000_0000h |

## A.2.5.2 WAKE-ON-RADIO CONTROL REGISTER (WOR_CTRL)

### A.2.5.2.1 Offset

| Register | Offset |
|---|---|
| WOR_CTRL | 0h |

### A.2.5.2.2 Diagram



### A.2.5.2.3 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25<br>WOR_DEBUG_REG | WAKE-ON-RADIO Debug Register Enable<br>WOR_DEBUG_REG alters the readback values of several read-only registers, for debug purposes. The registers which have a different readback value when WOR_DEBUG_REG=1 are:<br>• TIMESTAMP1<br>• TIMESTAMP2<br>• TIMESTAMP3<br>See the description of those registers, which indicates their nominal, and debug-mode readback values. |
| 24<br>WOR_RESUME | WAKE-ON-RADIO Resume<br>This bit causes the WOR state machine to advance from its WAIT_RESUME state. The state machine will enter WAIT_RESUME on any slot in which an MCU wakeup occurs (based on descriptor WAKE_ON_COMPLETE and/or WAKE_ON_TIMEOUT fields). After waking up (interrupting) the MCU, WOR will hold in WAIT_RESUME, giving software whatever time it needs to complete all required activity. Software then sets WOR_RESUME=1, causing the state machine to break out of WAIT_RESUME, advance to the next slot, and enter DSM. This bit is write-only. Writes of '0' have no effect. Readback value is always 0. Setting WOR_RESUME has no effect if WOR state machine is not in WAIT_RESUME.<br>1: Causes WOR state machine to advance out of WAIT_RESUME state, and begin the next slot<br>0: No effect. |
| 23-20<br>— | Reserved |
| 19-16<br>DSM_GUARDBAND | WAKE-ON-RADIO DSM Guardband<br>Determines the number of 32.768KHz clock cycles of guardband used by the WOR state machine in computing duration of the DSM for any slot. Increasing this setting by 1 LSB causes WOR to shorten the DSM duration by 1 32.768KHz clock cycle. This guardband takes into account synchronization, and other, delays within the RSIM, and ensures that DSM will wakeup will never occur "too late" with respect to the slot descriptor's START_TIME field. The current default setting is 7. Values below 7 should not be used. |
| 15-8<br>— | Reserved |
| 7<br>SKIP_FIRST_DSM | WAKE-ON-RADIO Skip DSM On First Slot<br>Setting this bit causes the WOR State Machine to skip the DSM entry/exit cycle for the first SLOT (SLOT 0) encountered after setting SLOTS_USED > 0, regardless of the setting of the NO_DSM field of the slot's descriptor. Subsequent slots, including SLOT 0 when it is re-encountered, will enter/exit DSM based on the descriptor NO_DSM. The SKIP_FIRST_DSM feature is useful, especially in Constant Interval Scheduling mode, when the desire is to begin RF operations immediately (at the start of the first EVENT_INTERVAL), as programmed in the descriptor START_TIME, without waiting out a DSM cycle<br>1: WOR skips DSM entry/exit on the first SLOT 0 after setting SLOTS_USED > 0, regardless of descriptor NO_DSM<br>0: WOR always obeys descriptor NO_DSM<br>**Note:** SKIP_FIRST_DSM should not be used if the SLOT 0 descriptor FUNCTION is set to "NO_RF". |
| 6-4<br>SLOTS_USED | WAKE-ON-RADIO Number Of Slots Used |

*Table continues on the next page...*

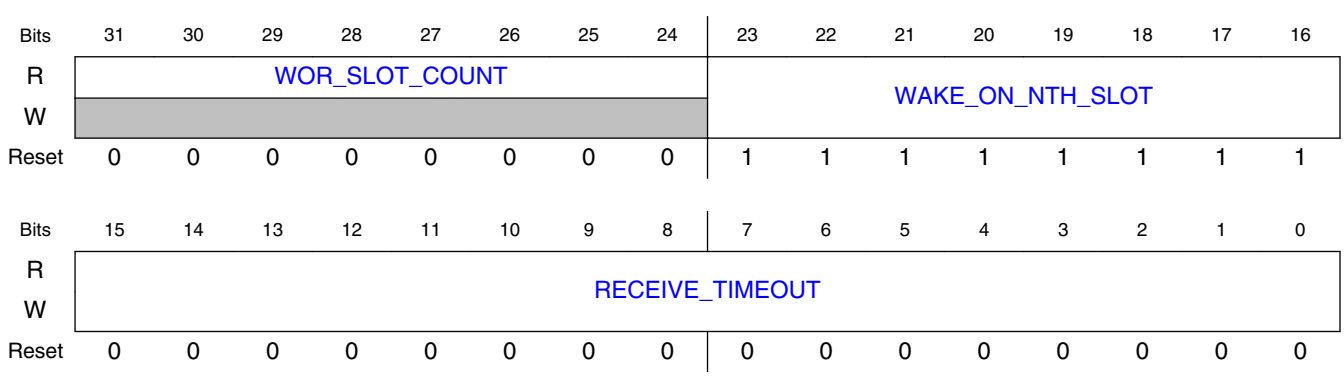
| Field | Function |
|---|---|
| | Determines the number of timeslots used to schedule future DSM and RF operations, for either scheduling mode. Up to 4 timeslots can be enabled. Increasing the number of timeslots used decreases average power consumption. Valid values are 0 ≤ SLOTS_USED ≤ 4. The SLOTS_USED register is the mechanism by which the WOR state machine is activated and de-activated. Setting SLOTS_USED to 0 disables the WOR state machine and puts the WOR functionality in an IDLE state. A subsequent write of a non-zero value to SL0TS_USED activates the state machine, initializing to SLOT 0, and starts a new WOR "session". |
| 3-2<br>WOR_PROTOCOL | WAKE-ON-RADIO Protocol Selector<br>Assigns the Wake-On-Radio function to one of the radio's protocol engines.<br>0: Not assigned<br>1: Assigned to 802.15.4<br>2: Assigned to GENERIC_FSK<br>3: Reserved |
| 1<br>SCHEDULING_MODE | WAKE-ON-RADIO Scheduling Mode<br>Determines the scheduling mode used by the WOR HW to organize future DSM and RF operations.<br>1: Constant-Interval Scheduling mode.<br>0: Timeslot Scheduling mode. |
| 0<br>WOR_EN | WAKE-ON-RADIO Enable<br>Wake-On-Radio Master Enable. In addition to enabling the block function, this bit gates the clock to the WOR module. This bit should be set, and remain set, whenever WOR is in use.<br>1: Wake-On-Radio is enabled.<br>0: Wake-On-Radio is disabled, and clocks to the module are gated off. |

## A.2.5.3 WAKE-ON-RADIO TIMEOUT REGISTER (WOR_TIMEOUT)

### A.2.5.3.1 Offset

| Register | Offset |
|---|---|
| WOR_TIMEOUT | 4h |

### A.2.5.3.2 Diagram



#### A.2.5.3.3 Fields

| Field | Function |
|---|---|
| 31-24<br>WOR_SLOT_COUNT | WAKE-ON-RADIO Absolute Slot Count<br>This read-only register indicates the number of slots that have elapsed since SLOTS_USED was set to a non-zero value to activate the WOR state machine. WOR_SLOT_COUNT can be considered an Absolute Slot Number. WOR_SLOT_COUNT counts slots up to a maximum of 255. If the number of elapsed slots exceeds 255, WOR_SLOT_COUNT will remain at 255. WOR_SLOT_COUNT is "sticky" in the sense that it will hold its value after the WOR session has ended by setting SLOTS_USED=0; WOR_SLOT_COUNT will clear to 0 when a new WOR session is started by taking SLOTS_USED from 0 to any non-zero value. |
| 23-16<br>WAKE_ON_NTH_SLOT | WAKE-ON-RADIO Force Wake On Nth Slot<br>If the WAKE_ON_COMPLETE bit is not set in any descriptor, WOR will not awaken the MCU even after a number of good packets are received. Additionally, if WAKE_ON_TIMEOUT is also not set in any descriptor, WOR will not wake up the MCU under any circumstances, which would not be desirable. This register provides a backup method to awaken the MCU, after *N+1* slots have elapsed, where *N* = WAKE_ON_NTH_SLOT[7:0], regardless of whether or not any good packets have been received, and regardless of the setting of the WAKE_ON_* descriptor bits. Applies to Constant-Interval Mode only. (For Timeslot mode, at least one slot *must* have a WAKE_ON_* bit set in its descriptor). |
| 15-0<br>RECEIVE_TIMEOUT | WAKE-ON-RADIO Receive Timeout<br>For any RX slot, determines how long RX stays on after the descriptor's START_TIME is reached, in microseconds. A timeout is declared if a good packet is not received before the expiration of this time period (START_TIME + RECEIVE_TIMEOUT + WINDOW_WIDENING). Applies to TIMESLOT mode only. |

### A.2.5.4 WAKE-ON-RADIO TIMESTAMP 1 (TIMESTAMP1)

#### A.2.5.4.1 Offset

| Register | Offset |
|---|---|
| TIMESTAMP1 | 8h |

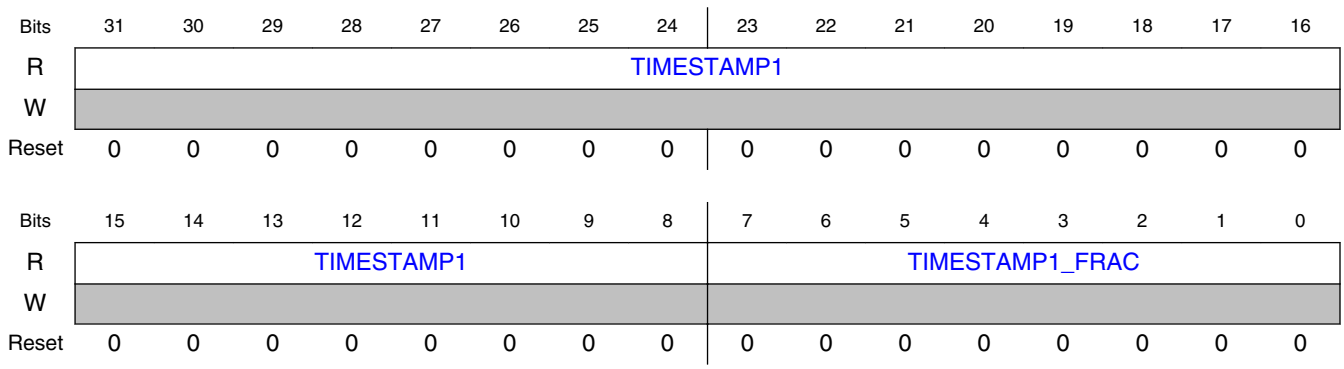
#### A.2.5.4.2 Function

Timestamp captured for a packet received on SLOT 1. During SLOT 1, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP1 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 1.

**Note:** Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

**Note:** If WOR_DEBUG=1, this register instead reads back WOR_ADDBACK[27:0], which is the number of microseconds that the WOR state machine "added back" to the assigned Link Layer's Event Timer, to correct for the amount of time that Link Layer was in DSM (Event Timer frozen). The WOR_ADDBACK readback value applies to the most recently-completed DSM cycle.

### A.2.5.4.3 Diagram



### A.2.5.4.4 Fields

| Field | Function |
|---|---|
| 31-8<br>TIMESTAMP1 | WAKE-ON-RADIO TIMESTAMP1<br>Timestamp captured for a packet received on SLOT 1. During SLOT 1, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP1 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 1. |
| 7-0<br>TIMESTAMP1_FRAC | WAKE-ON-RADIO TIMESTAMP 1 Fractional<br>TIMESTAMP1_FRAC[7:4] applies to 802.15.4 only. For other protocols, this field can be ignored. For 802.15.4, the captured timestamp represents a 28-bit number with 24 Integer bits and 4 Fractional bits. TIMESTAMP1_FRAC[7:4] is the fractional component, which appears to the right of the decimal point. The fractional component has been provided to allow for microsecond accuracy in capturing packet reception instants. The lower 4 bits, TIMESTAMP1_FRAC[3:0], shall always read back '0000'. |

## A.2.5.5 WAKE-ON-RADIO TIMESTAMP 2 (TIMESTAMP2)

### A.2.5.5.1 Offset

| Register | Offset |
|---|---|
| TIMESTAMP2 | Ch |

### A.2.5.5.2 Function

Timestamp captured for a packet received on SLOT 2. During SLOT 2, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP2 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 2.

**Note:** Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

**Note:** If WOR_DEBUG=1, this register instead reads back WW_DSM_ADJUST[19:0], which is the accumulated DSM component of the Window Widening adjustment value that is used to offset the start and end of receive operations during the timeslot.

