# Chapter 38
# Enhanced Direct Memory Access (eDMA)

## 38.1 Chip-specific eDMA information

This device has two DMAs. DMA0 has 16 channels and DMA1 has 8 channels.

## 38.2 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 16 channels

### 38.2.1 eDMA system block diagram

Figure 38-1 illustrates the components of the eDMA system, including the eDMA module ("engine").

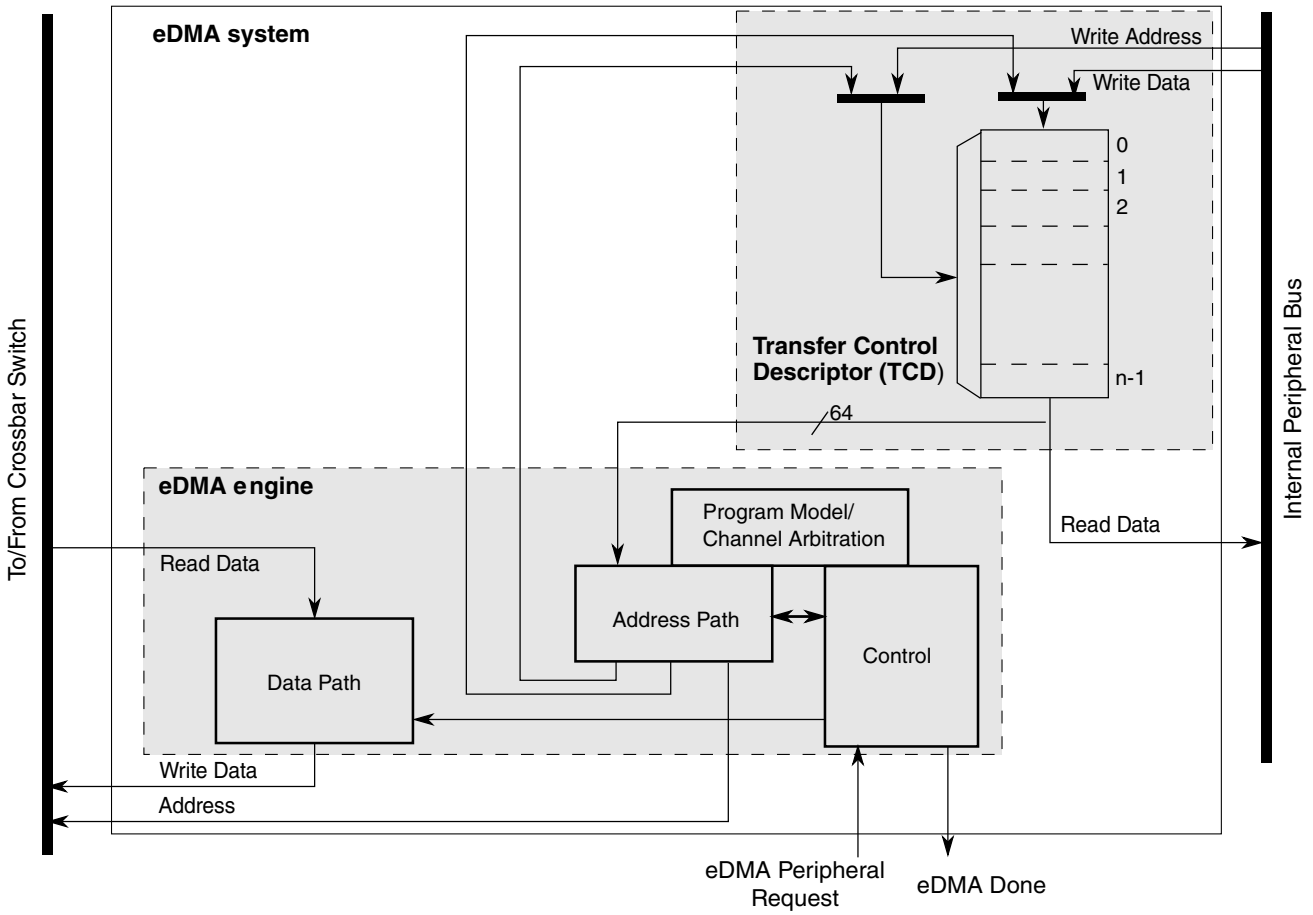

**Figure 38-1. eDMA system block diagram**

## 38.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

**Table 38-1. eDMA engine submodules**

| Submodule | Function |
|---|---|
| Address path | This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.<br><br>When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes |

*Table continues on the next page...*

**Table 38-1. eDMA engine submodules (continued)**

| Submodule | Function |
|---|---|
| | the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation. |
| Data path | This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.<br>The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase). |
| Program model/channel arbitration | This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic). |
| Control | This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/ destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write. |

The transfer-control descriptor local memory is further partitioned into:

**Table 38-2. Transfer control descriptor memory**

| Submodule | Description |
|---|---|
| Memory controller | This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled. |
| Memory array | TCD storage for each channel's transfer profile. |

## 38.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes

- 16-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

## 38.3 Modes of operation

The eDMA operates in the following modes:

**Table 38-3. Modes of operation**

| Mode | Description |
|---|---|
| Normal | In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.<br>A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data. |
| Debug | DMA operation is configurable in Debug mode via the control register:<br>• If CR[EDBG] is cleared, the DMA continues to operate.<br>• If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires. |
| Wait | Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode. |

## 38.4 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

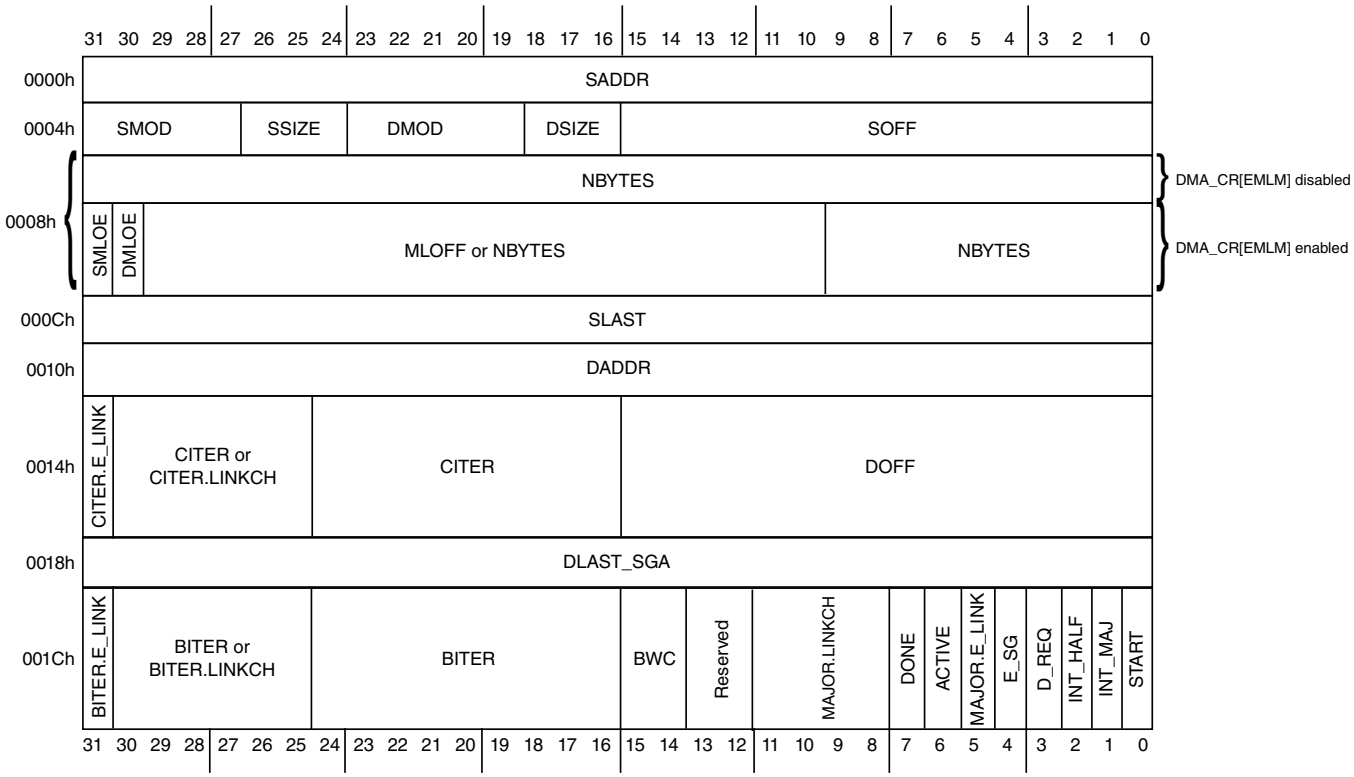
### 38.4.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 15. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

### 38.4.2 TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

## 38.4.3 TCD structure



## 38.4.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

## 38.4.5 DMA0 register descriptions

### 38.4.5.1 DMA0 Memory map

DMA0 base address: 4000_8000h

| Offset | Register | Width (In bits) | Access | Reset value |

## 38.4.5.2 Control Register (CR)

### 38.4.5.2.1 Offset

| Register | Offset |
|---|---|
| CR | 0h |

### 38.4.5.2.2 Function

The CR defines the basic operating configuration of the DMA.

Arbitration can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels are cycled through (from high to low channel number) without regard to priority.

**NOTE**

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.

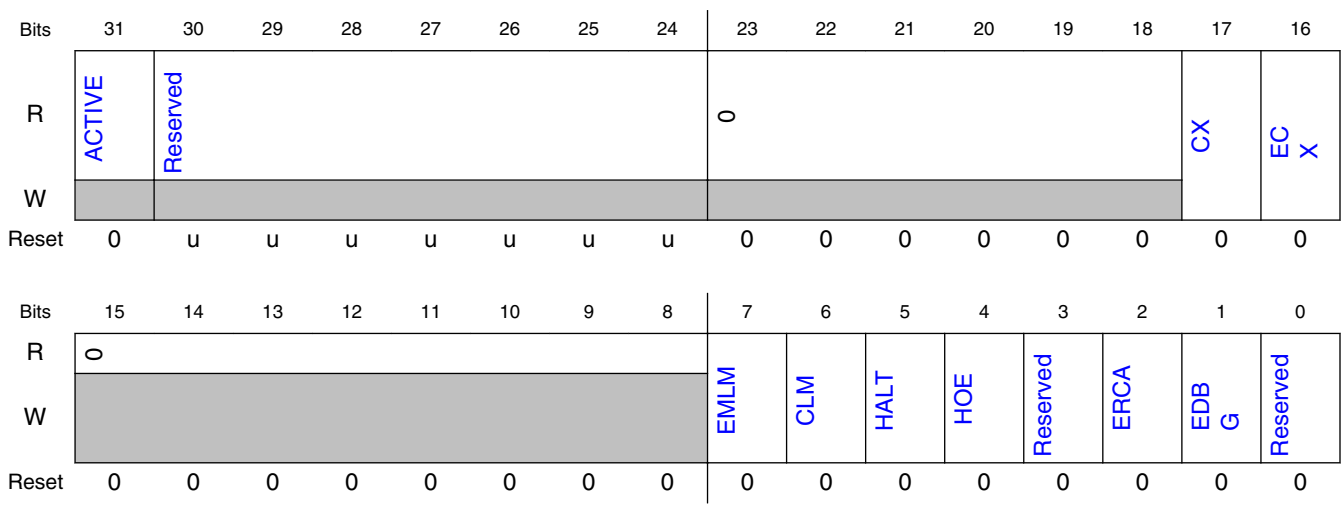
Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is

complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

### 38.4.5.2.3 Diagram



### 38.4.5.2.4 Fields

| Field | Function |
|---|---|
| 31<br>ACTIVE | DMA Active Status<br>0b - eDMA is idle.<br>1b - eDMA is executing a channel. |
| 30-24<br>— | eDMA version number<br>Reserved |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 23-18<br>— | Reserved |
| 17<br>CX | Cancel Transfer<br>0b - Normal operation<br>1b - Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed. |
| 16<br>ECX | Error Cancel Transfer<br>0b - Normal operation<br>1b - Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt. |
| 15-8<br>— | Reserved |
| 7<br>EMLM | Enable Minor Loop Mapping<br>0b - Disabled. TCDn.word2 is defined as a 32-bit NBYTES field.<br>1b - Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled. |
| 6<br>CLM | Continuous Link Mode<br>**NOTE:** Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, for example, if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing.<br>0b - A minor loop channel link made to itself goes through channel arbitration before being activated again.<br>1b - A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop. |
| 5<br>HALT | Halt DMA Operations<br>0b - Normal operation<br>1b - Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared. |
| 4<br>HOE | Halt On Error<br>0b - Normal operation<br>1b - Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared. |
| 3<br>— | Reserved<br>Reserved |
| 2<br>ERCA | Enable Round Robin Channel Arbitration<br>0b - Fixed priority arbitration is used for channel selection .<br>1b - Round robin arbitration is used for channel selection . |
| 1<br>EDBG | Enable Debug<br>0b - When in debug mode, the DMA continues to operate. |

*Table continues on the next page...*

| Field | Function |

## 38.4.5.3 Error Status Register (ES)

### 38.4.5.3.1 Offset

| Register | Offset |
|---|---|
| ES | 4h |

### 38.4.5.3.2 Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See Fault reporting and handling for more details.

## 38.4.5.4 Enable Request Register (ERQ)

### 38.4.5.4.1 Offset

| Register | Offset |
|---|---|
| ERQ | Ch |

### 38.4.5.4.2 Function

The ERQ register provides a bit map for the 16 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to this register.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

**NOTE**

Disable a channel's hardware service request at the source before clearing the channel's ERQ bit.

## 38.4.5.5 Enable Error Interrupt Register (EEI)

### 38.4.5.5.1 Offset

| Register | Offset |
|---|---|
| EEI | 14h |

### 38.4.5.5.2 Function

The EEI register provides a bit map for the 16 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

## 38.4.5.6 Clear Enable Error Interrupt Register (CEEI)

### 38.4.5.6.1 Offset

| Register | Offset |
|---|---|
| CEEI | 18h |

### 38.4.5.6.2 Function

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

### 38.4.5.6.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | 0 | 0 | | | 0 | | | |

## 38.4.5.7 Set Enable Error Interrupt Register (SEEI)

### 38.4.5.7.1 Offset

| Register | Offset |
|---|---|
| SEEI | 19h |

### 38.4.5.7.2 Function

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

### 38.4.5.7.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | 0 | 0 | | | 0 | | | |
| W | NOP | SAEE | 0 | | SEEI | | | |

## 38.4.5.8 Clear Enable Request Register (CERQ)

### 38.4.5.8.1 Offset

| Register | Offset |
|---|---|
| CERQ | 1Ah |

### 38.4.5.8.2 Function

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

**NOTE**

Disable a channel's hardware service request at the source before clearing the channel's ERQ bit.

### 38.4.5.8.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

## 38.4.5.9 Set Enable Request Register (SERQ)

### 38.4.5.9.1 Offset

| Register | Offset |
|---|---|
| SERQ | 1Bh |

### 38.4.5.9.2 Function

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

### 38.4.5.9.3 Diagram

## 38.4.5.10 Clear DONE Status Bit Register (CDNE)

### 38.4.5.10.1 Offset

| Register | Offset |
|---|---|
| CDNE | 1Ch |

### 38.4.5.10.2 Function

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

### 38.4.5.10.3 Diagram

|---|---|
| CERR | 1Eh |

#### 38.4.5.12.2 Function

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

#### 38.4.5.12.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 38.4.5.13 Clear Interrupt Request Register (CINT)

#### 38.4.5.13.1 Offset

| Register | Offset |
|---|---|
| CINT | 1Fh |

#### 38.4.5.13.2 Function

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

## 38.4.5.14 Interrupt Request Register (INT)

### 38.4.5.14.1 Offset

| Register | Offset |
|---|---|
| INT | 24h |

### 38.4.5.14.2 Function

The INT register provides a bit map for the 16 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

## 38.4.5.15 Error Register (ERR)

### 38.4.5.15.1 Offset

| Register | Offset |
|---|---|
| ERR | 2Ch |

### 38.4.5.15.2 Function

The ERR register provides a bit map for the 16 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the

contents of the EEI register, and then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI fields. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

## 38.4.5.16 Hardware Request Status Register (HRS)

### 38.4.5.16.1 Offset

| Register | Offset |
|---|---|
| HRS | 34h |

### 38.4.5.16.2 Function

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

**NOTE**

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

## 38.4.5.18 Channel Priority Register (DCHPRI3 - DCHPRI12)

### 38.4.5.18.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| DCHPRIn | FDh + (n × 1h) |

### 38.4.5.18.2 Function

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15.

### 38.4.5.18.3 Diagram

### 38.4.5.21.3 Fields

| Field | Function |
|---|---|
| 15-11<br>SMOD | Source Address Modulo<br>00000b - Source address modulo feature is disabled<br>00001-11111b - This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range. |
| 10-8<br>SSIZE | Source data transfer size<br>**NOTE:** Using a Reserved value causes a configuration error.<br>**NOTE:** The eDMA defaults to privileged data access for all transactions.<br>000b - 8-bit<br>001b - 16-bit<br>010b - 32-bit<br>011b - Reserved<br>100b - 16-byte burst<br>101b - 32-byte burst<br>110b - Reserved<br>111b - Reserved |

| 2-0<br>DSIZE | Destination data transfer size<br>See the SSIZE definition |

## 38.4.5.22 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (TCD0_NBYTES_MLOFFNO - TCD15_NBYTES_MLOFFNO)

### 38.4.5.22.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_NBYTES_MLOFFNO | 1008h + (n × 20h) |

### 38.4.5.22.2 Function

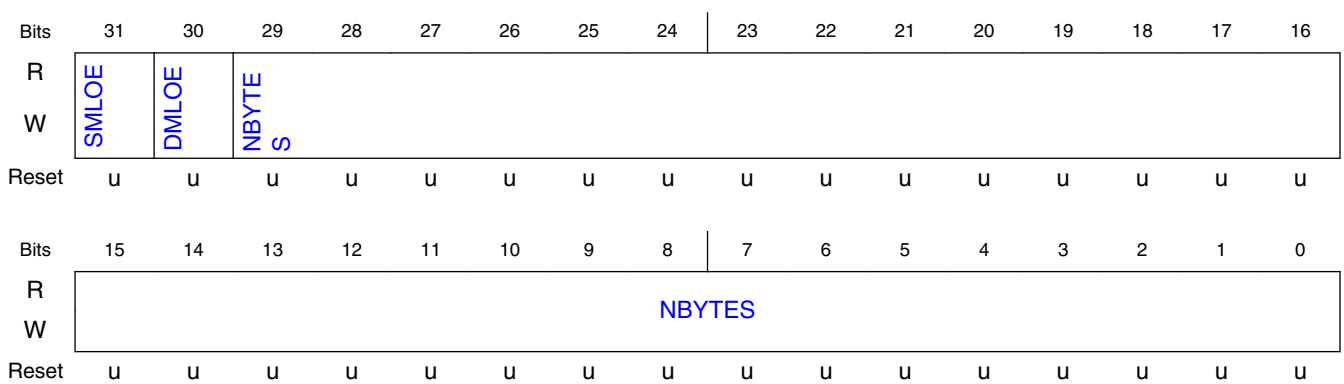
One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

### 38.4.5.22.3 Diagram



### 38.4.5.22.4 Fields

| Field | Function |
|---|---|
| 31<br>SMLOE | Source Minor Loop Offset Enable<br>Selects whether the minor loop offset is applied to the source address upon minor loop completion. |

*Table continues on the next page...*

| Field | Function |

| | 0b - The minor loop offset is not applied to the SADDR<br>1b - The minor loop offset is applied to the SADDR |
| 30<br>DMLOE | Destination Minor Loop Offset enable<br>Selects whether the minor loop offset is applied to the destination address upon minor loop completion.<br>0b - The minor loop offset is not applied to the DADDR<br>1b - The minor loop offset is applied to the DADDR |
| 29-0<br>NBYTES | Minor Byte Transfer Count<br>Number of bytes to be transferred in each service request of the channel.<br>As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. |

## 38.4.5.23 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (TCD0_NBYTES_MLOFFYES - TCD15_NBYTES_MLOFFYES)

### 38.4.5.23.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_NBYTES_MLOFFYES | 1008h + (n × 20h) |

### 38.4.5.23.2 Function

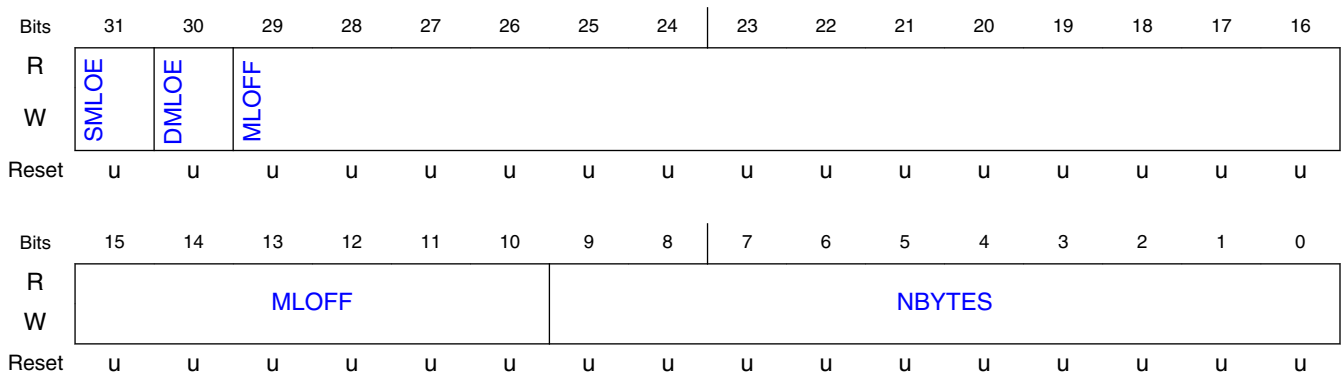
One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

### 38.4.5.23.3 Diagram



### 38.4.5.23.4 Fields

| Field | Function |
|---|---|
| 31<br>SMLOE | Source Minor Loop Offset Enable<br>Selects whether the minor loop offset is applied to the source address upon minor loop completion.<br>0b - The minor loop offset is not applied to the SADDR<br>1b - The minor loop offset is applied to the SADDR |
| 30<br>DMLOE | Destination Minor Loop Offset enable<br>Selects whether the minor loop offset is applied to the destination address upon minor loop completion.<br>0b - The minor loop offset is not applied to the DADDR<br>1b - The minor loop offset is applied to the DADDR |
| 29-10<br>MLOFF | If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes. |
| 9-0<br>NBYTES | Minor Byte Transfer Count<br>Number of bytes to be transferred in each service request of the channel.<br>As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. |

## 38.4.5.24 TCD Minor Byte Count (Minor Loop Mapping Disabled) (TCD0_NBYTES_MLNO - TCD15_NBYTES_MLNO)

### 38.4.5.24.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_NBYTES_MLNO | 1008h + (n × 20h) |

### 38.4.5.24.2 Function

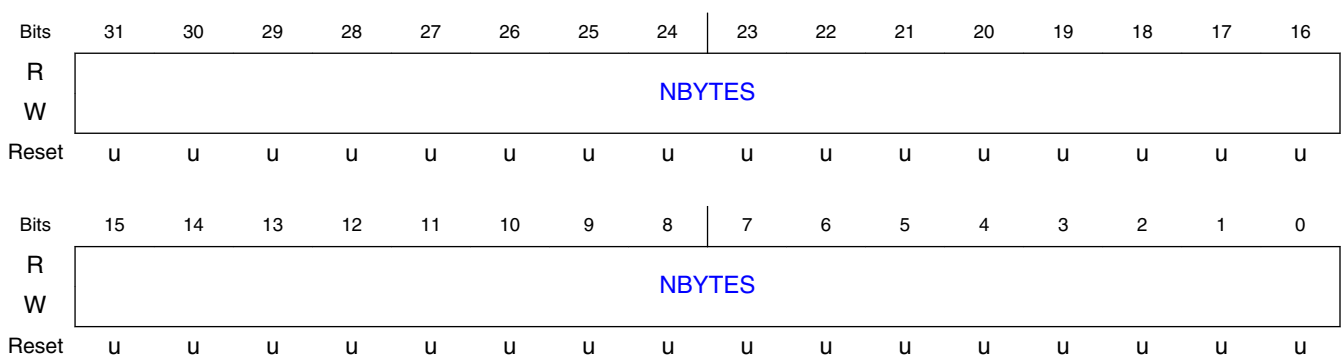
This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

### 38.4.5.24.3 Diagram



### 38.4.5.24.4 Fields

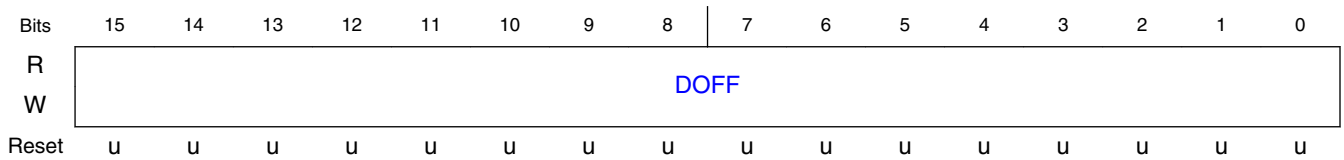
## 38.4.5.27 TCD Signed Destination Address Offset (TCD0_DOFF - TCD15_DOFF)

### 38.4.5.27.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_DOFF | 1014h + (n × 20h) |

### 38.4.5.27.2 Diagram



### 38.4.5.27.3 Fields

| Field | Function |
|---|---|
| 15-0<br>DOFF | Destination Address Signed Offset<br>Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed. |

## 38.4.5.28 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD15_CITER_ELINKNO)

### 38.4.5.28.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_CITER_ELINKNO | 1016h + (n × 20h) |

### 38.4.5.28.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD15_CITER_ELINKYES), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is cleared, this register is defined as follows.

### 38.4.5.28.3 Diagram

### 38.4.5.28.4 Fields

| Field | Function |
|---|---|
| 15<br>ELINK | Enable channel-to-channel linking on minor-loop complete<br>As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.<br>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.<br>**NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported.<br>0b - The channel-to-channel linking is disabled<br>1b - The channel-to-channel linking is enabled |
| 14-0<br>CITER | Current Major Iteration Count<br>This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.<br>**NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.<br>**NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001. |

## 38.4.5.29 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD15_CITER_ELINKYES)

### 38.4.5.29.1 Offset

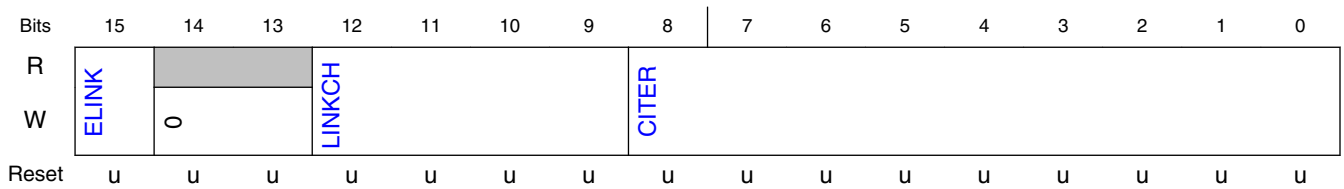
For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_CITER_ELINKYES | 1016h + (n × 20h) |

### 38.4.5.29.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD15_CITER_ELINKNO), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is set, this register is defined as follows.

### 38.4.5.29.3 Diagram



### 38.4.5.29.4 Fields

| Field | Function |
|---|---|
| 15<br>ELINK | Enable channel-to-channel linking on minor-loop complete<br>As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.<br>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.<br>**NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported.<br>0b - The channel-to-channel linking is disabled<br>1b - The channel-to-channel linking is enabled |
| 14-13<br>— | Reserved |
| 12-9<br>LINKCH | Minor Loop Link Channel Number<br>If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit. |
| 8-0<br>CITER | Current Major Iteration Count<br>This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.<br>**NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. |

| Field | Function |
|---|---|
| | **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001. |

## 38.4.5.30 TCD Last Destination Address Adjustment/Scatter Gather Address (TCD0_DLASTSGA - TCD15_DLASTSGA)

### 38.4.5.30.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_DLASTSGA | 1018h + (n × 20h) |

### 38.4.5.30.2 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Reset | u | u | u | u | u | u | u | u | u | u | u | u | u | u | u | u |

### 38.4.5.30.3 Fields

| Field | Function |
|---|---|
| 31-0<br>DLASTSGA | DLASTSGA<br>Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather).<br>If (TCDn_CSR[ESG] = 0) then:<br>• Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure.<br>• This field uses two's complement notation for the final destination address adjustment.<br>Otherwise: |

| Field | Function |
|---|---|
| | • This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported. |

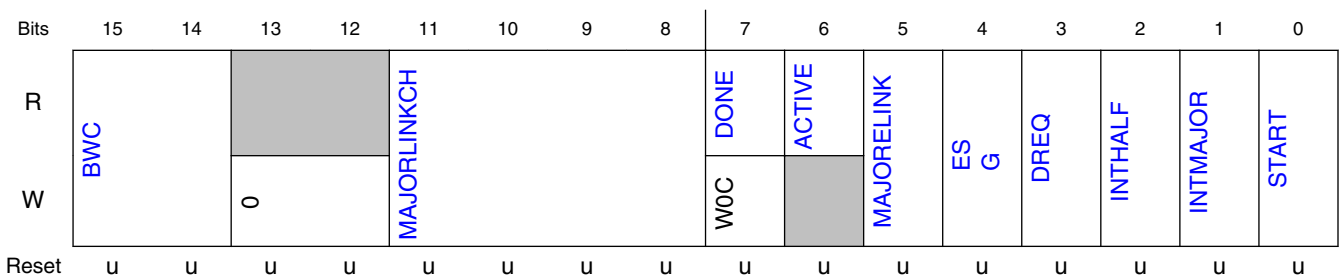
## 38.4.5.31 TCD Control and Status (TCD0_CSR - TCD15_CSR)

### 38.4.5.31.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_CSR | 101Ch + (n × 20h) |

### 38.4.5.31.2 Diagram



### 38.4.5.31.3 Fields

| Field | Function |
|---|---|
| 15-14 | Bandwidth Control |
| BWC | Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch.<br>**NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency.<br>00b - No eDMA engine stalls.<br>01b - Reserved<br>10b - eDMA engine stalls for 4 cycles after each R/W.<br>11b - eDMA engine stalls for 8 cycles after each R/W. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 13-12<br>— | Reserved |
| 11-8<br>MAJORLINKCH | Major Loop Link Channel Number<br>If (MAJORELINK = 0) then:<br>• No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted.<br>Otherwise:<br>• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit. |
| 7<br>DONE | Channel Done<br>This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated.<br>**NOTE:** This bit must be cleared to write the MAJORELINK or ESG bits. |
| 6<br>ACTIVE | Channel Active<br>This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected. |
| 5<br>MAJORELINK | Enable channel-to-channel linking on major loop complete<br>As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.<br>**NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.<br>0b - The channel-to-channel linking is disabled.<br>1b - The channel-to-channel linking is enabled. |
| 4<br>ESG | Enable Scatter/Gather Processing<br>As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory.<br>**NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.<br>0b - The current channel's TCD is normal format.<br>1b - The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution. |
| 3<br>DREQ | Disable Request<br>If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero.<br>0b - The channel's ERQ bit is not affected.<br>1b - The channel's ERQ bit is cleared when the major loop is complete. |
| 2<br>INTHALF | Enable an interrupt when major counter is half complete.<br>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress.<br>**NOTE:** If BITER = 1, do not use INTHALF. Use INTMAJOR instead.<br>0b - The half-point interrupt is disabled. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - The half-point interrupt is enabled. |
| 1<br>INTMAJOR | Enable an interrupt when major iteration count completes.<br>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero.<br>0b - The end-of-major loop interrupt is disabled.<br>1b - The end-of-major loop interrupt is enabled. |
| 0<br>START | Channel Start<br>If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution.<br>0b - The channel is not explicitly started.<br>1b - The channel is explicitly started via a software initiated service request. |

## 38.4.5.32 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD15_BITER_ELINKYES)

### 38.4.5.32.1 Offset

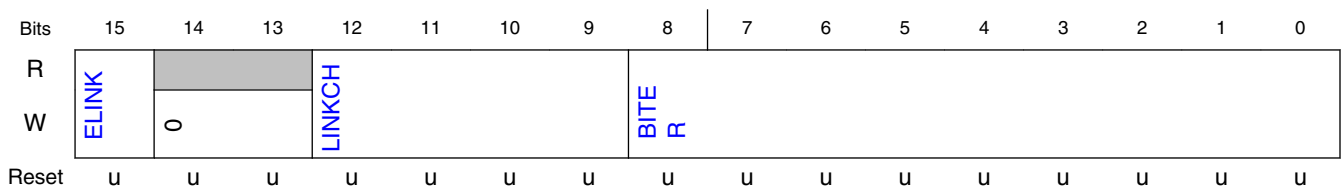
For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_BITER_ELINKYES | 101Eh + (n × 20h) |

### 38.4.5.32.2 Function

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

### 38.4.5.32.3 Diagram



### 38.4.5.32.4 Fields

| Field | Function |
|---|---|
| 15<br>ELINK | Enables channel-to-channel linking on minor loop complete<br>As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.<br>**NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.<br>0b - The channel-to-channel linking is disabled<br>1b - The channel-to-channel linking is enabled |
| 14-13<br>— | Reserved |
| 12-9<br>LINKCH | Link Channel Number<br>If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.<br>**NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. |
| 8-0<br>BITER | Starting major iteration count<br>As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.<br>**NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001. |

## 38.4.5.33 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD15_BITER_ELINKNO)

### 38.4.5.33.1 Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| TCDn_BITER_ELINKNO | 101Eh + (n × 20h) |

### 38.4.5.33.2 Function

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

### 38.4.5.33.3 Diagram

### 38.4.5.33.4 Fields

| Field | Function |
|---|---|
| 15<br>ELINK | Enables channel-to-channel linking on minor loop complete<br>As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.<br>**NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.<br>0b - The channel-to-channel linking is disabled<br>1b - The channel-to-channel linking is enabled |
| 14-0<br>BITER | Starting Major Iteration Count<br>As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.<br>**NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001. |

## 38.4.6 DMA1 register descriptions

### 38.4.6.1 DMA1 Memory map

DMA1 base address: 4100_8000h

| Offset | Register | Width (In bits) | Access | Reset value |

## 38.4.6.2 Control Register (CR)

#### 38.4.6.2.1 Offset

| Register | Offset |
|---|---|
| CR | 0h |

#### 38.4.6.2.2 Function

The CR defines the basic operating configuration of the DMA.

Arbitration can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels are cycled through (from high to low channel number) without regard to priority.

**NOTE**

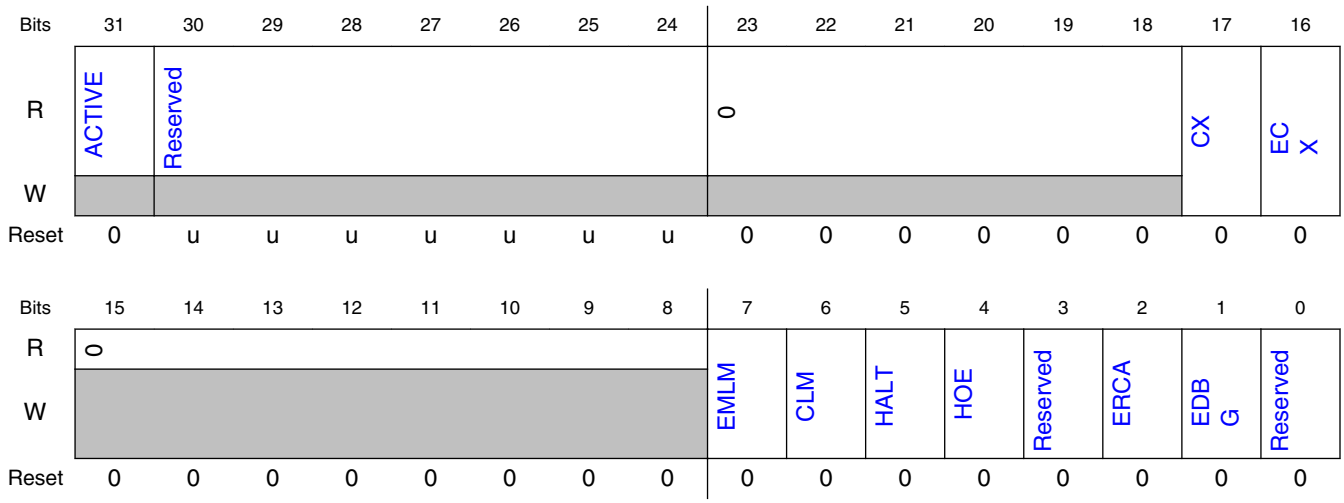
For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

### 38.4.6.2.3 Diagram



### 38.4.6.2.4 Fields

| Field | Function |
|---|---|
| 31<br>ACTIVE | DMA Active Status<br>0b - eDMA is idle.<br>1b - eDMA is executing a channel. |
| 30-24<br>— | eDMA version number<br>Reserved |
| 23-18<br>— | Reserved |
| 17<br>CX | Cancel Transfer<br>0b - Normal operation<br>1b - Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed. |
| 16<br>ECX | Error Cancel Transfer<br>0b - Normal operation<br>1b - Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt. |
| 15-8<br>— | Reserved |
| 7<br>EMLM | Enable Minor Loop Mapping<br>0b - Disabled. TCDn.word2 is defined as a 32-bit NBYTES field.<br>1b - Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | address, the destination address, or both. The NBYTES field is reduced when either offset is enabled. |
| 6<br>CLM | Continuous Link Mode<br>**NOTE:** Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, for example, if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing.<br>0b - A minor loop channel link made to itself goes through channel arbitration before being activated again.<br>1b - A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop. |
| 5<br>HALT | Halt DMA Operations<br>0b - Normal operation<br>1b - Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared. |
| 4<br>HOE | Halt On Error<br>0b - Normal operation<br>1b - Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared. |
| 3<br>— | Reserved<br>Reserved |
| 2<br>ERCA | Enable Round Robin Channel Arbitration<br>0b - Fixed priority arbitration is used for channel selection .<br>1b - Round robin arbitration is used for channel selection . |
| 1<br>EDBG | Enable Debug<br>0b - When in debug mode, the DMA continues to operate.<br>1b - When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared. |
| 0<br>— | Reserved<br>Reserved |

## 38.4.6.3 Error Status Register (ES)

### 38.4.6.3.1 Offset

| Register | Offset |
|---|---|
| ES | 4h |

### 38.4.6.3.2 Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See Fault reporting and handling for more details.

## 38.4.6.4 Enable Request Register (ERQ)

### 38.4.6.4.1 Offset

| Register | Offset |
|---|---|
| ERQ | Ch |

### 38.4.6.4.2 Function

The ERQ register provides a bit map for the 8 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to this register.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

**NOTE**

Disable a channel's hardware service request at the source before clearing the channel's ERQ bit.

## 38.4.6.5 Enable Error Interrupt Register (EEI)

### 38.4.6.5.1 Offset

| Register | Offset |
|---|---|
| EEI | 14h |

### 38.4.6.5.2 Function

The EEI register provides a bit map for the 8 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

## 38.4.6.6 Clear Enable Error Interrupt Register (CEEI)

### 38.4.6.6.1 Offset

| Register | Offset |
|---|---|
| CEEI | 18h |

### 38.4.6.6.2 Function

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

### 38.4.6.6.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | 0 | 0 | | | | 0 | | |

## 38.4.6.7 Set Enable Error Interrupt Register (SEEI)

### 38.4.6.7.1 Offset

| Register | Offset |
|---|---|
| SEEI | 19h |

### 38.4.6.7.2 Function

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

### 38.4.6.7.3 Diagram

## 38.4.6.8 Clear Enable Request Register (CERQ)

### 38.4.6.8.1 Offset

| Register | Offset |
|---|---|
| CERQ | 1Ah |

### 38.4.6.8.2 Function

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

**NOTE**

Disable a channel's hardware service request at the source before clearing the channel's ERQ bit.

### 38.4.6.8.3 Diagram

## 38.4.6.9 Set Enable Request Register (SERQ)

### 38.4.6.9.1 Offset

| Register | Offset |
|---|---|
| SERQ | 1Bh |

### 38.4.6.9.2 Function

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

### 38.4.6.9.3 Diagram

## 38.4.6.10 Clear DONE Status Bit Register (CDNE)

### 38.4.6.10.1 Offset

| Register | Offset |
|---|---|
| CDNE | 1Ch |

### 38.4.6.10.2 Function

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

### 38.4.6.10.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|

## 38.4.6.11 Set START Bit Register (SSRT)

### 38.4.6.11.1 Offset

| Register | Offset |
|---|---|
| SSRT | 1Dh |

### 38.4.6.11.2 Function

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

## 38.4.6.12 Clear Error Register (CERR)

### 38.4.6.12.1 Offset

| Register | Offset |
|---|---|
| CERR | 1Eh |

### 38.4.6.12.2 Function

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

### 38.4.6.12.3 Diagram

## 38.4.6.13 Clear Interrupt Request Register (CINT)

### 38.4.6.13.1 Offset

| Register | Offset |
|---|---|
| CINT | 1Fh |

### 38.4.6.13.2 Function

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests.

If the NOP bit is set, the command is ignored. This allows you to set a single, byte-wide register with a 32-bit write while not affecting the other registers addressed in the write. In such a case the other three bytes of the word would all have their NOP bit set so that that these register will not be affected by the write.

Reads of this register return all zeroes.

## 38.4.6.14 Interrupt Request Register (INT)

### 38.4.6.14.1 Offset

| Register | Offset |
|---|---|
| INT | 24h |

### 38.4.6.14.2 Function

The INT register provides a bit map for the 8 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

### 38.4.6.14.3 Diagram

## 38.4.6.15 Error Register (ERR)

### 38.4.6.15.1 Offset

| Register | Offset |
|---|---|
| ERR | 2Ch |

### 38.4.6.15.2 Function

The ERR register provides a bit map for the 8 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI register, and then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI fields. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

## 38.4.6.16 Hardware Request Status Register (HRS)

### 38.4.6.16.1 Offset

| Register | Offset |
|---|---|
| HRS | 34h |

### 38.4.6.16.2 Function

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

**NOTE**

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

### 38.4.6.16.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 38.4.6.17 Enable Asynchronous Request in Stop Register (EARS)

### 38.4.6.17.1 Offset

| Register | Offset |
|---|---|
| EARS | 44h |

### 38.4.6.17.2 Function

The EARS register is used to enable or disable the DMA requests in Enable Request Register (ERQ) by AND'ing the bits of these two registers.

### 38.4.6.17.3 Diagram

## 38.4.6.18 Channel Priority Register (DCHPRI3 - DCHPRI4)

### 38.4.6.18.1 Offset

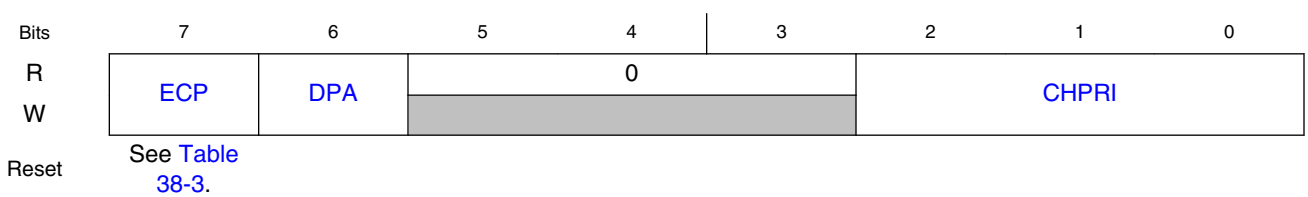
For n = 0 to 7:

| Register | Offset |
|---|---|
| DCHPRIn | FDh + (n × 1h) |

### 38.4.6.18.2 Function

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 7.

### 38.4.6.18.3 Diagram



### 38.4.6.18.4 Register reset values

| Register | Reset |
|---|---|
| DCHPRI3 | 03h |
| DCHPRI2 | 02h |

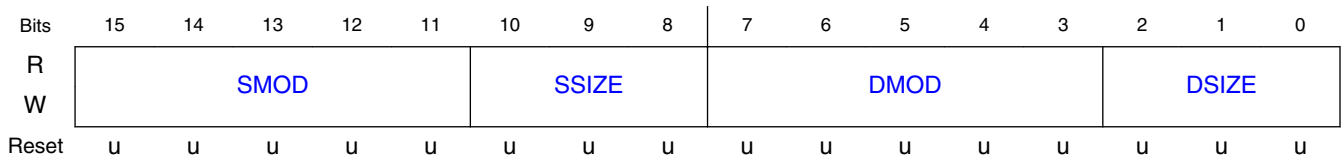
### 38.4.6.21 TCD Transfer Attributes (TCD0_ATTR - TCD7_ATTR)

#### 38.4.6.21.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_ATTR | 1006h + (n × 20h) |

## 38.4.6.21.2 Diagram



## 38.4.6.21.3 Fields

| Field | Function |
|---|---|
| 15-11<br>SMOD | Source Address Modulo<br>00000b - Source address modulo feature is disabled<br>00001-11111b - This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range. |
| 10-8<br>SSIZE | Source data transfer size<br>**NOTE:** Using a Reserved value causes a configuration error.<br>**NOTE:** The eDMA defaults to privileged data access for all transactions.<br>000b - 8-bit<br>001b - 16-bit<br>010b - 32-bit<br>011b - Reserved<br>100b - 16-byte<br>101b - 32-byte<br>110b - Reserved<br>111b - Reserved |

## 38.4.6.22 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (TCD0_NBYTES_MLOFFNO - TCD7_NBYTES_MLOFFNO)

### 38.4.6.22.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_NBYTES_MLOFFNO | 1008h + (n × 20h) |

### 38.4.6.22.2 Function

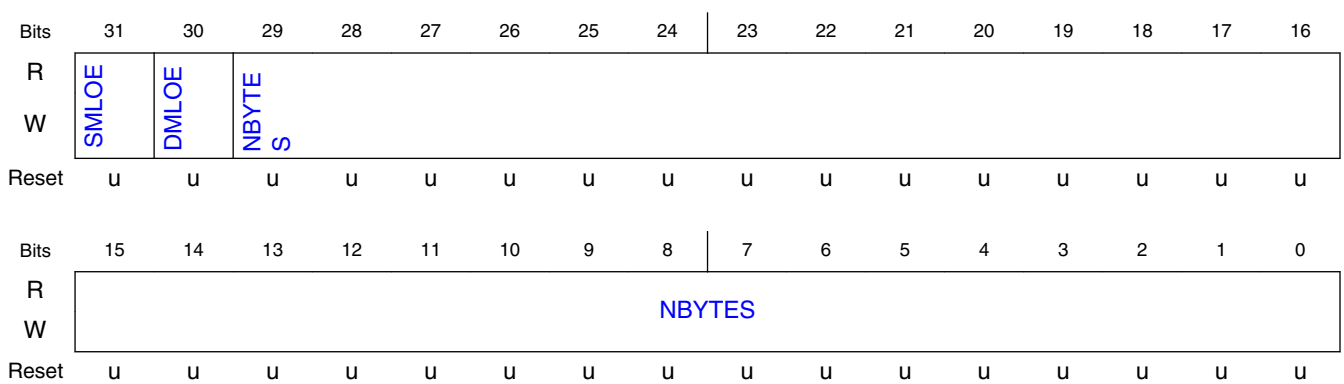
One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

### 38.4.6.22.3 Diagram



### 38.4.6.22.4 Fields

| Field | Function |
|---|---|
| 31<br>SMLOE | Source Minor Loop Offset Enable<br>Selects whether the minor loop offset is applied to the source address upon minor loop completion.<br>0b - The minor loop offset is not applied to the SADDR<br>1b - The minor loop offset is applied to the SADDR |
| 30<br>DMLOE | Destination Minor Loop Offset enable<br>Selects whether the minor loop offset is applied to the destination address upon minor loop completion.<br>0b - The minor loop offset is not applied to the DADDR<br>1b - The minor loop offset is applied to the DADDR |
| 29-0<br>NBYTES | Minor Byte Transfer Count<br>Number of bytes to be transferred in each service request of the channel.<br>As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. |

## 38.4.6.23 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (TCD0_NBYTES_MLOFFYES - TCD7_NBYTES_MLOFFYES)

### 38.4.6.23.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_NBYTES_MLOFFYES | 1008h + (n × 20h) |

### 38.4.6.23.2 Function

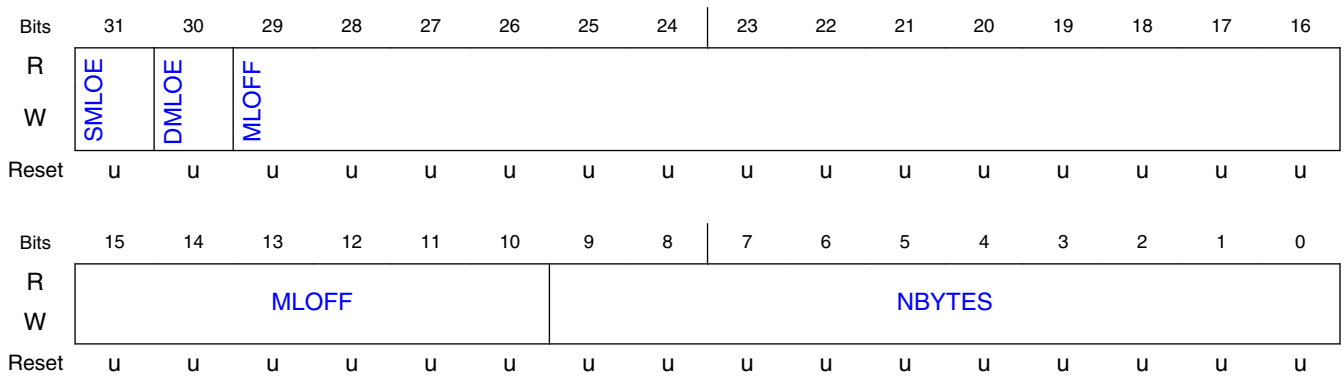
One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

### 38.4.6.23.3 Diagram



### 38.4.6.23.4 Fields

| Field | Function |
|---|---|
| 31<br>SMLOE | Source Minor Loop Offset Enable<br>Selects whether the minor loop offset is applied to the source address upon minor loop completion.<br>0b - The minor loop offset is not applied to the SADDR<br>1b - The minor loop offset is applied to the SADDR |
| 30<br>DMLOE | Destination Minor Loop Offset enable<br>Selects whether the minor loop offset is applied to the destination address upon minor loop completion.<br>0b - The minor loop offset is not applied to the DADDR<br>1b - The minor loop offset is applied to the DADDR |
| 29-10<br>MLOFF | If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes. |
| 9-0<br>NBYTES | Minor Byte Transfer Count<br>Number of bytes to be transferred in each service request of the channel.<br>As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. |

## 38.4.6.24 TCD Minor Byte Count (Minor Loop Mapping Disabled) (TCD0_NBYTES_MLNO - TCD7_NBYTES_MLNO)

### 38.4.6.24.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_NBYTES_MLNO | 1008h + (n × 20h) |

### 38.4.6.24.2 Function

This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

### 38.4.6.24.3 Diagram

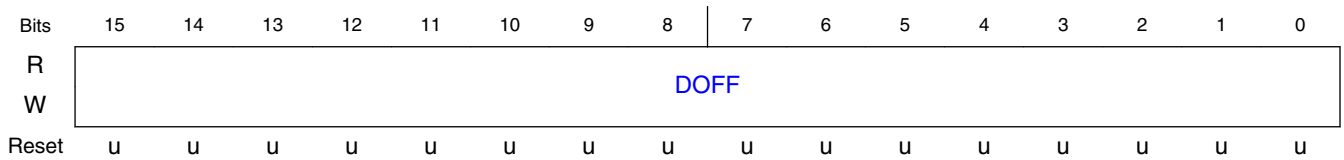
## 38.4.6.27 TCD Signed Destination Address Offset (TCD0_DOFF - TCD7_DOFF)

### 38.4.6.27.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_DOFF | 1014h + (n × 20h) |

### 38.4.6.27.2 Diagram



### 38.4.6.27.3 Fields

| Field | Function |
|---|---|
| 15-0<br>DOFF | Destination Address Signed Offset<br>Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed. |

## 38.4.6.28 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD7_CITER_ELINKNO)

### 38.4.6.28.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_CITER_ELINKNO | 1016h + (n × 20h) |

### 38.4.6.28.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD7_CITER_ELINKYES), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is cleared, this register is defined as follows.

### 38.4.6.28.3 Diagram

### 38.4.6.28.4 Fields

| Field | Function |
|---|---|
| 15<br>ELINK | Enable channel-to-channel linking on minor-loop complete<br>As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.<br>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.<br>**NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported.<br>0b - The channel-to-channel linking is disabled<br>1b - The channel-to-channel linking is enabled |
| 14-0<br>CITER | Current Major Iteration Count<br>This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.<br>**NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.<br>**NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001. |

## 38.4.6.29 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD7_CITER_ELINKYES)

### 38.4.6.29.1 Offset

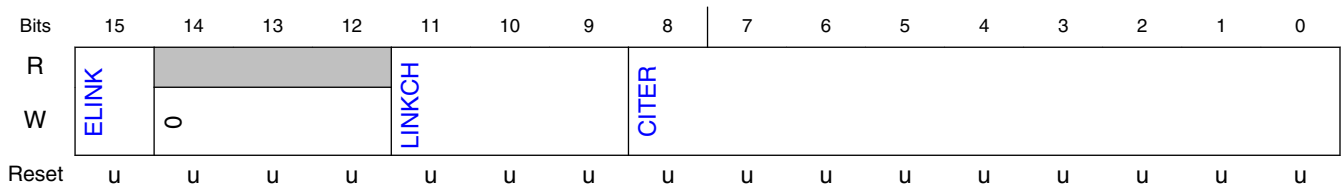
For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_CITER_ELINKYES | 1016h + (n × 20h) |

### 38.4.6.29.2 Function

This register contains the minor-loop channel-linking configuration and the channel's current iteration count. It is the same register as TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD7_CITER_ELINKNO), but its fields are defined differently based on the state of the ELINK field. If the ELINK field is set, this register is defined as follows.

### 38.4.6.29.3 Diagram



### 38.4.6.29.4 Fields

| Field | Function |
|---|---|
| 15<br>ELINK | Enable channel-to-channel linking on minor-loop complete<br>As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.<br>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.<br>**NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported.<br>0b - The channel-to-channel linking is disabled<br>1b - The channel-to-channel linking is enabled |
| 14-12<br>— | Reserved |
| 11-9<br>LINKCH | Minor Loop Link Channel Number<br>If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit. |
| 8-0<br>CITER | Current Major Iteration Count<br>This field is the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.<br>**NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. |

| Field | Function |
|---|---|
| | **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001. |

## 38.4.6.30 TCD Last Destination Address Adjustment/Scatter Gather Address (TCD0_DLASTSGA - TCD7_DLASTSGA)

### 38.4.6.30.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_DLASTSGA | 1018h + (n × 20h) |

### 38.4.6.30.2 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 38.4.6.30.3 Fields

| Field | Function |
|---|---|
| 31-0<br>DLASTSGA | DLASTSGA<br>Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather).<br>If (TCDn_CSR[ESG] = 0) then:<br>• Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure.<br>• This field uses two's complement notation for the final destination address adjustment.<br>Otherwise: |

| Field | Function |
|---|---|
| | • This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported. |

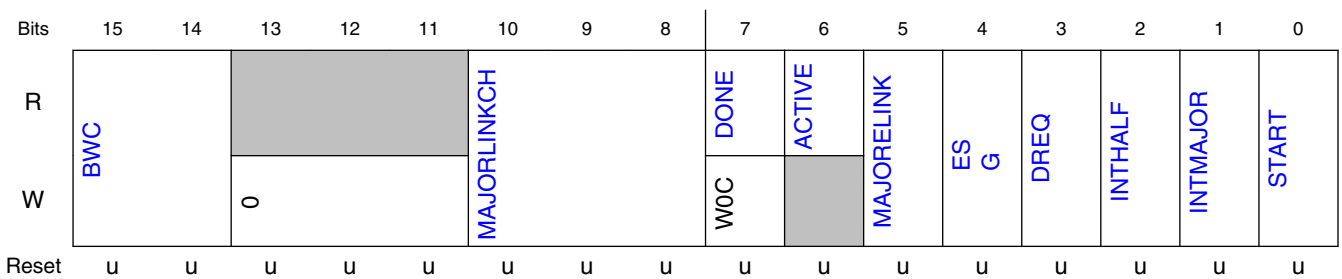
## 38.4.6.31 TCD Control and Status (TCD0_CSR - TCD7_CSR)

### 38.4.6.31.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_CSR | 101Ch + (n × 20h) |

### 38.4.6.31.2 Diagram



### 38.4.6.31.3 Fields

| Field | Function |
|---|---|
| 15-14 | Bandwidth Control |
| BWC | Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch.<br>**NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency.<br>00b - No eDMA engine stalls.<br>01b - Reserved<br>10b - eDMA engine stalls for 4 cycles after each R/W.<br>11b - eDMA engine stalls for 8 cycles after each R/W. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 13-11<br>— | Reserved |
| 10-8<br>MAJORLINKCH | Major Loop Link Channel Number<br>If (MAJORELINK = 0) then:<br>• No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted.<br>Otherwise:<br>• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit. |
| 7<br>DONE | Channel Done<br>This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated.<br>**NOTE:** This bit must be cleared to write the MAJORELINK or ESG bits. |
| 6<br>ACTIVE | Channel Active<br>This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected. |
| 5<br>MAJORELINK | Enable channel-to-channel linking on major loop complete<br>As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.<br>**NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.<br>0b - The channel-to-channel linking is disabled.<br>1b - The channel-to-channel linking is enabled. |
| 4<br>ESG | Enable Scatter/Gather Processing<br>As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory.<br>**NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.<br>0b - The current channel's TCD is normal format.<br>1b - The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution. |
| 3<br>DREQ | Disable Request<br>If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero.<br>0b - The channel's ERQ bit is not affected.<br>1b - The channel's ERQ bit is cleared when the major loop is complete. |
| 2<br>INTHALF | Enable an interrupt when major counter is half complete.<br>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress.<br>**NOTE:** If BITER = 1, do not use INTHALF. Use INTMAJOR instead.<br>0b - The half-point interrupt is disabled. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - The half-point interrupt is enabled. |
| 1<br>INTMAJOR | Enable an interrupt when major iteration count completes.<br>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero.<br>0b - The end-of-major loop interrupt is disabled.<br>1b - The end-of-major loop interrupt is enabled. |
| 0<br>START | Channel Start<br>If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution.<br>0b - The channel is not explicitly started.<br>1b - The channel is explicitly started via a software initiated service request. |

## 38.4.6.32 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD7_BITER_ELINKYES)

### 38.4.6.32.1 Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TCDn_BITER_ELINKYES | 101Eh + (n × 20h) |

### 38.4.6.32.2 Function

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

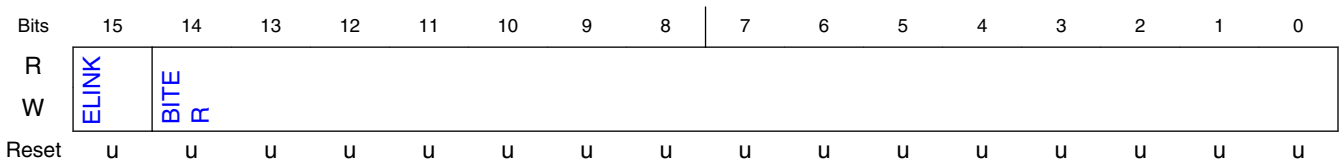
| Register | Offset |
|---|---|
| TCDn_BITER_ELINKNO | 101Eh + (n × 20h) |

#### 38.4.6.33.2 Function

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

#### 38.4.6.33.3 Diagram



#### 38.4.6.33.4 Fields

| Field | Function |
|---|---|
| 15<br>ELINK | Enables channel-to-channel linking on minor loop complete<br>As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.<br>**NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.<br>0b - The channel-to-channel linking is disabled<br>1b - The channel-to-channel linking is enabled |
| 14-0<br>BITER | Starting Major Iteration Count<br>As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.<br>**NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001. |

## 38.5 Functional description

The operation of the eDMA is described in the following subsections.

### 38.5.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

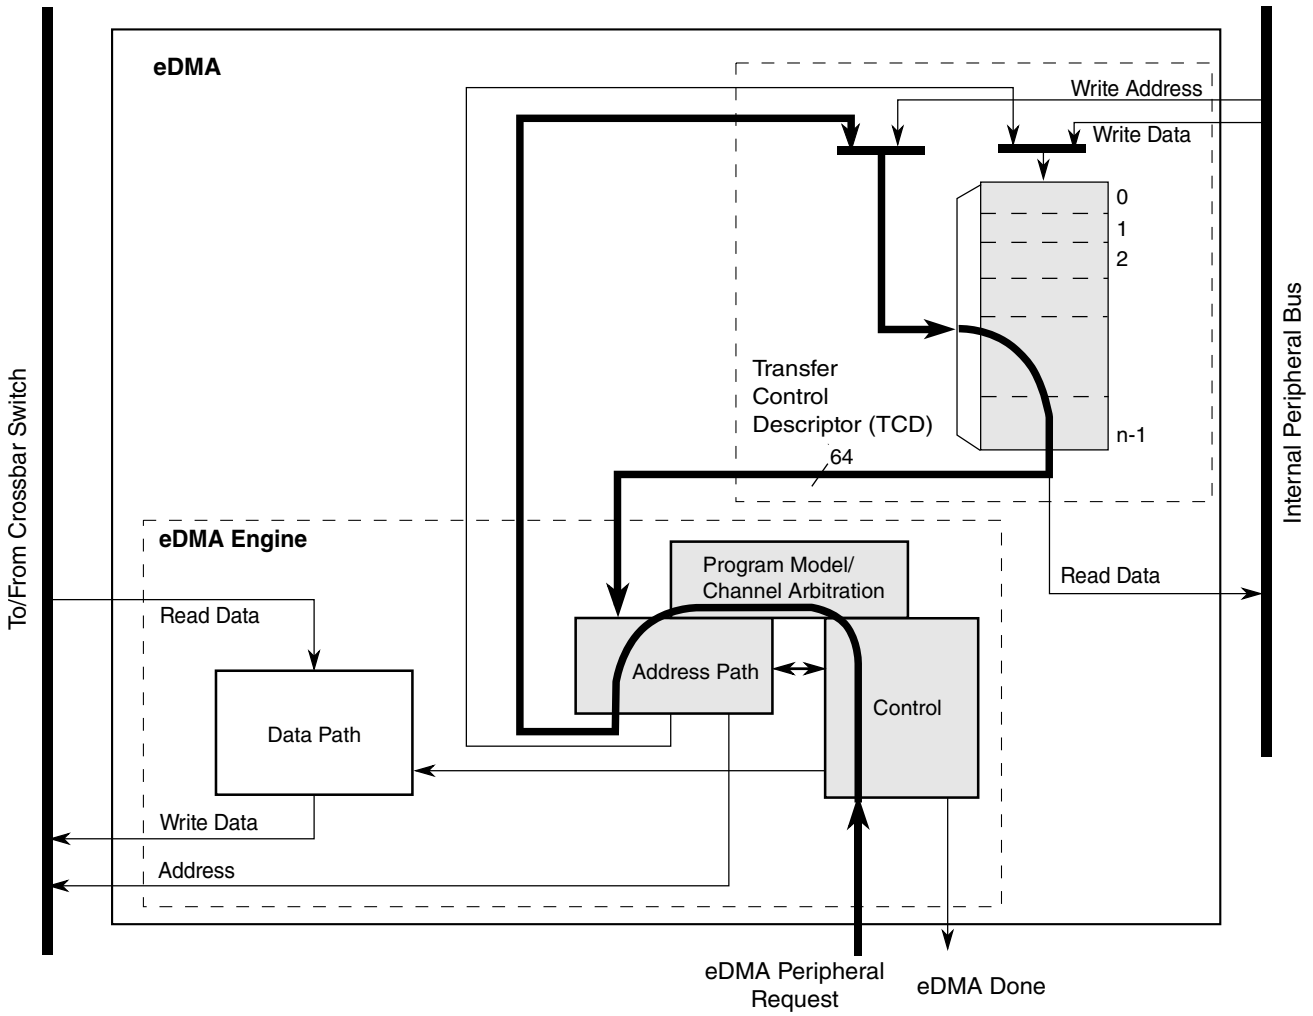


**Figure 38-2. eDMA operation, part 1**

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

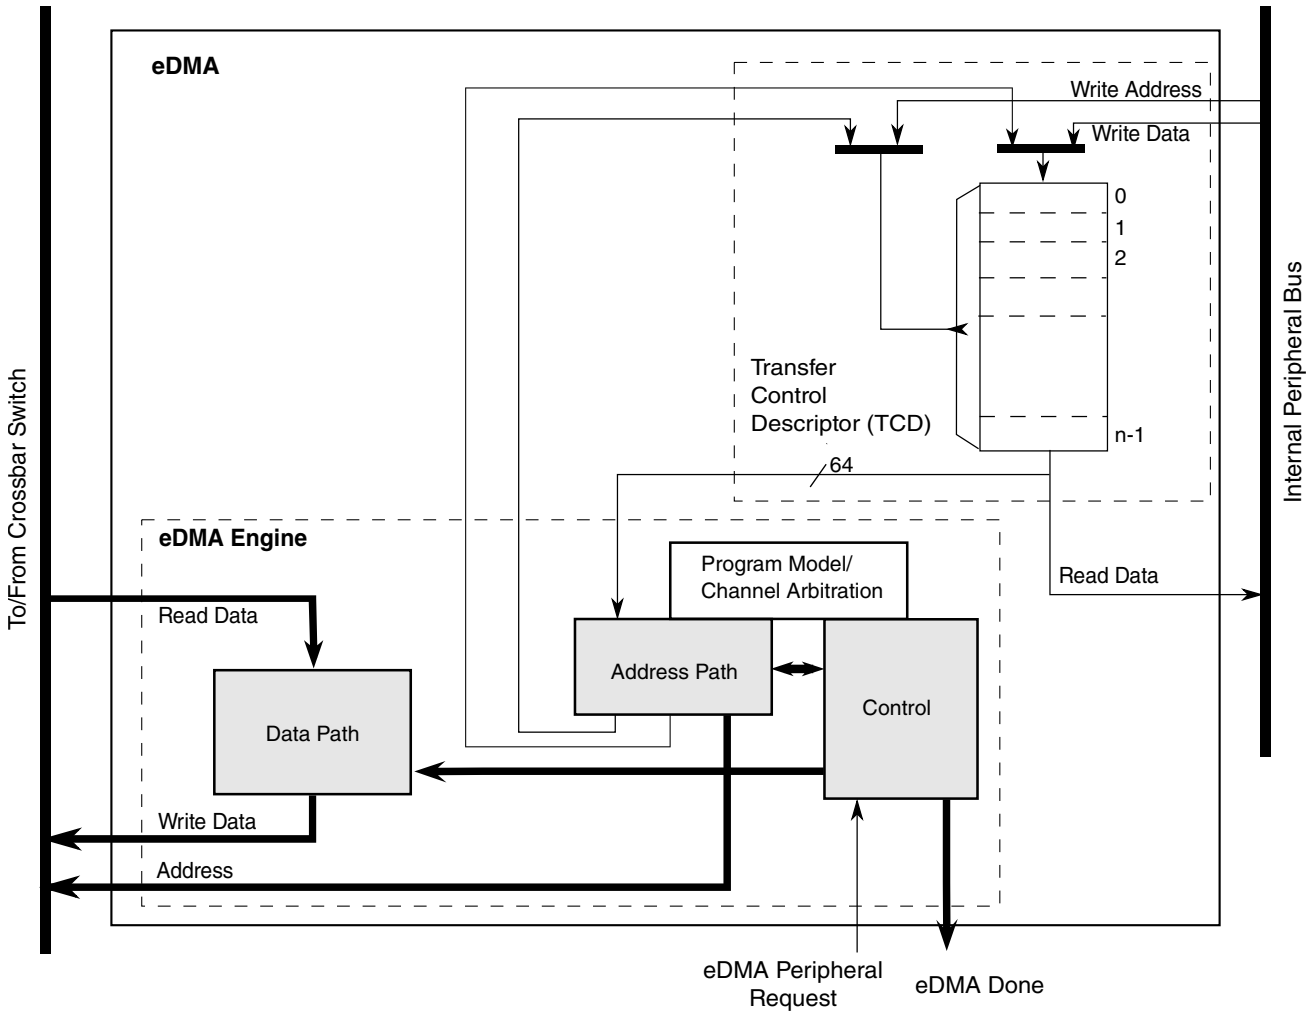

**Figure 38-3. eDMA operation, part 2**

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

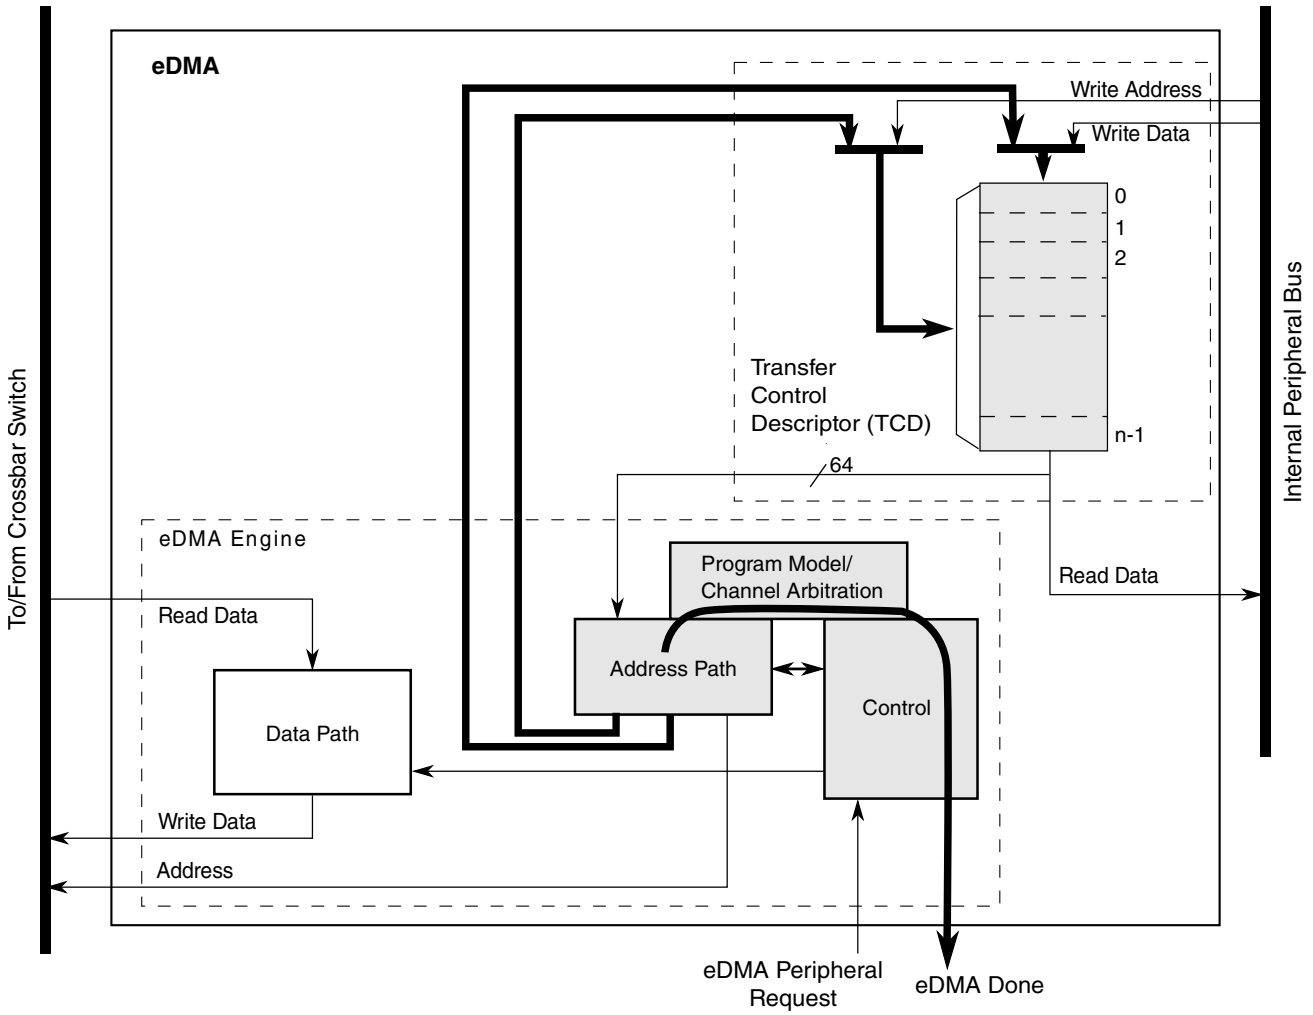

**Figure 38-4. eDMA operation, part 3**

## 38.5.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.

- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

**NOTE**

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration in undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error

occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

**NOTE**

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

### 38.5.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

### 38.5.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

#### 38.5.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

**NOTE**

All architectures will not meet the assumptions listed above. See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

**Table 38-4. eDMA peak transfer rates (Mbytes/sec)**

| System Speed, Width | Internal SRAM-to-Internal SRAM | 32 bit internal peripheral bus-to-Internal SRAM | Internal SRAM-to-32 bit internal peripheral bus |
|---|---|---|---|
| 48.0 MHz, 32 bit | 96.0 | 48.0 | 38.4 |
| 66.7 MHz, 32 bit | 133.3 | 66.7 | 53.3 |
| 83.3 MHz, 32 bit | 166.7 | 83.3 | 66.7 |
| 100.0 MHz, 32 bit | 200.0 | 100.0 | 80.0 |
| 133.3 MHz, 32 bit | 266.7 | 133.3 | 106.7 |
| 150.0 MHz, 32 bit | 300.0 | 150.0 | 120.0 |

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

### 38.5.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

**Table 38-5. Hardware service request process**

| Cycle | | Description |
|---|---|---|
| With internal peripheral bus read and internal SRAM write | With SRAM read and internal peripheral bus write | |
| 1 | | eDMA peripheral request is asserted. |
| 2 | | The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD*n*_CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* word 7. |
| 3 | | Channel arbitration begins. |
| 4 | | Channel arbitration completes. The transfer control descriptor local memory read is initiated. |
| 5–6 | | The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles |
| 7 | | The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here. |
| 8–11 | 8–12 | The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write. |
| 12 | 13 | This cycle represents the data phase of the last destination write. |
| 13 | 14 | The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* word 7 is read and checked for channel linking or scatter/gather requests. |
| 14 | 15 | The appropriate fields in the first part of the TCD*n* are written back into the local memory. |
| 15 | 16 | The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start. |
| 16 | 17 | The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request. |

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can

be processed every 11.5 cycles (4 + (4+5)/2 + 3). This is the time from Cycle 4 to Cycle x +5. The resulting peak request rate, as a function of the system frequency, is shown in the following table.

**Table 38-6. eDMA peak request rate (MReq/sec)**

| System frequency (MHz) | Request rate with zero wait states | Request rate with wait states |
|---|---|---|
| 48.0 | 5.3 | 4.2 |
| 66.6 | 7.4 | 5.8 |
| 83.3 | 9.2 | 7.2 |
| 100.0 | 11.1 | 8.7 |
| 133.3 | 14.8 | 11.6 |
| 150.0 | 16.6 | 13.0 |

A general formula to compute the peak request rate with overlapping requests is:

PEAKreq = freq / [ entry + (1 + read_ws) + (1 + write_ws) + exit ]

where:

**Table 38-7. Peak request formula operands**

| Operand | Description |
|---|---|
| PEAKreq | Peak request rate |
| freq | System frequency |
| entry | Channel startup (4 cycles) |
| read_ws | Wait states seen during the system bus read data phase |
| write_ws | Wait states seen during the system bus write data phase |
| exit | Channel shutdown (3 cycles) |

### 38.5.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

PEAKreq = 150 MHz / [ 4 + (1 + 1) + (1 + 3) + 3 ] cycles = 11.5 Mreq/sec

For an internal peripheral bus to SRAM transfer,

PEAKreq = 150 MHz / [ 4 + (1 + 2) + (1 + 1) + 3 ] cycles = 12.5 Mreq/sec

Assuming an even distribution of the two transfer types, the average peak request rate would be:

PEAKreq = (11.5 Mreq/sec + 12.5 Mreq/sec) / 2 = 12.0 Mreq/sec

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCD*n*_CSR[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

**Note**

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

## 38.6 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

### 38.6.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI*n* registers if a configuration other than the default is desired.