### A.2.5.5.3 Diagram

### A.2.5.5.4 Fields

| Field | Function |
|---|---|
| 31-8<br>TIMESTAMP2 | WAKE-ON-RADIO TIMESTAMP2 |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | Timestamp captured for a packet received on SLOT 2. During SLOT 2, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP2 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 2. |
| 7-0<br>TIMESTAMP2_FRAC | WAKE-ON-RADIO TIMESTAMP 2 Fractional<br>TIMESTAMP2_FRAC[7:4] applies to 802.15.4 only. For other protocols, this field can be ignored. For 802.15.4, the captured timestamp represents a 28-bit number with 24 Integer bits and 4 Fractional bits. TIMESTAMP2_FRAC[7:4] is the fractional component, which appears to the right of the decimal point. The fractional has been provided to allow for microsecond accuracy in capturing packet reception instants. The lower 4 bits, TIMESTAMP2_FRAC[3:0], shall always read back '0000'. |

## A.2.5.6 WAKE-ON-RADIO TIMESTAMP 3 (TIMESTAMP3)

### A.2.5.6.1 Offset

| Register | Offset |
|---|---|
| TIMESTAMP3 | 10h |

### A.2.5.6.2 Function

Timestamp captured for a packet received on SLOT 3. During SLOT 3, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP3 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 3.

**Note:** Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

**Note:** If WOR_DEBUG=1, this register instead reads back WW_RUN_ADJUST[19:0], which is the accumulated "run time" component of the Window Widening adjustment value that is used to offset the start and end of receive operations during the timeslot.

## A.2.5.7.3 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-20<br>WOR_STATE | WAKE-ON-RADIO Current State<br>This read-only register reflects the instantaneous state of the Wake-On-Radio state vector. A listing of the Wake-On-Radio states, along with the associated state vector, is below:<br>• DISABLED (0)<br>• COMP_DURATION1 (1)<br>• COMP_DURATION2 (2)<br>• SLEEP_REQ (3)<br>• IN_DSM (4)<br>• COMP_ADDBACK (5)<br>• COMP_WW (6)<br>• WAIT_SEQ_START (7)<br>• WAIT_SEQ_END (8)<br>• WAIT_RESUME (9) |
| 19<br>— | Reserved |
| 18 | WAKE-ON-RADIO Early DSM Exit Flag |

*Table continues on the next page...*

| Field | Function |
|---|---|
| WOR_DSM_EXIT_FLAG | This read-only flag indicates that, in the current slot, an event external to the radio has forced an early exit from DSM, before the WOR-computed DSM duration has expired. The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to an "DSM Early Exit wakeup", as described by the conditions above. The WOR_IRQ will become set, and the MCU awakened, even if the slot descriptor's WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits are both set to 0. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "DSM Early Exit wakeup", software must set WOR_RESUME to advance to the next slot. |
| 17<br>WOR_MAX_SLOT_FLAG | WAKE-ON-RADIO Maximum Slot Count Reached Flag<br>This read-only flag indicates that, in the current slot, the following conditions have all been met:<br>1. SCHEDULING_MODE is set to 1 (Constant Interval)<br>2. WOR_SLOT_COUNT[7:0] (absolute slot number) has matched WAKE_ON_NTH_SLOT[7:0]<br><br>The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to a "Maximum Slot Reached wakeup", as described by the conditions above. The WOR_IRQ will become set, and the MCU awakened, even if the slot descriptor's WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits are both set to 0. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "Maximum Slot Reached wakeup", software must set WOR_RESUME to advance to the next slot |
| 16<br>WOR_NO_RF_FLAG | WAKE-ON-RADIO NO_RF Slot Flag<br>This read-only flag indicates that, in the current slot, the following conditions have all been met:<br>1. The slot's descriptor FUNCTION is set to "NO_RF"<br>2. A DSM cycle has just completed (exited) during the slot<br>3. The slot's descriptor WAKE_ON_COMPLETE bit was set (or the WOR_SLOT_COUNT matched WAKE_ON_NTH_SLOT), requiring an MCU wakeup.<br><br>The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to a "NO_RF wakeup", as described by the conditions above. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "NO_RF wakeup", software must set WOR_RESUME to advance to the next slot |
| 15-14<br>— | Reserved |
| 13-12<br>SLOT | WAKE-ON-RADIO Current Slot<br>This read-only register reflects the instantaneous state of the WOR's SLOT counter, indicating which SLOT is currently in service by the WOR state machine. Software can determine which of the 4 descriptors is currently in effect based on this register. |
| 11-9<br>TIMESTAMP3_STS | WAKE-ON-RADIO Timestamp 3 Status<br>This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP3 register contents:<br><br>**TIMESTAMP3_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occured during the current, or most recent, SLOT 3 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP3 register.<br>**TIMESTAMP3_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 3 RX operation<br>**TIMESTAMP3_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 3 RX operation |
| 8-6<br>TIMESTAMP2_STS | WAKE-ON-RADIO Timestamp 2 Status<br>This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP2 register contents: |

*Table continues on the next page...*

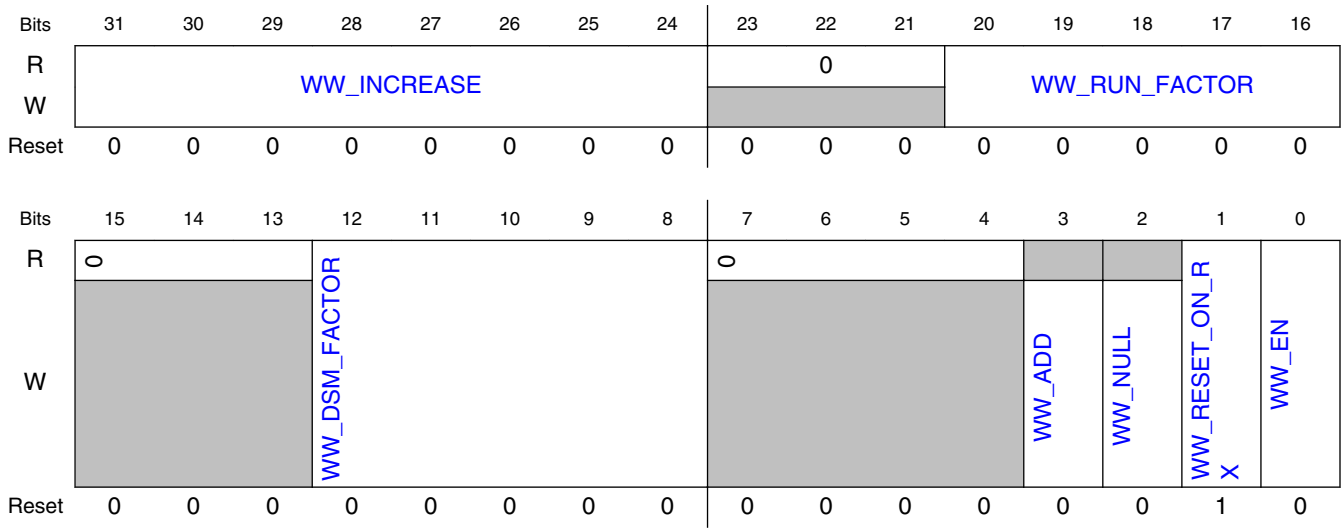
| Field | Function |
|---|---|
| | **TIMESTAMP2_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occured during the current, or most recent, SLOT 2 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP2 register.<br>**TIMESTAMP2_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 2 RX operation<br>**TIMESTAMP2_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 2 RX operation |
| 5-3<br>TIMESTAMP1_STS | WAKE-ON-RADIO Timestamp 1 Status<br>This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP1 register contents:<br>**TIMESTAMP1_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occured during the current, or most recent, SLOT 1 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP1 register.<br>**TIMESTAMP1_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 1 RX operation<br>**TIMESTAMP1_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 1 RX operation |
| 2-0<br>TIMESTAMP0_STS | WAKE-ON-RADIO Timestamp 0 Status<br>This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP0 register contents:<br>**TIMESTAMP0_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occured during the current, or most recent, SLOT 0 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP0 register.<br>**TIMESTAMP0_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 0 RX operation<br>**TIMESTAMP0_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 0 RX operation<br>**Note:** TIMESTAMP0 register (timestamp for SLOT 0) is captured into the assigned Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space. However TIMESTAMP0_STS[2:0], which applies to that register, resides in WOR (XCVR) address space. |

## A.2.5.8 WINDOW-WIDENING CONTROL REGISTER (WW_CTRL)

### A.2.5.8.1 Offset

| Register | Offset |
|---|---|
| WW_CTRL | 18h |

## A.2.5.8.2 Diagram



## A.2.5.8.3 Fields

| Field | Function |
|---|---|
| 31-24<br>WW_INCREASE | Window-widening Manual Increase Amount<br>This register allows software to increase (add to) the HW-computed window-widening adjustment. This incremental amount is added whenever a 1 is written to the WW_ADD register bit. The units of WW_INCREASE[7:0] are microseconds. It is an unsigned (positive only) addition. This is a one-time only addition (whever WW_ADD is set), and the window-widening adjustment value continues to accumulate after the increment. The capability to add to the HW-computed adjustment is intended for contingency or debug purposes only, as the HW-computed value should be accurate. |
| 23-21<br>— | Reserved |
| 20-16<br>WW_RUN_FACTOR | Window-widening Runtime Factor<br>Determines the rate of Window-widening that applies during RUNTIME (Reference Oscillator On). This setting should be based on the combined Sleep Clock Accuracy (SCA) of the Master + Slave. Each LSB is worth 64ppm of SCA drift. Valid values are 0 -> 16. The lower this factor, the greater the power savings. |
| 15-13<br>— | Reserved |
| 12-8<br>WW_DSM_FACTOR | Window-widening DSM Factor<br>WW_DSM_FACTOR[4:0]: Determines the rate of Window-widening that applies during DSM (Reference Oscillator Off). This setting should be based on the combined Sleep Clock Accuracy (SCA) of the Master + Slave. Each LSB is worth 64ppm of combined SCA drift. Valid values are 0 -> 16. The lower this factor, the greater the power savings. |
| 7-4<br>— | Reserved |
| 3<br>WW_ADD | Window-widening Add Command |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This bit allows software to increase (add to) the HW-computed window-widening adjustment. The incremental amount is determined by the WW_INCREASE[7:0] register. The capability to add to the HW-computed adjustment is intended for contingency or debug purposes only, as the HW-computed value should be accurate. This bit is write-only. Readback value is always 0.<br>1: Increase the HW-computed window-widening adjustment by amount WW_INCREASE[7:0].<br>0: No effect |
| 2<br>WW_NULL | Window-widening Null Command<br>This bit allows software to reset the accumulated window-widening adjustment to 0. This bit is write-only. Readback value is always 0.<br>1: Reset the accumulated window-widening adjustment to 0.<br>0: No effect. |
| 1<br>WW_RESET_ON_RX | Window-widening Reset on Received Good Packet<br>Enable a good packet reception to reset the accumulated window-widening adjustment to 0. A good packet is one that passes CRC verification, and passes packet filtering rules. Filtering rules vary by protocol.<br>1: Allow good packet reception to reset window-widening adjustment. This is the default.<br>0: Block good packet reception from resetting window-widening adjustment. |
| 0<br>WW_EN | Window-widening Enable<br>Master Enable for Window Widening. Typically, only slave devices employ window widening.<br>1: Window Widening is enabled.<br>0: Window Widening is disabled. |

## A.2.5.9 FREQUENCY HOP CONTROL REGISTER (HOP_CTRL)

| 18<br>XTAL_READY | RF Osciallator Xtal Ready<br>Oscillator warmup count complete.<br>0b - Indicates that the RF Oscillator is disabled or has not completed its warmup.<br>1b - Indicates that the RF Oscillator has completed its warmup count and is ready for use. |
| 17<br>RIF_LL_ACTIVE | Link Layer Active Indication<br>Reflects the state of the BTLE “Link Layer Active” status bit. RIF_LL_ACTIVE is to be used by the host as an 'early' indication to prevent host to do any operations while BTLE IP is doing transceiver operations, so as to reduce the peak power and noise. |
| 16 | BTLE System Clock Request |

*Table continues on the next page...*

| Field | Function |
|---|---|
| BTLE_SYSCLK_REQ | Reflects the state of the BTLE oscillator request signal. BTLE_SYSCLK_REQ is the BTLE control for the RF Oscillator. BTLE will deassert this signal upon entering DSM (deep sleep mode) to request oscillator turn-off, and will re-assert it prior to exiting DSM. The turn-on leadtime on this signal for exiting DSM, is programmable with the BTLE block. This read-only bit can thus be queried to ascertain the power-state of BTLE. |
| 15-14<br>— | Reserved |
| 13<br>TX_MODE | Transmit Mode<br>Indicates an TX transceiver operation is in progress. |
| 12<br>RX_MODE | Receive Mode<br>Indicates an RX transceiver operation is in progress. |
| 11-8<br>PLL_SEQ_STATE | PLL Sequence State<br>Reflects the state of the PLL digital state machine.<br>0000b - PLL OFF<br>0010b - CTUNE<br>0011b - CTUNE_SETTLE<br>0110b - HPMCAL1<br>1000b - HPMCAL1_SETTLE<br>1010b - HPMCAL2<br>1100b - HPMCAL2_SETTLE<br>1111b - PLLREADY |

| 0<br>BLE_RELINQUISH | BLE Relinquish Control<br>This bit forces the BLE protocol engine to immediately relinquish access to the RF Channel, in favor of another protocol with higher arbitration priority. BLE is denied RF channel access by blocking BLE access to the TSM; when this bit is subsequently cleared, BLE access is restored. |

## A.2.7.5 OVERWRITE VERSION (OVERWRITE_VER)

### A.2.7.5.1 Offset

| Register | Offset |
|---|---|
| OVERWRITE_VER | Ch |

### A.2.7.5.2 Function

The Overwrite Version allows software to store a version number of trim and calibration values which are used to overwrite the chip default values in the registers. Typically,

software would perform the overwrite of the defaults in transceiver registers and then write the version number from the file containing the overwrite values into this register.

**NOTE**

This register has no hardware connections, it is simply a designated storage location for a version number.

### A.2.7.5.3 Diagram

| 7-0<br>OVERWRITE_VER | Overwrite Version Number.<br>Points to the version number of the overwrites.h file used to initialize the device; can be used by software to identify a version-controlled set of non-default values to be written into the transceiver's register map. |

## A.2.7.6 DIGITAL TEST MUX CONTROL (DTEST_CTRL)

### A.2.7.6.1 Offset

| Register | Offset |
|---|---|
| DTEST_CTRL | 10h |

### A.2.7.6.2 Function

Digital Test Control. Allows selection and enablement of a page of DTEST signals to appear on the SoC DTEST pins.

**NOTE**

This register configures only the transceiver for DTEST mode; since DTEST pads on the SoC are multiplexed with other functions, SoC Port Pin programming is also required for each DTEST output

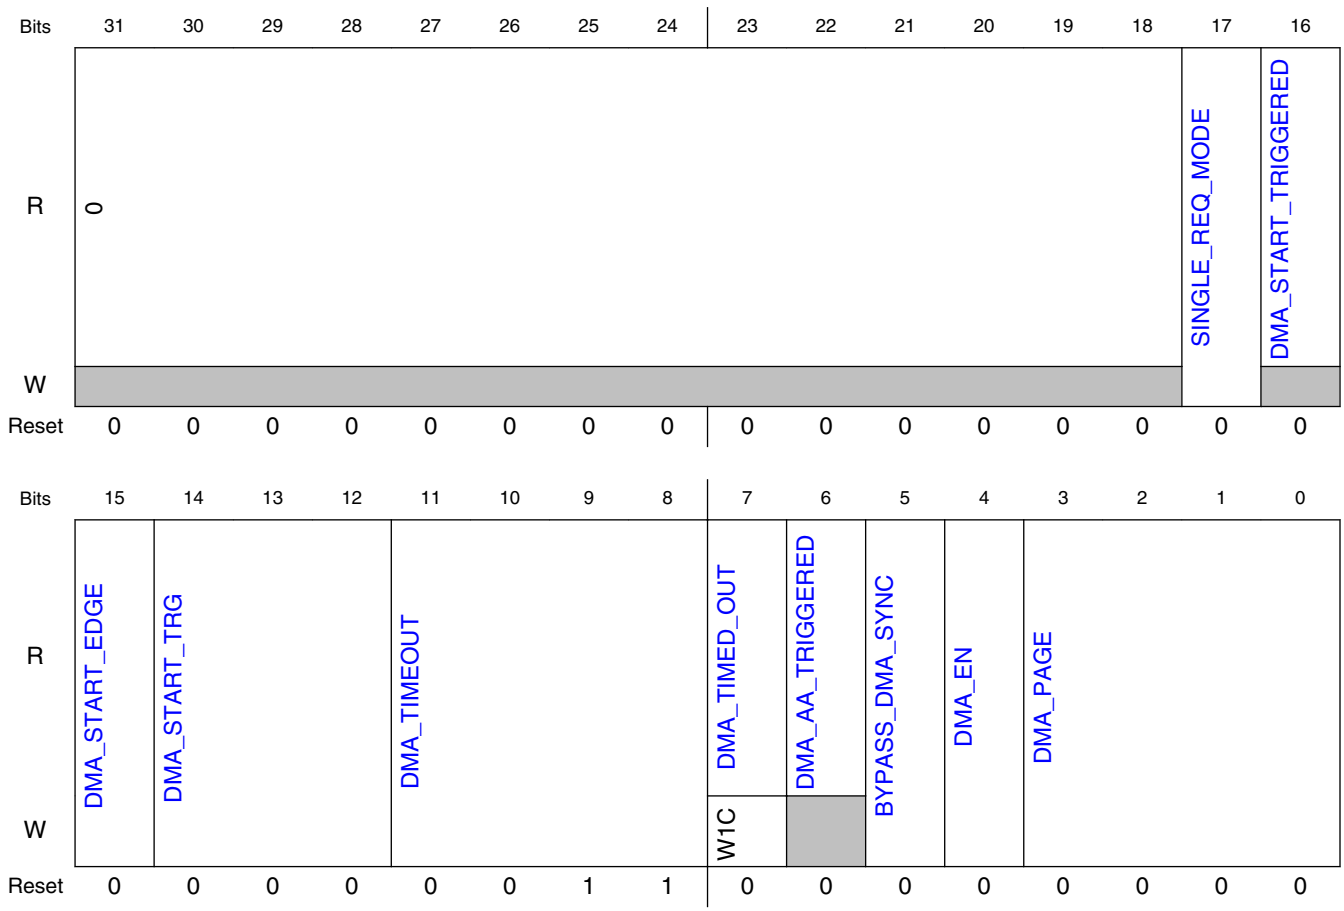
## A.2.7.7 TRANSCEIVER DMA CONTROL (DMA_CTRL)

## A.2.7.7.1 Offset

| Register | Offset |
|---|---|
| DMA_CTRL | 14h |

## A.2.7.7.2 Diagram



## A.2.7.7.3 Fields

| Field | Function |
|---|---|
| 31-18<br>— | Reserved |
| 17<br>SINGLE_REQ_MODE | DMA Single Request Mode<br>Configures the transceiver to transfer the entire block of DMA data with only a single initial request (ipd_req_radio_rx). The DMA2 controller must be configured accordingly. In this mode, the transceiver will use **ips_xfr_wait** to pace the individual transactions. Single Request Mode should not be used with |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | DMA Pages 11, 12, or 13, because the data rate is too low and therefore ips_xfr_wait would remain assserted for excessively long periods.<br>0b - Disable Single Request Mode. The transceiver will assert ipd_req_radio_rx whenever it has a new sample ready for transfer.<br>1b - Enable Single Request Mode. A single initial request by the transceiver will transfer the entire DMA block of data |
| 16<br>DMA_START_TRIGGERED | DMA Start Trigger Occurred<br>This read-only status bit becomes set, when, during a DMA session (DMA_PAGE > 0), the trigger source selected by DMA_START_TRG[2:0] occurs, with the edge sensitivity selected by DMA_START_EDGE. To clear this bit, set DMA_PAGE=0. |
| 15<br>DMA_START_EDGE | DMA Start Trigger Edge Selector<br>DMA_START_EDGE selects the edge sensitivity (rising or falling) of the selected start-trigger.<br>0b - Trigger fires on a rising edge of the selected trigger source<br>1b - Trigger fires on a falling edge of the selected trigger source |
| 14-12<br>DMA_START_TRG | DMA Start Trigger Selector<br>The DMA Start Trigger, if desired, can be selected from the sources in the following table:<br>0: no trigger<br>1: FSK PHY: gfsk_preamble_found<br>2: FSK PHY: aa_sfd_matched<br>3: ZBDEMOD: rx_preamble_det<br>4: ZBDEMOD: rx_sfd_detect<br>5: RXDIG: agc_dcoc_gain_chg<br>6: TSM: rx_dig_en<br>7: TSM: tsm_spare2_en |
| 11-8<br>DMA_TIMEOUT | DMA Timeout<br>In DMA Single Request Mode, adverse consequences may result if the transceiver's ips_xfr_wait signal is asserted for an excessively long period of time, which could occur due to mis-programming of the DMA2 controller, and/or the transceiver itself. DMA Timeout forces the transceiver's ips_xfr_wait low after *N* microseconds and sets the **DMA_TIMED_OUT** status bit, where *N*=DMA_TIMEOUT. DMA_TIMEOUT is only relavent when SINGLE_REQ_MODE=1, otherwise the transceiver does not assert ips_xfr_wait. |
| 7<br>DMA_TIMED_OUT | DMA Transfer Timed Out<br>Status bit indicates that the transceiver DMA, while operating in Single Request Mode, asserted ips_xfr_wait for a period in excess of the programmed **DMA_TIMEOUT** setting, resulting in a timeout condition where the transceiver has forced ips_xfr_wait low. After a timeout, before resuming DMA operations, set DMA_PAGE=0 to disable DMA, and write 1 to this bit to clear it.<br>0b - A DMA timeout has not occurred<br>1b - A DMA timeout has occurred in Single Request Mode since the last time this bit was cleared |
| 6<br>DMA_AA_TRIGGERED | DMA Access Address triggered<br>This status bit becomes set when the PHY indicates that a Network Address match has occurred. In some cases it may be desirable to delay the start of DMA transfers until such a match occurs; in such cases, software can poll this bit, and once it becomes set, immediately select the desired DMA_PAGE to initiate DMA transfers. This bit is intended for use with DMA_PAGE=13, but is available on all pages. Its usage is optional. |
| 5<br>BYPASS_DMA_SYNC | Bypass External DMA Synchronization<br>When using transceiver DMA with SINGLE_REQ_MODE=0, synchronization external to the transceiver must be bypassed in order to minimize bus access latency. Using DMA in this mode also requires that the MCU and transceiver both are configured to operate in the RF Oscillator clock domain.<br>0b - Don't Bypass External Synchronization. Use this setting if SINGLE_REQ_MODE=1.<br>1b - Bypass External Synchronization. This setting is mandatory if SINGLE_REQ_MODE=0. |
| 4 | DMA Enable |

*Table continues on the next page...*

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 0: no trigger<br>1: FSK PHY: gfsk_preamble_found<br>2: FSK PHY: aa_sfd_matched<br>3: ZBDEMOD: rx_preamble_det<br>4: ZBDEMOD: rx_sfd_detect<br>5: RXDIG: agc_dcoc_gain_chg<br>6: TSM: rx_dig_en<br>7: TSM: tsm_spare2_en |
| 11<br>DBG_SOFT_INFO_SEL | Packet RAM Debug PHY Soft Info Output Selector<br>When acquiring data in Packet RAM Debug Mode with the DBG_PAGE=DMDSOFT page, this bit selects the signal from the PHY used to capture the soft decision data.<br>0b - PHY output bit_valid_int is used to capture soft decision data<br>1b - PHY output demod_vout is used to capture soft decision data |
| 10<br>DBG_AA_TRIGGERED | Packet Ram Debug Access Address triggered<br>This status bit becomes set when the PHY indicates that a Network Address match has occurred. In some cases it may be desirable to delay the start of Packet RAM debug transfers until such a match occurs; in such cases, software can poll this bit, and once it becomes set, immediately select the desired DBG_PAGE to initiate data transfers to Packet RAM. This bit is intended for use with DBG_PAGE=13, but is available on all pages. Its usage is optional. |
| 9-8<br>DBG_RAM_FULL | DBG_RAM_FULL[1:0]<br>Status Bits indicating that Packet RAM0 (or RAM1) is full, and the Packet RAM Debug engine has attempted to write another word to that RAM. This, and any subsequent write attempts, will not alter the contents of the RAM, once it has reached capacity. Set DBG_PAGE=0 to clear the DBG_RAM_FULL[1:0] bits.<br>**NOTE:** If a Debug Stop Trigger is selected (DBG_STOP_TRG > 0), writes to RAM do not stop when DBG_RAM_FULL bit(s) become set; instead, writes continue after an address wrap-around to 0, and will continue indefinitely until either a stop trigger condition occurs, or the debug session is ended by taking DBG_PAGE=0. The DBG_RAM_FULL[1:0] remain a valid indicator that the RAM(s) has reached full status at least once during the debug session.<br>00b - Neither Packet RAM0 nor RAM1 is full<br>1xb - Packet RAM1 has been filled to capacity.<br>x1b - Packet RAM0 has been filled to capacity. |
| 7<br>ALL_PROTOCOLS_ALLOW | Allow IPS bus access to Packet RAM for any protocol at any time.<br>Each supported protocol has an associated IPS bus, with which it can access protocol-specific registers, as well as Packet RAM. Normally IPS bus access to the Packet RAM is restricted to the protocol currently selected by the XCVR_CTRL[PROTOCOL] register, and access attempts by other protocols will result in an assert of **ips_xfr_err** on the offending IPS interface. When ALL_PROTOCOLS_ALLOW=1, these inhibits are removed, and any IPS bus can access Packet RAM at any time without any error signalling.<br>0b - IPS bus access to Packet RAM is restricted to the protocol engine currently selected by XCVR_CTRL[PROTOCOL].<br>1b - All IPS bus access to Packet RAM permitted, regardless of XCVR_CTRL[PROTOCOL] setting |
| 6<br>XCVR_RAM_ALLOW | Allow Packet RAM Transceiver Access<br>This bit must be set before performing accesses to the Packet RAM using transceiver address space. Transceiver space accesses to Packet RAM are intended for debug purposes only; the individual protocol engines, and the associated IPS busses, have exclusive access to Packet RAM in mission modes. Transceiver space accesses to Packet RAM include direct accesses to RAM at transceiver addresses 0x700 - 0xFFF, as well as Packet RAM Debug Mode. When this bit is set, control of RAM clock gating and RAM chip enables are forced on continuously, taking these controls away from the protocol engines.<br>0b - Protocol Engines, and associated IPS busses, have exclusive access to Packet RAM (mission mode)<br>1b - Transceiver-space access to Packet RAM, including Packet RAM debug mode, are allowed |
| 5 | RAM Page Selector for XCVR Access |