3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
   - Software: setting the TCD*n*_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD*n*_SADDR, to the destination, as defined by TCD*n*_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

**Table 38-8. TCD Control and Status fields**

| TCD*n*_CSR field name | Description |
|---|---|
| START | Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware) |
| ACTIVE | Status bit indicating the channel is currently in execution |
| DONE | Status bit indicating major loop completion (cleared by software when using a software initiated DMA service) |
| D_REQ | Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service |
| BWC | Control bits for throttling bandwidth control of a channel |
| E_SG | Control bit to enable scatter-gather feature |
| INT_HALF | Control bit to enable interrupt when major loop is half complete |
| INT_MAJ | Control bit to enable interrupt when major loop completes |

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

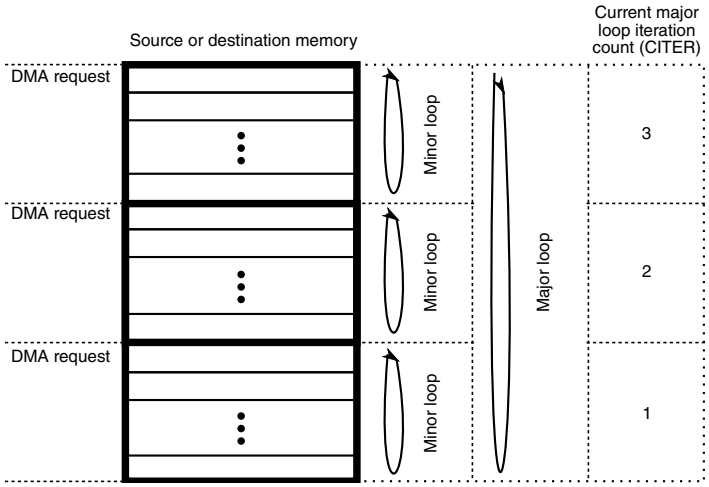

**Figure 38-5. Example of multiple loop iterations**

The following figure lists the memory array terms and how the TCD settings interrelate.

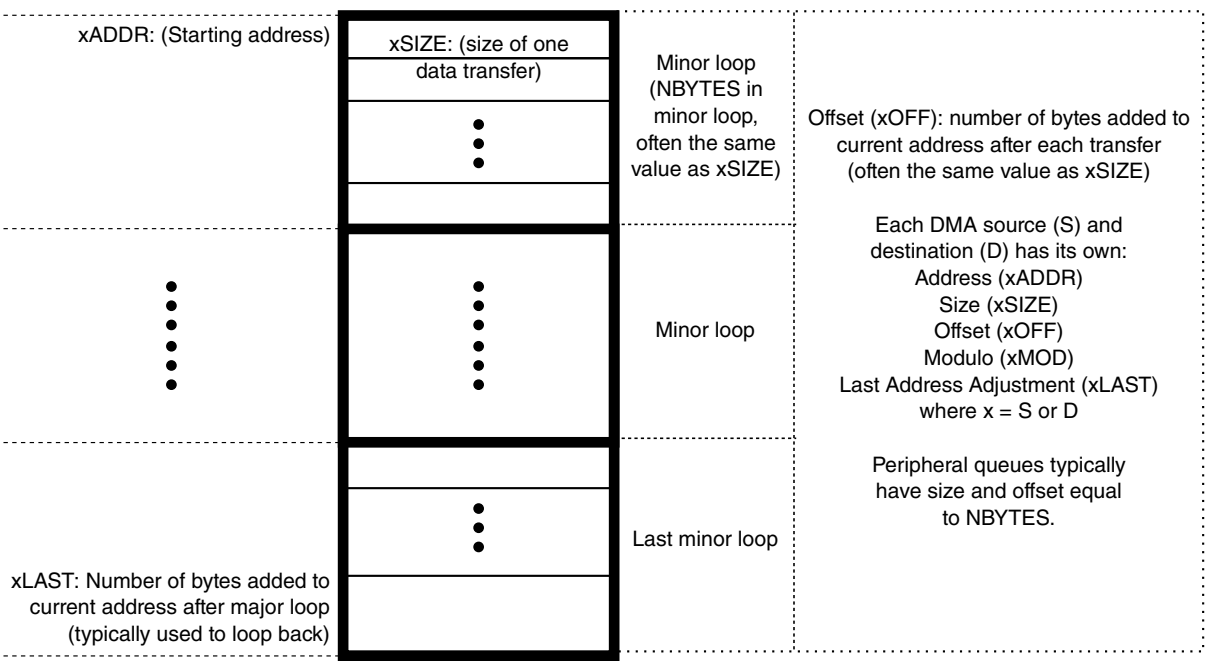

**Figure 38-6. Memory array terms**

## 38.6.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than channel priority error, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

## 38.6.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

### 38.6.3.1 Fixed channel arbitration

In this mode, the channel service request from the highest priority channel is selected to execute.

### 38.6.3.2 Round-robin channel arbitration

Channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels.

## 38.6.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

### 38.6.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
    d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
    e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
    f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
    g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

### 38.6.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.

f. Write 32-bits to location 0x2008 → third iteration of the minor loop.

g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

h. Write 32-bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:

    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.

    b. Write 32-bits to location 0x2010 → first iteration of the minor loop.

    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.

    d. Write 32-bits to location 0x2014 → second iteration of the minor loop.

    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.

    f. Write 32-bits to location 0x2018 → third iteration of the minor loop.

    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.

    h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.

14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).

15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[n] = 1.
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

#### 38.6.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567*x*) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a $2^4$ byte (16-byte) size queue.

**Table 38-9. Modulo example**

| Transfer Number | Address |
|---|---|
| 1 | 0x12345670 |
| 2 | 0x12345674 |
| 3 | 0x12345678 |
| 4 | 0x1234567C |
| 5 | 0x12345670 |
| 6 | 0x12345674 |

## 38.6.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

#### 38.6.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is

to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

| Stage | TCD*n*_CSR bits | | | State |
|---|---|---|---|---|
| | START | ACTIVE | DONE | |
| 1 | 1 | 0 | 0 | Channel service request via software |
| 2 | 0 | 1 | 0 | Channel is executing |
| 3a | 0 | 0 | 0 | Channel has completed the minor loop and is idle |
| 3b | 0 | 0 | 1 | Channel has completed the major loop and is idle |

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

| Stage | TCD*n*_CSR bits | | | State |
|---|---|---|---|---|
| | START | ACTIVE | DONE | |
| 1 | 0 | 0 | 0 | Channel service request via hardware (peripheral request asserted) |
| 2 | 0 | 1 | 0 | Channel is executing |
| 3a | 0 | 0 | 0 | Channel has completed the minor loop and is idle |
| 3b | 0 | 0 | 1 | Channel has completed the major loop and is idle |

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit.

The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

### 38.6.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and

DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

#### 38.6.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected as the channel arbitration mode. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

### 38.6.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit

2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done→ set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

**Note**

The TCD*n*_CITER[E_LINK] bit and the TCD*n*_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

**Table 38-10. Channel Linking Parameters**

| Desired Link Behavior | TCD Control Field Name | Description |
|---|---|---|
| Link at end of Minor Loop | CITER[E_LINK] | Enable channel-to-channel linking on minor loop completion (current iteration) |
| | CITER[LINKCH] | Link channel number when linking at end of minor loop (current iteration) |
| Link at end of Major Loop | CSR[MAJOR_E_LINK] | Enable channel-to-channel linking on major loop completion |
| | CSR[MAJOR_LINKCH] | Link channel number when linking at end of major loop |

## 38.6.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

### 38.6.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

### 38.6.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] bit during channel execution (see the diagram in TCD structure). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] bit at the same time the eDMA engine is retiring the channel. The TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] bit.
2. Read back the TCDn_CSR[MAJORELINK] bit.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

**NOTE**

The user must clear the The TCDn_CSR[DONE] bit before writing the TCDn_CSR[MAJORELINK] bit. The TCDn_CSR[DONE] bit is cleared automatically by the eDMA engine after a channel begins execution.

### 38.6.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] bit at the same time the eDMA engine is retiring the channel. The ESG bit would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the MAJORLINKCH field and the ESG bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD MAJOR.E_LINK and E_SG bits to zero on any writes to a channel's TCD word 7 if that channel's TCD.DONE bit is set indicating the major loop is complete.

**NOTE**

The user must clear the TCDn_CSR[DONE] bit before writing the MAJORELINK or ESG bits. The TCDn_CSR[DONE] bit is cleared automatically by the eDMA engine after a channel begins execution.

#### 38.6.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] bit is zero, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the MAJORLINKCH field may be used for other purposes. This method uses the MAJORLINKCH field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCDn_CSR[MAJORLINKCH] field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCDn_CSR[DREQ] bit.

Should a dynamic scatter/gather attempt fail, setting the DREQ bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

3. Write the TCDn_DLASTSGA register with the scatter/gather address.
4. Write 1b to the TCDn_CSR[ESG] bit.
5. Read back the 16 bit TCD control/status field.
6. Test the ESG request status and MAJORLINKCH value in the TCDn_CSR register:

   If ESG = 1b, the dynamic link attempt was successful.

   If ESG = 0b and the MAJORLINKCH (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If ESG = 0b and the MAJORLINKCH (ID) changed, the dynamic link attempt was successful (the new TCD's E_SG value cleared the ESG bit).

#### 38.6.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.DLAST_SGA field as a TCD identification (ID).

1. Write 1b to the TCDn_CSR[DREQ] bit.

   Should a dynamic scatter/gather attempt fail, setting the DREQ bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

2. Write the TCDn_DLASTSGA register with the scatter/gather address.
3. Write 1b to the TCDn_CSR[ESG] bit.
4. Read back the ESG bit.
5. Test the ESG request status:

   If ESG = 1b, the dynamic link attempt was successful.

   If ESG = 0b, read the 32 bit TCDn_DLASTSGA field.

   If ESG = 0b and the TCDn_DLASTSGA did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If ESG = 0b and the TCDn_DLASTSGA changed, the dynamic link attempt was successful (the new TCD's E_SG value cleared the ESG bit).

## 38.6.8 Suspend/resume a DMA channel with active hardware service requests

The DMA allows the user to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. Once the DMA and peripherals have been configured and are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, a specific procedure must be followed. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (SPI), Sigma Delta Analog to Digital Convertor (SDADC), or other module.

### 38.6.8.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status Register (DMA_HRSn) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ bit on appropriate DMA channel.

### 38.6.8.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting the its ERQ bit.
2. Enable the DMA service request at the peripheral.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the SPI_TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If the user needs to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to SPI_RSER[TFFF_RE]. Confirm that SPI_RSER[TFFF_RE] is 0.

2. Ensure there is no DMA service request from the SPI by verifying that DMA_HRS[HRS*n*] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ bit. If a service request is present, wait until the request has been processed and the HRS bit reads zero.

## 39.1 Chip-specific DMAMUX information

### 39.1.1 ARM Cortex-M0+ DMAMUX configuration

#### 39.1.1.1 DMAMUX request sources

This device includes a DMA request MUX that allows up to 32 DMA request signals to be mapped to any of the 8 DMA channels. Because of the mux there is not a correlation between any of the DMA request sources and a specific DMA channel.

Some of the modules support Asynchronous DMA operation as indicated by the last column in the following DMA source assignment table.

**Table 39-1. DMA request sources - DMA Channels 0-7**

| Source number | Source module | Source description | Asynch DMA capable |
|---|---|---|---|
| 0 | Low-Leakage Wake-up Unit 1 (LLWU1) | Wake-Up | Yes |
| 1 | Cryptographic Acceleration Unit version 3 (CAU3) | Data Request | No |
| 2 | Low-Power Timer 2 (LPTMR2) | Match | Yes |
| 3 | Timer / Pulse Width Modulation Module 3 (TPM3) | Channel 0 | Yes |
| 4 | Timer / Pulse Width Modulation Module 3 (TPM3) | Channel 1 | Yes |
| 5 | Timer / Pulse Width Modulation Module 3 (TPM3) | Overflow | Yes |
| 6 | Low-Power Inter-Integrated Circuit 3 (LPI2C3) | Master / Slave Receive | Yes |
| 7 | Low-Power Inter-Integrated Circuit 3 (LPI2C3) | Master / Slave Transmit | Yes |
| 8 | 2.4GHz Radio 0 (RF0) | Receive | No |
| 9 | Low-Power Serial Peripheral Interface 3 (LPSPI3) | Receive | Yes |
| 10 | Low-Power Serial Peripheral Interface 3 (LPSPI3) | Transmit | Yes |

*Table continues on the next page...*

**Table 39-1. DMA request sources - DMA Channels 0-7 (continued)**

| Source number | Source module | Source description | Asynch DMA capable |
|---|---|---|---|
| 11 | Low-Power Universal Asynchronous Receive / Transmit 3 (LPUART3) | Receive | Yes |
| 12 | Low-Power Universal Asynchronous Receive / Transmit 3 (LPUART3) | Transmit | Yes |
| 13 | PORTE | Pin Request | Yes |
| 14 | Low-Power Comparator 1 (LPCMP1) | Comparator 1 Trigger | Yes |
| 15 | Low-Power Timer 1 (LPTMR1) | LPTMR1 Trigger | Yes |
| 16 | Flexible Inout / Ouput 0 (FlexIO0) | Shifter 0 | Yes |

### 39.1.1.2 DMA transfers via TRGMUX1 DMAMUX1

The TRGMUX1_DMAMUX1 can trigger a DMA transfer on the first four DMA channels. The assignments are as follows.

**Table 39-2. TRGMUX1 DMAMUX1 channel assignments for periodic DMA triggering**

| DMA channel number | TRGMUX1_DMAMUX1 register fields |
|---|---|
| 0 | SEL0 |
| 1 | SEL1 |
| 2 | SEL2 |
| 3 | SEL3 |

## 39.1.2 ARM Cortex-M4 DMAMUX configuration

### 39.1.2.1 DMAMUX request sources

This device includes a DMA request MUX that allows up to 64 DMA request signals to be mapped to any of the 16 DMA channels. Because of the mux there is not a correlation between any of the DMA request sources and a specific DMA channel.

Some of the modules support Asynchronous DMA operation as indicated by the last column in the following DMA source assignment table.

**Table 39-3. DMA request sources - DMA Channels 0-15**

| Source number | Source module | Source description | Asynch DMA capable |
|---|---|---|---|
| 0 | Low-Leakage Wake-Up Unit 0 (LLWU0) | Wake-up Event | Yes |
| 1 | Low-Power Timer 0 (LPTMR0) | LPTMR0 Match | Yes |
| 2 | Low-Power Timer 1 (LPTMR1) | LPTMR1 Match | Yes |

#### 39.1.2.2 DMA transfers via TRGMUX1 DMAMUX1

The TRGMUX0_DMAMUX0 can trigger a DMA transfer on the first four DMA channels. The assignments are as follows.

**Table 39-4. TRGMUX0 DMAMUX0 channel assignments for periodic DMA triggering**

| DMA channel number | TRGMUX0_DMAMUX0 register fields |
|---|---|
| 0 | SEL0 |
| 1 | SEL1 |
| 2 | SEL2 |
| 3 | SEL3 |

## 39.2 Introduction

### 39.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

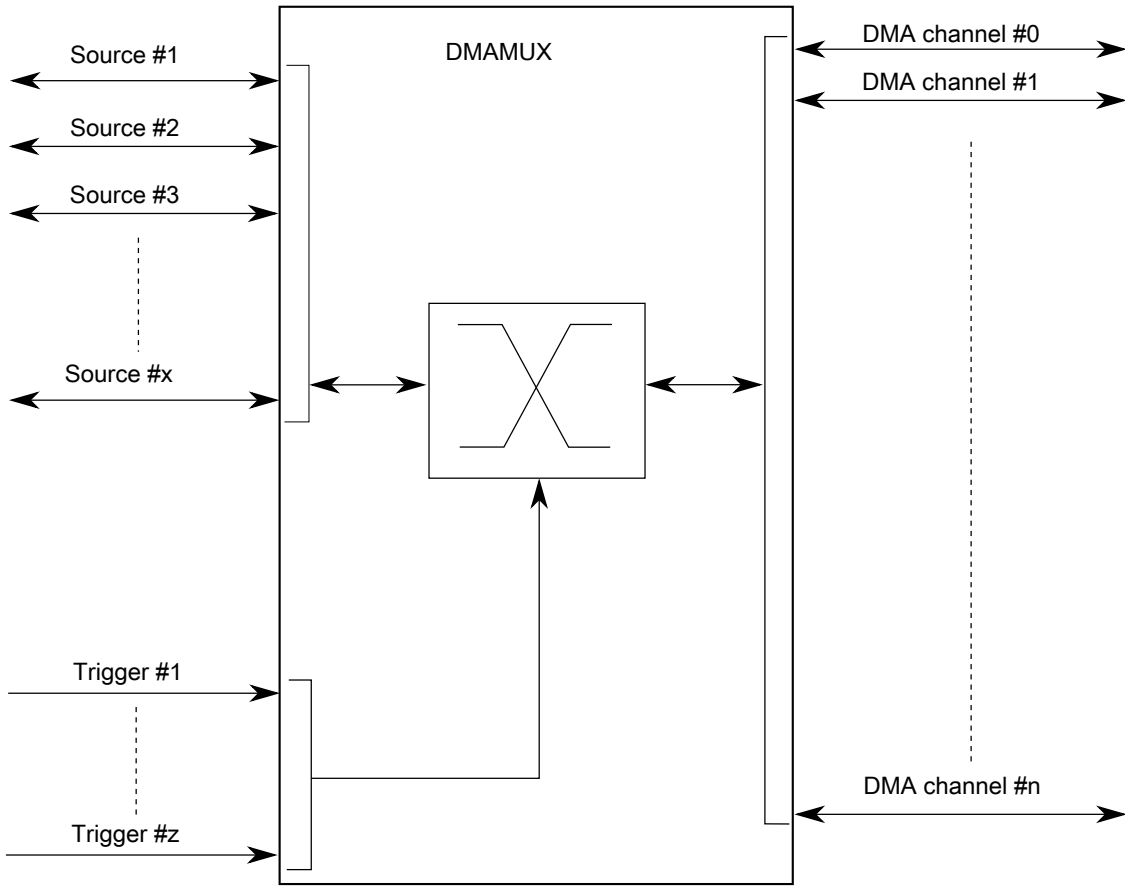

**Figure 39-1. DMAMUX block diagram**

## 39.2.2 Features

The DMAMUX module provides these features:

- Up to 64 peripheral slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - Each channel output can be individually configured to be Always On and not depend on any of the peripheral slots.
  - The first 4 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots.
- On every memory map configuration change for a any channel, this module signals to the DMA Controller to reset the internal state machine for that channel and it can accept a new request based on the new configuration.

### 39.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

  In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done in the registers of the periodic interrupt timer (LPIT). This mode is available only for channels 0 to 3.

## 39.3 External signal description

The DMAMUX has no external pins.

## 39.4 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

### 39.4.1 DMAMUX0 register descriptions

#### 39.4.1.1 DMAMUX0 Memory map

DMAMUX0 base address: 4002_1000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h - 3Ch | Channel a Configuration Register (CHCFG0 - CHCFG15) | 32 | RW | 0000_0000h |

## 39.4.1.2 Channel a Configuration Register (CHCFG0 - CHCFG15)

### 39.4.1.2.1 Offset

For a = 0 to 15:

| Register | Offset |
|---|---|
| CHCFGa | 0h + (a × 4h) |

### 39.4.1.2.2 Function

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

**NOTE**

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

## 39.5 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

### 39.5.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (LPIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the LPIT. See the section on periodic interrupt timer for more information on this topic.

### Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

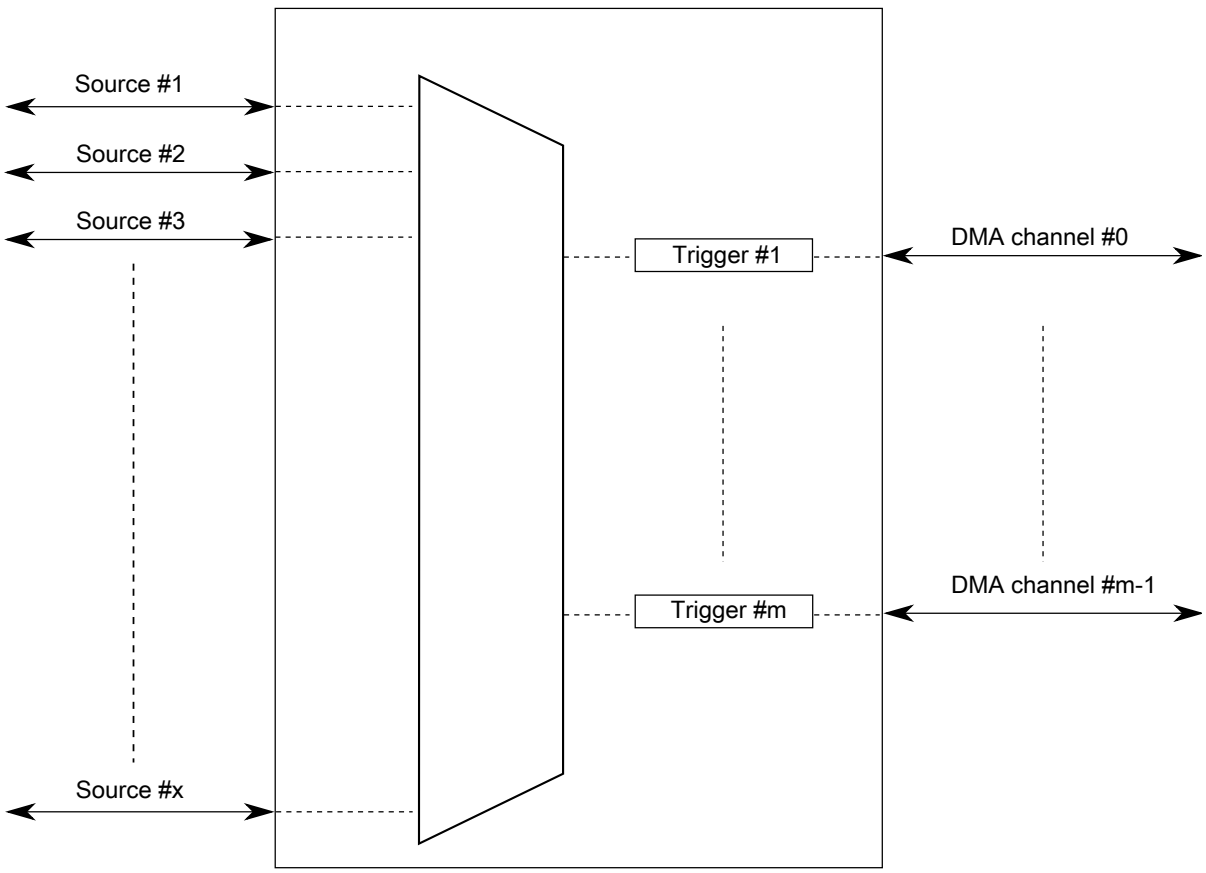

**Figure 39-2. DMAMUX triggered channels**

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

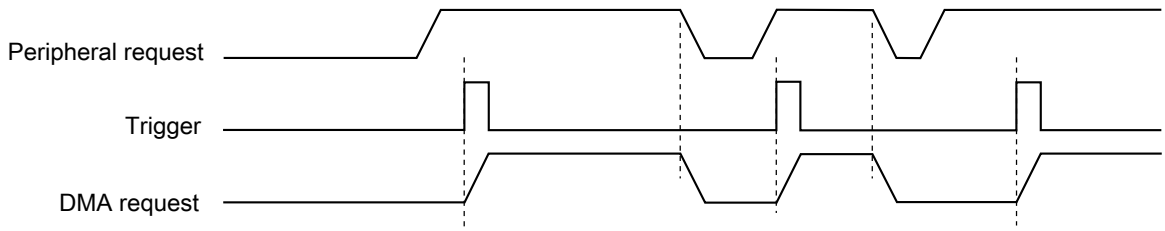

**Figure 39-3. DMAMUX channel triggering: normal operation**

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

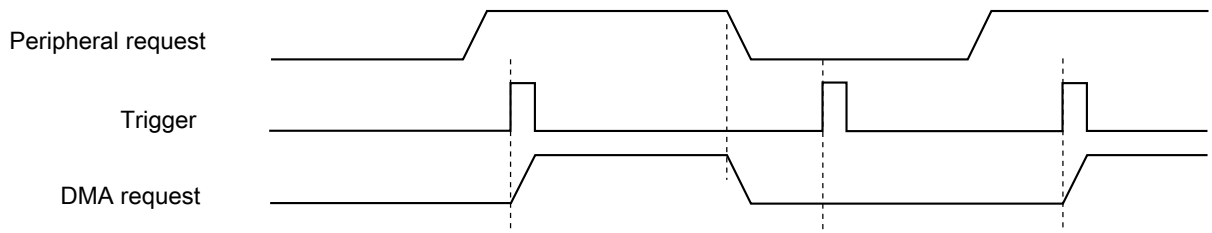

**Figure 39-4. DMAMUX channel triggering: ignored trigger**

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

### 39.5.2 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, each DMA Channel can be individually configured to function as an Always Enabled source. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the always enabled channel provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA channel can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

  By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

  In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and configured as "always enabled" channel. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

**NOTE**

When a channel is configured as "Always Enabled", then the peripheral DMA sources for that channel are ignored; i.e. SOURCE field has no effect.

## 39.6 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

### 39.6.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

### 39.6.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.

5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

**NOTE**

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00000000 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC0000005 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is setwhile CHCFG[TRIG] is cleared.

**NOTE**

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1 with no periodic triggering capability :

1. Write 0x00000000 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x80000005 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes long is 32-bits */
volatile unsigned long *CHCFG0 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned long *CHCFG1 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned long *CHCFG2 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned long *CHCFG3 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned long *CHCFG4 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0010);
volatile unsigned long *CHCFG5 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0014);
volatile unsigned long *CHCFG6 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0018);
volatile unsigned long *CHCFG7 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x001C);
volatile unsigned long *CHCFG8 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0020);
volatile unsigned long *CHCFG9 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0024);
volatile unsigned long *CHCFG10= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0028);
volatile unsigned long *CHCFG11= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x002C);
volatile unsigned long *CHCFG12= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0030);
volatile unsigned long *CHCFG13= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0034);
volatile unsigned long *CHCFG14= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0038);
volatile unsigned long *CHCFG15= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x003C);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00000000;
*CHCFG1 = 0x80000005;
```

### To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

### To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00000000 to CHCFG8.
3. Write 0x80000007 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

**Initialization/application information**

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes long is 32-bits */
volatile unsigned long *CHCFG0 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned long *CHCFG1 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned long *CHCFG2 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned long *CHCFG3 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned long *CHCFG4 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0010);
volatile unsigned long *CHCFG5 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0014);
volatile unsigned long *CHCFG6 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0018);
volatile unsigned long *CHCFG7 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x001C);
volatile unsigned long *CHCFG8 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0020);
volatile unsigned long *CHCFG9 = (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0024);
volatile unsigned long *CHCFG10= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0028);
volatile unsigned long *CHCFG11= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x002C);
volatile unsigned long *CHCFG12= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0030);
volatile unsigned long *CHCFG13= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0034);
volatile unsigned long *CHCFG14= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x0038);
volatile unsigned long *CHCFG15= (volatile unsigned long *) (DMAMUX_BASE_ADDR+0x003C);

In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00000000;
*CHCFG8 = 0x80000007;
```

#### 39.6.2.1 Configuration options

**Table 39-5. Channel Configuration Options**

| ENBL | TRIG | A_ON | Function | Mode |
|---|---|---|---|---|
| 0 | X | X | DMA channel is disabled | Disabled Mode |
| 1 | 0 | 0 | DMA channel is enabled with no triggering (transparent) | Normal Mode |
| 1 | 1 | 0 | DMA channel is enabled with triggering | Periodic Trigger Mode |
| 1 | 0 | 1 | DMA channel is always enabled | Always On Mode |
| 1 | 1 | 1 | DMA channel is always enabled with triggering | Always On Trigger Mode |

# Chapter 40
# Messaging Unit (MU)

## 40.1 Overview

The Messaging Unit module enables two processors within the SoC to communicate and coordinate by passing messages (e.g. data, status and control) through the MU interface. The MU also provides the ability for one processor to signal the other processor using interrupts.

The MU module contains two sets of registers (Processor A-facing, Processor B-facing). They work in synchronized clock domains.

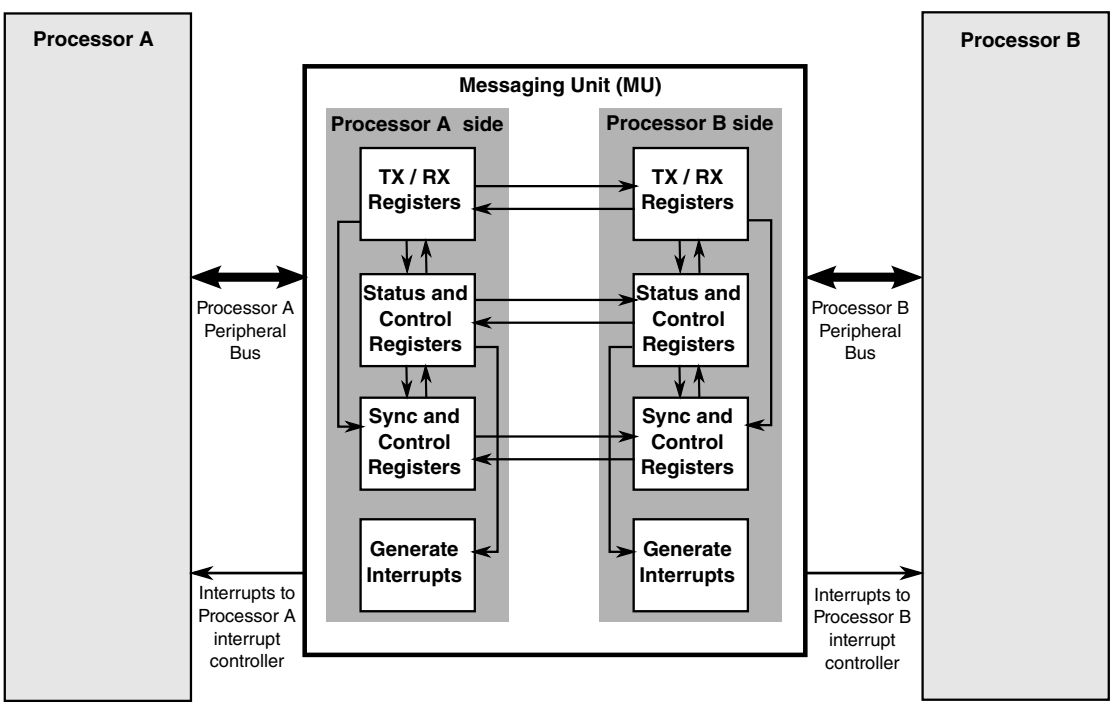

**Figure 40-1. MU Block Diagram**

### 40.1.1 Features

The MU includes the following features:

- Messaging control by interrupts or by polling
- Symmetrical processor interfaces with each side supporting the following:
  - Three general-purpose flags reflected to the other side
  - Four general-purpose interrupt requests reflected to the other side
  - Four receive registers with maskable interrupt
  - Four transmit registers with maskable interrupt
- The Processor B can take the Processor A out of low-power modes by asserting one of the interrupts to the Processor A and vice versa

**NOTE**

MU chapter references to Processor A may also correspond to Core 0 and references to Processor B may also correspond to Core 1 in other parts of this document.

### 40.1.2 Modes of Operation

The MU supports the modes described in the indicated sections:

- Low Power Modes

## 40.2 Register Definition

The MU provides transmit and receive data registers for the communication between Processor A and Processor B. Some control and status registers to the Processor A and Processor B sides for control operations (such as interrupts and reset), and for status checking of the other MU-side. The following diagram shows the MU registers schematic.

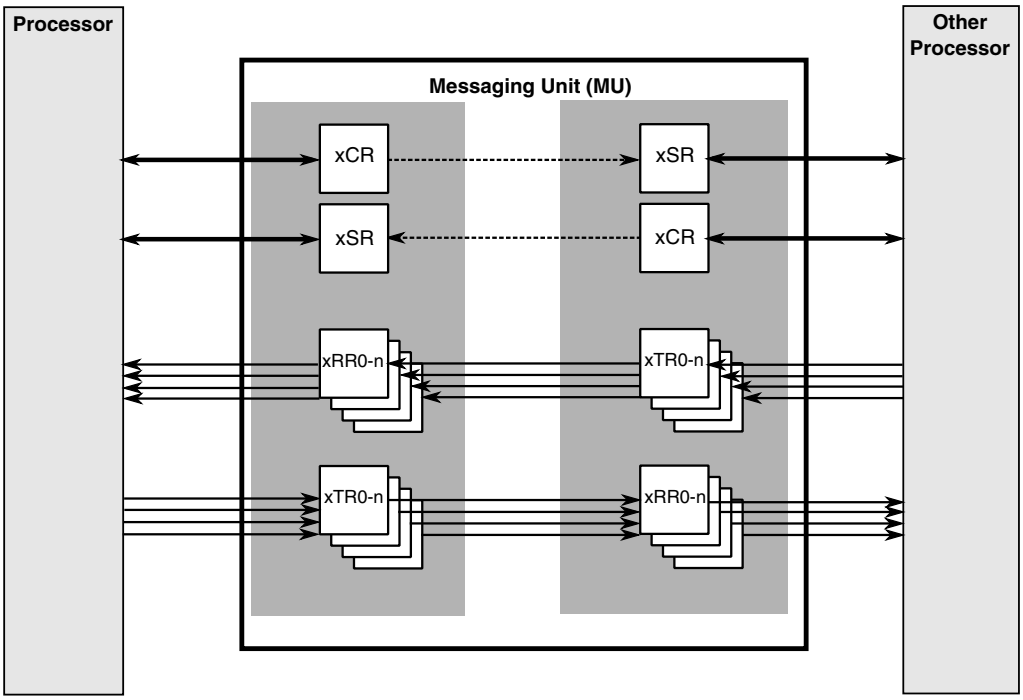

**Figure 40-2. MU Registers**

The detailed MU Register Definition can be found below.

**NOTE**

Writing to an RRn register can cause a transfer error.

## 40.2.1 MUA register descriptions

This section contains the detailed register descriptions for the MUA registers.

### 40.2.1.1 MU Memory map

MUA base address: 4002_5000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID Register (VER) | 32 | RO | 0101_0006h |
| 4h | Parameter Register (PAR) | 32 | RO | 0000_0000h |
| 20h - 2Ch | Transmit Register (TR0 - TR3) | 32 | RW | 0000_0000h |

*Table continues on the next page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 40h - 4Ch | Receive Register (RR0 - RR3) | 32 | RO | 0000_0000h |
| 60h | Status Register (SR) | 32 | W1C | 00F0_0000h |
| 64h | Control Register (CR) | 32 | RW | 0000_0000h |
| 68h | Core Control Register (CCR) | 32 | RW | See description. |

## 40.2.1.2 Version ID Register (VER)

### 40.2.1.2.1 Offset

| Register | Offset |
|---|---|
| VER | 0h |

### 40.2.1.2.2 Function

Use Version ID register to determine the version ID and feature set number of MUA.

### 40.2.1.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | MAJOR | | | | | | | | MINOR | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| R | FEATURE | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 |

### 40.2.1.2.4 Fields

| Field | Function |
|---|---|
| 31-24 | Major Version Number |
| MAJOR | This read only field returns the major version number for MUA. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 23-16<br>MINOR | Minor Version Number<br>This read only field returns the minor version number for MUA. |
| 15-0<br>FEATURE | Feature Specification Number<br>This read only field returns the feature set number for MUA.<br>000000000000x1xxb - Core Control and Status Registers are implemented in both MUA and MUB.<br>000000000000xx1xb - RAIP/RAIE register bits are implemented.<br>000000000000xxx0b - Standard features implemented |

## 40.2.1.3 Parameter Register (PAR)

### 40.2.1.3.1 Offset

| Register | Offset |
|---|---|
| PAR | 4h |

### 40.2.1.3.2 Function

Use Parameter register to determine the parameter settings of MUA.

### 40.2.1.3.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PARAMETER | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PARAMETER | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 40.2.1.3.4 Fields

| Field | Function |
|---|---|
| 31-0<br>PARAMETER | This bitfield contains the parameter settings of MUA. |

## 40.2.1.4 Transmit Register (TR0 - TR3)

### 40.2.1.4.1 Offset

For n = 0 to 3:

| Register | Offset |
|---|---|
| TRn | 20h + (n × 4h) |

### 40.2.1.4.2 Function

Use MUA Transmit Register (TRn, 32-bit, write-only) to transmit a message or data to MUB.

- You can only write to the TRn register when the TEn bit in SR register is set to "1".
- Reading the TRn register returns all zeros.

### 40.2.1.4.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | DATA | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | DATA | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 40.2.1.4.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DATA | DATA<br>MUA Transmit Register Data. (Write-only)<br>• Data written to the TRn register is reflected in the MUB Receive Register n (RRn). The TRn and RRn registers are not double-buffered, a write to the TRn register overrides the data readable at the RRn register.<br>• A write to the transmit register clears a "transmitter empty" bit (TEn) in the MUA Status Register (SR) on the transmitter side, and sets a "receiver full" bit (RFn) in the MUB Status Register (SR) on the receiver side (optionally triggering an interrupt 0 on the MUA side).<br>• Any write to the TRn register will update all status information. |

## 40.2.1.5 Receive Register (RR0 - RR3)

### 40.2.1.5.1 Offset

For n = 0 to 3:

| Register | Offset |
|---|---|
| RRn | 40h + (n × 4h) |

### 40.2.1.5.2 Function

Use MUA Receive Register (RRn, 32-bit, read-only) to receive a message or data from the MUB.

- Data written to the MUB TRn register is immediately reflected in the MUA RRn register.
- You can only read the RRn register when the RFn bit in the SR register is set to "1".
- Writing to the RRn register generates an error response to the MUA.