*Table continues on the next page...*

| Field | Function |
|---|---|
| XCVR_RAM_PAGE | This bit selects which of the 2 Packet RAM blocks is mapped into XCVR address space starting at XCVR_BASE + 0x700.<br>0b - RAM0 is mapped into XCVR address space, between XCVR_BASE + 0x700, and XCVR_BASE + 0xFFF<br>1b - RAM1 is mapped into XCVR address space, between XCVR_BASE + 0x700, and XCVR_BASE + 0xFFF |
| 4<br>DBG_EN | Packet RAM Debug Mode Enable<br>Setting DBG_EN=1 enables clock gating to the Packet RAM Debug engine. This bit should be set prior to the start of a Debug session, and remain set for the duration of the session. |
| 3-0<br>DBG_PAGE | Packet RAM Debug Page Selector<br>Selects the page of receiver data for storage to Packet RAM using Transceiver Packet RAM Debug Mode. Setting this register to a non-zero value enables the Packet RAM Debug Mode interface logic. Setting this register to zero disables the interface. **Note:** DBG_PAGE should be set to a non-zero value to begin an acquisition, only after the start and stop triggers have been programmed (DBG_START_TRG and DBG_STOP_TRG), if a trigger is desired. | 11-8<br>CRC_EC_SPKT_WND | Error correction short packet burst error window<br>This value determines the largest burst error corrected when short packets are processed. A value of zero will disable short packet error correction. The max value is 15. |
| 7-0<br>CRC_EC_SPKT_BYTES | Error Correction Short Packet Bytes<br>Short packets are defined as those where the number of bytes used in the CRC calculation, including the CRC value, do not exceed this value. The max value is 255. |

## A.2.8 XCVR_PHY register descriptions

**Note**

To decipher number formats such as ‘ufix4en2’ or ‘sfix8en3’:

General form: [u/s]fix[Nb]e[n][Nx]

Where,

| | |
|---|---|
| [u/s] | denotes whether the number is signed or not |
| fix | denotes that the number is fixed point, 2's complement |
| Nb | indicates total number of bits, including a sign bit if signed |
| e | indicates that the number is exponentiated like num x 2^(exponent) |
| n | indicates the exponent is negative |
| Nx | indicates the value of the exponent |

For example :

- ufix4en2(1101) = 1101 x 2^(-2) = 11.01 = 3.25 (decimal)
- sfix8en3(10011011) = -1100101 x 2^(-3) = -1100.101 = -12.625 (decimal)

### A.2.8.1 XCVR_RX_PHY_ADDR Memory map

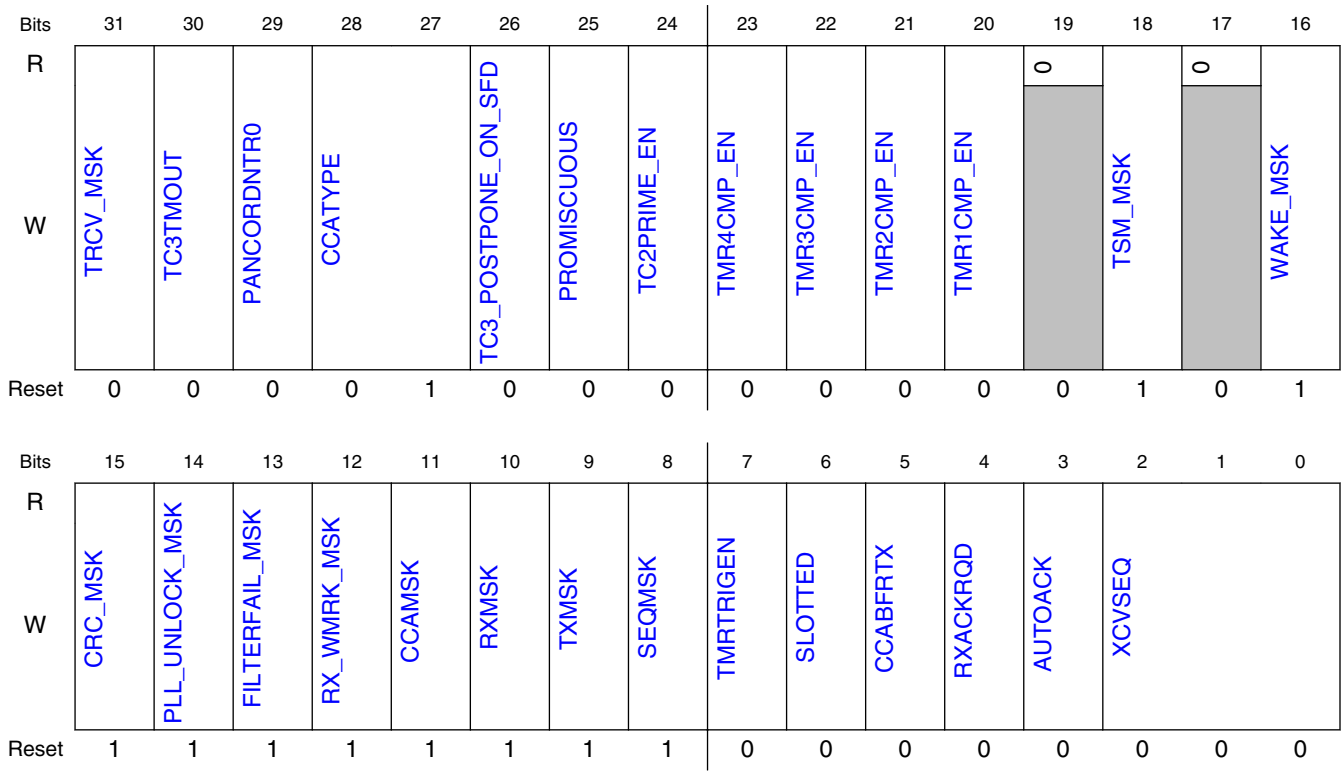
PHY Control Register

### A.3.2.3.3 Diagram



### A.3.2.3.4 Fields

| Field | Function |
|---|---|
| 31<br>TRCV_MSK | Transceiver Global Interrupt Mask<br>Transceiver Global Interrupt Mask<br>0b - Enable any unmasked interrupt source to assert zigbee interrupt<br>1b - Mask all interrupt sources from asserting zigbee interrupt |
| 30<br>TC3TMOUT | TMR3 Timeout Enable<br>TMR3 Timeout Enable<br>0b - TMR3 is a software timer only<br>1b - Enable TMR3 to abort Rx or CCCA operations. |
| 29<br>PANCORDNTR0 | Device is a PAN Coordinator on PAN0<br>Device is a PAN Coordinator on PAN0. Allows device to receive packets with no destination address, if Source PAN ID matches. |
| 28-27<br>CCATYPE | Clear Channel Assessment Type<br>Clear Channel Assessment Type. Selects one of four possible functions for CCA or Energy Detect, per below.<br>00b - ENERGY DETECT<br>01b - CCA MODE 1<br>10b - CCA MODE 2<br>11b - CCA MODE 3 |
| 26 | Postpone TC3 Timeout On SFD Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TC3_POSTPONE_ON_SFD | If this bit is set, if a TMR3 timeout occurs while a packet is being received (*rx_sfd_detect* = 1), the timeout-related abort will be deferred untl the packet reception is completed. If the packet is good, HW will signal Data Indication; otherwise the 802.15.4 ZSM (Sequence Manager) will return to SEQ_IDLE and await further commanding.<br>0b - TC3 Abort will occur on TMR3 timeout, regardless of rx_sfd_detect<br>1b - TC3 Abort will be deferred on TMR3 timeout if rx_sfd_detect is asserted; otherwise the TC3 Abort will occur immediately |
| 25<br>PROMISCUOUS | Promiscuous Mode Enable<br>Bypasses most packet filtering.<br>0b - normal mode<br>1b - all packet filtering except frame length checking (FrameLength>=5 and FrameLength<=127) is bypassed. |
| 24<br>TC2PRIME_EN | Timer 2 Prime Compare Enable<br>0b - Don't allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ<br>1b - Allow a match of the lower 16 bits of Event Timer to T2PRIMECMP to set TMR2IRQ |
| 23<br>TMR4CMP_EN | Timer 4 Compare Enable<br>0b - Don't allow an Event Timer Match to T4CMP to set TMR4IRQ<br>1b - Allow an Event Timer Match to T4CMP to set TMR4IRQ |
| 22<br>TMR3CMP_EN | Timer 3 Compare Enable<br>0b - Don't allow an Event Timer Match to T3CMP to set TMR3IRQ<br>1b - Allow an Event Timer Match to T3CMP to set TMR3IRQ |
| 21<br>TMR2CMP_EN | Timer 2 Compare Enable<br>0b - Don't allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ<br>1b - Allow an Event Timer Match to T2CMP or T2PRIMECMP to set TMR2IRQ |
| 20<br>TMR1CMP_EN | Timer 1 Compare Enable<br>0b - Don't allow an Event Timer Match to T1CMP to set TMR1IRQ<br>1b - Allow an Event Timer Match to T1CMP to set TMR1IRQ |
| 19<br>— | Reserved. |
| 18<br>TSM_MSK | Reserved.<br>0b - allows assertion of a TSM interrupt to generate a zigbee interrupt<br>1b - Assertion of a TSM interrupt will set the TSM_IRQ status bit, but a zigbee interrupt is not generated |
| 17<br>— | Reserved. |
| 16<br>WAKE_MSK | Reserved.<br>0b - Allows a wakeup from DSM to generate a zigbee interrupt<br>1b - Wakeup from DSM will set the WAKE_IRQ status bit, but a zigbee interrupt is not generated |
| 15<br>CRC_MSK | CRC Mask<br>CRC Mask<br>0b - sequence manager ignores CRCVALID and considers the receive operation complete after the last octet of the frame has been received.<br>1b - sequence manager requires CRCVALID=1 at the end of the received frame in order for the receive operation to complete successfully; if CRCVALID=0, sequence manager will return to preamble-detect mode after the last octet of the frame has been received. |
| 14<br>PLL_UNLOCK_MSK | PLL Unlock Interrupt Mask<br>0b - allows PLL unlock event to generate a zigbee interrupt<br>1b - A PLL unlock event will set the PLL_UNLOCK_IRQ status bit, but a zigbee interrupt is not generated |
| 13 | FilterFail Interrupt Mask |

*Table continues on the next page...*

| Field | Function |
|---|---|
| FILTERFAIL_MSK | FilterFail Interrupt Mask<br>0b - allows Packet Processor Filtering Failure to generate a zigbee interrupt<br>1b - A Packet Processor Filtering Failure will set the FILTERFAIL_IRQ status bit, but a zigbee interrupt is not generated |
| 12<br>RX_WMRK_MSK | RX Watermark Interrupt Mask<br>RX Watermark Interrupt Mask<br>0b - allows a Received Byte Count match to the RX_WTR_MARK threshold register to generate a zigbee interrupt<br>1b - A Received Byte Count match to the RX_WTR_MARK threshold register will set the RXWTRMRKIRQ status bit, but a zigbee interrupt is not generated |
| 11<br>CCAMSK | CCA Interrupt Mask<br>CCA Interrupt Mask<br>0b - allows completion of a CCA operation to generate a zigbee interrupt<br>1b - Completion of a CCA operation will set the CCA status bit, but a zigbee interrupt is not generated |
| 10<br>RXMSK | RX Interrupt Mask<br>0b - allows completion of a RX operation to generate a zigbee interrupt<br>1b - Completion of a RX operation will set the RXIRQ status bit, but a zigbee interrupt is not generated |
| 9<br>TXMSK | TX Interrupt Mask<br>0b - allows completion of a TX operation to generate a zigbee interrupt<br>1b - Completion of a TX operation will set the TXIRQ status bit, but a zigbee interrupt is not generated |
| 8<br>SEQMSK | Sequencer Interrupt Mask<br>0b - allows completion of an autosequence to generate a zigbee interrupt<br>1b - Completion of an autosequence will set the SEQIRQ status bit, but a zigbee interrupt is not generated |
| 7<br>TMRTRIGEN | Timer2 Trigger Enable<br>0b - programmed sequence initiates immediately upon write to XCVSEQ.<br>1b - allow timer TC2 (or TC2') to initiate a preprogrammed sequence (see XCVSEQ register). |
| 6<br>SLOTTED | Slotted Mode<br>Slotted Mode, for beacon-enabled networks. Applies only to Sequences T, TR, and R, ignored during all other sequences. Used, in concert with CCABFRTX, to determine how many CCA measurements are required prior to a transmit operation. Also used during R sequence to determine whether the ensuing transmit acknowledge frame (if any) needs to be synchronized to a backoff slot boundary. |
| 5<br>CCABFRTX | CCA Before TX<br>Applies only to Sequences T and TR, ignored during all other sequences.<br>0b - no CCA required, transmit operation begins immediately.<br>1b - at least one CCA measurement is required prior to the transmit operation (see also SLOTTED). |
| 4<br>RXACKRQD | Receive Acknowledge Frame required<br>Applies only to Sequence TR, ignored during all other sequences.<br>0b - An ordinary receive frame (any type of frame) follows the transmit frame.<br>1b - A receive Ack frame is expected to follow the transmit frame (non-Ack frames are rejected). |
| 3<br>AUTOACK | Auto Acknowledge Enable<br>Applies only to Sequence R and Sequence TR, ignored during other sequences<br>0b - sequence manager will not follow a receive frame with a Tx Ack frame, under any conditions; the autosequence will terminate after the receive frame.<br>1b - sequence manager will follow a receive frame with an automatic hardware-generated Tx Ack frame, assuming other necessary conditions are met. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 2-0<br>XCVSEQ | 802.15.4 Transceiver Sequence Selector<br>The Transceiver Sequence Selector register selects an autosequence for the sequence manager to execute. Sequence initiation can be immediate, or scheduled (see TMRTRIGEN). A write of XCVSEQ=IDLE will abort any ongoing sequence. A write of XCVSEQ=IDLE must always be performed after a sequence is complete, and before a new sequence is programmed. Any write to XCVSEQ other than XCVSEQ=IDLE during an ongoing sequence, shall be ignored. The mapping of XCVSEQ to sequence types is as follows:<br>000b - I (IDLE)<br>001b - R (RECEIVE)<br>010b - T (TRANSMIT)<br>011b - C (CCA)<br>100b - TR (TRANSMIT/RECEIVE)<br>101b - CCCA (CONTINUOUS CCA)<br>110b - Reserved<br>111b - Reserved |

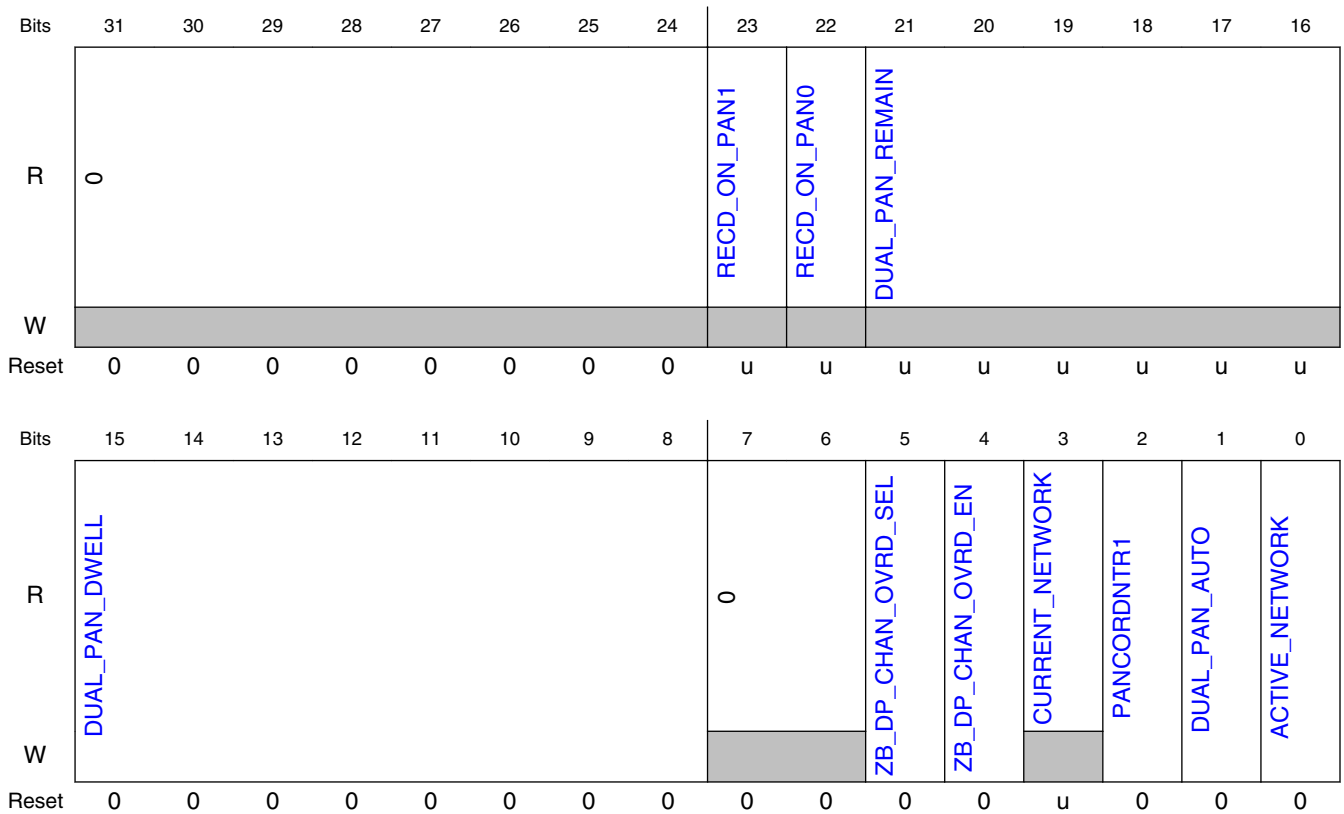
| DUAL_PAN_CTRL | 60h |

## A.3.2.25.2 Function

Dual PAN Control Register

## A.3.2.25.3 Diagram



## A.3.2.25.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved. |
| 23<br>RECD_ON_PAN1 | Last Packet was Received on PAN1<br>Indicates the packet which was just received, was received on PAN1. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN1 will be set if CURRENT_NETWORK=1 when the packet was received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN1 will be set only if a valid packet was received on PAN1 (PAN1's FILTERFAIL_FLAG is deasserted). RECD_ON_PAN1 remains valid until the start of the next autoseqeuence. |
| 22<br>RECD_ON_PAN0 | Last Packet was Received on PAN0<br>Indicates the packet which was just received, was received on PAN0. In Dual PAN mode operating on 2 different channels, RECD_ON_PAN0 will be set if CURRENT_NETWORK=0 when the packet was |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | received, regardless of FILTERFAIL status. In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN0 will be set only if a valid packet was received on PAN0 (PAN0's FILTERFAIL_FLAG is deasserted). RECD_ON_PAN0 remains valid until the start of the next autoseqeuence. |
| 21-16<br>DUAL_PAN_REMAIN | Time Remaining before next PAN switch in auto Dual PAN mode<br>This read-only register indicates time remaining before next PAN switch in auto Dual PAN mode. The units for this register, depend on the PRESCALER setting (bits [1:0]) in the DUAL_PAN_DWELL register. Tthe units are the same as the TIMEBASE determined by the prescaler, as per the following table:<br>DUAL_PAN_DWELL[1:0]=0b00 (TIMEBASE=0.5ms) DUAL_PAN_REMAIN UNITS=0.5ms<br>DUAL_PAN_DWELL[1:0]=0b01 (TIMEBASE=2.5ms) DUAL_PAN_REMAIN UNITS=2.5ms<br>DUAL_PAN_DWELL[1:0]=0b10 (TIMEBASE=10ms) DUAL_PAN_REMAIN UNITS=10ms<br>DUAL_PAN_DWELL[1:0]=0b11 (TIMEBASE=50ms) DUAL_PAN_REMAIN UNITS=50ms<br>The readback value indicates that between N-1 and N timebase units remain until the next PAN switch. For example, a DUAL_PAN_REMAIN readback value of 3, with a DUAL_PAN_DWELL PRESCALER setting of 2 (10ms), indicates that between 20ms (2*10ms) and 30ms (3*10ms), remain until the next automatic PAN switch. |
| 15-8<br>DUAL_PAN_DWELL | Dual PAN Channel Frequency Dwell Time<br>Channel Frequency Dwell Time. In Auto Dual PAN mode, hardware will toggle the PAN, after dwelling on the current PAN for the interval described below (assuming Preamble/SFD not detected). A write to DUAL_PAN_DWELL, always re-initilizes the DWELL TIMER to the programmed value. If a write to DUAL_PAN_DWELL occurs during an autosequence, the DWELL TIMER will begin counting down immediately. If a write to DUAL_PAN_DWELL occurs when there is no autosequence underway, the DWELL TIMER will not begin counting until the next autosequence begins; it will begin counting at the start of the sequence warmup.<br>DUAL_PAN_DWELL[1:0] select the timebase for the dwell time. There are 4 options:<br>DUAL_PAN_DWELL[1:0]=0b00 --> TIMEBASE=0.5ms<br>DUAL_PAN_DWELL[1:0]=0b01 --> TIMEBASE=2.5ms<br>DUAL_PAN_DWELL[1:0]=0b10 --> TIMEBASE=10ms<br>DUAL_PAN_DWELL[1:0]=0b11 --> TIMEBASE=50ms<br>DUAL_PAN_DWELL[7:2] select how many multiples of the time base to use, from 1 (DUAL_PAN_DWELL[7:2]=0) to 64 (DUAL_PAN_DWELL[7:2]=63). Given those definitions, the table below specifies the minimum and maximum dwell times for each TIMEBASE option:<br>DUAL_PAN_DWELL[1:0]=0b00 --> MIN_DWELL=0.5ms MAX_DWELL=32ms<br>DUAL_PAN_DWELL[1:0]=0b01 --> MIN_DWELL=2.5ms MAX_DWELL=160ms<br>DUAL_PAN_DWELL[1:0]=0b10 --> MIN_DWELL=10ms MAX_DWELL=640ms<br>DUAL_PAN_DWELL[1:0]=0b11 --> MIN_DWELL=50ms MAX_DWELL=3.2seconds<br>A write to DUAL_PAN_DWELL also causes the value of ACTIVE_NETWORK to get latched into the hardware. This latched value will be the starting point for the automatic dual-pan mode (i.e., start on PAN0 or on PAN1). The starting value takes effect immediately (if sequence is underway and DUAL_PAN_AUTO=1), or is otherwise delayed until sequence starts and DUAL_PAN_AUTO=1. |
| 7-6<br>— | Reserved. |
| 5<br>ZB_DP_CHAN_OVRD_SEL | Dual PAN Channel Override Selector<br>This bit works with **ZB_DP_CHAN_OVRD_EN** to allow one of the two Dual PAN channels to use Direct Frequency programming. See description for **ZB_DP_CHAN_OVRD_EN**. |
| 4 | Dual PAN Channel Override Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| ZB_DP_CHAN_OVRD_EN | In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to accomplish that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers -- integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the Zigbee mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1.<br><br>Two bits have been provided in 802.15.4 space to realize this feature: ZB_DP_CHAN_OVRD_SEL and ZB_DP_CHAN_OVRD_EN. When ZB_DP_CHAN_OVRD_EN=1, this enables one of the Dual PAN channels to use the direct frequency programming. The ZB_DP_CHAN_OVRD_SEL bit determines which channel uses the direct programming, according to the following:<br><br>If ZB_DP_CHAN_OVRD_EN=0, then PAN0 frequency is determined by register CHANNEL_NUM0[6:0] and PAN1 frequency is determined by register CHANNEL_NUM1[6:0].<br><br>If ZB_DP_CHAN_OVRD_EN=1 and ZB_DP_CHAN_OVRD_SEL=0, then PAN0 frequency is determined by DIRECT FREQUENCY PROGRAMMING and PAN1 frequency is determined by register CHANNEL_NUM1[6:0].<br><br>If ZB_DP_CHAN_OVRD_EN=1 and ZB_DP_CHAN_OVRD_SEL=1, then PAN0 frequency is determined by register CHANNEL_NUM0[6:0] and PAN1 frequency is determined by DIRECT FREQUENCY PROGRAMMING.<br><br>**NOTE:** Direct Frequency Programming is accomplished by setting the PLL's Integer, Numerator, and Denominator registers to the appropriate values for the desired RF frequency. |
| 3<br><br>CURRENT_NETWORK | Indicates which PAN is currently selected by hardware<br><br>This read-only bit indicates which PAN is currently selected by hardware in automatic Dual PAN mode<br>0b - PAN0 is selected<br>1b - PAN1 is selected |
| 2<br><br>PANCORDNTR1 | Device is a PAN Coordinator on PAN1<br><br>Device is a PAN Coordinator on PAN1. Allows device to receive packets with no destination address, if Source PAN ID matches. |
| 1<br><br>DUAL_PAN_AUTO | Activates automatic Dual PAN operating mode<br><br>Activates automatic Dual PAN operating mode. In this mode, PAN-switching is controlled by hardware at a pre-programmed rate, determined by DUAL_PAN_DWELL.<br>0: Manual Dual PAN mode (or Single PAN mode).<br>1: Auto Dual PAN Mode<br><br>Whenever DUAL_PAN_AUTO=0, CURRENT_NETWORK=ACTIVE_NETWORK at all times. In other words, software directly controls which PAN is selected. Whenever DUAL_PAN_AUTO=1, CURRENT_NETWORK is controlled by hardware. |
| 0<br><br>ACTIVE_NETWORK | Active Network Selector<br><br>Selects the PAN on which to transceive, by activating a PAN parameter set (PAN0 or PAN1). In Manual Dual PAN mode (or Single PAN mode), this bit selects the active PAN parameter set (channel and addressing parameters) which governs all autosequences. In Auto Dual PAN mode, this bit selects the PAN on which to begin transceiving, latched at the point at which DUAL_PAN_DWELL register is written.<br>0b - Select PAN0<br>1b - Select PAN1 |