### 40.2.1.5.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | DATA | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | DATA | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 40.2.1.5.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DATA | DATA<br>MUA Receive Register. (Read-only)<br>• Reflects the data written to MUB Transmit Register 0 (TRn).<br>• Reading the RRn register clears the "receiver full" bit (RFn) in the MUA Status Register (SR) on the receiver side, and sets the "transmitter empty" bit (TEn) in the MUB Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the MUB side).<br>• Any read of the RRn register will update all status information. |

## 40.2.1.6 Status Register (SR)

### 40.2.1.6.1 Offset

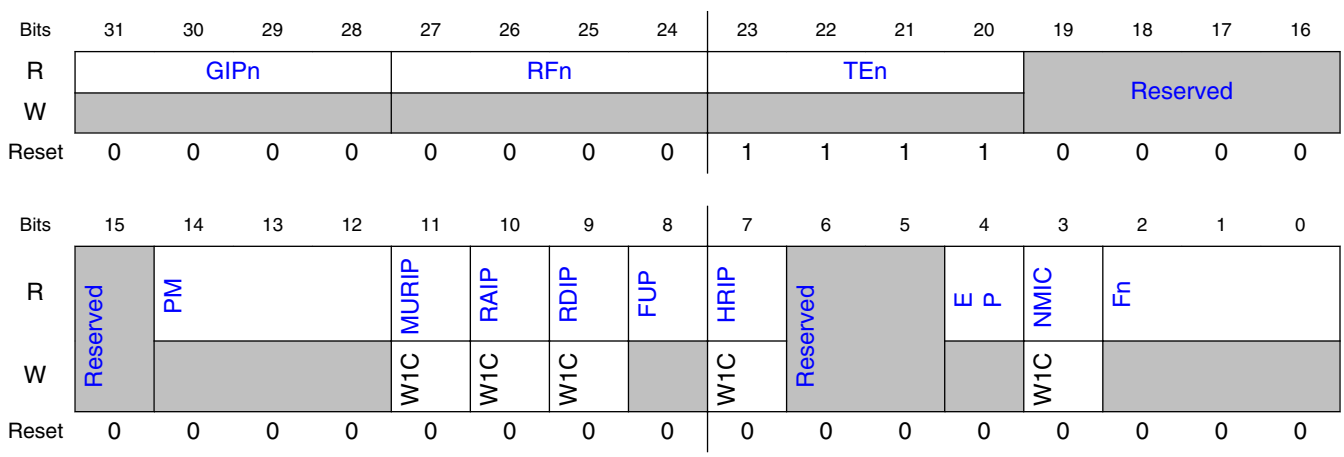
| Register | Offset |
|---|---|
| SR | 60h |

### 40.2.1.6.2 Function

Use the Processor A Status Register (SR, 32-bit, read-write) to show interrupt status from the Processor B, general purpose flags, and to set dual function control-status bits.

- Some dual-purpose bits are set by the MU logic, and cleared by the Processor A-side programmer
- Other dual-purpose bits are set by the Processor A-side programmer, and cleared by the MU logic.

### 40.2.1.6.3 Diagram



### 40.2.1.6.4 Fields

| Field | Function |
|---|---|
| 31-28<br>GIPn | GIPn<br>For n = {0, 1, 2, 3} MUA General Interrupt Request n Pending. (Read-Write)<br>• GIPn bit signals the MUA that the GIRn bit in the CR register on the MUB side was set from "0" to "1". If the GIEn bit in the MUA CR register is set to "1", a General Interrupt n request is issued. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | • The GIPn bit is cleared by writing it back as "1". Writing "0", or writing "1" when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. An example of a proper bit clearing sequence is: clear MUA register, set the desired bit, and write it to the MUA SR register, thus clearing the GIPn bit.<br>• GIPn bit is cleared when the MU is reset.<br><br>0000b - MUA general purpose interrupt n is not pending. (default)<br>0001b - MUA general purpose interrupt n is pending. |
| 27-24<br>RFn | RFn<br>For n = {0, 1, 2, 3} MUA Receive Register n Full. (Read-only)<br>• The RFn bit is set to "1" when the MUB TRn register is written on the MUB side.<br>• After the RFn bit is set to "1", the RFn bit signals the MUA side that new data is ready to be read by the MUA in the MUA RRn register, and a Receive n interrupt is issued on the MUA side (if the RIEn bit in the MUA CR register has been set to "1").<br>• RFn bit is cleared when the MUA RRn register is read, and when the MU is reset.<br><br>0000b - MUA RRn register is not full (default).<br>0001b - MUA RRn register has received data from MUB TRn register and is ready to be read by the MUA. |
| 23-20<br>TEn | TEn<br>For n = {0, 1, 2, 3} MUA Transmit Register n Empty. (Read-only)<br>• The TEn bit is set to "1" after the MUB RRn register is read on the MUB side.<br>• After the TEn bit is set to "1", the TEn bit signals the MUA side that the MUA TRn register is ready to be written on the MUA side, and a Transmit n interrupt is issued on the MUA side (if the TEn bit in the MUA CR register is set to "1").<br>• TEn bit is cleared after the MUA TRn register is written on the MUA side.<br>• TEn bit is set to "1" when the MU is reset.<br><br>0000b - MUA TRn register is not empty.<br>0001b - MUA TRn register is empty (default). |
| 19-15<br>— | Reserved |
| 14-12<br>PM | PM<br>Processor B-side Power Mode. (Read-only)<br>• PM[2:0] bits indicate the Processor B-side power mode.<br><br>**NOTE:** The Processor B Power Mode is platform-specific.<br><br>000b - The MUB processor is in Run Mode.<br>001b - The MUB processor is in COO Mode.<br>010b - The MUB processor is in WAIT Mode.<br>011b - The MUB processor is in STOP/VLPS Mode.<br>100b - The MUB processor is in LLS/VLLS Mode. |
| 11<br>MURIP | MURIP<br>MU Reset Interrupt Pending. (Read-Write)<br>• MURIP bit signals Processor A that Processor B initiated a MU reset by setting MUR bit in MUB_CR register.<br>• MURIP bit is set to "1" after Processor B initiated a MU reset. The interrupt generated by a Processor B MU reset is ORed with the Processor A general purpose interrupt 3. The Processor A general purpose interrupt 3 is issued when the Processor B set MUR bit in MUB_CR, if the interrupt is enabled by the MURIE bit.<br>• To clear the MURIP bit, write "1", which also clears general purpose interrupt 3.<br>• Only system reset can reset MURIP. MU reset cannot reset this bit. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 0b - Processor B did not issue MU reset<br>1b - Processor B issued MU reset |
| 10<br>RAIP | RAIP<br>Processor B Reset Asserted Interrupt Pending. (Read-Write)<br>• RAIP bit signals the Processor A that the Processor B has entered reset.<br>• RAIP bit is set to "1" after the Processor B enters reset. The interrupt generated by a Processor B reset assertion is ORed with the Processor A general purpose interrupt 3. The Processor A general purpose interrupt 3 is issued when the Processor B enters reset, if the interrupt is enabled by the RAIE bit.<br>• To clear the RAIP bit, write "1", which also clears general purpose interrupt 3.<br>• When Processor A comes out of reset, the RAIP bit has value "0" (default). Processor A will then monitor the reset of Processor B and will assert RAIP if its reset asserts.<br><br>0b - Processor B did not enter reset<br>1b - Processor B entered reset |
| 9<br>RDIP | RDIP<br>Processor B Reset De-asserted Interrupt Pending. (Read-Write)<br>• RDIP bit signals the Processor A that the Processor B has come out of reset.<br>• RDIP bit is set to "1" after the Processor B comes out of reset. The interrupt generated by a Processor B reset de-assertion is ORed with the Processor A general purpose interrupt 3. The Processor A general purpose interrupt 3 is issued when the Processor B comes out of reset if the interrupt is enabled by the RDIE bit.<br>• To clear the RDIP bit, write "1", which also clears general purpose interrupt 3.<br>• When Processor A comes out of reset, the RDIP bit has value "0"(default). Processor A then monitors the reset of Processor B and will assert RDIP when reset deasserts.<br><br>0b - Processor B did not exit reset<br>1b - Processor B exited from reset |
| 8<br>FUP | FUP<br>MUA Flags Update Pending. (Read-only)<br>• FUP bit is set to "1" when the MUA side sends a Flags Update request to the MUB side.<br>• A Flags Update request is generated when there is a change to the Fn[2:0] bits of the MUA CR register. No flag update changes are allowed while the FUP bit is set to "1". Any write to the Fn[2:0] bits of the MUA CR register, while the FUP bit is set to "1", will not generate a Flags Update event, and the Fn[2:0] bits will stay unchanged.<br>• FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU MUB side, and during MU reset.<br><br>0b - No flags updated, initiated by the MUA, in progress (default)<br>1b - MUA initiated flags update, processing |
| 7<br>HRIP | HRIP<br>Processor A Hardware reset interrupt pending<br>• HRIP bit indicates if Processor A had been reset by HR bit in MUB_CCR<br>• HRIP is set to "1" if Processor B set HR in MUB_CCR to "1" and HRM in MUA_CCR is cleared.<br>• Write "1" to clear HRIP.<br><br>0b - MUB didn't issue hardware reset to Processor A<br>1b - MUB had initiated a hardware reset to Processor A through HR bit. |
| 6-5<br>— | Reserved |
| 4<br>EP | EP<br>MUA Side Event Pending. (Read-only) |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | • EP bit is set to "1" when the MUA side mechanism sends an event update request to the MUB side.<br>• EP bit is cleared when the event update acknowledge is received. An "event" is any hardware message that is reflected in the MUB SR register on the MUB side (for example, "transmit register 0 written"). During normal operations, you do not have to deal with the state of the EP bit because the event update mechanism works automatically.<br>• To ensure events have been posted to MUB before entering STOP mode, you should verify that the EP bit is cleared. If EP bit is set to "1", you should wait and continue to poll it (EP bit) before entering STOP mode.<br>• Reading the MUA SR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP or WAIT modes; otherwise, the EP bit may be set by subsequent additional actions.<br>• The EP bit is cleared when the MU resets.<br><br>0b - The MUA side event is not pending (default).<br>1b - The MUA side event is pending. |
| 3<br>NMIC | NMIC<br>Processor A Non-Maskable-Interrupt Clear. (Write-only)<br>• NMIC bit is used by the Processor A-side MU Non-Maskable Interrupt service routine to clear the non-maskable interrupt.<br>• Writing NMIC bit as "1" signals the MU to clear the NMI bit in the MUB CR register, thus de-asserting the interrupts and enabling the NMI bit to receive another interrupt.<br>• The NMIC bit is always read as "0"; therefore it (NMIC bit) cannot be polled. The NMIC bit can only be used as part of the interrupt service routine, in which the NMIC bit should only be written as "1" once.<br>• The NMIC bit is cleared when the MU resets.<br><br>0b - Default<br>1b - Writing "1" clears the NMI bit in the MUB CR register. |
| 2-0<br>Fn | Fn<br>For n = {0, 1, 2} MUA Side Flag n. (Read-only)<br>• Fn bit is the MUA side flag that reflects the values written to the Fn bit in the MUB control register.<br>• Every time that the Fn bit in the MUB CR register is written, the Fn bit in the MUB CR register write event updates the Fn bit in the MUA SR register after the event update latency, which is measured in terms of the number of clocks of the MUB and the MUA.<br><br>000b - Fn bit in the MUB CR register is written 0 (default).<br>001b - Fn bit in the MUB CR register is written 1. |

## 40.2.1.7 Control Register (CR)

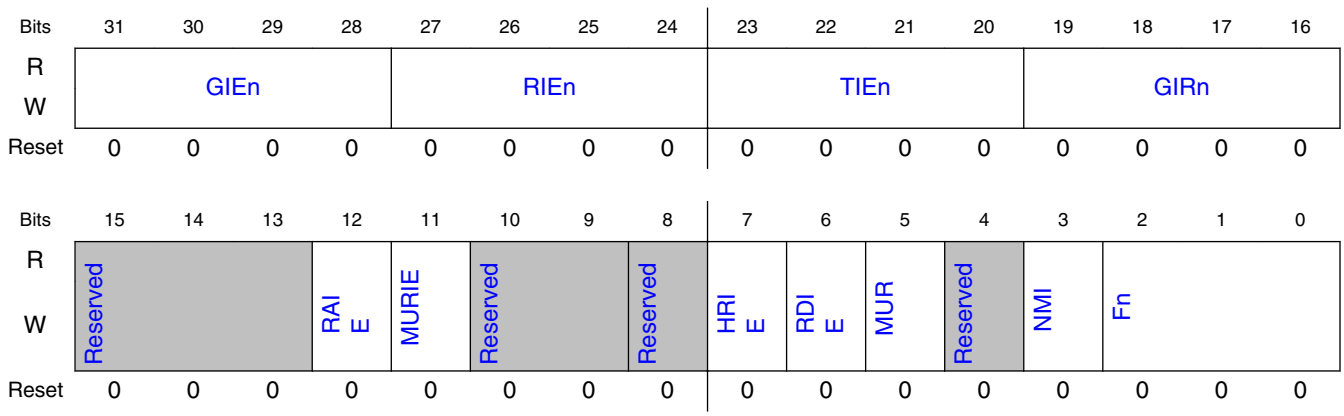
### 40.2.1.7.1 Offset

| Register | Offset |
|---|---|
| CR | 64h |

### 40.2.1.7.2 Function

Use the Control Register (CR, 32-bit, read-write) to enable the MU interrupts on the MUA-side, and trigger events and interrupts on the MUB-side (general purpose interrupt, flag update).

### 40.2.1.7.3 Diagram



### 40.2.1.7.4 Fields

| Field | Function |
|---|---|
| 31-28<br>GIEn | GIEn<br>For n = {0, 1, 2, 3} MUA General Purpose Interrupt Enable n. (Read-Write)<br>• GIEn bit enables MUA General Interrupt n.<br>• If GIEn bit is set to "1" (enabled), then a General Interrupt n request is issued when the GIPn bit in the MUA SR register is set to "1".<br>• If GIEn is cleared (disabled), then the value of the GIPn bit is ignored and no General Interrupt n request will be issued.<br>• GIEn bit is cleared when the MU resets.<br><br>0000b - Disables MUA General Interrupt n. (default)<br>0001b - Enables MUA General Interrupt n. |
| 27-24<br>RIEn | RIEn<br>For n = {0, 1, 2, 3} MUA Receive Interrupt Enable n. (Read-Write)<br>• RIEn bit enables MUA Receive Interrupt n.<br>• If RIEn bit is set to "1" (enabled), then an MUA Receive Interrupt n request is issued when the RFn bit in the MUA SR register is set to "1".<br>• If RIEn bit is cleared (disabled), then the value of the RFn bit is ignored and no MUA Receive Interrupt n request will be issued.<br>• RIEn bit is cleared when the MU resets.<br><br>0000b - Disables MUA Receive Interrupt n. (default)<br>0001b - Enables MUA Receive Interrupt n. |
| 23-20<br>TIEn | TIEn<br>For n = {0, 1, 2, 3} MUA Transmit Interrupt Enable n. (Read-Write) |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | • TIEn bit enables MUA Transmit Interrupt n.<br>• If TIEn bit is set to "1" (enabled), then an MUA Transmit Interrupt n request is issued when the TEn bit in the MUA SR register is set to "1".<br>• If TIEn bit is cleared (disabled), then the value of the TEn bit is ignored and no MUA Transmit Interrupt n request will be issued.<br>• TIEn bit is cleared when the MU resets.<br><br>0000b - Disables MUA Transmit Interrupt n. (default)<br>0001b - Enables MUA Transmit Interrupt n. |
| 19-16<br>GIRn | GIRn<br>For n = {0, 1, 2, 3} MUA General Purpose Interrupt Request n. (Read-Write)<br>• Writing "1" to the GIRn bit sets the GIPn bit in the MUB SR register on the Processor B-side. If the GIEn bit in the MUB CR register is set to "1" on the MUB side, a General Purpose Interrupt n request is triggered.<br>• The GIRn bit is cleared if the GIPn bit (in the MUB SR register on the MUB side) is cleared by writing it (GIPn bit) as "1", thereby signalling the MUA that the interrupt was accepted (cleared by the software). The GIPn bit cannot be written as "0" on the MUA side.<br>• To ensure proper operations, you must verify that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit).<br>• GIRn bit is cleared when the MU resets.<br><br>0000b - MUA General Interrupt n is not requested to the MUB (default).<br>0001b - MUA General Interrupt n is requested to the MUB. |

1. Reset value loaded during Processor A reset from Flash IFR.

## 40.2.1.8.4 Fields

| Field | Function |
|---|---|
| 31-6<br>— | Reserved |
| 5-4<br>BOOT | Slave Processor B Boot Config.<br>Configures the boot source for Processor B when Processor B is slave core.<br>00b - Boot from Dflash base<br>01b - Reserved<br>10b - Boot from CM0+ RAM base<br>11b - Reserved |
| 3<br>CLKE | MUB clock enable<br>When set, forces MUB platform clock to remain enabled even after MUB-side has entered a stop mode. When clear, allows MUB to gate its platform clock whenever desired after entering a stop mode. Note that if MUA also enters a stop mode, then this bit is overidden to allow MUB to gate its platform clock.<br>0b - MUB platform clock gated when MUB-side enters a stop mode.<br>1b - MUB platform clock kept running after MUB-side enters a stop mode, until MUA also enters a stop mode. |
| 2<br>RSTH | Processor B Reset Hold<br>When set, will cause the Processor B to be held in reset following any reset event. When cleared, allows the Processor B to be released from reset.<br>Setting this bit will not force the Processor B into reset. It will only hold Processor B if it resets itself.<br>0b - Release Processor B from reset<br>1b - Hold Processor B in reset |
| 1<br>HRM | When set, HR bit in MUB CCR has no effect<br>Processor A Hardware Reset Mask. (Read-Write)<br>• The Processor B can give a hardware reset to the Processor A by setting the HR bit in the MUB CCR Register to “1”.<br>• When the HRM bit is set to “1” by the Processor A, the HR reset issued by the Processor B is masked (disabled by the Processor A).<br>• When the HRM bit is cleared, the HR reset issued by the Processor B to the Processor A is not masked (enabled by the Processor A).<br>0b - HR bit in MUB CCR is not masked, enables the hardware reset to the Processor A (default after hardware reset).<br>1b - HR bit in MUB CCR is masked, disables the hardware reset request to the Processor A. |
| 0<br>HR | HR<br>Processor B Hardware Reset. (Read-Write)<br>• HR bit asserts and de-asserts the hardware reset of the Processor B.<br>• Set HR bit to "1" to start a hardware reset of the Processor B.<br>• Clear the HR bit to de-assert the Processor B hardware reset input.<br>• Assert the HR bit for a minimum of 3 clock cycles. The RAIP bit in MUA SR register indicates the state of the Processor on MUB-side. As soon as the Processor B goes into Reset (MUA RAIP bit is set to "1"), the HR bit can be de-asserted.<br>• Strobe-setting the HR bit will not cause an internal MU reset but will be routed outside MU to Processor B reset logic<br>• The HR reset issued by the Processor A to the Processor B is maskable by the Processor B (according to the settings of the HRM bit in the MUB CCR register). If the HRM bit (in the MUB CCR register) is set to "1", then the HR reset is masked; if the HRM bit (in the MUB CCR register) is cleared (default), then the HR reset is enabled.<br>• The HR bit does not return to the reset value during the software (MUR) reset. |

| Field | Function |
|---|---|
| | 0b - De-assert Hardware reset to the Processor B. (default)<br>1b - Assert Hardware reset to the Processor B. |

## 40.2.2 MUB register descriptions

This section contains the detailed register descriptions for the MUB registers.

### 40.2.2.1 MU Memory map

MUB base address: 4102_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID Register (VER) | 32 | RO | 0101_0006h |
| 4h | Parameter Register (PAR) | 32 | RO | 0000_0000h |
| 20h - 2Ch | Transmit Register (TR0 - TR3) | 32 | RW | 0000_0000h |
| 40h - 4Ch | Receive Register (RR0 - RR3) | 32 | RO | 0000_0000h |
| 60h | Status Register (SR) | 32 | W1C | 00F0_0000h |
| 64h | Control Register (CR) | 32 | RW | 0000_0000h |
| 68h | Core Control Register (CCR) | 32 | RW | See description. |

### 40.2.2.2 Version ID Register (VER)

#### 40.2.2.2.1 Offset

| Register | Offset |
|---|---|
| VER | 0h |

#### 40.2.2.2.2 Function

Use Version ID register to determine the version ID and feature set number of MUB.

#### 40.2.2.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | MAJOR | | | | | | | | MINOR | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | FEATURE | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 |

#### 40.2.2.2.4 Fields

| Field | Function |
|---|---|
| 31-24<br>MAJOR | Major Version Number<br>This read only field returns the major version number for MUB. |
| 23-16<br>MINOR | Minor Version Number<br>This read only field returns the minor version number for MUB. |
| 15-0<br>FEATURE | Feature Specification Number<br>This read only field returns the feature set number for MUB.<br>000000000000x1xxb - Core Control and Status Registers are implemented in both MUA and MUB.<br>000000000000xx1xb - RAIP/RAIE register bits are implemented.<br>000000000000xxx0b - Standard features implemented |

### 40.2.2.3 Parameter Register (PAR)

#### 40.2.2.3.1 Offset

| Register | Offset |
|---|---|
| PAR | 4h |

#### 40.2.2.3.2 Function

Use Parameter register to determine the parameter settings of MUB.

#### 40.2.2.3.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PARAMETER | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PARAMETER | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### 40.2.2.3.4 Fields

| Field | Function |
|---|---|
| 31-0<br>PARAMETER | This bitfield contains the parameter settings of MUB. |

### 40.2.2.4 Transmit Register (TR0 - TR3)

#### 40.2.2.4.1 Offset

For n = 0 to 3:

| Register | Offset |
|---|---|
| TRn | 20h + (n × 4h) |

#### 40.2.2.4.2 Function

Use MUB Transmit Register (TRn, 32-bit, write-only) to transmit a message or data to MUA.

- You can only write to the TRn register when the TEn bit in SR register is set to "1".
- Reading the TRn register returns all zeros.

### 40.2.2.4.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | DATA | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | DATA | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 40.2.2.4.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DATA | DATA<br>MUB Transmit Register Data. (Write-only)<br>• Data written to the TRn register is reflected in the MUA Receive Register n (RRn). The TRn and RRn registers are not double-buffered, a write to the TRn register overrides the data readable at the RRn register.<br>• A write to the transmit register clears a "transmitter empty" bit (TEn) in the MUB Status Register (SR) on the transmitter side, and sets a "receiver full" bit (RFn) in the MUA Status Register (SR) on the receiver side (optionally triggering an interrupt 0 on the MUB side).<br>• Any write to the TRn register will update all status information. |

## 40.2.2.5 Receive Register (RR0 - RR3)

### 40.2.2.5.1 Offset

For n = 0 to 3:

| Register | Offset |
|---|---|
| RRn | 40h + (n × 4h) |

### 40.2.2.5.2 Function

Use MUB Receive Register (RRn, 32-bit, read-only) to receive a message or data from the MUA.

- Data written to the MUA TRn register is immediately reflected in the MUB RRn register.

- You can only read the RRn register when the RFn bit in the SR register is set to "1".
- Writing to the RRn register generates an error response to the MUB.

#### 40.2.2.5.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | DATA | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | DATA | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### 40.2.2.5.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DATA | DATA<br>MUB Receive Register. (Read-only)<br>• Reflects the data written to MUA Transmit Register 0 (TRn).<br>• Reading the RRn register clears the "receiver full" bit (RFn) in the MUB Status Register (SR) on the receiver side, and sets the "transmitter empty" bit (TEn) in the MUA Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the MUA side).<br>• Any read of the RRn register will update all status information. |

### 40.2.2.6 Status Register (SR)

#### 40.2.2.6.1 Offset

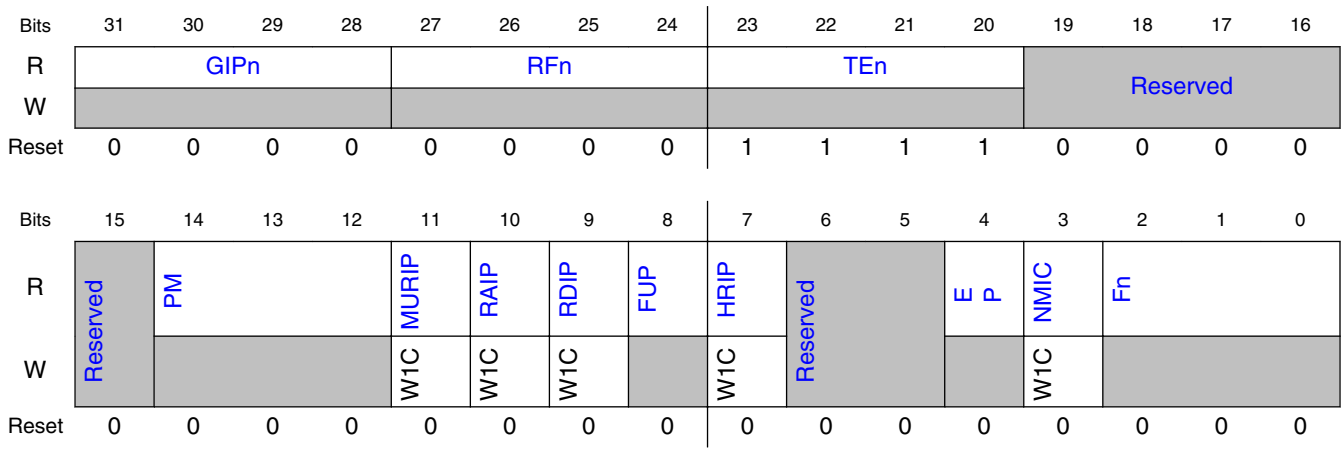
| Register | Offset |
|---|---|
| SR | 60h |

#### 40.2.2.6.2 Function

Use the Processor B Status Register (SR, 32-bit, read-write) to show interrupt status from the Processor A, general purpose flags, and to set dual function control-status bits.

- Some dual-purpose bits are set by the MU logic, and cleared by the Processor B-side programmer
- Other dual-purpose bits are set by the Processor B-side programmer, and cleared by the MU logic.

### 40.2.2.6.3 Diagram



### 40.2.2.6.4 Fields

| Field | Function |
|---|---|
| 31-28<br>GIPn | GIPn<br>For n = {0, 1, 2, 3} MUB General Interrupt Request n Pending. (Read-Write)<br>• GIPn bit signals the MUB that the GIRn bit in the CR register on the MUA side was set from "0" to "1". If the GIEn bit in the MUB CR register is set to "1", a General Interrupt n request is issued.<br>• The GIPn bit is cleared by writing it back as "1". Writing "0", or writing "1" when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. An example of a proper bit clearing sequence is: clear MUB register, set the desired bit, and write it to the MUB SR register, thus clearing the GIPn bit.<br>• GIPn bit is cleared when the MU is reset.<br><br>0000b - MUB general purpose interrupt n is not pending. (default)<br>0001b - MUB general purpose interrupt n is pending. |
| 27-24<br>RFn | RFn<br>For n = {0, 1, 2, 3} MUB Receive Register n Full. (Read-only)<br>• The RFn bit is set to "1" when the MUA TRn register is written on the MUA side.<br>• After the RFn bit is set to "1", the RFn bit signals the MUB side that new data is ready to be read by the MUB in the MUB RRn register, and a Receive n interrupt is issued on the MUB side (if the RIEn bit in the MUB CR register has been set to "1").<br>• RFn bit is cleared when the MUB RRn register is read, and when the MU is reset.<br><br>0000b - MUB RRn register is not full (default).<br>0001b - MUB RRn register has received data from MUA TRn register and is ready to be read by the MUB. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 23-20<br>TEn | TEn<br>For n = {0, 1, 2, 3} MUB Transmit Register n Empty. (Read-only)<br>• The TEn bit is set to "1" after the MUA RRn register is read on the MUA side.<br>• After the TEn bit is set to "1", the TEn bit signals the MUB side that the MUB TRn register is ready to be written on the MUB side, and a Transmit n interrupt is issued on the MUB side (if the TEn bit in the MUB CR register is set to "1").<br>• TEn bit is cleared after the MUB TRn register is written on the MUB side.<br>• TEn bit is set to "1" when the MU is reset.<br><br>0000b - MUB TRn register is not empty.<br>0001b - MUB TRn register is empty (default). |
| 19-15<br>— | Reserved |
| 14-12<br>PM | PM<br>Processor A-side Power Mode. (Read-only)<br>• PM[2:0] bits indicate the Processor A-side power mode.<br><br>**NOTE:** The Processor A Power Mode is platform-specific.<br><br>000b - The MUA processor is in Run Mode.<br>001b - The MUA processor is in COO Mode.<br>010b - The MUA processor is in WAIT Mode.<br>011b - The MUA processor is in STOP/VLPS Mode.<br>100b - The MUA processor is in LLS/VLLS Mode. |
| 11<br>MURIP | MURIP<br>MU Reset Interrupt Pending. (Read-Write)<br>• MURIP bit signals Processor B that Processor A initiated a MU reset by setting MUR bit in MUA_CR register.<br>• MURIP bit is set to "1" after Processor A initiated a MU reset. The interrupt generated by a Processor A MU reset is ORed with the Processor B general purpose interrupt 3. The Processor B general purpose interrupt 3 is issued when the Processor A set MUR bit in MUA_CR, if the interrupt is enabled by the MURIE bit.<br>• To clear the MURIP bit, write "1", which also clears general purpose interrupt 3.<br>• Only system reset can reset MURIP. MU reset cannot reset this bit.<br><br>0b - Processor A did not issue MU reset<br>1b - Processor A issued MU reset |
| 10<br>RAIP | RAIP<br>Processor A Reset Asserted Interrupt Pending. (Read-Write)<br>• RAIP bit signals the Processor B that the Processor A has entered reset.<br>• RAIP bit is set to "1" after the Processor A enters reset. The interrupt generated by a Processor A reset assertion is ORed with the Processor B general purpose interrupt 3. The Processor B general purpose interrupt 3 is issued when the Processor A enters reset, if the interrupt is enabled by the RAIE bit.<br>• To clear the RAIP bit, write "1", which also clears general purpose interrupt 3.<br>• When Processor B comes out of reset, the RAIP bit has value "0" (default). Processor B will then monitor the reset of Processor A and will assert RAIP if its reset asserts.<br><br>0b - Processor A did not enter reset<br>1b - Processor A entered reset |
| 9<br>RDIP | RDIP<br>Processor A Reset De-asserted Interrupt Pending. (Read-Write)<br>• RDIP bit signals the Processor B that the Processor A has come out of reset. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | • RDIP bit is set to "1" after the Processor A comes out of reset. The interrupt generated by a Processor A reset de-assertion is ORed with the Processor B general purpose interrupt 3. The Processor B general purpose interrupt 3 is issued when the Processor A comes out of reset if the interrupt is enabled by the RDIE bit.<br>• To clear the RDIP bit, write "1", which also clears general purpose interrupt 3.<br>• When Processor B comes out of reset, the RDIP bit has value "0"(default). Processor B then monitors the reset of Processor A and will assert RDIP when reset deasserts.<br><br>0b - Processor A did not exit reset<br>1b - Processor A exited from reset |
| 8<br>FUP | FUP<br>MUB Flags Update Pending. (Read-only)<br>• FUP bit is set to "1" when the MUB side sends a Flags Update request to the MUA side.<br>• A Flags Update request is generated when there is a change to the Fn[2:0] bits of the MUB CR register. No flag update changes are allowed while the FUP bit is set to "1". Any write to the Fn[2:0] bits of the MUB CR register, while the FUP bit is set to "1", will not generate a Flags Update event, and the Fn[2:0] bits will stay unchanged.<br>• FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU MUA side, and during MU reset.<br><br>0b - No flags updated, initiated by the MUB, in progress (default)<br>1b - MUB initiated flags update, processing |
| 7<br>HRIP | HRIP<br>Processor B Hardware reset interrupt pending<br>• HRIP bit indicates if Processor B had been reset by HR bit in MUA_CCR<br>• HRIP is set to "1" if Processor A set HR in MUA_CCR to "1" and HRM in MUB_CCR is cleared.<br>• Write "1" to clear HRIP.<br><br>0b - MUA didn't issue hardware reset to Processor B<br>1b - MUA had initiated a hardware reset to Processor B through HR bit. |
| 6-5<br>— | Reserved |
| 4<br>EP | EP<br>MUB Side Event Pending. (Read-only)<br>• EP bit is set to "1" when the MUB side mechanism sends an event update request to the MUA side.<br>• EP bit is cleared when the event update acknowledge is received. An "event" is any hardware message that is reflected in the MUA SR register on the MUA side (for example, "transmit register 0 written"). During normal operations, you do not have to deal with the state of the EP bit because the event update mechanism works automatically.<br>• To ensure events have been posted to MUA before entering STOP mode, you should verify that the EP bit is cleared. If EP bit is set to "1", you should wait and continue to poll it (EP bit) before entering STOP mode.<br>• Reading the MUB SR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP or WAIT modes; otherwise, the EP bit may be set by subsequent additional actions.<br>• The EP bit is cleared when the MU resets.<br><br>0b - The MUB side event is not pending (default).<br>1b - The MUB side event is pending. |
| 3<br>NMIC | NMIC<br>Processor B Non-Maskable-Interrupt Clear. (Write-only)<br>• NMIC bit is used by the Processor B-side MU Non-Maskable Interrupt service routine to clear the non-maskable interrupt. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | • Writing NMIC bit as "1" signals the MU to clear the NMI bit in the MUA CR register, thus de-asserting the interrupts and enabling the NMI bit to receive another interrupt.<br>• The NMIC bit is always read as "0"; therefore it (NMIC bit) cannot be polled. The NMIC bit can only be used as part of the interrupt service routine, in which the NMIC bit should only be written as "1" once.<br>• The NMIC bit is cleared when the MU resets.<br><br>0b - Default<br>1b - Writing "1" clears the NMI bit in the MUA CR register. |
| 2-0<br>Fn | Fn<br><br>For n = {0, 1, 2} MUB Side Flag n. (Read-only)<br>• Fn bit is the MUB side flag that reflects the values written to the Fn bit in the MUA control register.<br>• Every time that the Fn bit in the MUA CR register is written, the Fn bit in the MUA CR register write event updates the Fn bit in the MUB SR register after the event update latency, which is measured in terms of the number of clocks of the MUA and the MUB.<br><br>000b - Fn bit in the MUA CR register is written 0 (default).<br>001b - Fn bit in the MUA CR register is written 1. |

## 40.2.2.7 Control Register (CR)

### 40.2.2.7.1 Offset

| Register | Offset |
|---|---|
| CR | 64h |

### 40.2.2.7.2 Function

Use the Control Register (CR, 32-bit, read-write) to enable the MU interrupts on the MUB-side, and trigger events and interrupts on the MUA-side (general purpose interrupt, flag update).

| 0<br><br>HR | HR<br><br>Processor A Hardware Reset. (Read-Write)<br>• HR bit asserts and de-asserts the hardware reset of the Processor A.<br>• Set HR bit to "1" to start a hardware reset of the Processor A.<br>• Clear the HR bit to de-assert the Processor A hardware reset input.<br>• Assert the HR bit for a minimum of 3 clock cycles. The RAIP bit in MUB SR register indicates the state of the Processor on MUA-side. As soon as the Processor A goes into Reset (MUB RAIP bit is set to "1"), the HR bit can be de-asserted.<br>• Strobe-setting the HR bit will not cause an internal MU reset but will be routed outside MU to Processor A reset logic<br>• The HR reset issued by the Processor B to the Processor A is maskable by the Processor A (according to the settings of the HRM bit in the MUA CCR register). If the HRM bit (in the MUA CCR register) is set to "1", then the HR reset is masked; if the HRM bit (in the MUA CCR register) is cleared (default), then the HR reset is enabled.<br>• The HR bit does not return to the reset value during the software (MUR) reset.<br><br>0b - De-assert Hardware reset to the Processor A. (default)<br>1b - Assert Hardware reset to the Processor A. |

## 40.3 Functional Description

**Table 40-1. Major Features of the MU**

| Major Feature | Description |
|---|---|
| Interprocessor Interrupts | • The MU has 12 interrupt sources on each side (Processor A-side, Processor B-side) that are used for signaling the other processor. The interrupts can be used for notification of RX/TX events and general-purpose signaling between the processors. |
| MU Reset | • The Processor A/B can issue a reset to the entire MU, using a control bit (MUR) in the Processor A/B Control Register (CR).<br>• The MUR bit is a self-clearing bit. |
| Processor B/A Boot Configuration | • The Boot Source for Processor B/A can be configured with the BOOT bits in the CCR register. See BOOT bits in CCR register for details |
| Processor B/A Reset Hold | • Processor B/A can be held in reset following any reset event. This is done by setting the RSTH bit in the CCR register.<br>• Processor B/A will be released from reset when this bit is cleared.<br>• The value at reset is loaded from Flash IFR. |
| Processor A/B Clock Enable | • The Processor A/B platform clock can be enabled to continue running when Processor A/B enters Stop Mode, until Processor B/A also enters Stop Mode. This allows Processor B/A to continue accessing peripherals on Processor A/B's AIPS bus even when it has entered a Stop Mode. |
| Status and Control Communications between Cores | • The MU provides a way for the two cores to communicate using the status and control registers present on both the Processor B and Processor A sides of the MU.<br>• The status register of one MU side reflects the status of the other MU side.<br>• The control register is used for control operations, such as enabling an interrupt and sending an interrupt to the other processor. |
| Synchronized Message Transfers between Cores | • The transfer of data messages between cores uses transmit empty and receive full flags provided on both sides of the MU.<br>• The update of these transmit and receive flags is accomplished using a synchronization mechanism. There is inherent latency between updating the flag on one side and reflecting its status on other side. For more about latency, see Event Update Timing |
| Accessing Shared Memory Directly and Avoiding Collisions | • For sending data or messages from one MU-side to the other MU-side, the MU provides 4 transmit registers and 4 receive registers on each side of the MU.<br>• The Processor A or Processor B can access shared memory resources of the SoC directly. However, to avoid simultaneous access to shared memory by both cores, the MU provides a method (to prevent simultaneous access) using interrupts and transmit-receive registers for both processors. |
| Memory-Mapped Registers | • The MU is connected as a peripheral under the Peripheral bus on both sides—on the Processor A-side, the Processor A Peripheral Bus, and on the Processor B-side, the Processor B Peripheral Bus. |

### 40.3.1 Processor A Side Memory-Mapping

The messaging, control, and status registers of the Processor A-side for the MU are mapped to the Processor A memory as a regular peripheral. The Peripheral bus data bus is 32 bits wide inside the MU module.

### 40.3.2 Processor B Side Memory-Mapping

The messaging, control, and status registers of the Processor B-side for the MU are mapped to the Processor B memory as a regular peripheral. The Peripheral bus data bus is 32 bits wide inside the MU module.