# A.3.2.28 SOURCE ADDRESS MANAGEMENT TABLE (SAM_TABLE)

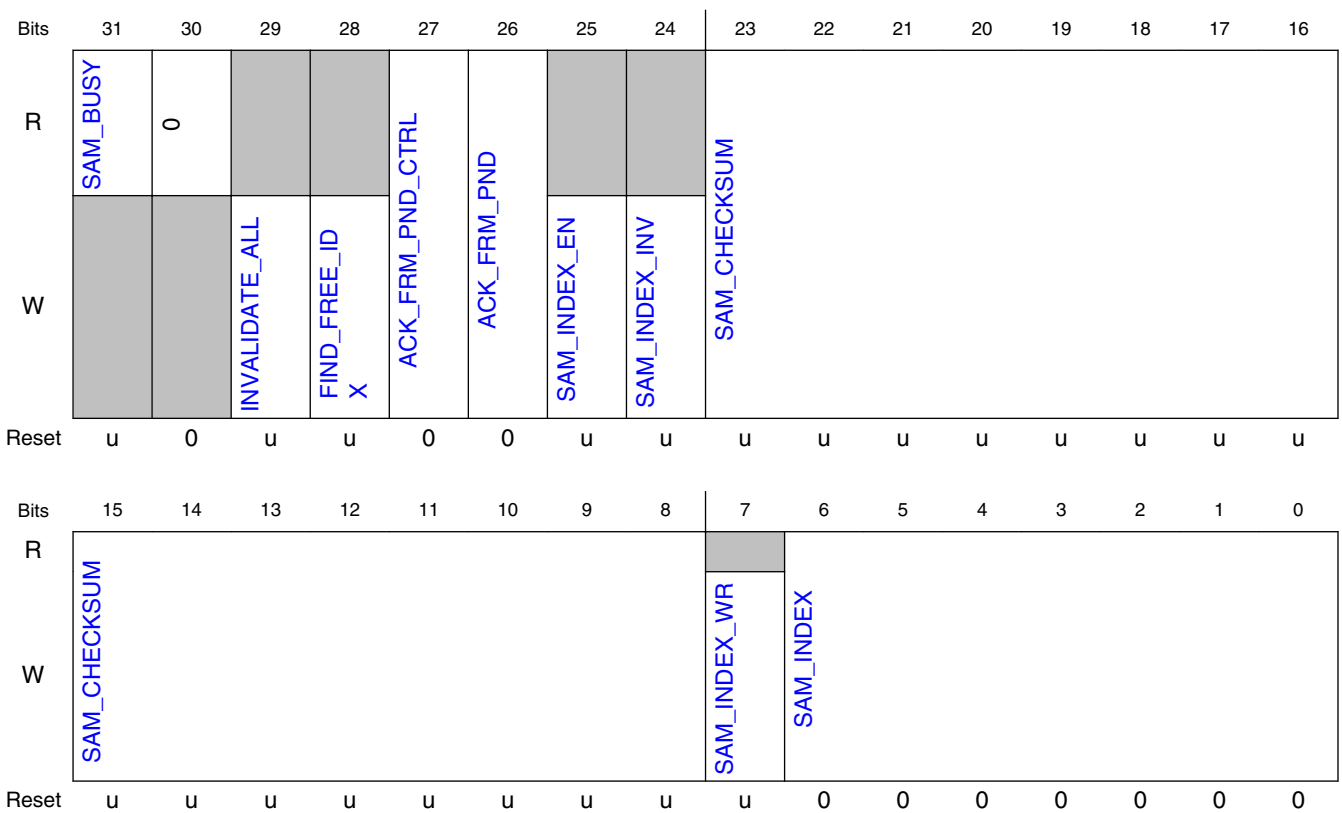
## A.3.2.28.1 Offset

| Register | Offset |
|---|---|
| SAM_TABLE | 6Ch |

## A.3.2.28.2 Function

Source Address Management Table

## A.3.2.28.3 Diagram



## A.3.2.28.4 Fields

| Field | Function |
|---|---|
| 31<br>SAM_BUSY | SAM Table Update Status Bit |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | Hardware is in the process of updating the Source Address table, either in response to a poll indication from the packet processor, or due to software setting FIND_FREE_IDX=1. In the latter case, software should poll SAM_BUSY until low before accessing the "First Free Index" registers. Read-only bit. |
| 30<br>— | Reserved. |
| 29<br>INVALIDATE_ALL | Invalidate Entire SAM Table<br>Writing a 1 to this bit clears all 128 Valid bits. Invalidates the entire table. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate. |
| 28<br>FIND_FREE_IDX | Find First Free Index<br>After modifying Valid bits (enabling or invalidating), write this bit to 1 to force hardware to update the "First Free Index" registers to account for the changed Valid bits. This hardware update process takes 4us. Software can poll SAM_BUSY to determine when the table update is complete. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate. |
| 27<br>ACK_FRM_PND_CTRL | Manual Control for AutoTxAck FramePending field<br>0b - the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet is determined by hardware<br>1b - the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet tracks ACK_FRM_PEND |
| 26<br>ACK_FRM_PND | State of AutoTxAck FramePending field when SAM Accelleration is Disabled<br>Software can take manual control of the FramePending field of the Frame Control Field of the next automatic TX acknowledge packet, by setting ACK_FRM_PND_CTRL=1; in that case FramePending will track the state of this bit. The FramePending field also tracks this bit if Source Address Management is completely disabled, i.e.,<br>SAP0_EN=SAA0_EN=SAP1_EN=SAA1_EN=0<br>Otherwise, the FramePending field is determined by Source Address Management (SAM) hardware. |
| 25<br>SAM_INDEX_EN | Enable the SAM table index selected by SAM_INDEX |
| 24<br>SAM_INDEX_INV | Invalidate the SAM table index selected by SAM_INDEX |
| 23-8<br>SAM_CHECKSUM | Software-computed source address checksum, to be installed into a table index<br>Software-computed source address checksum, to be installed into a table index. The value on SAM_CHECKSUM[15:0] can be installed into the table with a single, atomic 32-bit write; in that case, the write data would contain the desired SAM_INDEX[6:0] and SAM_CHECKSUM[15:0], and SAM_INDEX_WR=1.<br>If SAM_INDEX_WR=0, then the SAM_INDEX[6:0] register is written, but the checksum is *not* written to the table.<br>The readback value of SAM_CHECKSUM[15:0] is the contents of the SAM Table at the location pointed to by SAM_INDEX[6:0]. To readback from a specific table index, software should first write the desired index to SAM_INDEX[6:0], and then read back the checksum from the table on SAM_CHECKSUM[15:0]. |
| 7<br>SAM_INDEX_WR | Enables SAM Table Contents to be updated<br>For 32-bit writes, SAM_INDEX_WR must be set to indicate that the table entry specified by SAM_INDEX[6:0] is to be written; if SAM_INDEX_WR=0, the table entry is not written, but the SAM_INDEX[6:0] register is updated. For 8-bit writes, this bit is ignored. |
| 6-0<br>SAM_INDEX | Contains the SAM table index to be enabled or invalidated |

| Field | Function |
|---|---|
| | Contains the table index to be enabled or invalidated. Software must ensure that the index is within the range of the desired partition. |

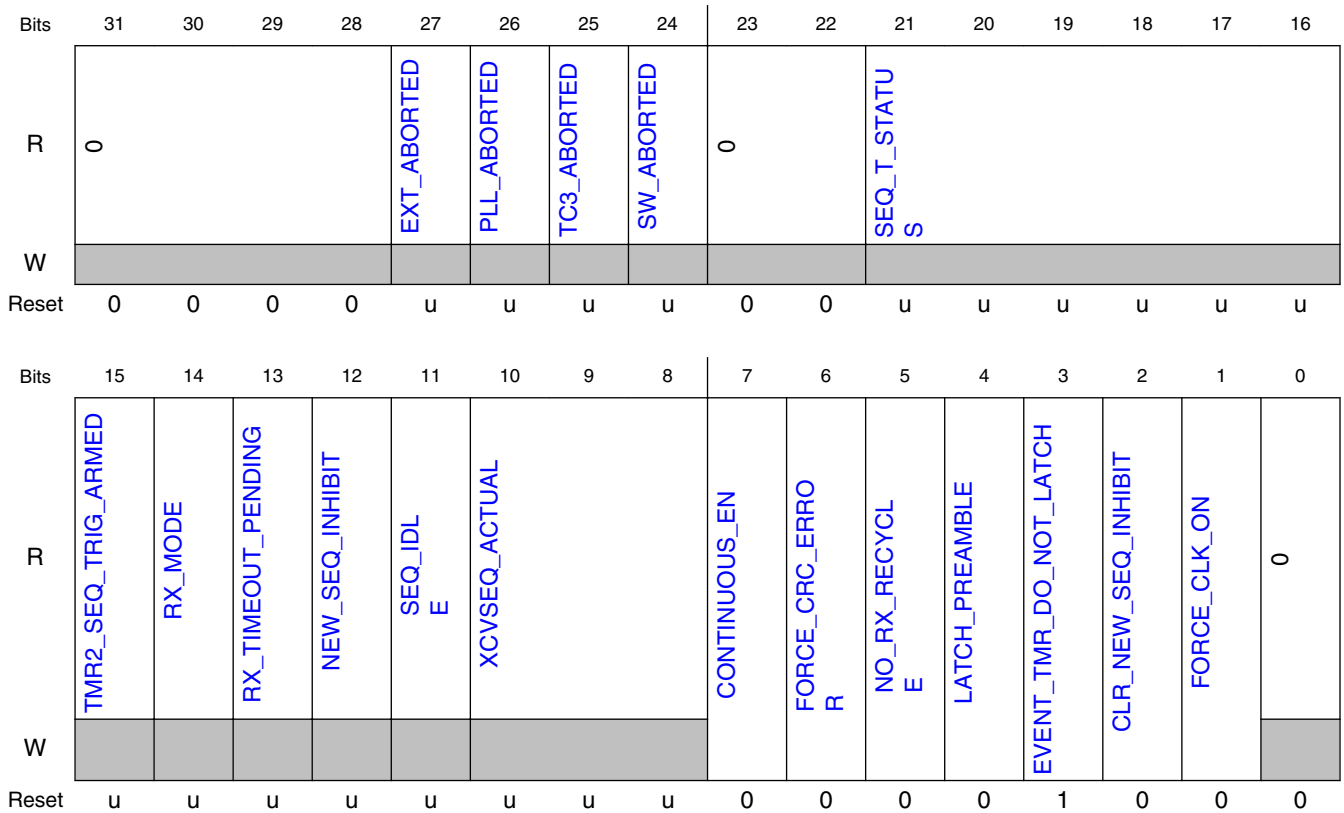
# A.3.2.31 SEQUENCE CONTROL AND STATUS (SEQ_CTRL_STS)

## A.3.2.31.1 Offset

| Register | Offset |
|---|---|
| SEQ_CTRL_STS | 78h |

## A.3.2.31.2 Diagram



## A.3.2.31.3 Fields

| Field | Function |
|---|---|
| 31-28<br>— | Reserved. |
| 27<br>EXT_ABORTED | Autosequence has terminated due to a Wake-On-Radio command<br>when asserted, indicates that the autosequence has terminated due to an external event, such as a Wake-On-Radio stop command. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| 26<br>PLL_ABORTED | Autosequence has terminated due to an PLL unlock event<br>when asserted, indicates that the autosequence has terminated due to an PLL unlock event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| 25<br>TC3_ABORTED | autosequence has terminated due to an TMR3 timeout<br>when asserted, indicates that the autosequence has terminated due to an TC3 (TMR3) timeout during a receive operation. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| 24<br>SW_ABORTED | Autosequence has terminated due to a Software abort. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | when asserted, indicates that the autosequence has terminated due to an Software abort. Software can abort any programmed autosequence by writing Sequence I to XCVSEQ. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| 23-22<br>—— | Reserved. |
| 21-16<br>SEQ_T_STATUS | Status of the just-completed or ongoing Sequence T or Sequence TR<br>Status of the just-completed (or ongoing) Sequence T or Sequence TR autosequence. This register is valid at all times during, and after, the Sequence T or Sequence TR. Not valid for other types of autosequences. This is a read-only register. The bits of this register map to status, according to the following table:<br>[0] 1st CCA complete (CCABFRTX=1)<br>[1] 2nd CCA complete (SLOTTED=1)<br>[2] Tx operation complete<br>[3] Rx Recycle occurred (Sequence TR only)<br>[4] Rx operation complete (Sequence TR only)<br>[5] TxAck operation complete(Sequence TR only) |
| 15<br>TMR2_SEQ_TRIG_ARMED | indicates that TMR2 has been programmed and is armed to trigger a new autosequence<br>when asserted, indicates that TMR2 has been programmed and is "armed" to trigger a new autosequence, when Zigbee Sequence Manager timer-triggering mode is selected (i.e., TMRTRIGEN=1). When timer-triggering mode is selected, TMR2 must be re-programmed (using either T2CMP or T2PRIMECMP), in advance of each new sequence. Once TMR2 is programmed, this bit will be asserted, and will remain asserted until the new sequence commences (at TMR2 match). Hardware will deassert this bit when the new sequence starts. When TMRTRIGEN=0, this bit should be ignored. Read-only bit. |
| 14<br>RX_MODE | RX Operation in Progress<br>when asserted, this Sequence Manager Output indicates that an RX operation is in progress. An RX operation can be part of a complex transmit autosequence such as a Sequence TR. CCA and ED operations are considered RX operations, during which rx_mode is asserted. Read-only bit. |
| 13<br>RX_TIMEOUT_PENDING | Indicates a TMR3 RX Timeout is Pending<br>when asserted, indicates that a TMR3 timeout (RX timeout) flag has been set by Hardware, but the Sequence Manager has not yet aborted because an RX operation is not currently underway. This would be the case, for example, during a Sequence TR, if a TMR3 timeout were to occur during the transmit operation of this sequence; the sequence would not be aborted by Hardware until the receive operation begins. This bit will always be 0 if TC3TMOUT=0. Read-only bit. |
| 12<br>NEW_SEQ_INHIBIT | New Sequence Inhibit<br>When asserted, indicates that a new programmed autosequence has commenced (TMR2 match has occurred if TMRTRIGEN=1). Once this bit is asserted, software is blocked from commanding any "new" autosequences (other than Sequence I to abort the current sequence), until the current sequence completes. Hardware will ignore a sequence-change command from software while this bit is asserted. Hardware will automatically deassert this bit once the sequence completes. Read-only bit. |
| 11<br>SEQ_IDLE | ZSM Sequence Idle Indicator |
| 10-8<br>XCVSEQ_ACTUAL | Indicates the programmed sequence that has been recognized by the ZSM Sequence Manager<br>Reflects the programmed sequence that has been recognized by the Zigbee Sequence Manager. Takes into account the fact that sequence-change commands from software are ignored while a sequence is underway (see NEW_SEQ_INHIBIT). Read-only bits. |
| 7 | Enable Continuous TX or RX Mode |

*Table continues on the next page...*

| Field | Function |
|---|---|
| CONTINUOUS_EN | Continuous Mode Enable (Continuous TX or RX).<br>**Note:** Dual PAN mode should not be engaged in Continuous TX or RX modes.<br>0b - normal operation<br>1b - Continuous TX or RX mode is enabled (depending on XCVSEQ setting). |
| 6<br>FORCE_CRC_ERROR | Induce a CRC Error in Transmitted Packets<br>0b - normal operation<br>1b - Force the next transmitted packet to have a CRC error |
| 5<br>NO_RX_RECYCLE | Disable Automatic RX Sequence Recycling<br>when asserted, prevents the Zigbee Sequence Manager (ZSM) from automatically re-starting (recycling) the receiver when a packet is received which results in a FilterFail or CRC failure. Normally, on a RX recycle, the ZSM returns to the RX_WU (warmup) state, and then resumes from there with a new, foreshortened, Rx warmup, in search of a new preamble. When this bit is set, the Sequence Manager will instead return to idle state, and issue a SEQIRQ, after a FilterFail or CRC failure. |
| 4<br>LATCH_PREAMBLE | Stickiness Control for Preamble Detection<br>0b - Don't make PREAMBLE_DET and SFD_DET bits of PHY_STS (SEQ_STATE) Register "sticky", i.e, these status bits reflect the realtime, dynamic state of preamble_detect and sfd_detect<br>1b - Make PREAMBLE_DET and SFD_DET bits of PHY_STS (SEQ_STATE) Register "sticky", i.e.,occurrences of preamble and SFD detection are latched and held until the start of the next autosequence |
| 3<br>EVENT_TMR_DO_NOT_LATCH | Overrides the automatic hardware latching of the Event Timer<br>when asserted, overrides the automatic hardware latching of the Event Timer that prevents the timer from updating while software reads the 3 Event Timer bytes. This allows the Event Timer LS byte to continue to update without reading the upper 2 bytes. Overriding the automatic latching of the Event Timer should be used with caution, as it can allow the Event Timer lower bytes to get out-of-sync with the upper bytes. However, it can be useful when polling the Event Timer LS byte for a value that is just a few counts in the future. |
| 2<br>CLR_NEW_SEQ_INHIBIT | Overrides the automatic hardware locking of the programmed XCVSEQ while an autosequence is underway<br>when asserted, overrides the automatic hardware locking of the programmed XCVSEQ while an autosequence is underway. Asserting this feature will allow software to change the programmed autosequence "on-the-fly", without aborting and returning to idle between sequences. Overriding the hardware lockout of XCVSEQ should be used with caution, since the Sequence Manager is not designed (or verified) for manual state transitions between one type of autosequence and other (i.e., Sequence T -> Sequence R). |
| 1<br>FORCE_CLK_ON | Force On 802.15.4 phy_gck<br>Force On 802.15.4 phy_gck<br>0b - Allow TSM to control 802.15.4 phy_gck, for minimum power consumption (default)<br>1b - Force on 802.15.4 phy_gclk at all times, for debug purposes only |

| 31-30<br>— | Reserved. |
| 29-24<br>CCCA_BUSY_CNT | Number of CCA Measurements resulting in Busy Channel<br>For Sequence CCCA mode only, this register indicates the number of "busy" CCA attempts which occurred during the autosequence, before the channel was detected to be idle. This register can also be |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | read in real-time (during the autosequence) to determine how many busy CCA attempts have occurred to that point. The register saturates at 63 (i.e, if there are more than 63 busy attempts, the register will continue to read 63). This register is automatically cleared to zero by hardware when the next autosequence commences. Read-only register. |
| 23-16<br>RX_BYTE_COUNT | Realtime Received Byte Count<br>During packet reception, this read-only register is a real-time indicator of the number of bytes that have been received. This register will read 0 until SFD and PHR have been received. It will read 1 after the first byte of Frame Control Field has been received, etc. |
| 15-14<br>— | Reserved. |
| 13<br>PLL_ABORTED | Autosequence has terminated due to an PLL unlock event<br>when asserted, indicates that the autosequence has terminated due to an PLL unlock event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. This bit is a read-only mirror of the register bit of the same name in the ABORT_STS (SEQ_CTRL_STS) register. |
| 12<br>PLL_ABORT | Raw PLL Abort Signal<br>This bit reflects the instantaneous, consolidated status of the PLL unlock detection circuits; if asserted high, indicates that at least one of the three PLL unlock detect mechanisms is currently reporting an unlocked condition. |
| 11<br>CRCVALID | CRC Valid Indicator<br>Cyclic Redundancy Check Valid: This flag indicates the compare result between the FCS field, in the most-recently received frame, and the internally calculated CRC value. This flag is cleared at next receiver warm up.<br>0b - Rx FCS != calculated CRC (incorrect)<br>1b - Rx FCS = calculated CRC (correct) |
| 10<br>FILTERFAIL_FLAG_SEL | Consolidated Filter Fail Flag<br>0: The incoming, or just-received packet, passed packet filtering rules.<br>1: The incoming, or just-received packet, failed packet filtering rules<br>When FILTERFAIL_FLAG_SEL=1, a non-zero FILTERFAIL_CODE is present (see FILTERFAIL_CODE registers).<br>In Dual PAN mode, FILTERFAIL_FLAG_SEL applies to either or both networks, as follows:<br>**A:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=0, FILTERFAIL_FLAG_SEL applies to PAN0.<br>**B:** If PAN0 and PAN1 occupy different channels and CURRENT_NETWORK=1, FILTERFAIL_FLAG_SEL applies to PAN1.<br>**C:** If PAN0 and PAN1 occupy the same channel, FILTERFAIL_FLAG_SEL is the logical 'AND' of the individual PANs' FILTERFAIL_FLAG bits. |
| 9<br>SFD_DET | SFD Detected<br>0: an 802.15.4 preamble-and-SFD have not been detected.<br>1: An 802.15.4 preamble-and-SFD have been detected.<br>The function of this read-only bit depends on the setting of the LATCH_PREAMBLE bit of the SEQ_MGR_CTRL register. If LATCH_PREAMBLE=1, any preamble-and-SFD detection during a Sequence R (even false detections), will set this bit, and it will remain set (sticky) until the start of the next autosequence. If LATCH_PREAMBLE=0, this bit is not sticky, and reflects the instantaneous state of the SFD-detection circuit; for false SFD, the bit will clear when the false nature of the SFD is recognized (i.e., an RX recycle). When LATCH_PREAMBLE=0, SFD_DET should be considered valid only while an autosequence is underway. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 8<br>PREAMBLE_DET | Preamble Detected<br>0: an 802.15.4 preamble has not been detected.<br>1: An 802.15.4 preamble has been detected.<br>The function of this read-only bit depends on the setting of the LATCH_PREAMBLE bit of the SEQ_MGR_CTRL register. If LATCH_PREAMBLE=1, any preamble detection during a Sequence R (even false detections), will set this bit, and it will remain set (sticky) until the start of the next autosequence. If LATCH_PREAMBLE=0, this bit is not sticky, and reflects the instantaneous state of the preamble-detection circuit; for false preambles, the bit will clear when the false nature of the preamble is recognized. When LATCH_PREAMBLE=0, PREAMBLE_DET should be considered valid only while an autosequence is underway. |

### A.3.2.38.4 Fields

| Field | Function |
|---|---|
| 31-0<br>LENIENCY_LSB | Leniency LSB Register<br>The Packet Processor performs filtering on all received packets, in order to determine whether the packet is intended for the device. The packet filtering is based on rules. In case any of the packet filtering rules need to be overriden, a 40-bit "leniency register" has been provided. When the leniency register is programmed to its default value (0), all hardware packet filtering rules are in effect, and if an incoming packet violates any rule, a "Filter Fail" will occur (packet will be rejected). When a given leniency register bit is asserted, the packet filtering rule assigned to that bit will not be in effect, and if any incoming packet violates that rule (but no other rules), then a "Filter Fail" will not occur, the packet will not be rejected, the packet will be treated as "intended for the device", and software will be notified of the incoming packet. For a desciption of the function of the individual leniency bits, see the 802.15.4 Link Layer Controller chapter. |

### A.3.3.26.3 Fields

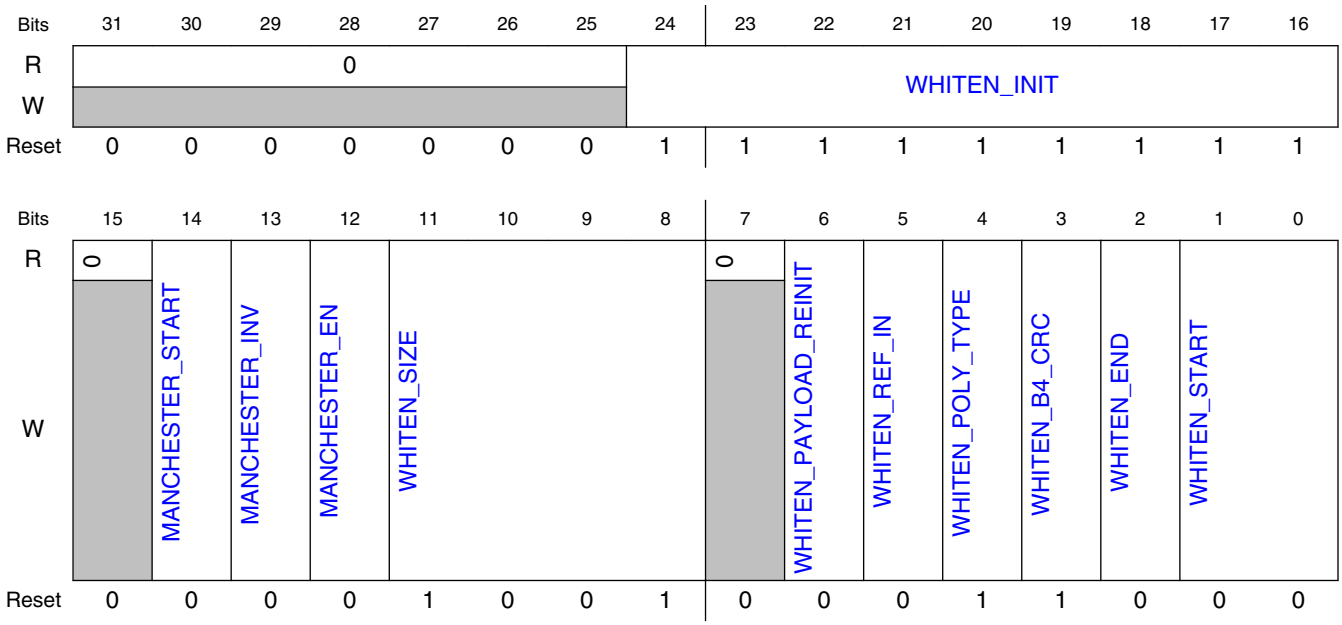
| Field | Function |
|---|---|
| 31-0<br>CRC_XOR_OUT | CRC XOR OUT Register<br>XOR mask for CRC result (for no mask, should be 0) |