### 40.3.3 MU Messaging

The MU provides 32-bit status and control registers to the Processor B and Processor A sides for control operations (such as interrupts and reset), and for status checking of the other MU-side.

For messaging, the MU has four, 32-bit write-only transmit registers and four, 32-bit read-only receive registers on the Processor B and Processor A-sides. These registers are used for sending messages to each other. These messages can be also be controlled using the 3 general purpose flags provided in the control and status registers of either MU-side.

#### 40.3.3.1 Programmer Model

The messaging logic is used in conjunction with external memory. You have various messaging methods, which you can use to implement a messaging protocol. Some of these messages could mean “I have just written a message of N words, starting at offset X in the memory,” or “I have just finished reading the previous data block that was sent.” Having the messaging logic independent from the memory array does not restrict you to a predefined hardware protocol. On the other hand, the software needed to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric; they are duplicated and are available on both the Processor B-side and the Processor A-side. The messaging mechanisms are:

- Four, 32-bit write-only transmit registers, which are each reflected in four, read-only receive registers in the other processor’s side. You can use these registers to transfer 32-bit word messages or frame information of messages written to the shared memory (number of words, initial address, and message type code).

- A write to a transmit register on the transmitter side clears a “transmitter empty” bit in the Status Register on the transmitter side, and sets a “receiver full” bit in the Status Register on the receiver side. The setting of the bit at the receiver side can optionally trigger an interrupt at the receiver side (maskable receive interrupt).
- A read of one of the receive registers at the receiver side clears the “receiver full” bit in the Status Register at the receiver side, and sets the “transmitter empty” bit in the Status Register on the transmitter side. The setting of the “transmitter empty” bit can optionally trigger an interrupt at the transmitter side (maskable transmit interrupt).
- Four general purpose flags are reflected in the Status Register on the receiver side
- A read/write access to any reserved location and a write to a read-only register on the Processor A-side of the MU will generate a module transfer error acknowledge to the Processor A.
- A read/write access to any reserved location and write to a read-only register on the Processor B-side of the MU will generate a module transfer error acknowledge to the Processor B.

#### 40.3.3.2 Messaging Examples

The following are messaging examples:

- **Passing short messages:** Transmit register(s) can be used to pass short messages from one to four words in length. For example, when a four-word message is desired, only one of the registers needs to have its corresponding interrupt enable bit set at the receiver side; the message’s first three words are written to the registers whose interrupt is masked, and the fourth word is written to the other register (which triggers an interrupt at the receiver side).
- **Passing frame information:** Transmit registers can be used to pass frame information for long messages written to the shared system (SDRAM and SyncFLASH). Such frame information normally includes a start address, number of words, and perhaps a message type code.
- **Passing event notices and requests:** Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the general interrupts, such as acknowledging that a long message was read from the shared system memory.
- **Passing fixed length data:** Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general interrupt (Processor A or Processor B) to signal the other processor that the data is ready.
- **Passing announcements:** The three flags can be used by a processor to announce its current program state or other billboard messages to the other processor.

Figure 40-2 shows the MU registers schematic.

## 40.3.4 Low Power Modes

This section describes the low power operating modes of the MU module.

### 40.3.4.1 Processor Low Power Modes

The Processors have four power modes:

- Run
- WAIT
- STOP/VLPS
- LLS/VLLS

The Processor can be awakened from a low-power mode by any enabled Processor side MU interrupt, as reflected in the xSR “status” register (RF0–3, TE0–3, GIP0–3 bits are set) and enabled in the xCR control register. Using these bits, the Processor can actively control when to wake the other Processor.

While the Processor is in STOP/VLPS mode (such that the xSR register bits cannot be updated with events), special logic drives the enabled Processor interrupts directly from the other Processor-side (instead of from the xSR register).

While the Processor is in STOP/VLPS mode, the asynchronous Processor interrupt will be asserted to wake the Processor:

- If any transmit data register of the other Processor-side is full, because of a write to it (transmit data register); that is, its “empty” bit in the xSR register is cleared while its corresponding receive interrupt is enabled on the Processor-side.
- If any receive data register of the other Processor-side is empty, because of a read on the other Processor -side; that is, its “full” bit in the xSR register is cleared while its corresponding transmit interrupt is enabled on the Processor-side.
- If any general purpose interrupt is set in the xCR register while the corresponding interrupt is enabled on the Processor-side.
- If the other Processor issues a non-maskable interrupt to the Processor.

The logic enables the other Processor to operate independently while the Processor is in any power mode (including STOP/VLPS). However, the Processor power mode change protocol should be handled with care regarding:

- The interrupts that are enabled on the Processor-side
- The events that could be triggered by the other Processor-side
- The compatibility with the other Processor protocol of entering STOP/VLPS mode

If the Processor is in STOP/VLPS mode and an event on the other Processor is triggered, the EP bit (in the xSR register) will remain high until the Processor wakes up.

Before entering STOP/VLPS mode, the Processor programmer should verify that the EP bit (in the xSR register) is cleared. This check is needed to ensure that all pending updates from the Processor, including the power mode change when STOP/VLPS or WAIT is executed, will be updated in the xSR register.

- If the other Processor is in STOP/VLPS mode or LLS/VLLS mode, the EP bit (in the xSR register) may be stuck high; in this case, the Processor need not check the EP bit before entering STOP/VLPS mode.

## 40.3.5 Event Update Timing

Each processor's MU messaging side (Processor A or Processor B) has a hardware mechanism to send "event update requests" to the other processor's side. An "event" is considered when any information change should be reflected at the Status Register of the receiving processor. The event update latency is the delay between the event being ready at one processor and the resulting update at the Status Register of the other processor.

- The minimum event latency is "1 clock of the sending side" + "2 1/2 clocks of the receiving side". The minimum case is if there is no event pending when the new event occurs.
- The maximum event latency is "6 clocks of the sending side" + "6 1/2 clocks of the receiving side." The maximum case is if the event occurred just after a previous event was sent to the other side. The event update latency will vary between the above-mentioned minimum and maximum latencies, depending on the time at which the subsequent event is triggered.

## 40.3.6 Interrupts

The MU controls the Processor B interrupt requests to the Processor A, and the Processor A interrupt requests to the Processor B.

This section describes all the interrupts that the module generates.

### 40.3.6.1 Interrupts to the Processors

There are 12 interrupt sources from the MU to the Processors:

- Four receive interrupts (asserted when the Processors receive full bits are set and enabled in the xCR register) for each of the receive registers
- Four transmit interrupts (asserted when the Processor transmit empty bits are set and enabled in the xCR register) for each of the transmit registers
- Four general purpose interrupts (asserted when the GIP bits are set and enabled in the xCR register)

All the interrupts are maskable in the Processor Control Register (xCR). The MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, Receive 0 and Receive 1 interrupts or any of the transmit and general purpose interrupts) can be asserted at one time. The priority of these interrupts should be resolved by the interrupt controller at the chip level.

The General Purpose Interrupt Pending bits (GIP0, GIP1, GIP2, and GIP3) should be cleared by the software (as part of the interrupt service routine) to de-assert the request to the interrupt controller.

#### 40.3.6.2 General Purpose Interrupt Clearing Sequence

When a Processor writes to the general interrupt bit (GIR), the write event is synchronized to the other Processor clock to set the general interrupt request pending bit (GIP). When the GIP bit is set, and if the general purpose interrupt is enabled on the transmitting Processor side (GIE bit is set), then the receiving Processor general purpose interrupt is issued to the transmitting Processor. The transmitting Processor clears this interrupt by writing a “1” on the GIP bit. The interrupt is de-asserted as soon as the GIP bit is written. The write event of the GIP bit is synchronized to the other Processor clock. The synchronized signal clears the GIR bit. The software should not write the GIR bit again until the GIR bit is cleared.

### 40.3.7 Interrupt Messaging Protocols

#### 40.3.7.1 Messaging Protocols using Interrupts

The example below describes a four-word messaging sequence sent by the Processor to the other Processor.

In this example, the first, second, and third receive interrupts are disabled, and the fourth receive interrupt is enabled. We write registers sequentially for n = 0, 1, 2, 3. For n = 0, 1, 2, the interrupts are disabled, therefore no interrupt will go to the other core (although interrupt conditions occur). For n = 3, the interrupt is enabled, and the last Receive Interrupt request is generated.

1. Write Sequence

- The Processor writes the message information sequentially to its Transmit Registers 0, 1, 2.
- When the write to the Transmit Register 3 occurs, the RF3 bit of the xSR is set after synchronization, and it immediately trigger the Receive Full 3 interrupt to the other Processor.

2. Read Sequence
   - The other Processor receives the Receive Full 3 interrupt and starts reading the message transferred from the receive registers.
   - After Receive Register 3 is read, the interrupt bit is cleared.

The following table and diagram describe the messaging model using transmit/receive registers and interrupt messaging protocol.

**Table 40-2. Interrupt Messaging Protocol (Generalized)**

| Sequence | Action | Description |
|---|---|---|
| 1 | Processor A Data write | A data write to the TRn register by Processor A is immediately reflected in the Processor B RRn register. |
| 2 | Clear Tx Empty bit and Set Rx Full bit | The data write to the TRn register<br>• Clears the transmitter empty bit (TEn) in the Processor A Transmit Status Register<br>• Sets the receiver full bit (RFn) in the Processor B Receive Status Register |
| 3 | Generate Receive Interrupt request | The setting of the receiver full bit (RFn) in the Receive Status Register generates a Receive Interrupt request to Processor B. |
| 4 | Processor B Data read | After receiving the Receive Interrupt request, Processor B performs a data read of the RRn register. |
| 5 | Clear Rx Full bit and Set Tx Empty bit | Reading the data out of the RRn register<br>• Clears the receiver full bit (RFn) in the Processor B Receive Status Register<br>• Sets the transmitter empty bit (TEn) in the Processor A Transmit Status Register |
| 6 | Generate Transmit Interrupt request | The setting of the transmitter empty bit (TEn) in the Transmit Status Register generates a Transmit Interrupt request to Processor A. |

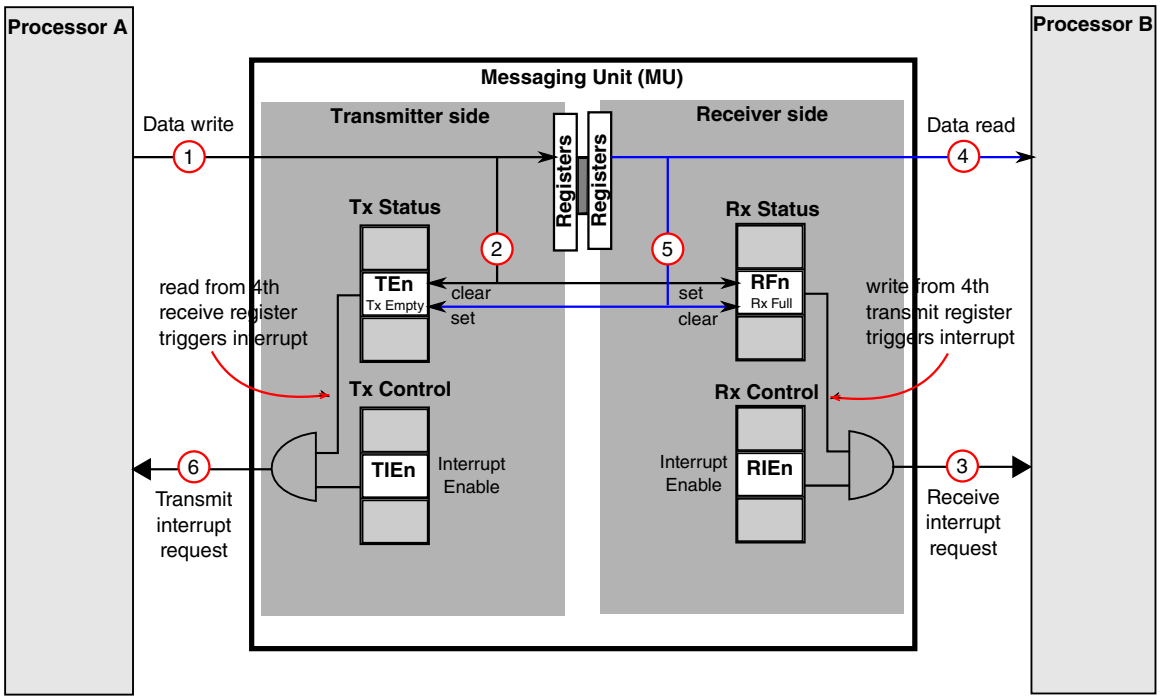

**Figure 40-3. Messaging Model Using Transmit and Receive Registers**

The messaging hardware can be used by software to implement messaging protocols for a wide array of message types. Full support is given for both interrupt and polling management schemes.

### 40.3.7.2 Messaging Protocols using Event Interrupts

Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the two general interrupts.

Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general purpose interrupt to signal the other processor that the data is ready.

The three flags can be used by a processor to announce to the other processor the program state it is currently in, or to announce similar messages.

Table 40-3 and Figure 40-4 describe the event sequence when the Processor triggers an interrupt.

**Table 40-3. Interrupt Messaging Protocol (Generalized)**

| Sequence | Action | Description |
|---|---|---|
| 1 | Processor A sets General Interrupt request bit | Processor A sets its associated General Interrupt request bit (GIRn = 1) in the control register (ACR). |
| 2 | General Interrupt Request Pending status bit is set | The General Interrupt Request Pending status bit (GIPn) in the status register (BSR) is set to "1" |
| 3 | General Interrupt request to Processor B is generated | Setting the GIPn bit generates the General Interrupt request to Processor B (Interrupt Request Enable bit, GIEn, must be set for Processor B) |
| 4 | Processor B reads status register | The Processor B reads the GIPn bit in the BSR register. |
| 5 | Processor B services the interrupt | - |
| 6 | Processor B sets GIPn bit to clear interrupt | The Processor B writes "1" to the corresponding GIPn bit to clear the interrupt |
| 7 | GIRn bit is cleared | Setting the GIPn bit to "1" clears the General Interrupt request bit (GIRn) in the Processor A control register (ACR). |

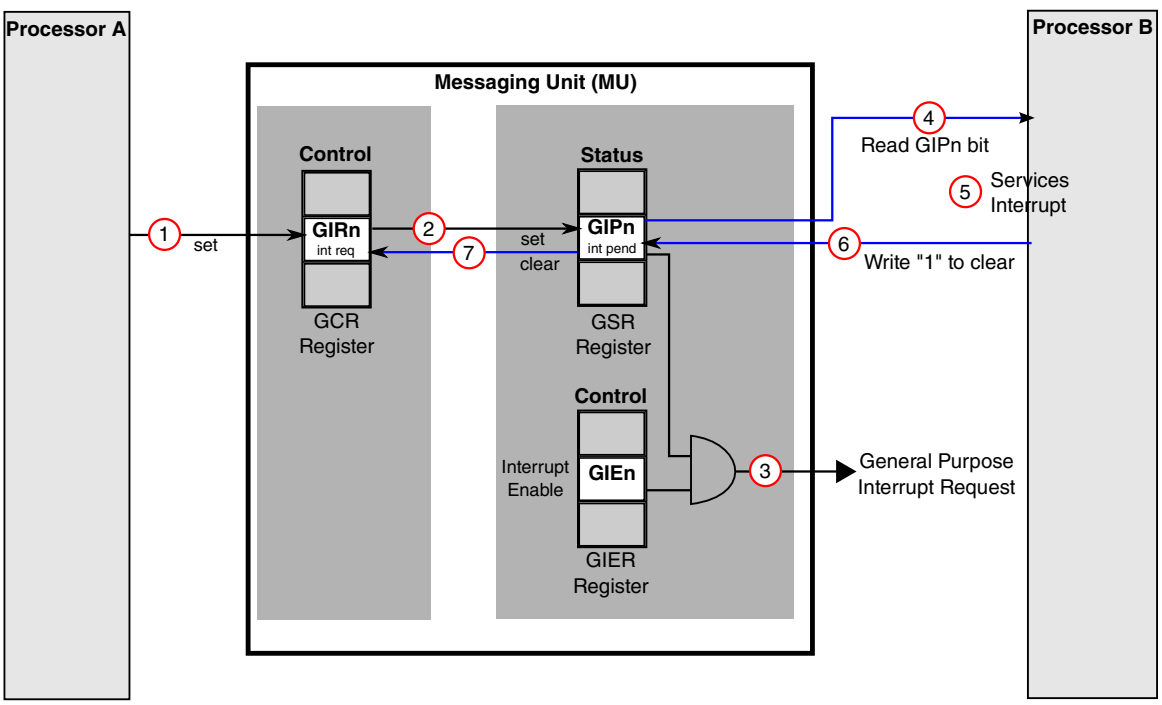

**Figure 40-4. Messaging Model Using a General Purpose Interrupt**

## 40.3.8 Exclusive Access to Shared Memory

You can use the MU to signal one processor about its current access to the shared memory, so that the data is not overwritten by the other processor during the exclusive memory access period.

The following tables describe the signaling protocol that the Processor A uses to inform the Processor B about its current access (write) to the shared memory, assuming that the set of bits and registers (GIRn bit, RRn register, TRn register) are reserved to support exclusive access to the shared memory protocol.

**Table 40-4. How the Processor A Performs an Exclusive Access to Shared Memory**

| Sequence | Action | Description |
|---|---|---|
| 1 | Processor A sends GIRn request to Processor B using Processor A control register | When the Processor A wants to perform an exclusive access to the shared memory, the Processor A sends an GIR0 request to the Processor B. |
| 2 | Processor A sends an exclusive-access request using a transmit data register (TRn) | The Processor A will send an exclusive-access request (command, location, and length of target access) to Processor B using a selected transmit data register (TR0). |
| 3 | Processor A waits for a dedicated interrupt from Processor B | The Processor A waits for a dedicated interrupt (as an acknowledgement) triggered by the Processor B before proceeding. |
| 4 | Processor A accesses shared memory | After receiving a dedicated interrupt from the Processor B, Processor A proceeds. |

**Table 40-5. How the Processor B Scans for Transaction Information**

| Sequence | Action | Description |
|---|---|---|
| 1 | Processor B receives an interrupt from a receive data register (RRn) | - |
| 2 | Processor B reads the receive data register (RRn) | - |
| 3 | Processor B scans the receive data register contents | For transaction information (whether Processor A has requested an exclusive-access) |

**Table 40-6. How the Processor B Accepts Exclusive Access by Processor A**

| Sequence | Action | Description |
|---|---|---|
| 1 | Processor B triggers a dedicated interrupt | Processor B acknowledges the Processor A request by triggering a dedicated interrupt (ack) to the Processor A. |
| 2 | Processor B sends a code message to Processor A | Along with the acknowledge interrupt, the Processor B sends a code message to the Processor A through the selected transmit register (TRn). The message informs the Processor A that it can exclusively access the shared memory. |

**Table 40-7. How the Processor B Rejects Exclusive Access by Processor A**

| Sequence | Action | Description |
|---|---|---|
| 1 | Processor B ignores Processor A request for exclusive access | If the Processor B does not want to give go-ahead permission to the Processor A, Processor B ignores the exclusive access request. |

## 40.3.9 Packet Data Transfers

The following example describes the packet transfer sequence between the Processor B and Processor A subsystems:

**Table 40-8. Packet Data Transfer Sequence**

| Action | Sequence | Description |
|---|---|---|
| Processor B requests DMA | 1 | The Processor B sends a DMA request to initiate the packet data transfer |
| DMA data transfer | 2 | DMA acknowledges. |
| | 3 | DMA starts transferring data from the specified Processor B location to the specified shared memory |
| | 4 | DMA interrupts the Processor B to signal that the packet transfer has finished. |
| Processor B informs Processor A that data is in shared memory | 5 | Using an MU Processor B-side transmit register, the Processor B sends a packet information message to the Processor A to inform the Processor A of the arrival of new packet data that is stored in shared memory. The message contains the command, location, and length of packet data information. |
| Processor A receives interrupt | 6 | The Processor A receives an interrupt (assuming its corresponding Processor A MU-side receive interrupt is enabled), and the pending processing task becomes active and processes packet data from memory. |
| Processor A reads data, writes data | 7 | The Processor A reads or processes packet data from shared memory. |
| | 8 | The Processor A writes the result from packet processing to a separate buffer. |
| Processor A informs Processor B that transfer is finished | 9 | After the processing of the packet data finishes, the Processor A informs the Processor B (using the MU Processor A-side transmit register, ATRn). |
| Processor A sends interrupt to Processor B (request for more data) | 10 | The Processor B receives the next interrupt from the Processor A, in which the Processor A requests more packet data. |

## 40.3.10 Resets

The MU has two sources of reset, and each reset has a different function from the MU or system perspective.

- One asynchronous system that is connected to both sides of the MU interface.
- One programmable hardware reset (MUR bit) in the CR and CCR register (on the Processor A and B side).

**Table 40-9. MU programmable resets**

| Reset | Description |
|---|---|
| Processor A/B MU reset | • Processor A/B MU Reset bit (MUR) of the CR register<br>• The MUR reset affects the messaging section on both the Processor A and the Processor B sides. The MUR reset causes most of control and status registers to return to their default values and all internal states to be cleared.<br>• The instruction immediately following assertion of the MUR bit should not write to MU registers. Such a write may be overwritten by the reset sequence and the register will remain with the reset value. You should wait at least one instruction (after assertion of the MUR bit) before attempting a write to MU registers. |

**NOTE**

MUR bit assertion may cause unpredictable behavior if, for example, the other Processor is concurrently testing an MU register bit (TE bit in Processor B/A SR register). Before asserting the MUR bit, you should verify that the other Processor is not presently engaged in an MU signalling activity.

## 40.4 Software Restrictions

This section describes certain software restrictions when accessing the MU.

### 40.4.1 General Restrictions

This section lists the restrictions that apply to both the sides (Processor A, Processor B) of the MU.

#### 40.4.1.1 Write-After-Write to a Transmit Register

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver will attempt to retrieve the data.
- Before attempting to write the transmit register again, the transmitter side should wait for a “Transmitter Empty” interrupt, or should poll the “Transmitter Empty” bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being read on the receiver side of the MU.

#### 40.4.1.2 Read-After-Read from a Receive Register

A read of a receive register signals the transmitter side that data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a “Receiver Full” interrupt or polling the “Receiver Full” bit in the Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter will attempt to write the data.
- Before attempting to read the receive register again, the receiver side should wait for a “Receiver Full” interrupt, or should poll the “Receiver Full” bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being written on the transmitter side of the MU.

### 40.4.2 Processor Restrictions

This section lists the restrictions that apply each side of the processor in the MU.

#### 40.4.2.1 Before Entering Low Power Mode

Before entering Low Power mode, the Processor should verify that the Processor Event Pending (EP) bit in the Status Register is cleared.

- If the Event Pending bit (EP) is still set to “1”, then the Processor should wait and poll the EP bit until it is cleared, before executing the LPM instruction.
- Note that if the other Processor is in Low Power mode (programmed for clock gating in CCM), the EP bit may be stuck high. In this case, the other Processor clock must be turned ON to get the EP bit cleared before the Processor can enter Low Power mode.
- To discover which power mode the other Processor is in, the Processor can check the PM bits in the xSR register.

#### 40.4.2.2 Before Setting a General Interrupt Request Bit (GIR0–3)

Before setting a General Interrupt Request bit (GIR0–3), you must verify that the GIRn bit is cleared, which means that a general interrupt is not pending. Generally, setting the GIRn bit while the bit is set to “1” will be ignored, but in some cases it may issue a second interrupt. This restriction is meant to prevent this indeterministic behavior.

### 40.4.2.3 Reset Bit Restrictions

The reset bit (MUR, HR) restrictions are:

- Before asserting the MUR bit in the CR register, verify that the Processor B/A-side is not engaged in some MU activity.
- Do not write to an MU register in the instruction immediately after the assertion of the MUR bit in the CR register, because the written data can be overridden by the reset value.

# Chapter 41
# Watchdog timer (WDOG)

## 41.1 Chip-specific WDOG information

### 41.1.1 WDOG clocks

The following table shows the WDOG module clocks and corresponding chip clocks.

**Table 41-1. WDOG module clocks and corresponding chip clocks**

| Module clock | Chip clock |
|---|---|
| BUS_CLK | SLOW_CLK |
| LPO_CLK | LPO_CLK |
| INTCLK | SIRC_CLK |
| ERCLK | SOSC_CLK |

### 41.1.2 WDOG low-power modes

This table shows the WDOG low-power modes and the corresponding chip low-power modes.

**Table 41-2. WDOG low-power modes**

| Module mode | Chip mode |
|---|---|
| Wait | Wait, VLPW |
| Standby | Stop, VLPS |
| Stop | Stop, VLPS |
| Power Down | LLS, VLLSx |

**NOTE**

To enable the WDOG module when the chip is in Stop mode, write ones to both the STNDBYEN bit and the STOPEN bit of the Watchdog Status and Control Register High.

## 41.2 Introduction

The Watchdog Timer (WDOG) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.

### 41.2.1 Features

Features of the WDOG module include:

- Configurable clock source inputs independent from the bus clock
  - Bus clock (slow clock)
  - LPO clock
  - INTCLK (internal clock)
  - ERCLK (external reference clock)
- Programmable timeout period
  - Programmable 16-bit timeout value
  - Optional fixed 256 clock prescaler when longer timeout periods are needed
- Robust write sequence for counter refresh
  - Refresh sequence of writing 0xA602 and then 0xB480
- Window mode option for the refresh mechanism
  - Programmable 16-bit window value
  - Provides robust check that program flow is faster than expected
  - Early refresh attempts trigger a reset.
- Optional timeout interrupt to allow post-processing diagnostics

- Interrupt request to CPU with interrupt vector for an interrupt service routine (ISR)
- Forced reset occurs 128 bus clocks after the interrupt vector fetch.

- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered.
- Robust write sequence for unlocking write-once configuration bits
  - Unlock sequence of writing 0xC520 and then 0xD928 for allowing updates to write-once configuration bits
  - Software must make updates within 128 bus clocks after unlocking and before WDOG closing unlock window.

## 41.2.2 Block diagram

The following figure shows a block diagram of the WDOG module.

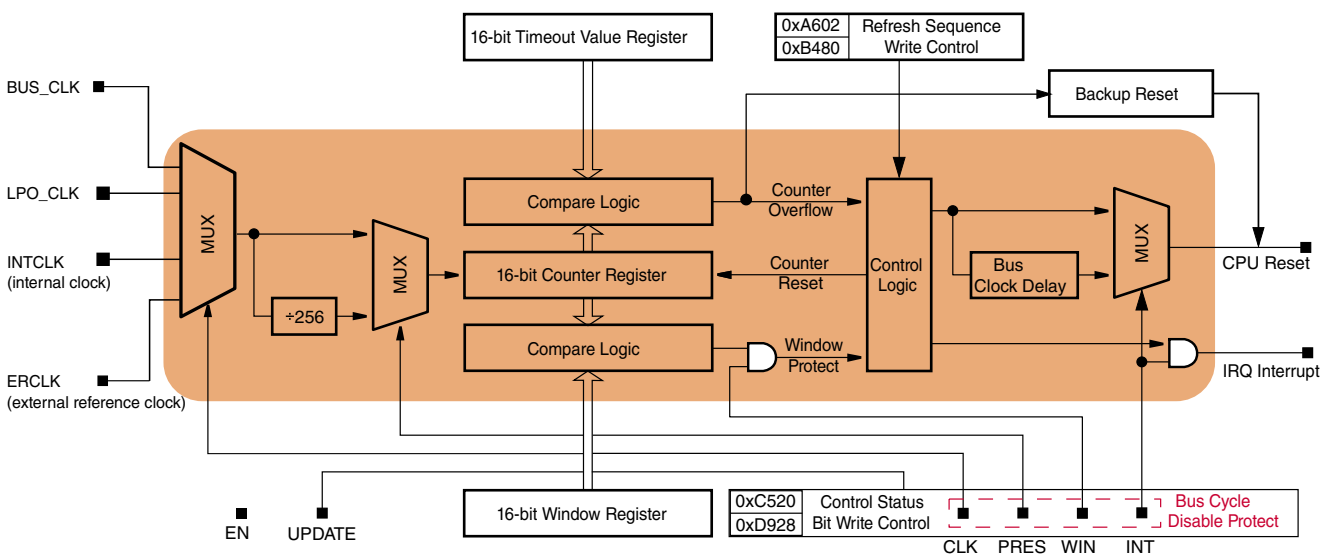

**Figure 41-1. WDOG block diagram**

# 41.3 Memory map and register definition

## 41.3.1 WDOG0 register descriptions

### 41.3.1.1 WDOG0 Memory map

WDOG0 base address: 4002_A000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Watchdog Control and Status Register (CS) | 32 | RW | 0000_2980h |
| 4h | Watchdog Counter Register (CNT) | 32 | RW | 0000_0000h |
| 8h | Watchdog Timeout Value Register (TOVAL) | 32 | RW | 0000_0400h |
| Ch | Watchdog Window Register (WIN) | 32 | RW | 0000_0000h |

### 41.3.1.2 Watchdog Control and Status Register (CS)

#### 41.3.1.2.1 Offset

| Register | Offset |
|---|---|
| CS | 0h |

#### 41.3.1.2.2 Function

This section describes the function of Watchdog Control and Status Register.

**NOTE**

TST is cleared (0:0) on POR only. Any other reset does not affect the value of this field.

## 41.3.1.3 Watchdog Counter Register (CNT)

### 41.3.1.3.1 Offset

| Register | Offset |
|---|---|
| CNT | 4h |

### 41.3.1.3.2 Function

This section describes the watchdog counter register.

The watchdog counter register provides access to the value of the free-running watchdog counter. Software can read the counter register at any time.

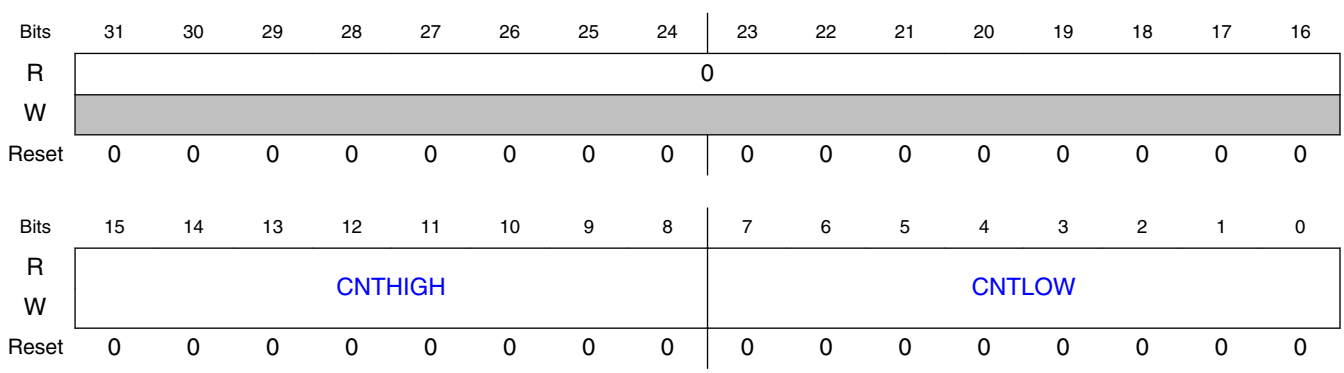
Software cannot write directly to the watchdog counter; however, two write sequences to these registers have special functions:

1. The *refresh sequence* resets the watchdog counter to 0x0000. See the "Refreshing the Watchdog" section.
2. The *unlock sequence* allows the watchdog to be reconfigured without forcing a reset (when CS[UPDATE] = 1). See the "Configure for reconfigurable" section.

**NOTE**

All other writes to this register are illegal and force a reset.

### 41.3.1.3.3 Diagram



#### 41.3.1.3.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-8<br>CNTHIGH | High byte of the Watchdog Counter |
| 7-0<br>CNTLOW | Low byte of the Watchdog Counter |

### 41.3.1.4 Watchdog Timeout Value Register (TOVAL)

#### 41.3.1.4.1 Offset

| Register | Offset |
|---|---|
| TOVAL | 8h |

#### 41.3.1.4.2 Function

This section describes the watchdog timeout value register. TOVAL contains the 16-bit value used to set the timeout period of the watchdog.

The watchdog counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, the watchdog forces a reset triggering event.

**NOTE**

Do not write 0 to the TOVAL register (if CS[TST]=11b, then TOVALHIGH cannot be written as 0; if CS[TST]=10b, then TOVALLOW cannot be 0); otherwise, the watchdog always generates a reset.

#### 41.3.1.4.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |

| TOVAL | 8h |

#### 41.3.2.4.2 Function

This section describes the watchdog timeout value register. TOVAL contains the 16-bit value used to set the timeout period of the watchdog.

The watchdog counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, the watchdog forces a reset triggering event.

**NOTE**

Do not write 0 to the TOVAL register (if CS[TST]=11b, then TOVALHIGH cannot be written as 0; if CS[TST]=10b, then TOVALLOW cannot be 0); otherwise, the watchdog always generates a reset.

## 41.4 Functional description

The WDOG module provides a fail safe mechanism to ensure the system can be reset to a known state of operation in case of system failure, such as the CPU clock stopping or there being a run away condition in the software code. The watchdog counter runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not, it generates a reset triggering event.

**The timeout period, window mode, and clock source are all programmable but must be configured within 128 bus clocks after a reset.**

### 41.4.1 Clock source

The watchdog counter has the following clock source options selected by programming CS[CLK]:

- bus clock
- Low-Power Oscillator clock (LPO_CLK)
- internal clock
- external clock

The options allow software to select a clock source independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the watchdog counter continues to run if the bus clock is somehow halted; see Backup reset.

**NOTE**

The *default* clock source of WDOG should be enabled after its funcitonal reset is deasserted, for the WDOG module to function properly.

An optional fixed prescaler for all clock sources allows for longer timeout periods. When CS[PRES] is set, the clock source is prescaled by 256 before clocking the watchdog counter.

The following table summarizes the different watchdog timeout periods which could be available, as an example.

**Table 41-3. Watchdog timeout availability (example)**

| Reference clock | Prescaler | Watchdog time-out availability |
|---|---|---|
| LPO_CLK | Pass through | ~1 ms–65.5 s (if LPO_CLK = 1 kHz); (~1 ms–65.5 s)/128 (if LPO_CLK = 128 kHz). [1] |
| | ÷256 | ~256 ms–16,777.2 s (if LPO_CLK = 1 kHz); ~2 ms–131.1 s (if LPO_CLK = 128 kHz). |
| Internal clock 8 MHz | Pass through | 125 ns–8.1925 ms |
| | ÷256 | 32 µs–2.09728 s |
| 1 MHz (from bus or external) | Pass through | 1 µs–65.54 ms |
| | ÷256 | 256 µs–16.777 s |
| 20 MHz (from bus or external) | Pass through | 50 ns–3.277 ms |
| | ÷256 | 12.8 µs–838.8 ms |

1. The default timeout value after reset is approximately 1024 ms (if LPO_CLK = 1 kHz), or 1024/128 ms (if LPO_CLK = 128 kHz).

**NOTE**

When the programmer switches clock sources during reconfiguration, the watchdog hardware holds the counter at zero for 2.5 periods of the previous clock source and 2.5 periods of the new clock source after the configuration time period ( 128 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

## 41.4.2 Watchdog refresh mechanism

The watchdog resets the MCU if the watchdog counter is not refreshed. A robust refresh mechanism makes it very unlikely that the watchdog can be refreshed by runaway code.

To refresh the watchdog counter, software must execute a refresh write sequence before the timeout period expires. In addition, if window mode is used, software must not start the refresh sequence until after the time value set in the WIN register. See the following figure.

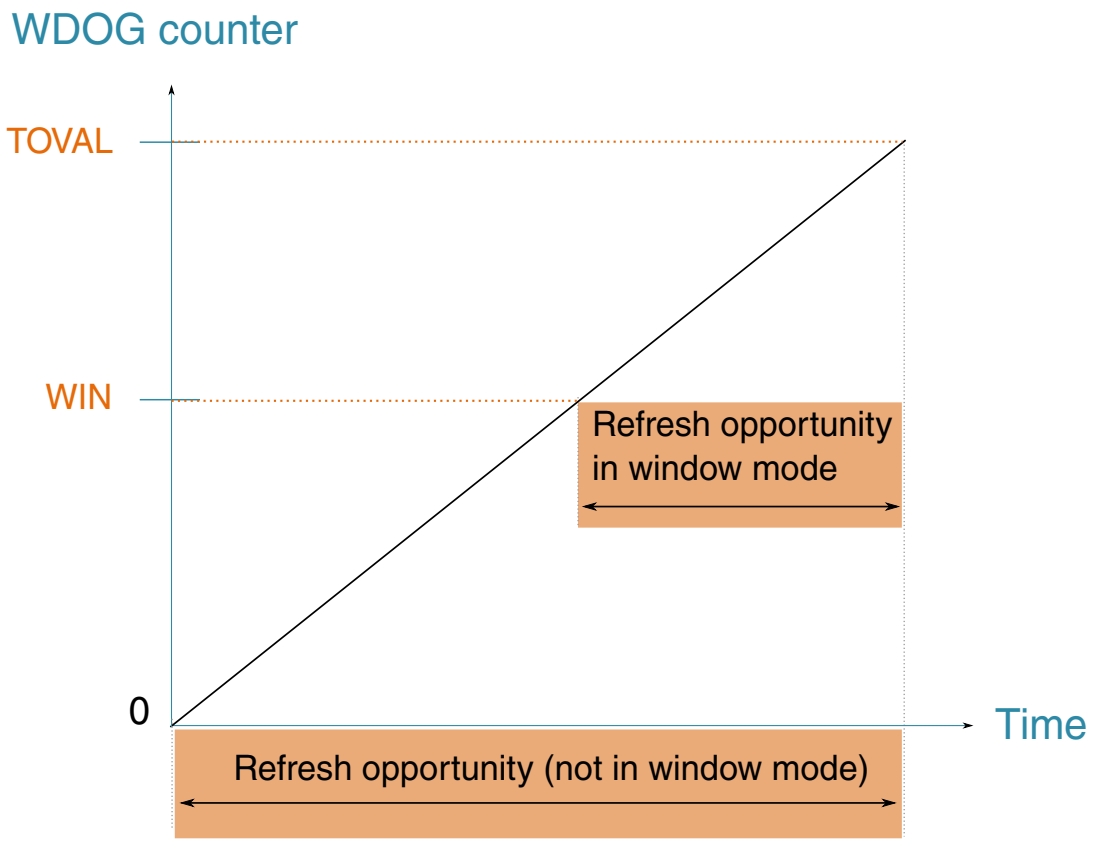

**Figure 41-2. Refresh opportunity for the Watchdog counter**

### 41.4.2.1 Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, the WDOG can be programmed to force a reset when refresh attempts are early.