## A.3.3.27 WHITENER CONFIGURATION (WHITEN_CFG)

### A.3.3.27.1 Offset

| Register | Offset |
|---|---|
| WHITEN_CFG | 7Ch |

## A.3.3.27.2 Diagram



## A.3.3.27.3 Fields

| Field | Function |
|---|---|
| 31-25<br>— | Reserved. |
| 24-16<br>WHITEN_INIT | Initialization Value for Whitening/De-whitening |
| 15<br>— | Reserved. |
| 14<br>MANCHESTER_START | Configure Manchester Encoding Start Point<br>0b - Start Manchester coding at start-of-payload<br>1b - Start Manchester coding at start-of-header |
| 13<br>MANCHESTER_INV | Configure for Inverted Manchester Encoding<br>0b - Manchester coding as per 802.3<br>1b - Manchester coding as per 802.3 but with the encoding signal inverted |
| 12<br>MANCHESTER_EN | Configure for Manchester Encoding/Decoding<br>0b - Disable Manchester encoding (TX) and decoding (RX)<br>1b - Enable Manchester encoding (TX) and decoding (RX) |
| 11-8<br>WHITEN_SIZE | Length of Whitener LFSR |
| 7<br>— | Reserved. |
| 6 | Configure for Whitener re-initialization |

*Table continues on the next page...*

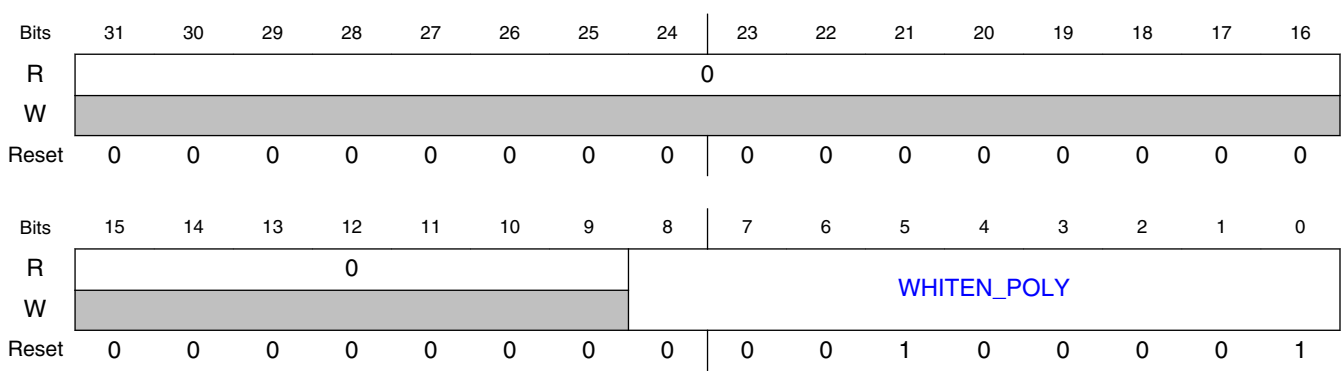
| Field | Function |
|---|---|
| WHITEN_PAYLOAD_REINIT | 0b - Don't re-initialize Whitener LFSR at start-of-payload<br>1b - Re-initialize Whitener LFSR at start-of-payload |
| 5<br>WHITEN_REF_IN | Whiten Reflect Input<br>The input data stream is reflected, bit-wise, per byte, if this register bit is asserted. Bit 7 becomes bit 0, bit 6 becomes bit 1, etc. This register bit will only cause the reflection of the payload data bits as they are used in the whiten calculation and will not cause any change in the output bit order. |
| 4<br>WHITEN_POLY_TYPE | Whiten Polynomial Type<br>A Fibonacci type LFSR is used with the whiten polynomial if this register bit is asserted. Otherwise, a Galois type LFSR is used. |
| 3<br>WHITEN_B4_CRC | Congifure for Whitening-before-CRC<br>Sets the order of Bit Stream Processing for TX and RX.<br>0b - CRC before whiten/de-whiten<br>1b - Whiten/de-whiten before CRC |
| 2<br>WHITEN_END | Configure end-of-whitening<br>0b - end whiten at end-of-payload<br>1b - end whiten at end-of-crc |
| 1-0<br>WHITEN_START | Configure Whitener Start Point<br>00b - no whitening<br>01b - start whitening at start-of-H0<br>10b - start whitening at start-of-H1 but only if LENGTH > WHITEN_SZ_THR<br>11b - start whitening at start-of-payload but only if LENGTH > WHITEN_SZ_THR |

# A.3.3.28 WHITENER POLYNOMIAL (WHITEN_POLY)

## A.3.3.28.1 Offset

| Register | Offset |
|---|---|
| WHITEN_POLY | 80h |

## A.3.3.28.2 Diagram



### A.3.3.28.3 Fields

| Field | Function |
|---|---|
| 31-9<br>— | Reserved. |
| 8-0<br>WHITEN_POLY | Whitener Polynomial<br>The 9-bit polynomial used in the whiten calculation. The polynomial value must be right-justified if smaller than 9-bits. |

## A.3.3.29 WHITENER SIZE THRESHOLD (WHITEN_SZ_THR)

### A.3.3.29.1 Offset

| Register | Offset |
|---|---|
| WHITEN_SZ_THR | 84h |

### A.3.3.29.2 Diagram

| 31-24<br>— | Reserved. |

*Table continues on the next page...*

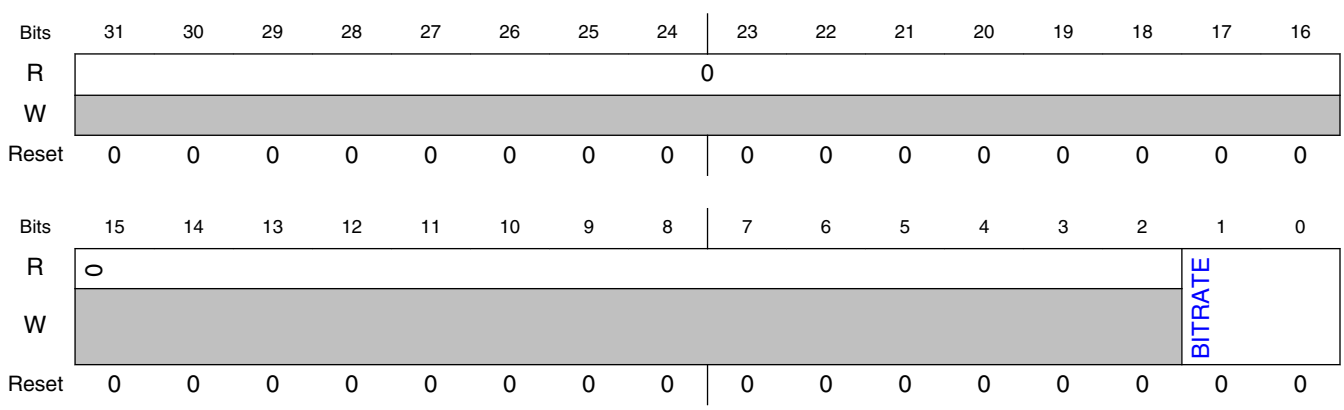
| Field | Function |
|---|---|
| 23<br>REC_BAD_PKT | Receive Bad Packets<br>Enable Packets which fail H0-filtering, H1-filtering, or Maximum Length-filtering, to be fully received without an RX recycle (intended for debug purposes)<br>0b - packets which fail H0, H1, or LENGTH_MAX result in an automatic recycle after the header is received and parsed<br>1b - packets which fail H0, H1, or LENGTH_MAX are received in their entirety |
| 22-16<br>LENGTH_MAX | Maximum Length for Received Packets<br>Sets the Maximum Length Packet that can be received, in multiples of 16 bytes. LENGTH_MAX is compared directly against the extracted LENGTH field of the header (not the adjusted length). LENGTH_MAX=0 (default) is a special case that implies no limit. |
| 15-12<br>— | Reserved. |
| 11-0<br>WHITEN_SZ_THR | Whitener Size Threshold<br>Minimum Packet Length (extracted LENGTH field) required to enable whiten. Requires WHITEN_START=2 or 3 |

# A.3.3.30 BIT RATE (BITRATE)

## A.3.3.30.1 Offset

| Register | Offset |
|---|---|
| BITRATE | 88h |

## A.3.3.30.2 Diagram



### A.3.3.30.3 Fields

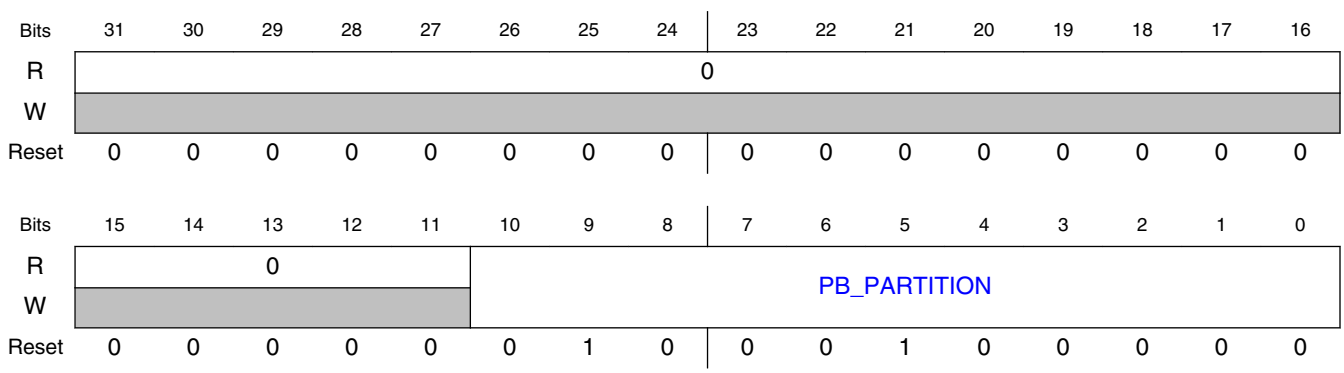
| Field | Function |
|---|---|
| 31-2<br>— | Reserved. |
| 1-0<br>BITRATE | Bit Rate<br>Selects the Bit Rate for the Generic FSK Link Layer. The blocks which interface to the Link Layer (e.g., PHY, CRC/Whitener), also adapt to the selected bit rate.<br>**NOTE:** For FSK FAD (Fast Antenna Diversity), only the 1Mbit/sec bit rate is supported.<br>00b - 1Mbit/sec<br>01b - 500Kbit/sec<br>10b - 250Kbit/sec (not supported if WHITEN_CFG[MANCHESTER_EN]=1)<br>11b - 2Mbit/sec (not supported if WHITEN_CFG[MANCHESTER_EN]=1) |

## A.3.3.31 PACKET BUFFER PARTITION POINT (PB_PARTITION)

### A.3.3.31.1 Offset

| Register | Offset |
|---|---|
| PB_PARTITION | 8Ch |

### A.3.3.31.2 Diagram



### A.3.3.31.3 Fields

| Field | Function |
|---|---|
| 31-11<br>— | Reserved. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 10-0<br>PB_PARTITION | Packet Buffer Partition Point<br>The Packet Buffer Partition Point defines the starting point for the RX segment of the Packet Buffer. The partitioning of the consolidated RAM between TX and RX is controlled by this configurable TX/RX Partition Point. PB_PARTITION can be programmed with any value between 0 (base of RAM0) and 1088 (after the last address of RAM1). The consolidated RAM is partitioned such that the TX buffer resides before the Partition Point (RAM entries 0 to (PB_PARTITION-1)), and the RX buffer resides after it (RAM entries PB_PARTITION to 1087). Programming the Partition Point register to 0 dedicates the entire consolidated RAM to RX; programming the Partition Point register to 1088 dedicates the entire consolidated RAM to TX; programming the Partition Point register to any value between 1 and 1087 yields a split TX/RX buffer. The TX segment (if any) is always first in the Packet Buffer, starting at Packet RAM address 0 of RAM0. Since the Packet Buffer RAM word-width is 2 bytes, the units for PB_PARTITION is "words". (Multiply by 2 to convert to byte addressing) |

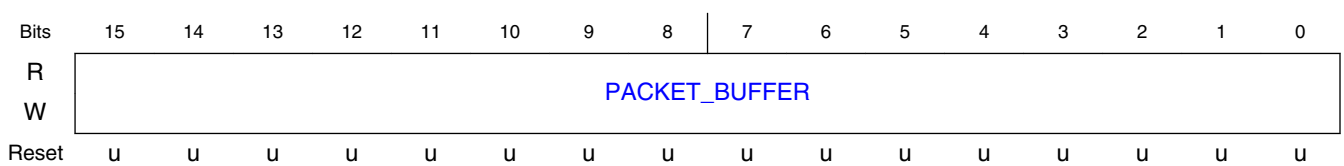
## A.3.3.32 PACKET BUFFER (PACKET_BUFFER_0 - PACKET_BUFFER_1087)

### A.3.3.32.1 Offset

For a = 0 to 1087:

| Register | Offset |
|---|---|
| PACKET_BUFFER_a | 700h + (a × 2h) |

### A.3.3.32.2 Diagram



### A.3.3.32.3 Fields

| Field | Function |
|---|---|
| 15-0<br>PACKET_BUFFER | PACKET BUFFER RAM<br>Storage for packet data. |