When Window mode is enabled, the watchdog must be refreshed after the counter has reached a minimum expected time value; otherwise, the watchdog resets the MCU. The minimum expected time value is specified in the WIN register. Setting CS[WIN] enables Window mode.

### 41.4.2.2 Refreshing the Watchdog

The refresh write sequence can be

- either two 16-bit writes ( 0xA602, 0xB480) or four 8-bit writes (0xA6, 0x02, 0xB4, 0x80; applicable to Cortex-M core cases) if WDOG_CS[CMD32EN] is 0;
- one 32-bit write (0xB480_A602) if WDOG_CS[CMD32EN] is 1.

to the CNT register. Both methods must occur before the WDG timeout; otherwise, the watchdog resets the MCU.

**Note**

Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

The example codes can be found at the end of this chapter.

## 41.4.3 Configuring the Watchdog

### 41.4.3.1 Configuring the Watchdog Once

**All watchdog control bits, timeout value, and window value are write-once after reset *within 128 bus clocks*. This means that after a write has occurred they cannot be changed unless a reset occurs.** This is guaranteed by the user configuring the window and timeout value first, followed by the other control bits, and ensuring that CS[UPDATE] is also set to 0.

This provides a robust mechanism to configure the watchdog and ensure that a runaway condition cannot mistakenly disable or modify the watchdog configuration after configured.

The new configuration takes effect only after all registers except CNT are written after reset. Otherwise, the WDOG uses the reset values by default. If window mode is not used (CS[WIN] is 0), writing to WIN is not required to make the new configuration take effect.

### 41.4.3.2 Reconfiguring the Watchdog

In some cases (like when supporting a bootloader function), you may want to reconfigure or disable the watchdog, *without forcing a reset first*.

- By setting CS[UPDATE] to 1 on the initial configuration of the watchdog after a reset, you can reconfigure the watchdog at any time by executing an unlock sequence.
- Conversely, if CS[UPDATE] remains 0, the only way to reconfigure the watchdog is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

#### 41.4.3.2.1 Unlocking the Watchdog

The unlock sequence is a write to the CNT register of 0xC520 followed by 0xD928 at any time after the watchdog has been configured. On completing the unlock sequence, the user must reconfigure the watchdog within 128 bus clocks; otherwise, the watchdog closes the unlock window.

**NOTE**

Due to the 128 bus clocks requirement for reconfiguring the watchdog, some delays must be inserted before executing STOP or WAIT instructions after reconfiguring the watchdog. This ensures that the watchdog's new configuration takes effect before the MCU enters low power mode. Otherwise, the MCU may not be waken up from low power mode.

The example codes can be found at end of this chapter.

### 41.4.4 Using interrupts to delay resets

- **When interrupts are enabled (CS[INT] = 1):** After a reset-triggering event (like a counter timeout or invalid refresh attempt), the watchdog first generates an interrupt request. Next, the watchdog delays 128 bus clocks (from the interrupt vector fetch, not the reset-triggering event) before forcing a reset, to allow the interrupt service routine (ISR) to perform tasks (like analyzing the stack to debug code).
- **When interrupts are disabled (CS[INT] = 0):** the watchdog does not delay the forcing a reset.

### 41.4.5 Backup reset

**NOTE**

A clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the backup reset function is not available.

The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the watchdog counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

Backup reset becomes valid when interrupt is enabled and the watchdog clock is from non bus clock. If interrupt is enabled, once the bus clock is cut off before exiting interrupt routine, the normal watchdog reset will be blocked. Under this case, the second overflow will cause backup reset directly.

### 41.4.6 Functionality in debug and low-power modes

By default, the watchdog is not functional in Debug mode, Wait mode, or Stop mode. However, the watchdog can remain functional in these modes as follows:

- **For Debug mode,** set CS[DBG]. (This way the watchdog is functional in Debug mode even when the CPU is held by the Debug module.)
- **For Wait mode,** set CS[WAIT].
- **For Stop mode,** set CS[STOP], CS[WAIT], and ensure the clock source is active in Stop mode.

**NOTE**

The watchdog can generate interrupt in Stop mode.

For Debug mode and Stop mode, in addition to the above configurations, a clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the watchdog cannot function.

### 41.4.7 Fast testing of the watchdog

Before executing application code in safety critical applications, users are required to test that the watchdog works as expected and resets the MCU. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 k clocks).

To help minimize the startup delay for application code after reset, the watchdog has a feature to test the watchdog more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for timeout against the corresponding byte of the timeout value register. (For complete coverage when testing the high byte of the counter, the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.)

Using this test feature reduces the test time to 512 clocks (not including overhead, such as user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

On a power-on reset, the POR bit in the system reset register is set, indicating the user should perform the WDOG fast test.

### 41.4.7.1 Testing each byte of the counter

The test procedure follows these steps:

1. Program the preferred watchdog timeout value in the TOVAL register during the watchdog configuration time period.
2. Select a byte of the counter to test using the CS[TST] = 10b for the low byte; CS[TST] = 11b for the high byte.
3. Wait for the watchdog to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because the RAM is not affected by a watchdog reset, the timeout period of the watchdog counter can be compared with the software counter to verify the timeout period has occurred as expected.
4. The watchdog counter times out and forces a reset.
5. Confirm the WDOG flag in the system reset register is set, indicating that the watchdog caused the reset. (The POR flag remains clear.)
6. Confirm that CS[TST] shows a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, selecting the other byte in step 2.

**NOTE**

CS[TST] is cleared by a POR only and not affected by other resets.

### 41.4.7.2 Entering user mode

After successfully testing the low and high bytes of the watchdog counter, the user can configure CS[TST] to 01b to indicate the watchdog is ready for use in application user mode. Thus if a reset occurs again, software can recognize the reset trigger as a real watchdog reset caused by runaway or faulty application code.

As an ongoing test when using the default clock source, software can periodically read the CNT register to ensure the counter is being incremented.

## 41.5 Application Information

The watchdog is enabled by default after reset. To disable or reconfigure the watchdog, it is better to be done before the first watchdog timeout. It is suggested to disable or reconfigure the watchdog at the very beginning of the software code, e.g. beginning of the startup or main function.

**NOTE**

When the watchdog is configured by user, it needs at least 2.5 periods of watchdog clock to take effect. This means interval between two configures by user must be larger than 2.5 clocks.

**NOTE**

When Chip startup from BOOT ROM then jump to flash, the watchdog would be disabled in the beginning of bootloader, and enabled when bootloader exits. If there is any code in the flash program want to reconfigure the watchdog, it must be run 2.5 watchdog clocks later after the bootloader exits.

To disable or reconfigure the watchdog without forcing a reset, WDOG_CS[UPDATE] bit must be set during the initial configuration of the WDOG module. Then, the unlock sequence can be used at any time within the timeout limit to reconfigure the watchdog.

### 41.5.1 Disable Watchdog

To disable the watchdog, first do unlock sequence, then unset the WDOG_CS[EN] bit. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK; //disable watchdog
EnableInterrupts; //enable global interrupt
```

### 41.5.2 Disable Watchdog after Reset

All of watchdog registers are unlocked by reset. Therefore, unlock sequence is unnecessary, but it needs to write all of watchdog registers to make the new configuration take effect. The code snippet below shows an example of disabling watchdog after reset.

```
DisableInterrupts; // disable global interrupt
WDOG_CS &= ~WDOG_CS_EN_MASK; // disable watchdog
WDOG_TOVAL= 0xFFFF;
while(WDOG_CS[ULK]);  // waiting for lock
while(~WDOG_CS[RCS]); // waiting for new configuration to take effect
EnableInterrupts; // enable global interrupt
```

## 41.5.3 Configure Watchdog

The watchdog can be configured once by set the WDOG_CS[UPDATE]=0. After that, the watchdog cannot be reconfigured until a reset. If set WDOG_CS[UPDATE]=1 when configuring the watchdog, the watchdog can be reconfigured without forcing a reset. The following example code shows how to configure the watchdog without window mode, clock source as LPO, interrupt enabled and timeout value to 256 clocks. The code snippet below shows an example for 32-bit write.

*Configure once*

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

*Configure for reconfigurable*

```
DisableInterrupts; //disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

## 41.5.4 Refreshing the Watchdog

To refresh the watchdog and reset the watchdog counter to zero, a refresh sequence is required. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xB480A602; // refresh watchdog
EnableInterrupts; // enable global interrupt
```

# Chapter 42
# External Watchdog Monitor (EWM)

## 42.1 Chip-specific EWM information

### 42.1.1 EWM clocks

This table shows the EWM clocks and the corresponding chip clocks.

**Table 42-1. EWM clock connections**

| Module clock | Chip clock |
|---|---|
| Low Power Clock | 1 kHz LPO Clock |

### 42.1.2 EWM low-power modes

This table shows the EWM low-power modes and the corresponding chip low-power modes.

**Table 42-2. EWM low-power modes**

| Module mode | Chip mode |
|---|---|
| Wait | Wait, VLPW |
| Stop | Stop, VLPS, LLS |

### 42.1.3 $\overline{\text{EWM_OUT}}$ pin state in low power modes

During Wait, Stop and Power Down modes the $\overline{\text{EWM_OUT}}$ pin preserves its state before entering Wait or Stop mode. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

## 42.2 Introduction

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the RESET_B pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent EWM_OUT_b signal that when asserted resets or places an external circuit into a safe mode. The EWM_OUT_b signal is asserted upon the EWM counter time-out. An optional external input EWM_in is provided to allow additional control of the assertion of EWM_OUT_b signal.

### 42.2.1 Features

Features of EWM module include:

- Independent LPO_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO_CLK clock cycles.
- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of EWM_OUT_b.
- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 15 peripheral bus clock cycles.

- One output port, EWM_OUT_b, when asserted is used to reset or place the external circuit into safe mode.
- One Input port, EWM_in, allows an external circuit to control the assertion of the EWM_OUT_b signal.

## 42.2.2 Modes of Operation

This section describes the module's operating modes.

### 42.2.2.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next *15* peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

### 42.2.2.2 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

### 42.2.3 Block Diagram

This figure shows the EWM block diagram.

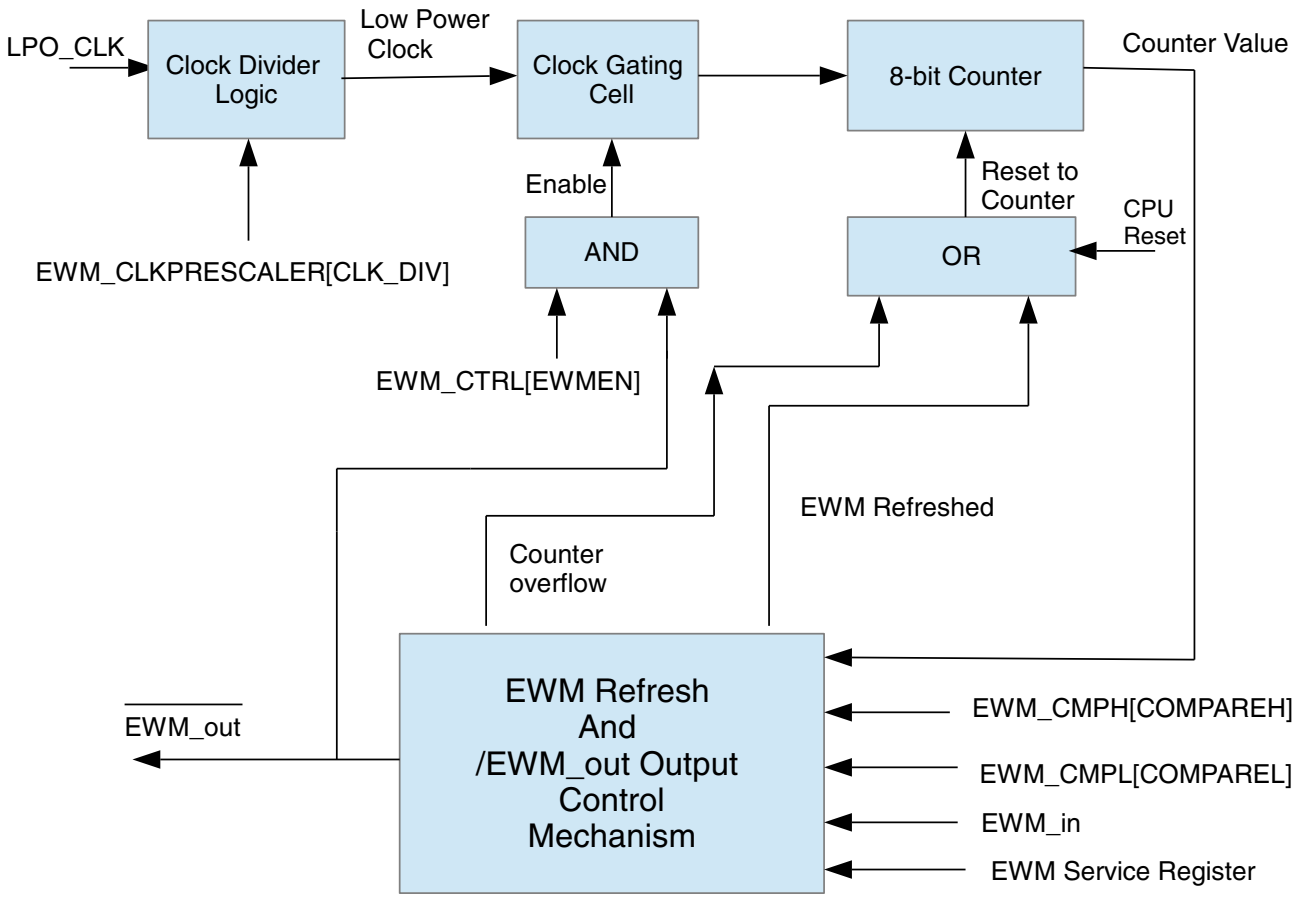

**Figure 42-1. EWM Block Diagram**

## 42.3 EWM Signal Descriptions

The EWM has two external signals, as shown in the following table.

**NOTE**

All active-low signals are now represented with the suffix "_b" throughout the chapter.

**Table 42-3. EWM Signal Descriptions**

| Signal | Description | I/O |
|---|---|---|
| EWM_in | EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active low. | I |
| EWM_OUT_b | EWM reset out signal | O |

## 42.4 Memory Map/Register Definition

This section contains the module memory map and registers.

**NOTE**

EWM only supports 8-bit register access. 16-bit and 32-bit access are not possible.

### 42.4.1 EWM register descriptions

#### 42.4.1.1 EWM Memory map

EWM base address: 4002_2000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Control Register (CTRL) | 8 | RWONCE | 00h |
| 1h | Service Register (SERV) | 8 | WORZ | 00h |
| 2h | Compare Low Register (CMPL) | 8 | RWONCE | 00h |
| 3h | Compare High Register (CMPH) | 8 | RWONCE | FFh |
| 5h | Clock Prescaler Register (CLKPRESCALER) | 8 | RWONCE | 00h |

#### 42.4.1.2 Control Register (CTRL)

##### 42.4.1.2.1 Offset

| Register | Offset |
|---|---|
| CTRL | 0h |

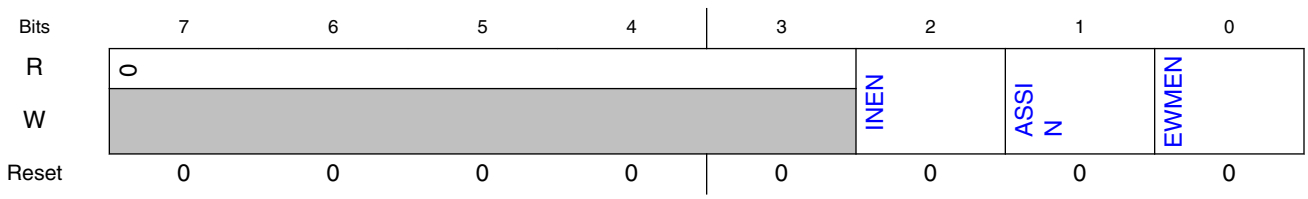
#### 42.4.1.2.2 Function

The CTRL register is cleared by any reset.

**NOTE**

This register can be written only once after a CPU reset. Writing this register more than once, generates a bus transfer error.

#### 42.4.1.2.3 Diagram



#### 42.4.1.2.4 Fields

| Field | Function |
|---|---|
| 7-3<br>— | Reserved |
| 2<br>INEN | Input Enable.<br>This bit when set, enables the EWM_in port. |
| 1<br>ASSIN | EWM_in's Assertion State Select.<br>Default assert state of the EWM_in signal is logic zero. Setting the ASSIN bit inverts the assert state of EWM_in signal to a logic one. |
| 0<br>EWMEN | EWM enable.<br>This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the EWM_OUT_b signal. This bit when unset, keeps the EWM module disabled. It cannot be re-enabled until a next reset, due to the write-once nature of this bit. |

### 42.4.1.3 Service Register (SERV)

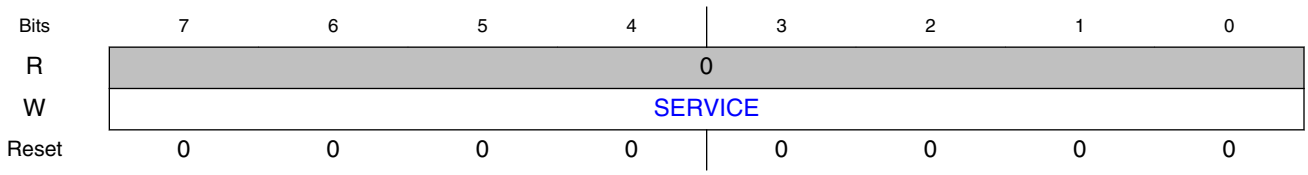
#### 42.4.1.3.1 Offset

| Register | Offset |
|---|---|
| SERV | 1h |

#### 42.4.1.3.2 Function

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

#### 42.4.1.3.3 Diagram



#### 42.4.1.3.4 Fields

| Field | Function |
|---|---|
| 7-0<br>SERVICE | SERVICE<br>The EWM refresh mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM refresh is invalid if either of the following conditions is true.<br>• The first or second data byte is not written correctly.<br>• The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called *EWM_refresh_time*.<br>15 peripheral bus clock cycles are required for *EWM_refresh_time* |

### 42.4.1.4 Compare Low Register (CMPL)

#### 42.4.1.4.1 Offset

| Register | Offset |
|---|---|
| CMPL | 2h |

#### 42.4.1.4.2 Function

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

**NOTE**

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

#### 42.4.1.4.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R<br>W | COMPAREL | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### 42.4.1.4.4 Fields

| Field | Function |
|---|---|
| 7-0<br>COMPAREL | COMPAREL<br>To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum refresh time is required. |

### 42.4.1.5 Compare High Register (CMPH)

#### 42.4.1.5.1 Offset

| Register | Offset |
|---|---|
| CMPH | 3h |

#### 42.4.1.5.2 Function

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

**NOTE**

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

**NOTE**

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

#### 42.4.1.5.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R<br>W | COMPAREH | | | | | | | |
| Reset | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

#### 42.4.1.5.4 Fields

| Field | Function |
|---|---|
| 7-0<br>COMPAREH | COMPAREH<br>To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum refresh time is required. |

### 42.4.1.6 Clock Prescaler Register (CLKPRESCALER)

#### 42.4.1.6.1 Offset

| Register | Offset |
|---|---|
| CLKPRESCALER | 5h |

#### 42.4.1.6.2 Function

This CLKPRESCALER register is reset to 0x00 after a CPU reset.

**NOTE**

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

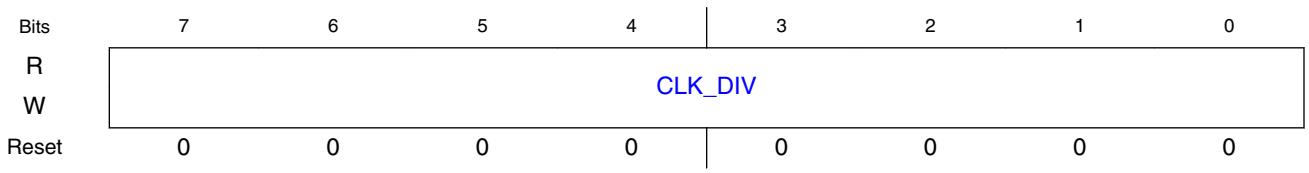
**NOTE**

Write the required prescaler value before enabling the EWM.

**NOTE**

The implementation of this register is chip-specific. See the Chip Configuration details.

#### 42.4.1.6.3 Diagram



#### 42.4.1.6.4 Fields

| Field | Function |
|---|---|
| 7-0<br>CLK_DIV | CLK_DIV<br>Selected low power clock source for running the EWM counter can be prescaled as below.<br>• Prescaled clock frequency = low power clock source frequency / ( 1 + CLK_DIV ) |

## 42.5 Functional Description

The following sections describe functional details of the EWM module.

**NOTE**

When the BUS_CLK is lost, then EWM module doesn't generate the EWM_OUT_b signal and no refresh operation is possible

### 42.5.1 The EWM_OUT_b Signal

The EWM_OUT_b is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions.

The EWM_OUT_b signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.

The EWM_OUT_b signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM_in pin is enabled and EWM_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM_OUT_b pin)

The EWM_OUT_b is asserted after any reset by the virtue of the external pull-down mechanism on the EWM_OUT_b signal. Then, to deassert the EWM_OUT_b signal, set EWMEN bit in the CTRL register to enable the EWM.

If the EWM_OUT_b signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the EWM_OUT_b signal only after the EWM is enabled by the EWMEN bit in the CTRL register.

**Note**

EWM_OUT_b pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

## 42.5.2 EWM_OUT_b pin state in low power modes

During Wait, Stop and Power Down modes the EWM_OUT_b pin enters a high-impedance state. A user has the option to control the logic state of the pin using an external pull device or by configuring the internal pull device. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

## 42.5.3 The EWM_in Signal

The EWM_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the EWM_OUT_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the EWM_OUT_b signal that controls the gating circuit.

The EWM_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM_in functionality (setting the CTRL[INEN] bit), the EWM_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the EWM_OUT_b stays in the deasserted state; otherwise, the EWM_OUT_b output signal is asserted.

**Note**

The user must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM_in pin is deasserted.

### 42.5.4 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

### 42.5.5 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1), EWM_OUT_b is asserted.

### 42.5.6 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

**Table 42-4. EWM Refresh Mechanisms**

| Condition | Mechanism |
|---|---|
| An EWM refresh action completes when:<br>CMPL < Counter < CMPH. | The software behaves as expected and the EWM counter is reset to zero. The EWM_OUT_b output signal remains in the deasserted state if, during the EWM refresh action, the EWM_in input has been in deasserted state.. |
| An EWM refresh action completes when Counter < CMPL | The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal. |
| Counter value reaches CMPH prior to completion of EWM refresh action. | Software has not refreshed the EWM. The EWM counter is reset to zero and the EWM_OUT_b output signal is asserted irrespective of the input EWM_in signal. |

## 42.5.7 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK_DIV]. This divided clock is used to run the EWM counter.

**NOTE**

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

# Chapter 43
# Cyclic Redundancy Check (CRC)

## 43.1 Introduction

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

### 43.1.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or bytewise. This option is required for certain CRC standards. A bytewise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the bytewise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

### 43.1.2 Block diagram

The following is a block diagram of the CRC.

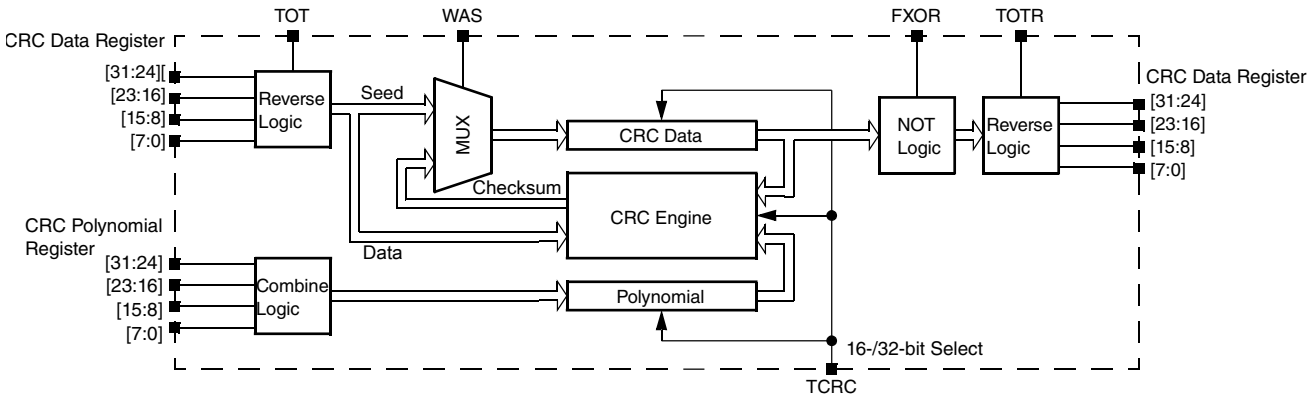


**Figure 43-1. Programmable cyclic redundancy check (CRC) block diagram**

## 43.1.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

### 43.1.3.1 Run mode

This is the basic mode of operation.

### 43.1.3.2 Low-power modes (Wait or Stop)

Any CRC calculation in progress stops when the MCU enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the MCU.

# 43.2 Memory map and register descriptions

## 43.2.1 CRC register descriptions

### 43.2.1.1 CRC Memory map

CRC base address: 4002_F000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | CRC Data register (DATA) | 32 | RW | FFFF_FFFFh |
| 4h | CRC Polynomial register (GPOLY) | 32 | RW | 0000_1021h |
| 8h | CRC Control register (CTRL) | 32 | RW | 0000_0000h |

## 43.2.1.2 CRC Data register (DATA)

### 43.2.1.2.1 Offset

| Register | Offset |
|---|---|
| DATA | 0h |

### 43.2.1.2.2 Function

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

### 43.2.1.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | HU | | | | | | | | HL | | | | | | | |

### 43.2.1.2.4 Fields

| Field | Function |
|---|---|
| 31-24<br>HU | CRC High Upper Byte<br>In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes. |
| 23-16<br>HL | CRC High Lower Byte<br>In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes. |
| 15-8<br>LU | CRC Low Upper Byte<br>When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation. |
| 7-0<br>LL | CRC Low Lower Byte<br>When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation. |

## 43.2.1.3 CRC Polynomial register (GPOLY)

### 43.2.1.3.1 Offset

| Register | Offset |
|---|---|
| GPOLY | 4h |

#### 43.2.1.3.2 Function

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

#### 43.2.1.3.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | HIGH | | | | | | | | | | | | | | | |

## 43.3 Functional description

### 43.3.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program CRC_CTRL[WAS], CRC_GPOLY,necessary parameters for transposition and CRC result inversion in the applicable registers. Asserting CRC_CTRL[WAS] enables the programming of the seed value into the CRC_DATA register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting CRC_CTRL[WAS] and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

### 43.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

#### 43.3.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear CRC_CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See Transpose feature and CRC result complement for details.

3. Write a 16-bit polynomial to the CRC_GPOLY[LOW] field. The CRC_GPOLY[HIGH] field is not usable in 16-bit CRC mode.
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to CRC_DATA[LU:LL]. CRC_DATA[HU:HL] are not used.
6. Clear CRC_CTRL[WAS] to start writing data values.
7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[LU:LL].

Transpose and complement operations are performed on the fly while reading or writing values. See Transpose feature and CRC result complement for details.

#### 43.3.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set CRC_CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See Transpose feature and CRC result complement for details.
3. Write a 32-bit polynomial to CRC_GPOLY[HIGH:LOW].
4. Set CRC_CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to CRC_DATA[HU:HL:LU:LL].
6. Clear CRC_CTRL[WAS] to start writing data values.
7. Write data values into CRC_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC_DATA[HU:HL:LU:LL].
8. When all values have been written, read the final CRC result from CRC_DATA[HU:HL:LU:LL]. The CRC is calculated bytewise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on the fly while reading or writing values. See Transpose feature and CRC result complement for details.

### 43.3.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on the fly while being read or written.

Some protocols use little endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

### 43.3.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] or CTRL[TOTR] fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC data register:

1. CTRL[TOT] or CTRL[TOTR] is 00.

   No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 01

   Bits in a byte are transposed, while bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}

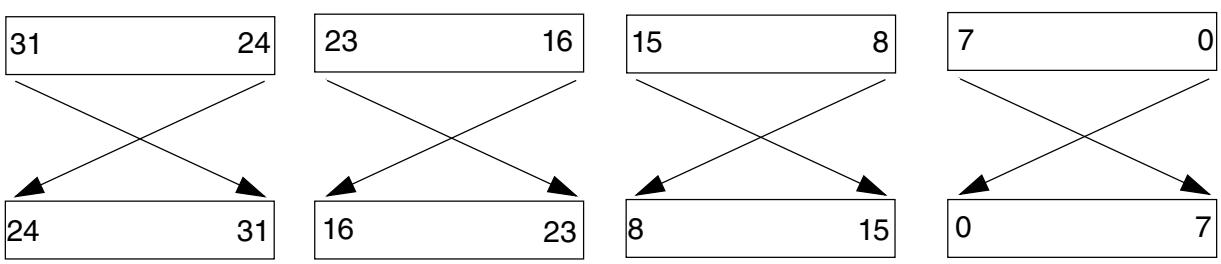

**Figure 43-2. Transpose type 01**

3. CTRL[TOT] or CTRL[TOTR] is 10.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes = {reg[0:7], reg[8:15],reg[16:23], reg[24:31]}

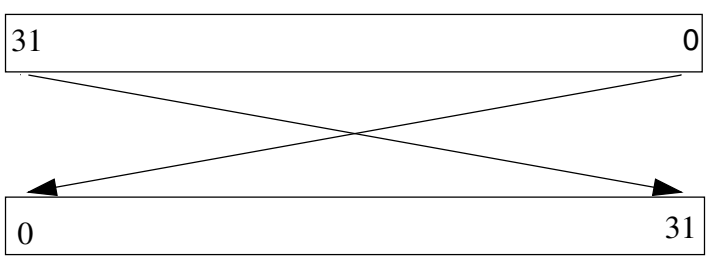

**Figure 43-3. Transpose type 10**

4. CTRL[TOT] or CTRL[TOTR] is 11.

Bytes are transposed, but bits are not transposed.

reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}

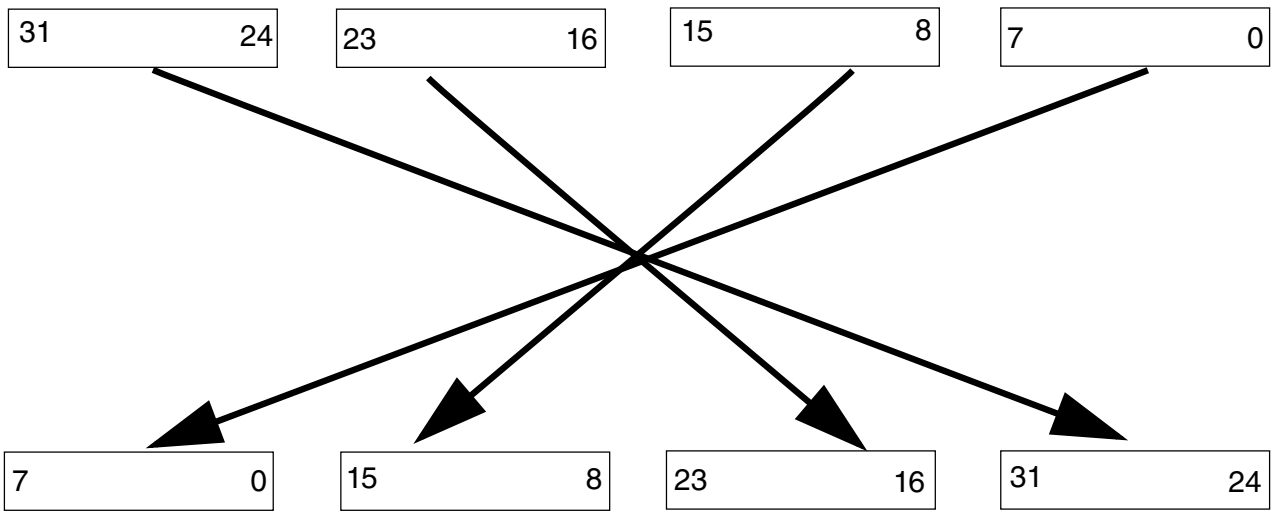

**Figure 43-4. Transpose type 11**

**NOTE**

For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only. When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[HU:HL] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

## 43.3.4 CRC result complement

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[FXOR] is cleared, reading the CRC data register accesses the raw checksum value.

# Chapter 44
# Standalone TRNG

## 44.1 Standalone True Random Number Generator (SA-TRNG).

The Standalone True Random Number Generator (SA-TRNG) is a hardware accelerator module that generates a 512-bit entropy as needed by an entropy-consuming module or by other post-processing functions. A typical entropy consumer is a pseudo random-number generator (PRNG) that can be implemented to achieve both true randomness and cryptographic-strength random numbers using the TRNG output as its entropy seed. The PRNG is not part of this module.

The entropy generated by a TRNG is intended for direct use by functions that generate secret keys, per-message secrets, random challenges, and other similar quantities used in cryptographic algorithms. In each of these cases, it is important that a random number be difficult to guess or predict. It is important that a random number is at least as difficult to predict as it is difficult to break the cryptographic algorithm with which it is being used. This stringent requirement is particularly difficult to fulfill if the entropy source from a TRNG contains bias and/or correlation. To increase the trustworthiness/quality of the generated random data, PRNGs are often used to post process the output of a TRNG.

This document describes only the TRNG design functionality and usage.

Note that before entropy can be obtained from the TRNG, it must be initialized and instantiated in a particular mode by setting the appropriate TRNG registers.

The TRNG contains the following sub modules: IP Slave bus (SkyBlue bus) interface, the TRNG Core and the free running oscillator (OSC).

### 44.1.1 Standalone True Random Number Generator Block Diagram

The following figure is a top-level diagram of the True Random Number Generator.

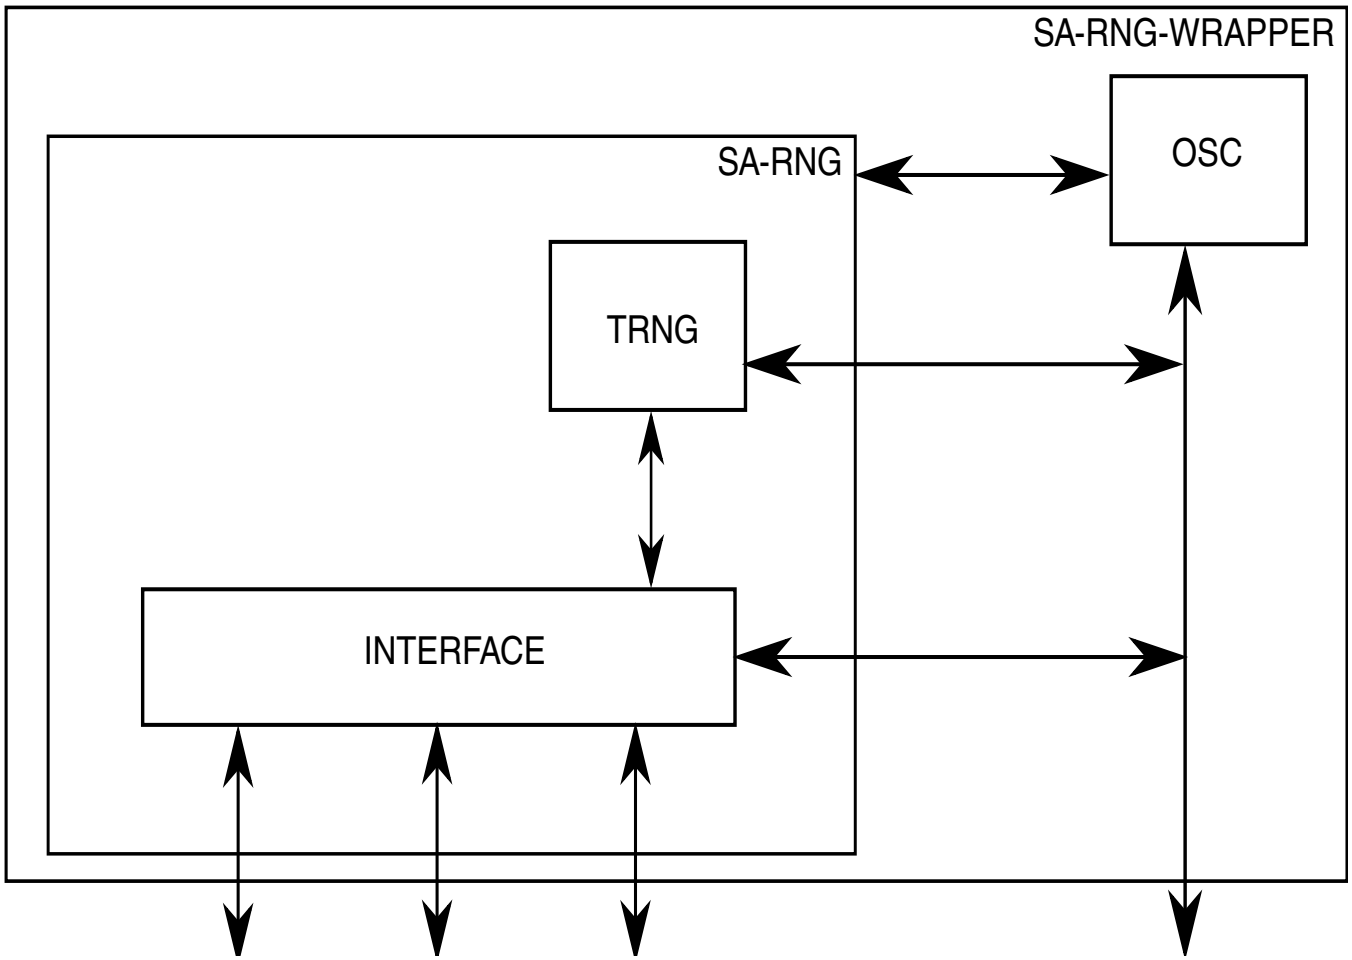

**Figure 44-1. SA TRNG Block Diagram**

## 44.1.2 TRNG Functional Description.

The TRNG consists of several functional sub-modules. Its overall functionality can be easily described from the top level in terms of generating entropy for seed generation. The functionality of each sub-module is briefly described in the following subsections.

TRNG is based on collecting bits from a random noise source. This random noise source is a ring oscillator that is sensitive to random noise (temperature variations, voltage variations, cross-talk and other random noise) within the device in which the TRNG is used. This noise causes various small changes in the period of the oscillator. Therefore, if the count of the ring oscillator clock cycles is sampled after a known period of time, this count will vary each time the sample is taken. By using the variance in this count over a large number of samples, random bits can be derived.

The TRNG comprises two entropy sources, each of which provides a single bit of output. Concatenated together, these 2 output bits are expected to provide 1 bit of entropy every 100 clock cycles. In addition to generating entropy, the TRNG also performs several statistical tests on its output.

## 44.1.3 SA-TRNG hardware functional description.

SA-TRNG functionality consists of several major subcomponents. This table describes these subcomponents.

**Table 44-1. SA-TRNG subcomponents.**

| Description | Cross-reference(s) |
|---|---|
| **Interfaces** | |
| Register interface<br>• Used for access to configuration, control, status and debugging registers | Register interface (IP Slave bus) |
| True Random Number Generator (TRNG) | Standalone True Random Number Generator (SA-TRNG). |

### 44.1.3.1 Software Use Cases for the Stand Alone TRNG.

There are four things that a user (programmer/integrator) will want to do with a TRNG.

- Initialization.

  Set up the parameters to proper values, and start generation of the first block of entropy. This is done once.

- Read entropy from the TRNG, and start generation of the next block of entropy.

  This is done many times and is the normal flow of operation.

- Run a self-test on the TRNG, to assure proper continued operation.

  This involves taking TRNG off-line, setting some self-test parameters, running TRNG, and then reading the statistical test registers, to see that they are within proper operation values. This may not be needed, as TRNG has built-in self-test.

- Off-line determination and checking of TRNG parameter values.

  This is done in development in order to determine the proper initialization and self-test parameters. The TRNG is taken off-line. Test parameter values are written and entropy generation is started. If the statistical tests indicate poor operation (i.e., failing statistical tests), the entropy_delay value should be increased and entropy

generation should be re-started. Every case is a variation of setting TRNG parameter values, starting or re-starting entropy generation and reading out the entropy. This process requires pausing or stopping and re-starting the TRNG.

The TRNG is designed to operate as a slave module on the standard IP Slave Bus. By understanding the TRNG register descriptions in "TRNG Register Descriptions" section below, the TRNG module can be controlled via the IP slave bus. In order to write to most TRNG registers, the MCTL register must be initialized in programming mode as described in the "TRNG Register Descriptions" section. At Power On Reset (POR) or asynchronous system hard reset, the TRNG resets to programming mode. TRNG will not generate entropy until it is out of programming mode (in run mode) and access to Entropy Registers have been enabled.

Here is an example program flow of using the TRNG.

- After POR the TRNG will be reset into programming mode with the OK to stop bit set(MCTL[TSTOP_OK]=1). The TRNG must be put into Run Mode for Entropy Generation to begin (MCTL[PRGM]=0). Additionally, in order to have access to the Entropy registers and other critical TRNG registers, the TRNG access bit must be set (MCTL[TRNG_ACC]=1). Using the default self test limits that exist after bootup, the entropy valid bit can be polled until asserted (MCTL[ENT_VAL]=1). Alternatively, if using the interrupt, and the interrupts are enabled via the INT_MASK register and the ipi_rng_int_b is asserted when MCTL[ENT_VAL]=1.
- After the polling completes, the 512-bit entropy generated by the TRNG can be read. The values can be read in any order from entropy register 0 to register 15 (ENT0 to ENT 15). After reading ENT 15, the old entropy value is reset and a new entropy value is generated.

**NOTE**

Reading ENT 15 always resets the entropy, so should always be read last.

- You can poll again for the new entropy value or you can use the Interrupt Status Register to handle reading the entropy values when the entropy valid interrupt is triggered.
- The interrupt can be masked or cleared as needed. See the Interrupt Status Register description.
- To change the self-test limits,the seed counters, how fast the entropy is generated, and how entropy is sampled, see the register description section. In particular, see the the TRNG Frequency Count Minimum Limit Register (FRQMIN), the seed control register(SCML), the statistical run length registers, and other parameter registers.
- Once in Run Mode, the entropy is re-generated automatically after ENT 15 is read. To stop the TRNG or access to TRNG registers at any point while in running mode,

you can always set MCTL[TRNG_ACC]=0. Setting the TRNG back to programming mode (MCTL[PRGM]=1) also achieves the purpose of stopping entropy generation.

### 44.1.4 Another TRNG usage example.

The TRNG can be used by a post processing pseudo-random number generator function. For example, TRNG can be used to seed a hardware or software based implementation of a DRBG defined by SP800-90.

### 44.1.5 TRNG register descriptions

All accesses of undefined addresses always return zero and assert IPS transfer error. Writes to undefined and read-only addresses are ignored. Undefined addresses are those undocumented, protected or reserved addresses within and outside the range of the addresses defined in the memory map below. The register addresses shown in the Memory Map below represents how these registers are accessed over the register bus as 32-bit words. Accesses to registers must use full-word (32-bit) reads or writes.

The format and fields in each TRNG register are defined below. Some of the register format figures apply to several different registers. In such cases a different register name will be associated with each of the register offset addresses that appear at the top of the register format figure. Although these registers share the same format, they are independent registers. In addition, many registers can be accessed at multiple addresses. In these cases there will be a single register name and the list of addresses at which that register is accessible will be indicated as aliases. Unless noted in the individual register descriptions, registers are reset only at Power-On Reset (POR) or with an asyncronous system hard reset.

#### 44.1.5.1 TRNG Memory map

TRNG base address: 4102_9000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Miscellaneous Control Register (MCTL) | 32 | RW | 0001_2001h |
| 4h | Statistical Check Miscellaneous Register (SCMISC) | 32 | RW | 0001_0022h |
| 8h | Poker Range Register (PKRRNG) | 32 | RW | 0000_09A3h |

## 44.1.5.2 Miscellaneous Control Register (MCTL)

### 44.1.5.2.1 Offset

| Register | Offset |
|---|---|
| MCTL | 0h |

### 44.1.5.2.2 Function

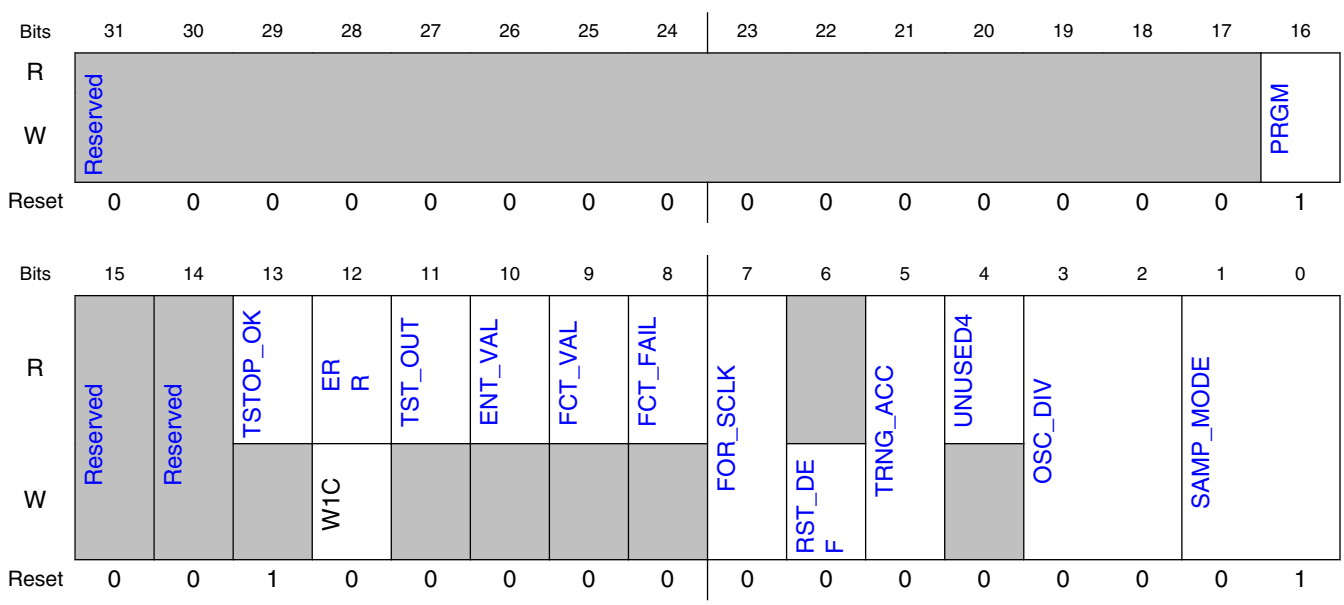
This register is intended to be used for programming, configuring and testing the RNG. It is the main register to read/write, in order to enable Entropy generation, to stop entropy generation and to block access to entropy registers. This is done via the special TRNG_ACC and PRGM bit below.

The Miscellaneous Control Register is a read/write register used to control the RNG's True Random Number Generator (TRNG) access, operation and test.

**NOTE**

Note that in many cases two RNG registers share the same address, and a particular register at the shared address is selected based upon the value in the PRGM field of the MCTL register.

### 44.1.5.2.3 Diagram



### 44.1.5.2.4 Fields

| Field | Function |
|---|---|
| 31-17<br>— | Reserved. |
| 16<br>PRGM | Programming Mode Select. When this bit is 1, the TRNG is in Program Mode, otherwise it is in Run Mode. No Entropy value will be generated while the TRNG is in Program Mode. Note that different RNG registers are accessible at the same address depending on whether PRGM is set to 1 or 0. This is noted in the RNG register descriptions. |
| 15<br>— | Reserved. |
| 14<br>— | Reserved. |
| 13<br>TSTOP_OK | TRNG_OK_TO_STOP. Software can check that this bit is a 1 before transitioning TRNG to low power mode (TRNG clock stopped). TRNG turns on the TRNG free-running ring oscillator whenever new entropy is being generated and turns off the ring oscillator when entropy generation is complete. If the TRNG clock is stopped while the TRNG ring oscillator is running, the oscillator will continue running even though the TRNG clock is stopped. To make sure the ring oscillator is stopped, assert ipg_stop input and verify ipg_rng_stop_ack is asserted after at at least two (2) clock cycles. TSTOP_OK is asserted when the TRNG ring oscillator is not running. |
| 12<br>ERR | Read: Error status. 1 = error detected. 0 = no error.<br>Write: Write 1 to clear errors. Writing 0 has no effect. |
| 11<br>TST_OUT | Read only: Test point inside ring oscillator. |
| 10<br>ENT_VAL | Read only: Entropy Valid. Will assert only if TRNG ACC bit is set, and then after an entropy value is generated. Will be cleared at most one (1) bus clock cycle after reading the ENT15 register. (ENT0 through ENT14 should be read before reading ENT15). |
| 9<br>FCT_VAL | Read only: Frequency Count Valid. Indicates that a valid frequency count may be read from FRQCNT. |
| 8<br>FCT_FAIL | Read only: Frequency Count Fail. The frequency counter has detected a failure. This may be due to improper programming of the FRQMAX and/or FRQMIN registers, or a hardware failure in the ring oscillator. This error may be cleared by writing a 1 to the ERR bit. |
| 7<br>FOR_SCLK | Force System Clock. If set, the system clock is used to operate the TRNG, instead of the ring oscillator. This is for test use only, and indeterminate results may occur. This bit is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously to writing this bit. This bit is cleared by writing the RST_DEF bit to 1. |
| 6<br>RST_DEF | Reset Defaults. Writing a 1 to this bit clears various TRNG registers, and bits within registers, to their default state. This bit is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously to writing this bit. Reading this bit always produces a 0. |
| 5<br>TRNG_ACC | TRNG Access Mode. If this bit is set to 1, the TRNG will generate an Entropy value that can be read via the ENT0-ENT15 registers. The Entropy value may be read once the ENT VAL bit is asserted. Also see ENTa register descriptions (For a = 0 to 15). |
| 4<br>UNUSED4 | This bit is unused. Always reads zero. |
| 3-2 | Oscillator Divide. Determines the amount of dividing done to the ring oscillator before it is used by the TRNG. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| OSC_DIV | This field is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously to writing this field. This field is cleared to the default POR value by writing the RST_DEF bit to 1.<br>00b - use ring oscillator with no divide<br>01b - use ring oscillator divided-by-2<br>10b - use ring oscillator divided-by-4<br>11b - use ring oscillator divided-by-8 |
| 1-0<br>SAMP_MODE | Sample Mode. Determines the method of sampling the ring oscillator while generating the Entropy value:<br>This field is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously with writing this field. This field is cleared to the POR default value by writing the RST_DEF bit to 1.<br>00b - use Von Neumann data into both Entropy shifter and Statistical Checker<br>01b - use raw data into both Entropy shifter and Statistical Checker<br>10b - use Von Neumann data into Entropy shifter. Use raw data into Statistical Checker<br>11b - undefined/reserved. |

## 44.1.5.3 Statistical Check Miscellaneous Register (SCMISC)

### 44.1.5.3.1 Offset

| Register | Offset |
|---|---|
| SCMISC | 4h |

### 44.1.5.3.2 Function

The Statistical Check Miscellaneous Register contains the Long Run Maximum Limit value and the Retry Count value. This register is accessible only when the MCTL[PRGM] bit is 1, otherwise this register will read zeroes, and cannot be written.

### 44.1.5.3.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | Reserved | | | | | | | | | | | | RTY_CT | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | Reserved | | | | | | | | LRUN_MAX | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 |

#### 44.1.5.3.4 Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved. |
| 19-16<br>RTY_CT | RETRY COUNT. If a statistical check fails during the TRNG Entropy Generation, the RTY_CT value indicates the number of times a retry should occur before generating an error. This field is writable only if MCTL[PRGM] bit is 1. This field will read zeroes if MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |
| 15-8<br>— | Reserved. |
| 7-0<br>LRUN_MAX | LONG RUN MAX LIMIT. This value is the largest allowable number of consecutive samples of all 1, or all 0, that is allowed during the Entropy generation. This field is writable only if MCTL[PRGM] bit is 1. This field will read zeroes if MCTL[PRGM] = 0. This field is cleared to the POR reset value by writing the MCTL[RST_DEF] bit to 1. |

### 44.1.5.4 Poker Range Register (PKRRNG)

#### 44.1.5.4.1 Offset

| Register | Offset |
|---|---|
| PKRRNG | 8h |

#### 44.1.5.4.2 Function

The Poker Range Register defines the difference between the TRNG Poker Maximum Limit and the minimum limit. These limits are used during the TRNG Statistical Check Poker Test.

#### 44.1.5.4.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | Reserved | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | PKR_RNG | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 1 |

#### 44.1.5.4.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved. Always 0. |
| 15-0<br>PKR_RNG | Poker Range. During the TRNG Statistical Checks, a "Poker Test" is run which requires a maximum and minimum limit. The maximum is programmed in the PKRMAX[PKR_MAX] register, and the minimum is derived by subtracting the PKR_RNG value from the programmed maximum value. This field is writable only if MCTL[PRGM] bit is 1. This field will read zeroes if MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. Note that the minimum allowable Poker result is PKR_MAX - PKR_RNG + 1. |

### 44.1.5.5 Poker Square Calculation Result Register (PKRSQ)

#### 44.1.5.5.1 Offset

| Register | Offset | Description |
|---|---|---|
| PKRSQ | Ch | Accessible at this address when MCTL[PRGM] = 0] |

#### 44.1.5.5.2 Function

The Poker Square Calculation Result Register is a read-only register used to read the result of the TRNG Statistical Check Poker Test's Square Calculation. This test starts with the PKRMAX value and decreases towards a final result, which is read here. For the Poker Test to pass, this final result must be less than the programmed PKRRNG value. Note that this offset (0x0C) is used as PKRMAX if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as PKRSQ readback register, as described here.

#### 44.1.5.5.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | | PKR_SQ | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PKR_SQ | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### 44.1.5.5.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved. |
| 23-0<br>PKR_SQ | Poker Square Calculation Result.<br>During the TRNG Statistical Checks, a "Poker Test" is run which starts with the value PKRMAX[PKR_MAX]. This value decreases according to a "sum of squares" algorithm, and must remain greater than zero, but less than the PKRRNG[PKR_RNG] limit. The resulting value may be read through this register, if MCTL[PRGM] bit is 0. Note that if MCTL[PRGM] bit is 1, this register address is used to access the Poker Test Maximum Limit in register PKRMAX, as defined in the previous section. |

### 44.1.5.6 Poker Maximum Limit Register (PKRMAX)

#### 44.1.5.6.1 Offset

| Register | Offset | Description |
|---|---|---|
| PKRMAX | Ch | Accessible at this address when MCTL[PRGM] = 1] |

#### 44.1.5.6.2 Function

The Poker Maximum Limit Register defines Maximum Limit allowable during the TRNG Statistical Check Poker Test. Note that this offset (0x0C) is used as PKRMAX only if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as the PKRSQ readback register.

#### 44.1.5.6.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | | PKR_MAX | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PKR_MAX | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 |

#### 44.1.5.6.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved. |
| 23-0<br>PKR_MAX | Poker Maximum Limit.<br>During the TRNG Statistical Checks, a "Poker Test" is run which requires a maximum and minimum limit. The maximum allowable result is programmed in the PKRMAX[PKR_MAX] register. This field is writable only if MCTL[PRGM] bit is 1. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. Note that the PKRMAX and PKRRNG registers combined are used to define the minimum allowable Poker result, which is PKR_MAX - PKR_RNG + 1. Note that if MCTL[PRGM] bit is 0, this register address is used to read the Poker Test Square Calculation result in register PKRSQ, as defined in the following section. |

### 44.1.5.7 Seed Control Register (SDCTL)

#### 44.1.5.7.1 Offset

| Register | Offset |
|---|---|
| SDCTL | 10h |

#### 44.1.5.7.2 Function

The Seed Control Register contains two fields. One field defines the length (in system clocks) of each Entropy sample (ENT_DLY), and the other field indicates the number of samples that will taken during each TRNG Entropy generation (SAMP_SIZE).

### 44.1.5.7.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | ENT_DLY | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | SAMP_SIZE | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 0 | 0 |

### 44.1.5.7.4 Fields

| Field | Function |
|---|---|
| 31-16<br>ENT_DLY | Entropy Delay. Defines the length (in system clocks) of each Entropy sample taken. This field is writable only if MCTL[PRGM] bit is 1. This field will read zeroes if MCTL[PRGM] = 0. This field is cleared to its reset value at POR. |
| 15-0<br>SAMP_SIZE | Sample Size. Defines the total number of Entropy samples that will be taken during Entropy generation. This field is writable only if MCTL[PRGM] bit is 1. This field will read zeroes if MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |

## 44.1.5.8 Sparse Bit Limit Register (SBLIM)

### 44.1.5.8.1 Offset

| Register | Offset | Description |
|---|---|---|
| SBLIM | 14h | Accessible at this address when MCTL[PRGM] = 1] |

### 44.1.5.8.2 Function

The Sparse Bit Limit Register is used when Von Neumann sampling is selected during Entropy Generation. It defines the maximum number of consecutive Von Neumann samples which may be discarded before an error is generated. Note that this address (0x14) is used as SBLIM only if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this address is used as TOTSAM readback register.

#### 44.1.5.8.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | Reserved | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | Reserved | | | | | | SB_LIM | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 |

#### 44.1.5.8.4 Fields

| Field | Function |
|---|---|
| 31-10<br>— | Reserved. Always 0. |
| 9-0<br>SB_LIM | Sparse Bit Limit. During Von Neumann sampling (if enabled by MCTL[SAMP_MODE], samples are discarded if two consecutive raw samples are both 0 or both 1. If this discarding occurs for a long period of time, it indicates that there is insufficient Entropy. The Sparse Bit Limit defines the maximum number of consecutive samples that may be discarded before an error is generated. This field is writable only if MCTL[PRGM] bit is 1. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. Note that if MCTL[PRGM] bit is 0, this register address is used to read the Total Samples count in register TOTSAM, as defined in the following section. |

### 44.1.5.9 Total Samples Register (TOTSAM)

#### 44.1.5.9.1 Offset

| Register | Offset | Description |
|---|---|---|
| TOTSAM | 14h | Accessible at this address when MCTL[PRGM] = 0] |

#### 44.1.5.9.2 Function

The Total Samples Register is a read-only register used to read the total number of samples taken during Entropy generation. It is used to give an indication of how often a sample is actually used during Von Neumann sampling. Note that this offset (0x14) is used as SBLIM if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as TOTSAM readback register, as described here.

### 44.1.5.9.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | Reserved | | | | | | | | | | | | TOT_SAM | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | TOT_SAM | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 44.1.5.9.4 Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved. Always 0. |
| 19-0<br>TOT_SAM | Total Samples. During Entropy generation, the total number of raw samples is counted. This count is useful in determining how often a sample is used during Von Neumann sampling. The count may be read through this register, if MCTL[PRGM] bit is 0. Note that if MCTL[PRGM] bit is 1, this register address is used to access the Sparse Bit Limit in register SBLIM, as defined in the previous section. |

## 44.1.5.10 Frequency Count Minimum Limit Register (FRQMIN)

### 44.1.5.10.1 Offset

| Register | Offset |
|---|---|
| FRQMIN | 18h |

### 44.1.5.10.2 Function

The Frequency Count Minimum Limit Register defines the minimum allowable count taken by the Entropy sample counter during each Entropy sample. During any sample period, if the count is less than this programmed minimum, a Frequency Count Fail is flagged in MCTL[FCT_FAIL] and an error is generated.

### 44.1.5.10.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 44.1.5.10.4 Fields

| Field | Function |
|---|---|
| 31-22<br>— | Reserved. Always 0. |
| 21-0<br>FRQ_MIN | Frequency Count Minimum Limit. Defines the minimum allowable count taken during each entropy sample. This field is writable only if MCTL[PRGM] bit is 1. This field will read zeroes if MCTL[PRGM] = 0. This field is cleared to its reset value at POR. |

## 44.1.5.11 Frequency Count Maximum Limit Register (FRQMAX)

### 44.1.5.11.1 Offset

| Register | Offset | Description |
|---|---|---|
| FRQMAX | 1Ch | Accessible at this address when MCTL[PRGM] = 1] |

### 44.1.5.11.2 Function

The Frequency Count Maximum Limit Register defines the maximum allowable count taken by the Entropy sample counter during each Entropy sample. During any sample period, if the count is greater than this programmed maximum, a Frequency Count Fail is flagged in MCTL[FCT_FAIL] and an error is generated. Note that this address (001C) is used as FRQMAX only if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this address is used as FRQCNT readback register.

### 44.1.5.11.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | Reserved | | | | | | | | | | FRQ_MAX | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | FRQ_MAX | | | | | | | | | | | | | | | |
| Reset | 0 | 1 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 44.1.5.11.4 Fields

| Field | Function |
|---|---|
| 31-22<br>— | Reserved. Always 0. |
| 21-0<br>FRQ_MAX | Frequency Counter Maximum Limit. Defines the maximum allowable count taken during each entropy sample. This field is writable only if MCTL[PRGM] bit is 1. This field is cleared to its reset value at POR. Note that if MCTL[PRGM] bit is 0, this register address is used to read the Frequency Count result in register FRQCNT, as defined in the FRQ_CT field. |

## 44.1.5.12 Frequency Count Register (FRQCNT)

### 44.1.5.12.1 Offset

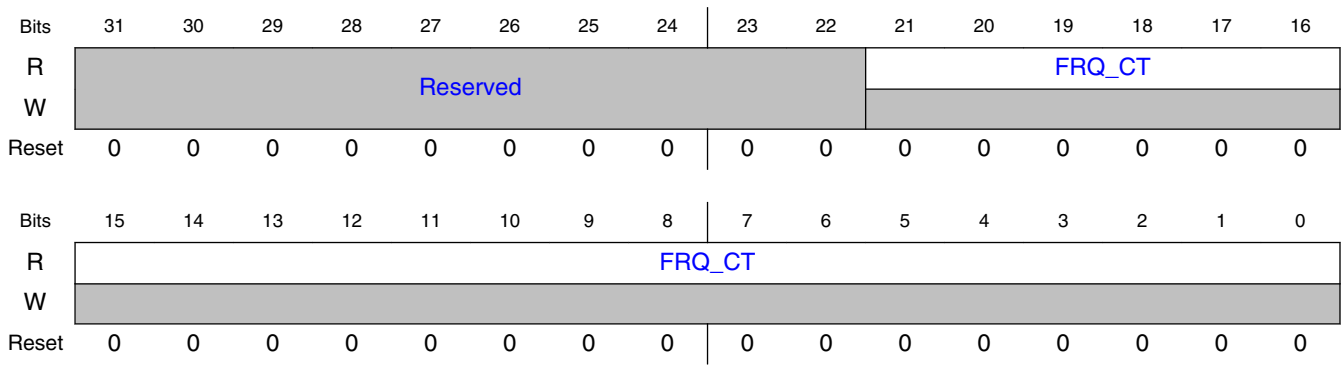
| Register | Offset | Description |
|---|---|---|
| FRQCNT | 1Ch | Accessible at this address when MCTL[PRGM] = 0] |

### 44.1.5.12.2 Function

The Frequency Count Register is a read-only register used to read the frequency counter within the TRNG entropy generator. It will read all zeroes unless PRGM[MCTL] = 0 and MCTL[TRNG_ACC] = 1. Note that this offset (0x1C) is used as FRQMAX if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as live FRQCNT readback register, as described here. This register must be read once, as a full 32-bit. A subsequent

read is only valid when MCTL[FCT_VAL] bit is HIGH. A read clears this register. The next read when MCTL[FCT_VAL] bit is HIGH must be treated as a different value from the previous one, even though the counts might be the same.

### 44.1.5.12.3 Diagram



### 44.1.5.12.4 Fields

| Field | Function |
|---|---|
| 31-22<br>— | Reserved. Always 0. |
| 21-0<br>FRQ_CT | Frequency Count. If MCTL[TRNG_ACC] = 1, Reads a sample frequency count taken during entropy generation. Requires MCTL[PRGM] = 0. Note that if MCTL[PRGM] bit is 1, this register address is used to access the Frequency Maximum Limit in register FRQMAX, as defined in the FRQ_MAX field. |

## 44.1.5.13 Statistical Check Monobit Count Register (SCMC)

### 44.1.5.13.1 Offset

| Register | Offset | Description |
|---|---|---|
| SCMC | 20h | Accessible at this address when MCTL[PRGM] = 0] |

### 44.1.5.13.2 Function

The Statistical Check Monobit Count Register is a read-only register used to read the final monobit count after entropy generation. This counter starts with the value in SCML[MONO_MAX], and is decremented each time a one is sampled. Note that this offset (0x20) is used as SCML if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as SCMC readback register, as described here.

### 44.1.5.13.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | Reserved | | | | | | | | | | | | | | | |

### 44.1.5.13.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved. Always 0. |
| 15-0<br>MONO_CT | Monobit Count. Reads the final Monobit count after entropy generation. Requires MCTL[PRGM] = 0. Note that if MCTL[PRGM] bit is 1, this register address is used to access the Statistical Check Monobit Limit in register SCML, as defined in the previous section. |

## 44.1.5.14 Statistical Check Monobit Limit Register (SCML)

### 44.1.5.14.1 Offset

| Register | Offset | Description |
|---|---|---|
| SCML | 20h | Accessible at this address when MCTL[PRGM] = 1] |

### 44.1.5.14.2 Function

The Statistical Check Monobit Limit Register defines the allowable maximum and minimum number of ones/zero detected during entropy generation. To pass the test, the number of ones/zeroes generated must be less than the programmed maximum value, and the number of ones/zeroes generated must be greater than (maximum - range). If this test fails, the Retry Counter in SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this offset (0x20) is used as SCML only if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as SCMC readback register.

### 44.1.5.14.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | MONO_MAX | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 |

### 44.1.5.14.4 Fields

| Field | Function |
|---|---|
| 31-16<br>MONO_RNG | Monobit Range. The number of ones/zeroes detected during entropy generation must be greater than MONO_MAX - MONO_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |
| 15-0<br>MONO_MAX | Monobit Maximum Limit. Defines the maximum allowable count taken during entropy generation. The number of ones/zeroes detected during entropy generation must be less than MONO_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |

## 44.1.5.15 Statistical Check Run Length 1 Limit Register (SCR1L)

### 44.1.5.15.1 Offset

| Register | Offset | Description |
|---|---|---|
| SCR1L | 24h | Accessible at this address when MCTL[PRGM] = 1] |

### 44.1.5.15.2 Function

The Statistical Check Run Length 1 Limit Register defines the allowable maximum and minimum number of runs of length 1 detected during entropy generation. To pass the test, the number of runs of length 1 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 1 must be greater than (maximum - range). If this test fails, the Retry Counter in SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x24) is used as SCR1L only if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this address is used as SCR1C readback register.

### 44.1.5.15.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 44.1.5.15.4 Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved. Always 0. |
| 30-16<br>RUN1_RNG | Run Length 1 Range. The number of runs of length 1 (for both 0 and 1) detected during entropy generation must be greater than RUN1_MAX - RUN1_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |
| 15<br>— | Reserved. Always 0. |
| 14-0<br>RUN1_MAX | Run Length 1 Maximum Limit. Defines the maximum allowable runs of length 1 (for both 0 and 1) detected during entropy generation. The number of runs of length 1 detected during entropy generation must be less than RUN1_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |

## 44.1.5.16 Statistical Check Run Length 1 Count Register (SCR1C)

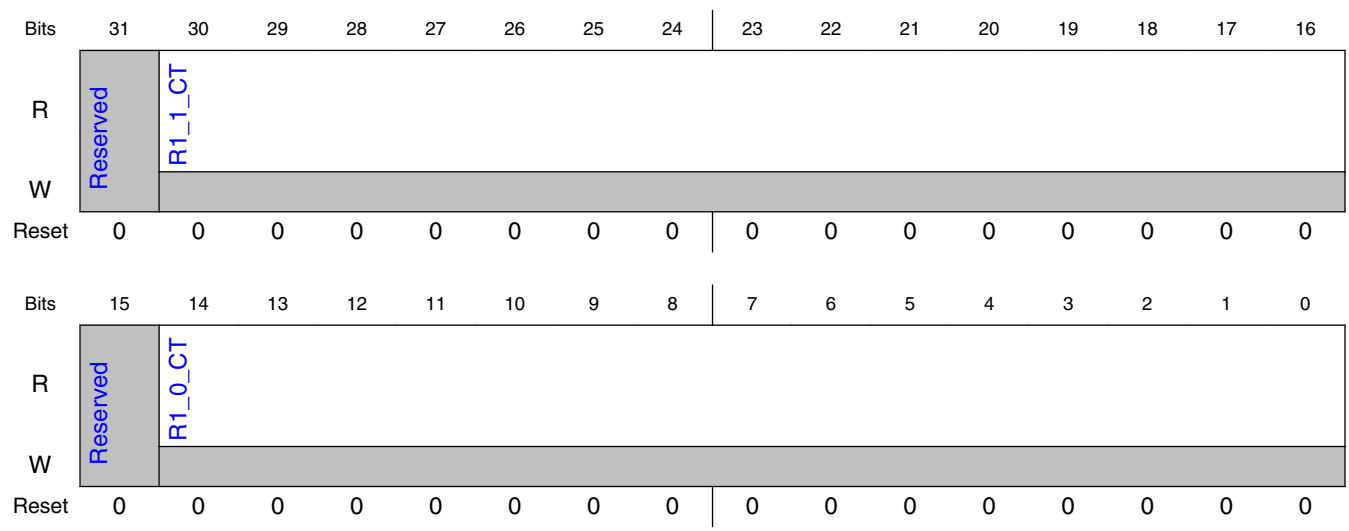
### 44.1.5.16.1 Offset

| Register | Offset | Description |
|---|---|---|
| SCR1C | 24h | Accessible at this address when MCTL[PRGM] = 0] |

### 44.1.5.16.2 Function

The Statistical Check Run Length 1 Counters Register is a read-only register used to read the final Run Length 1 counts after entropy generation. These counters start with the value in SCR1L[RUN1_MAX]. The R1_1_CT decrements each time a single one is sampled (preceded by a zero and followed by a zero). The R1_0_CT decrements each time a single zero is sampled (preceded by a one and followed by a one). Note that this offset (0x24) is used as SCR1L if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as SCR1C readback register, as described here.

### 44.1.5.16.3 Diagram



### 44.1.5.16.4 Fields

| Field | Function |
|---|---|
| 31 | Reserved. Always 0. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| — | |

| 27-16<br>RUN4_RNG | Run Length 4 Range. The number of runs of length 4 (for both 0 and 1) detected during entropy generation must be greater than RUN4_MAX - RUN4_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |
| 15-12<br>— | Reserved. Always 0. |
| 11-0<br>RUN4_MAX | Run Length 4 Maximum Limit. Defines the maximum allowable runs of length 4 (for both 0 and 1) detected during entropy generation. The number of runs of length 4 detected during entropy generation must be less than RUN4_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |

## 44.1.5.23 Statistical Check Run Length 5 Count Register (SCR5C)

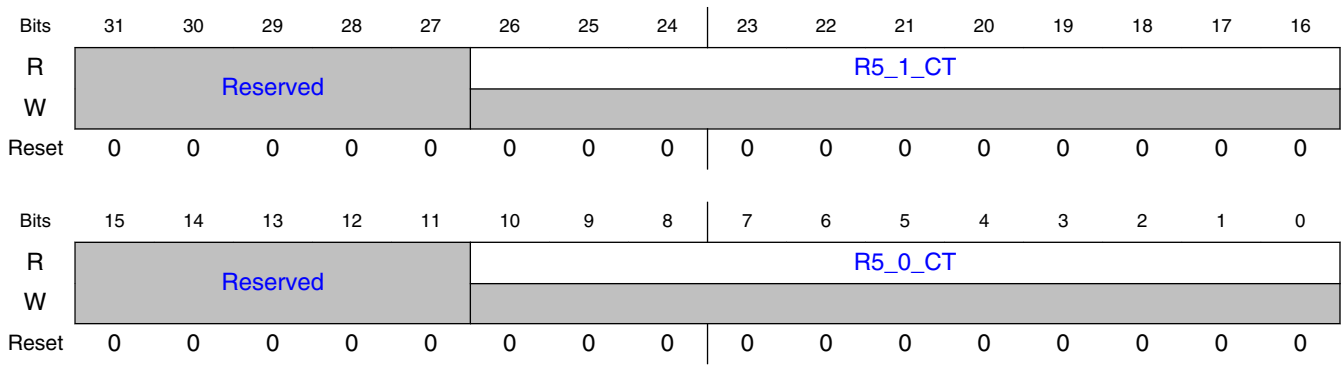
### 44.1.5.23.1 Offset

| Register | Offset | Description |
|---|---|---|
| SCR5C | 34h | Accessible at this address when MCTL[PRGM] = 0] |

### 44.1.5.23.2 Function

The Statistical Check Run Length 5 Counters Register is a read-only register used to read the final Run Length 5 counts after entropy generation. These counters start with the value in SCR5L[RUN5_MAX]. The R5_1_CT decrements each time five consecutive ones are sampled (preceded by a zero and followed by a zero). The R5_0_CT decrements each time five consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x34) is used as SCR5L if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as SCR5C readback register, as described here.

### 44.1.5.23.3 Diagram



### 44.1.5.23.4 Fields

| Field | Function |
|---|---|
| 31-27<br>— | Reserved. Always 0. |
| 26-16<br>R5_1_CT | Runs of One, Length 5 Count. Reads the final Runs of Ones, length 5 count after entropy generation. Requires MCTL[PRGM] = 0. |
| 15-11<br>— | Reserved. Always 0. |
| 10-0<br>R5_0_CT | Runs of Zero, Length 5 Count. Reads the final Runs of Ones, length 5 count after entropy generation. Requires MCTL[PRGM] = 0. |

## 44.1.5.24 Statistical Check Run Length 5 Limit Register (SCR5L)

### 44.1.5.24.1 Offset

| Register | Offset | Description |
|---|---|---|
| SCR5L | 34h | Accessible at this address when MCTL[PRGM] = 1] |

### 44.1.5.24.2 Function

The Statistical Check Run Length 5 Limit Register defines the allowable maximum and minimum number of runs of length 5 detected during entropy generation. To pass the test, the number of runs of length 5 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 5 must be greater than (maximum - range). If this test fails, the Retry Counter in SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x34) is used as SCR5L only if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this address is used as SCR5C readback register.

### 44.1.5.24.4 Fields

| Field | Function |
|---|---|
| 31-27<br>— | Reserved. Always 0. |
| 26-16<br>RUN5_RNG | Run Length 5 Range. The number of runs of length 5 (for both 0 and 1) detected during entropy generation must be greater than RUN5_MAX - RUN5_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |
| 15-11<br>— | Reserved. Always 0. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 10-0<br>RUN5_MAX | Run Length 5 Maximum Limit. Defines the maximum allowable runs of length 5 (for both 0 and 1) detected during entropy generation. The number of runs of length 5 detected during entropy generation must be less than RUN5_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |

## 44.1.5.25 Statistical Check Run Length 6+ Count Register (SCR6PC)

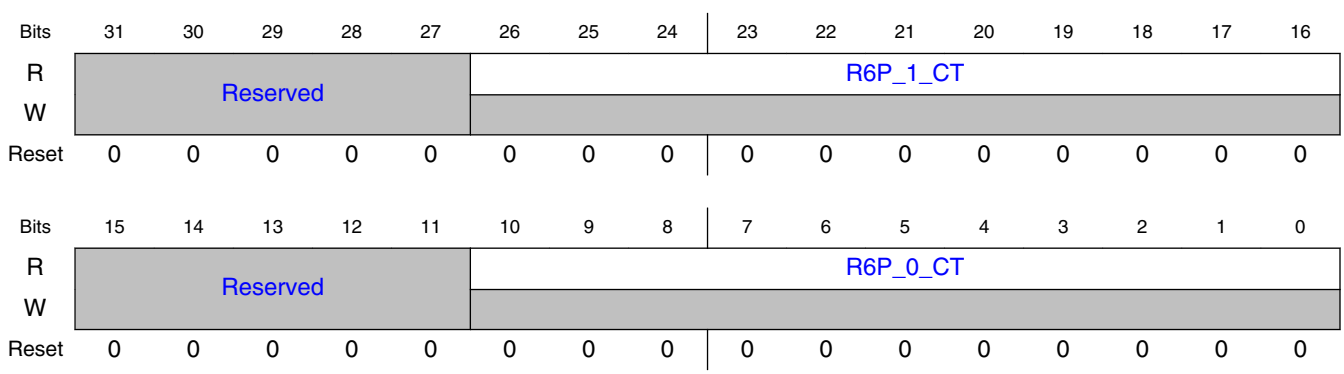
### 44.1.5.25.1 Offset

| Register | Offset | Description |
|---|---|---|
| SCR6PC | 38h | Accessible at this address when MCTL[PRGM] = 0] |

### 44.1.5.25.2 Function

The Statistical Check Run Length 6+ Counters Register is a read-only register used to read the final Run Length 6+ counts after entropy generation. These counters start with the value in SCR6PL[RUN6P_MAX]. The R6P_1_CT decrements each time six or more consecutive ones are sampled (preceded by a zero and followed by a zero). The R6P_0_CT decrements each time six or more consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x38) is used as SCR6PL if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as SCR6PC readback register, as described here.

### 44.1.5.25.3 Diagram



#### 44.1.5.25.4 Fields

| Field | Function |
|---|---|
| 31-27<br>— | Reserved. Always 0. |
| 26-16<br>R6P_1_CT | Runs of One, Length 6+ Count. Reads the final Runs of Ones, length 6+ count after entropy generation. Requires MCTL[PRGM] = 0. |
| 15-11<br>— | Reserved. Always 0. |
| 10-0<br>R6P_0_CT | Runs of Zero, Length 6+ Count. Reads the final Runs of Ones, length 6+ count after entropy generation. Requires MCTL[PRGM] = 0. |

### 44.1.5.26 Statistical Check Run Length 6+ Limit Register (SCR6PL)

#### 44.1.5.26.1 Offset

| Register | Offset | Description |
|---|---|---|
| SCR6PL | 38h | Accessible at this address when MCTL[PRGM] = 1] |

#### 44.1.5.26.2 Function

The Statistical Check Run Length 6+ Limit Register defines the allowable maximum and minimum number of runs of length 6 or more detected during entropy generation. To pass the test, the number of runs of length 6 or more (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 6 or more must be greater than (maximum - range). If this test fails, the Retry Counter in SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this offset (0x38) is used as SCR6PL only if MCTL[PRGM] is 1. If MCTL[PRGM] is 0, this offset is used as SCR6PC readback register.

### 44.1.5.26.3 Diagram

| 31-27<br>— | Reserved. Always 0. |
| 26-16<br>RUN6P_RNG | Run Length 6+ Range. The number of runs of length 6 or more (for both 0 and 1) detected during entropy generation must be greater than RUN6P_MAX - RUN6P_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |
| 15-11<br>— | Reserved. Always 0. |
| 10-0<br>RUN6P_MAX | Run Length 6+ Maximum Limit. Defines the maximum allowable runs of length 6 or more (for both 0 and 1) detected during entropy generation. The number of runs of length 6 or more detected during entropy generation must be less than RUN6P_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the MCTL[RST_DEF] bit to 1. |

## 44.1.5.27 Status Register (STATUS)

### 44.1.5.27.1 Offset

| Register | Offset |
|---|---|
| STATUS | 3Ch |

### 44.1.5.27.2 Function

Various statistical tests are run as a normal part of the TRNG's entropy generation process. The least-significant 16 bits of the STATUS register reflect the result of each of these tests. The status of these bits will be valid when the TRNG has finished its entropy generation process. Software can determine when this occurs by polling the ENT_VAL bit in the Miscellaneous Control Register.

Note that there is a very small probability that a statistical test will fail even though the TRNG is operating properly. If this happens the TRNG will automatically retry the entire entropy generation process, including running all the statistical tests. The value in RETRY_CT is decremented each time an entropy generation retry occurs. If a statistical check fails when the retry count is nonzero, a retry is initiated. But if a statistical check fails when the retry count is zero, an error is generated by the RNG. By default RETRY_CT is initialized to 1, but software can increase the retry count by writing to the RTY_CT field in the SCMISC register.

All 0s will be returned if this register address is read while the RNG is in Program Mode (see PRGM field in MCTL register. If this register is read while the RNG is in Run Mode the value returned will be formatted as follows.

### 44.1.5.27.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 44.1.5.28 Entropy Read Register (ENT0 - ENT15)

### 44.1.5.28.1 Offset

For a = 0 to 15:

| Register | Offset | Description |
|---|---|---|
| ENTa | 40h + (a × 4h) | Word a |

### 44.1.5.28.2 Function

The RNG TRNG can be programmed to generate an entropy value that is readable via the SkyBlue bus. To do this, set the MCTL[TRNG_ACC] bit to 1. Once the entropy value has been generated, the MCTL[ENT_VAL] bit will be set to 1. At this point, ENT0 through ENT15 may be read to retrieve the 512-bit entropy value. Note that once ENT15 is read, the entropy value will be cleared and a new value will begin generation, so it is important that ENT15 be read last. These registers are readable only when MCTL[PRGM] = 0 (Run Mode) , MCTL[TRNG_ACC] = 1 (TRNG access mode) and MCTL[ENT_VAL] = 1. After at most one (1) bus clock cycle of reading a valid ENT15 register value, reading any ENT0 through ENT15 register would return zeros.

### 44.1.5.28.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | ENT | | | | | | | | | | | | | | | |

### 44.1.5.28.4 Fields

| Field | Function |
|---|---|
| 31-0<br>ENT | Entropy Value. Will be non-zero only if MCTL[PRGM] = 0 Run Mode) and MCTL[ENT_VAL] = 1 (Entropy Valid). The most significant bits of the entropy are read from the lowest offset, and the least significant bits are read from the highest offset. Note that reading the highest offset also clears the entire entropy value, and starts a new entropy generation. |

# 44.1.5.29 Statistical Check Poker Count 1 and 0 Register (PKRCNT10)

## 44.1.5.29.1 Offset

| Register | Offset |
|---|---|
| PKRCNT10 | 80h |

## 44.1.5.29.2 Function

The Statistical Check Poker Count 1 and 0 Register is a read-only register used to read the final Poker test counts of 1h and 0h patterns. The Poker 0h Count increments each time a nibble of sample data is found to be 0h. The Poker 1h Count increments each time a nibble of sample data is found to be 1h. Note that this register is readable only if MCTL[PRGM] is 0, otherwise zeroes will be read.

## 44.1.5.29.3 Diagram

## 44.1.5.38 Interrupt Control Register (INT_CTRL)

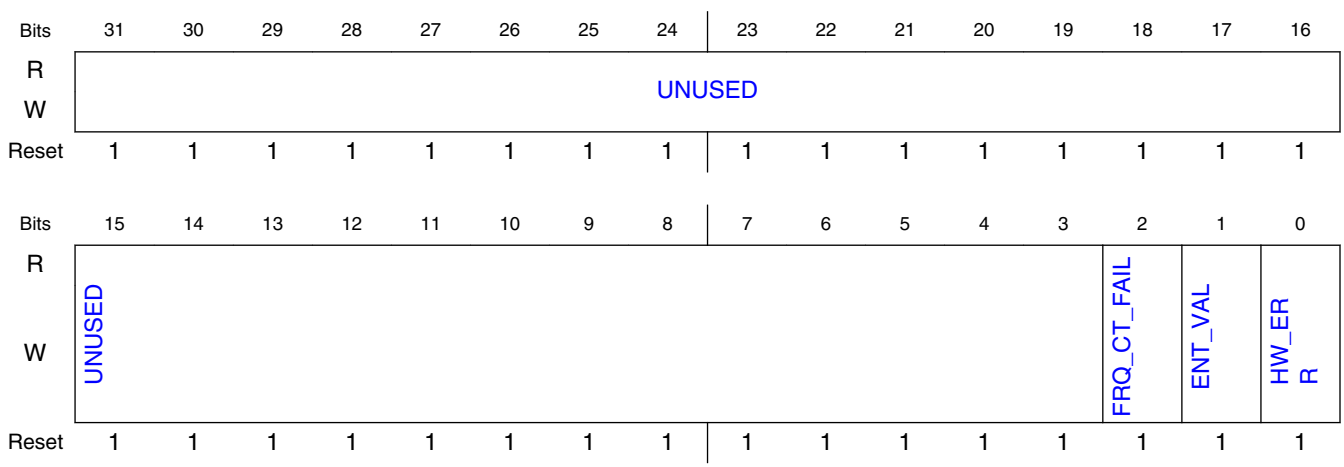
### 44.1.5.38.1 Offset

| Register | Offset |
|---|---|
| INT_CTRL | A4h |

### 44.1.5.38.2 Function

The Interrupt Control Register is a read/write register used to control the status for the (currently) three important interrupts that are generated by the TRNG. See INT_STATUS register description. Each interrupt can be cleared by de-asserting the corresponding bit in the INT_CTRL register. Only a new interrupt will reassert the corresponding bit in the status register. Even if the interrupt is cleared or masked, interrupt status information can be read from the MCTL register.

### 44.1.5.38.3 Diagram



#### 44.1.5.38.4 Fields

### 44.1.5.39 Mask Register (INT_MASK)

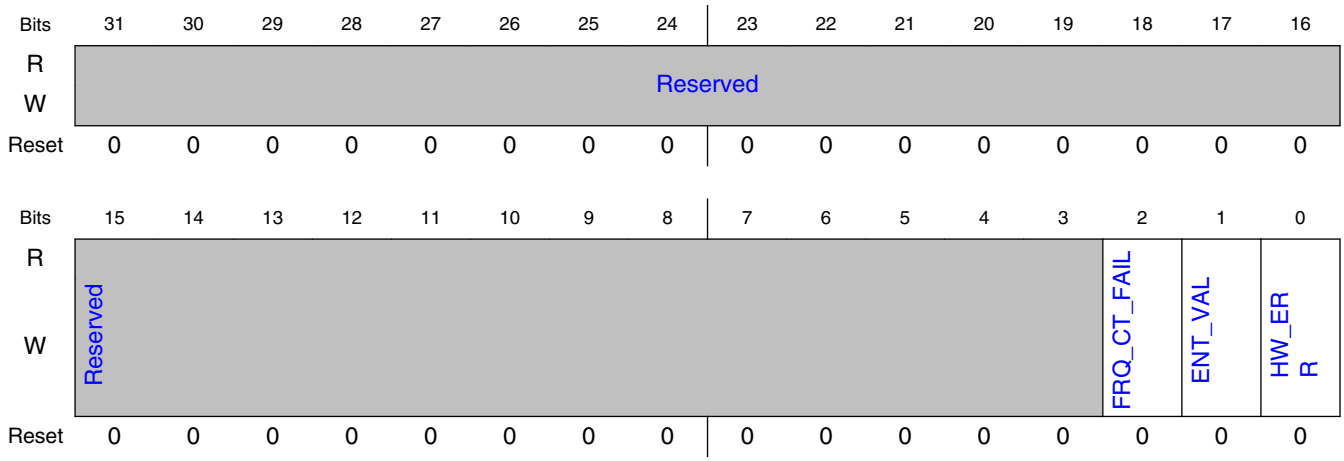
#### 44.1.5.39.1 Offset

| Register | Offset |
|---|---|
| INT_MASK | A8h |

#### 44.1.5.39.2 Function

The Interrupt Mask Register is a read/write register used to disable/mask the status reporting of the (currently) three important interrupts that are generated by the TRNG. See INT_STATUS register descrption. Each interrupt can be masked/disabled by de-asserting the corresponding bit in the INT_MASK register. Only setting this bit high will re-enable the interrupt in the status register. Even if the interrupt is cleared or masked, interrupt status information can be read from the MCTL register.

### 44.1.5.39.3 Diagram



### 44.1.5.39.4 Fields

| 0<br>HW_ERR | Bit position that can be cleared if corresponding bit of INT_STATUS has been asserted.<br>0b - Corresponding interrupt of INT_STATUS is masked.<br>1b - Corresponding bit of INT_STATUS is active. |

## 44.1.5.40 Interrupt Status Register (INT_STATUS)

### 44.1.5.40.1 Offset

| Register | Offset |
|---|---|
| INT_STATUS | ACh |

### 44.1.5.40.2 Function

The Interrupt Status Register is a read register used to control and provide status for the (currently) three important interrupts that are generated by the TRNG. The TRNG interrupt signal alerts that TRNG has either generated a Frequency Count Fail, Entropy Valid or Error Interrupt. The cause of the interrupt can be decoded by checking the least significant bits of the INT_STATUS register. Each interrupt can be temporarily cleared by de-asserting the corresponding bit in the INT_CTRL register. To mask the interrupts, clear the corresponding bits in the INT_MASK register. The description of each of the 3 interrupts is defined in the Block Guide under the MCTL register description. Even if the interrupt is cleared or masked, interrupt status information can be read from the MCTL register.

### 44.1.5.40.3 Diagram

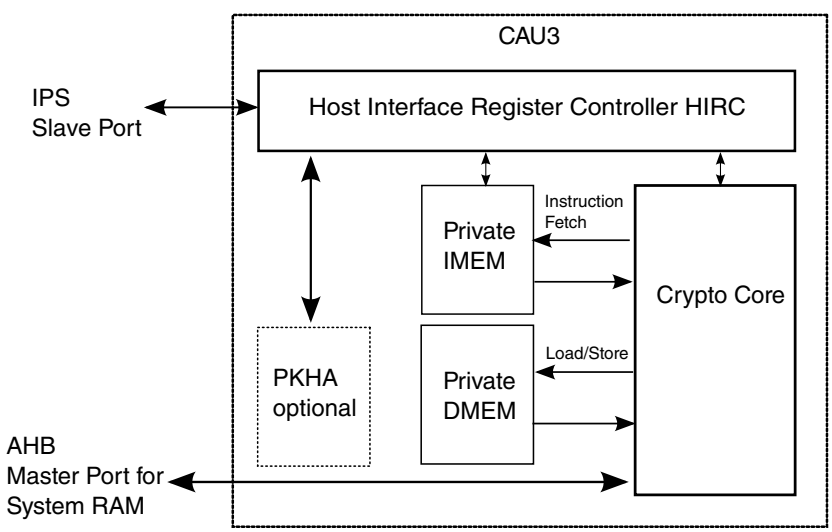
# Chapter 45
# Cryptographic Acceleration Unit (CAU3)

## 45.1 Introduction

The Version 3 Cryptographic Acceleration Unit (CAU3) is a bus mastering IP module that provides hardware acceleration of a variety of cryptographic symmetric key and secure hash algorithms including DES, 3DES, AES-{128,192,256}, SHA-{1,256,512} as well as acceleration of basic public key cryptography including Elliptical Curve Cryptography (ECC). The execution of these algorithms is controlled by optimized firmware developed by NXP that executes on the CAU3 module.

The CAU3 includes four major components: a NXP-programmable 4-stage pipeline CryptoCore, two private memories for local instruction (IMEM) and data (DMEM) storage and a host interface register controller (HIRC) that connects the system IPS slave peripheral bus to the CAU3. The figure bellow describes these components.

**Figure 45-1. CAU3 Major Components**



From the system perspective, the CAU3 is a two-terminal device with a bus master connection to the system AHB bus fabric (for accessing crypto data in system RAM and specific slave peripheral modules) and a slave connection to the IPS bus (for the host to program and control the CAU3).

The host interface is optimized to provide a streamlined mechanism to quickly initialize the CAU3 with minimal overhead, while the CryptoCore is a single-issue 4-stage pipelined processor. The CryptoCore's instruction set architecture includes a combination of standard integer instructions needed for general processing as well as a set of crypto instructions specifically defined to accelerate the supported cryptographic algorithms.

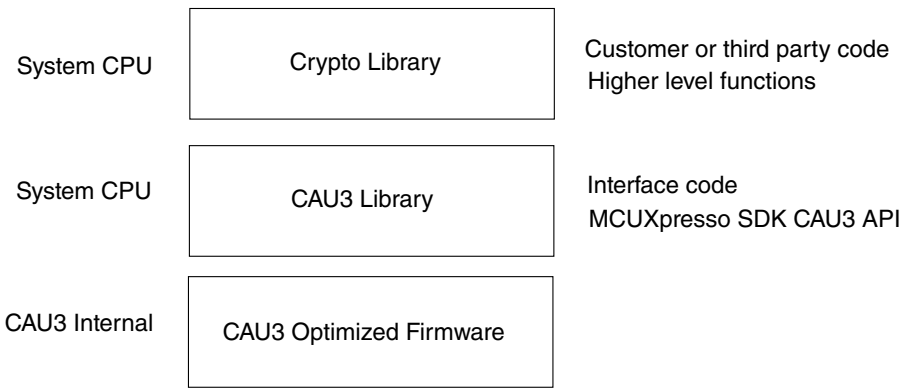
The general flow of operations contains the following steps:

1. Since the CAU3 is a shared system module, its "ownership" must first be claimed by the host processor. This is accomplished via a hardware semaphore implemented in the HIRC submodule. Once ownership has been acquired, the host processor continues with the subsequent steps.
2. The host programs the needed input arguments by writing their values directly into the CryptoCore's programming model including a starting PC value which indexes into a branch table based at address 0x0 of the IMEM.IRAM memory. The final operation is a write to the CryptoCore's CMD register which initiates execution.
3. The CryptoCore follows a "run to completion" model, and following a write to its CMD register, executes the selected firmware routine(s) to perform the desired cryptographic function(s).
4. Once the function's execution is complete, the CAU3 provides a user- programmable signaling mechanism. The task completion can be configured to: generate an interrupt back to the host, signal an event completion to the host, generate a DMA request to the appropriate DMA, and simply change the state of its RUN/STOP/ HALT status (to allow host polling).
5. After receiving the appropriate notification, the host processor releases the CAU3 semaphore, making the module available again.

Within the CAU3's micro-architecture, the HIRC submodule contains a number of local control, status and configuration registers and supports read/write access to the CryptoCore's programming model (General-purpose registers R[0-31], PC, CMD, CF) and the ability to read/write the CAU3's private memories (IMEM, DMEM).

NXP provides an optimized C-function library that implements the appropriate software building blocks to execute the high-level security functions as well as an optimized firmware library containing the CryptoCore code. The figure below describes the CAU3 software stack.

**Figure 45-2. CAU3 Software Stack**



## 45.2 Block Diagram

A more detailed view of the CAU3 micro-architecture is presented below. The CryptoCore's design is partitioned into three major functions: an instruction fetch pipeline for controlling accesses of firmware instructions from the private, local IMEM, both IRAM and IROM, the execution unit pipeline for register-to-register operations and the load/store unit for accessing system RAM using the AHB master bus port and private accesses to the local DMEM.DRAM.

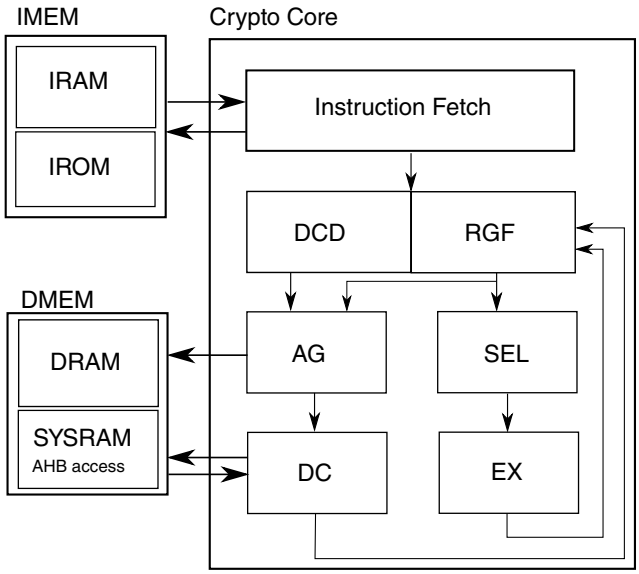


**Figure 45-3. CryptoCore Highest Level block diagram**

The CAU3's local private memories (IMEM and DMEM.DRAM) provide zero wait-state response to instruction fetches and data loads/stores from the CryptoCore. These memories can be initialized indirectly under control of the host processor, but once the firmware is written into the IMEM.IRAM, the host processor access port is typically disabled. Once disabled, the local memories are only accessible by the CryptoCore. The IMEM.IRAM storage includes a function branch table based at address 0 followed by the specific CAU3 firmware functions needed in a given system. The IMEM.IROM includes a small number of firmware functions, mostly involving CAU3 initialization and/or handling of a security violation detected at the SoC level. These functions include zeroing out the local DMEM.DRAM and CryptoCore registers to protect any key information. The DMEM.DRAM is used for local private storage, for both temporary variables and secret key management. It is also used to store data used during public key calculations.

## 45.3 Overview

The CAU3 is a cryptographic sub-system that includes a dedicated core, a dedicated instruction memory (IRAM and IROM) and a dedicated data RAM for autonomously implement symmetric keys algorithms, such as 3DES, AES-128/192/256, AES-CBC, AES-CCM, AES-GCM as well as secure hash functions including SHA-1, SHA-256 and SHA-512. Hardware acceleration for public key algorithms including RSA and ECC is also provided.

The set of implemented algorithms provides excellent support for network security standards, such as SSL and IPsec.

The cryptographic algorithms are implemented in the CAU3 firmware using dedicated instructions that are executed by a cryptographic core to efficiently execute the cryptographic algorithms. Hardware acceleration is provided for the algorithms that are not completely implemented in the CAU3 module, allowing fine-grained partitioning of functions between hardware and software:

- Implement the basic security kernel functions using the cryptographic core processor instructions
- Implement higher level functions in software by using the standard processor core instructions in addition to the calls to CAU3 firmware with its cryptographic core instructions

The CAU3 implements a set of cryptographic functions programmed in the module local private instruction memory (IRAM and/or IROM) . These firmware instructions are executed by the cryptographic core. The module can access cipher text or plain text stored in the system RAM without the host CPU intervention using a crossbar master AHB interface. A private RAM (DMEM.DRAM) provides local storage of temporary data variables and secret key management, to avoid exposing the data in any system memory.

## 45.4 Features

The CAU3 includes the following distinctive features:

- Backwards compatible with MMCAU
  - Symmetric key functions: DES, 3DES, AES-{128,192,256}
  - Secure hash functions: SHA-1, SHA-256
- Added SHA-512 secure hash acceleration
- AES-CBC, AES-CCM, AES-GCM
- RSA and ECC acceleration
- Programmable task completion signaling: interrupt, event completion, DMA request
- Significantly improved performance and power efficiency
- Common, portable CAU3 library written in C
- ARM embedded TLS library reference design
- Hardware size appropriate for low cost CM0+ and CM4 MCUs
- Flexible architecture

## 45.5 CAU3 register descriptions

This section describes the CAU3 registers. Certain register resources of the CAU3 programming model can only be accessed while in secure privileged mode. Additionally, unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error unless noted otherwise. Due to security concerns, in general, any IPS read access that is error terminated must respond with zeroes as the data. Refer to Access to Memory Mapped Registers for details.

### 45.5.1 CAU3 Memory map

CAU3 base address: 4102_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|

## 45.5.4 Control Register (CR)

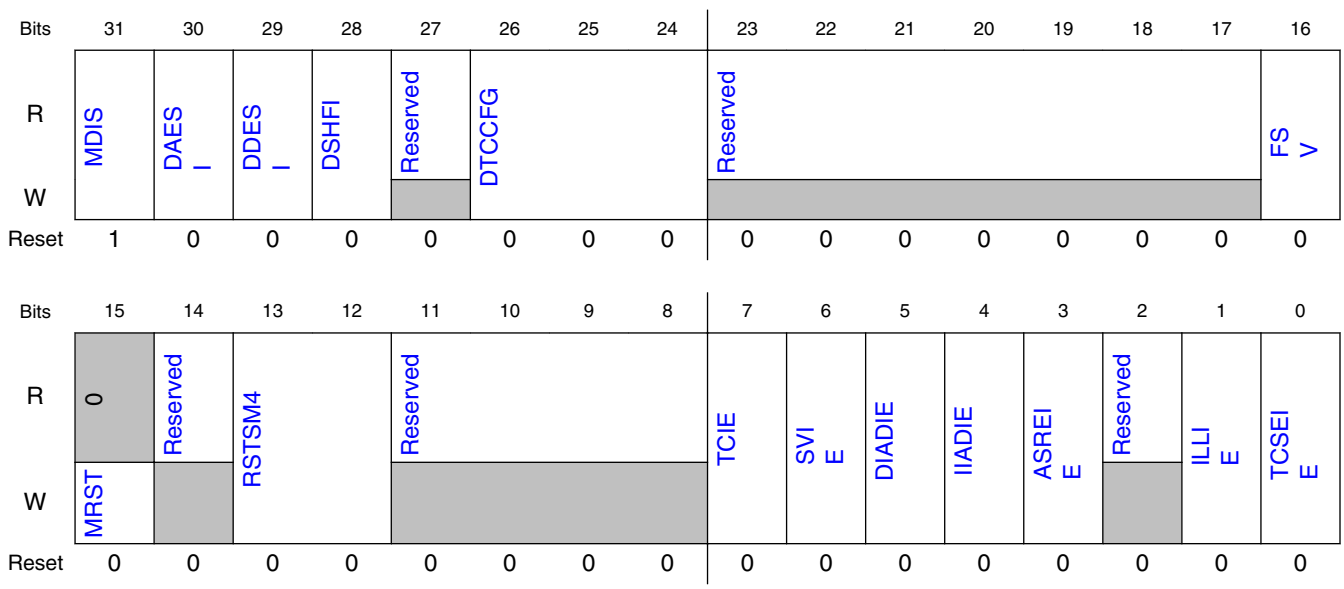
### 45.5.4.1 Offset

| Register | Offset |
|---|---|
| CR | 10h |

### 45.5.4.2 Function

This register provides control bits for CAU3 operation. This register can only be accessed by a bus master operating in secure, privileged mode. Accesses to this register are also allowed when the CryptoCore is in low power mode.

### 45.5.4.3 Diagram



### 45.5.4.4 Fields

| Field | Function |
|---|---|
| 31<br>MDIS | Module Disable<br>If set, this bit disables the CAU3 program execution and then puts the CryptoCore into low power mode by disabling the module clocks and consequently disabling all functions of the module. While disabled, accesses to CAU3 register resources are not allowed with the exception of PCT, MCFG, CR and SR registers which are accessible. In case of SR, it is only accessible for read operations. Furthermore, |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | blocked accesses return a transfer error. MDIS should be set only when CAU3 is at STOP state. If MDIS is negated, the CryptoCore exits from the low power mode by restoring the clocks. See section Access to Memory Mapped Registers for details.<br>0b - CAU3 exits from low power mode<br>1b - CAU3 enters low power mode |
| 30<br>DAESI | Disable AES Instructions<br>If set, this bit disables all AES crypto instructions (AESS, AESIS, AESSC, AESISC, AESR and AESIR). If the execution of an AES instruction is attemped and this bit is set, that instruction is treated as an illegal instruction and is terminated with a stop-with-error condition. This bit field is sticky, meaning that once it is written to logic 1 it cannot be cleared by a subsequent write access. It is only cleared by a hardware reset. This bit should be changed only when the CCore is in STOP or HALT states.<br>0b - AES instructions are enabled<br>1b - AES instructions are disabled |
| 29<br>DDESI | Disable DES Instructions<br>If this bit is set, the DES instructions are disabled (DESR and DESK), meaning that they are considered invalid instructions. Any attempt to execute those instructions when this bit is set generates an stop-with-error program termination. This bit is sticky, meaning that once written to logic 1 it cannot be changed by a subsequent write access. Only a hardware reset clears this bit. This bit should be changed only when the CCore is in STOP or HALT states.<br>0b - DES instructions are enabled<br>1b - DES instructions are disabled |
| 28<br>DSHFI | Disable Secure Hash Function Instructions<br>This control bit disables the Secure Hash Functions instructions (HFP, HFC, HFM, HF2A, HF2B, HF2C, and HF2D), meaning that these functions are interpreted as invalid instructions. Any attempt to execute Secure Hash instructions when this bit is set generates a stop-with-error program termination. This bit is sticky, meaning that once written to logic 1 it cannot be changed by a subsequent write access. Only a hardware reset clears this bit. This bit should be changed only when the CCore is in STOP or HALT states.<br>0b - Secure Hash Functions are enabled<br>1b - Secure Hash Functions are disabled |
| 27<br>— | Reserved |
| 26-24<br>DTCCFG | Default Task Completion Configuration<br>This control field defines the action to be taken after a task is completed. Note that the task completion report status can be modified by the CMD register bit field [2:0]. In case CMD[2:0]=0 the DTCCFG is used to report the task completion status. If CMD[2:0]!=0 then the CMD[2:0] is used in the place of DTCCFG. The decoding of CMD[2:0] and DTCCFG bits have the same meaning. This bit should be changed only when the CCore is in STOP or HALT states.<br>000b - no explicit action<br>001b - Issue an Interrupt Request<br>010b - Assert Event Completion Signal<br>100b - Issue a DMA request |
| 23-17<br>— | Reserved |
| 16<br>FSV | Force Security Violation Test<br>The force security violation bit simulates a system security violation event. This bit is used for software test of the security violation counter measures implemented in the crypto core. This bit is sticky. Once set it remains set until a Module (MRST) or hardware reset occurs.<br>0b - no violation is forced<br>1b - force security violation |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 15<br>MRST | Module Reset<br>The Module reset is self negated by the crypto core hardware. It is always read as logic zero. This control bit is used to force a task to end as if a STOP instruction is executed by the CCore. If a task is running it is terminated. If the CCore is at Security Violation Stop state as a result of a force security violation, setting FSV bit, it exits this state and transitions to the STOP state. If the CCore is at Security Violation Run (SEVR) or Initialization Run (INIR) or STOP state, setting MRST has no effect. The memory mapped registers, IMEM and DMEM, are not affected by this bit.<br>**NOTE:** MRST must not set along with FSV or when FSV is already set.<br>0b - no action<br>1b - reset |
| 14<br>— | Reserved |
| 13-12<br>RSTSM4 | Reset Semaphore<br>The Reset Semaphore field is used to release a semaphore lock. In order to clear the semaphore lock, thus releasing the semaphore, the master must have Secure and Priority access attributes and write to this bit field the sequence: "01" followed by "10". After completing this sequence the semaphore is released and these bits are read as "00". If the previously described write sequence is not executed the value on these bits correspond to the latest written value. Thus reading "00" after the "01","10" write sequence indicates that the semaphore was released. If the master does not have Secure and Privilege attributes these bits will not change value and a transfer error is indicated. Note that this procedure can be executed by any master with Secure and Privilege attributes, regardless of the master ID and DID.<br>00b - Idle state<br>01b - Wait for second write<br>10b - Clears semaphore if previous state was "01"<br>11b - Reserved |
| 11-8<br>— | Reserved |
| 7<br>TCIE | Task completion with no error interrupt enable<br>This bit enables the CAU3 to issue an interrupt request in case a task was completed with no error, which means a STOP instruction is executed and TKCS= "1001".<br>0b - Disables task completion with no error to generate an interrupt request<br>1b - Enables task completion with no error to generate an interrupt request |
| 6<br>SVIE | Security Violation Interrupt Enable<br>This bit enables the crypto core to issue an error interrupt request in case a security violation occurs.<br>0b - Security violation interruption is not enabled<br>1b - Security violation interruption is enabled |
| 5<br>DIADIE | DMEM Illegal Address Interrupt Enable<br>This bit enables the crypto core to issue an interrupt request in case of an illegal address is used for a DMEM access.<br>0b - DMEM illegal address interruption is not enabled<br>1b - DMEM illegal address interruption is enabled |
| 4<br>IIADIE | IMEM Illegal Address Interrupt Enable<br>This bit enables the crypto core to issue an error interrupt request in case an illegal address is used for an IMEM access. If the origin of the access is the IPS bus, then a transfer error is returned independent of the state of this enable bit.<br>0b - IMEM illegal address interruption is not enabled<br>1b - IMEM illegal address interruption is enabled |
| 3<br>ASREIE | AHB Slave Response Error Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This bit enables the crypto core to issue an error interrupt request in case an AHB slave response error is detected (HRESP != 0) in an AHB access.<br>0b - AHB slave response error interruption is not enabled<br>1b - AHB slave response error interruption is enabled |
| 2<br>— | Reserved |
| 1<br>ILLIE | Illegal Instruction Interrupt Enable<br>This bit enables the crypto core to issue an error interrupt request when an illegal instruction is detected.<br>0b - Illegal instruction interrupt requests are disabled<br>1b - illegal Instruction interrupt requests are enabled |
| 0<br>TCSEIE | Task completion with software error interrupt enable<br>This bit enables the CAU3 to issue an interrupt request in case a task was completed with software indicated error, which means a STOP instruction is executed and TKCS= "1010".<br>0b - Disables task completion with software error to generate an interrupt request<br>1b - Enables task completion with software error to generate an interrupt request |

## 45.5.5 Status Register (SR)

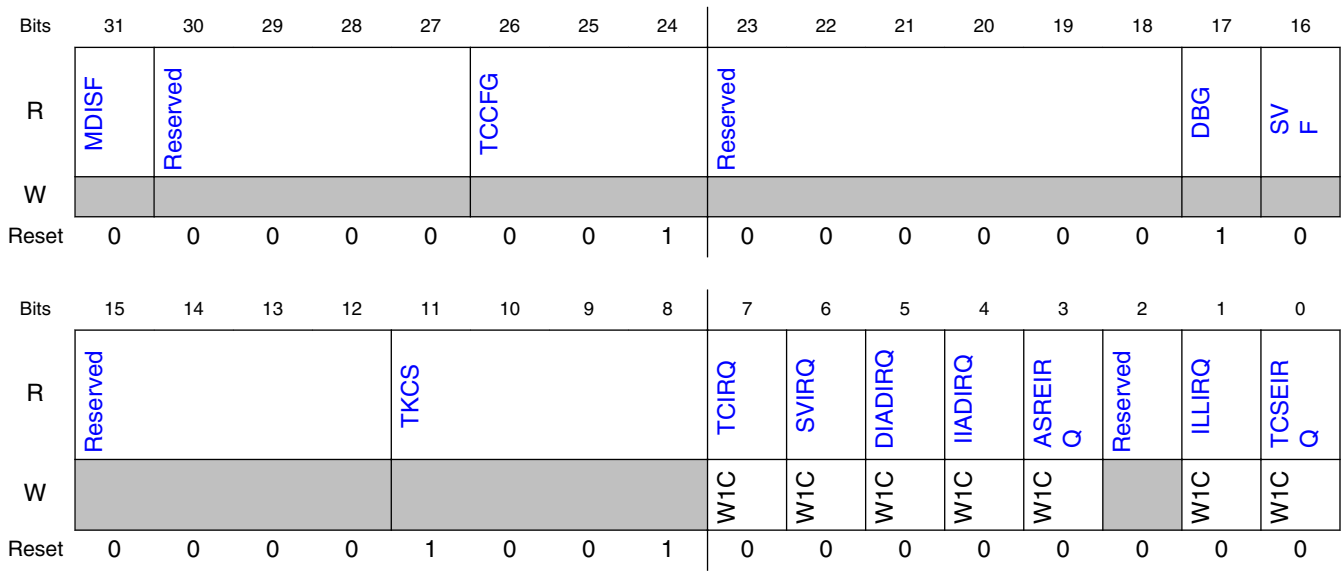
### 45.5.5.1 Offset

| Register | Offset |
|---|---|
| SR | 14h |

### 45.5.5.2 Function

This register contains the Status bits of the CAU3. In low power mode i.e. MDISF= 1, reads are allowed but writes are not effective and are terminated with error.

### 45.5.5.3 Diagram



### 45.5.5.4 Fields

| Field | Function |
|---|---|
| 31<br>MDISF | Module disable flag<br>This Flag indicates that the CCore is in low power mode, meaning that the clocks to the module are allowed to be gated off. This flag is set due to the MDIS bit in the control register being set and the CCore being at STOP state or when the IPG STOP request is acknowledged. Note that immediately out of reset the CryptoCore is running the initialization routine, thus this bit remains 0x0 until that routine ends, when it transitions to 0x1 indicating the low power mode.<br>0b - CCore is not in low power mode<br>1b - CCore is in low power mode |
| 30-27<br>— | Reserved |
| 26-24<br>TCCFG | Task completion configuration<br>The Task Completion Configuration shows the selected task completion status for the task being executed. The value in this field is a copy of the CMD.CMD[2:0] field if CMD.CMD[2:0]!=0. Else it is a copy of the CR.DTCCFG field. It is updated when a task starts execution.<br>000b - No action<br>001b - Assert an interrupt request<br>010b - Assert the Event Completion Signal<br>100b - Issue a DMA request |
| 23-18<br>— | Reserved |
| 17<br>DBG | Debug mode<br>This flag indicates that CAU3 is in debug mode. The debug mode is active out of reset and remains active until DBGCSR[DDBG]= 1, when it is disabled. Since the access to the DBGCSR debug register is |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | blocked out of debug mode, this flag provides the information to the host controller that the CAU3 debug features and access to debug registers are not blocked.<br>0b - CAU3 is not in debug mode<br>1b - CAU3 is in debug mode |
| 16<br>SVF | Security violation flag<br>The security violation flag, if set, indicates that the external SoC security violation signal, input to the CAU3, was asserted during at least 2 clock cycles, or that the force security violation bit, CR[FSV], was set . This flag is cleared only by a hardware reset if an SoC security violation occurred. In case of a forced security violation it can also be cleared by setting the software reset bit CR[MRST], but the security violation routine is not aborted in this scenario.<br>0b - SoC security violation is not asserted<br>1b - SoC security violation was asserted |
| 15-12<br>— | Reserved |
| 11-8<br>TKCS | Task completion status<br>The task Completion Status field signals to the software the current status of the CAU3 core. The low order three bits [2:0] are sourced from the STOP instruction operand, TKCS[3:0] = {1, STOP operand[2:0]} or from the HALT instruction imm16 data in debug mode TKCS[3:0] = {0, HALT imm16[2:0]}. Values of this field other than the shown below are reserved.<br>0000b - Initialization RUN<br>0001b - Running<br>0010b - Debug Halted<br>1001b - Stop - Error Free<br>1010b - Stop - Error<br>1110b - Stop - Security Violation, assert security violation output signal and set SVIRQ<br>1111b - Stop - Security Violation and set SVIRQ |
| 7<br>TCIRQ | Task completion with no error interrupt request<br>This flag indicates the end of a task execution with no error. It is set due to a STOP instruction execution and SR[TKCS]= "1001" and SR[TCCFG]= "001". It is cleared by the Host CPU application software by writing 1 to this bit.<br>0b - Task not finished or finished with error<br>1b - Task execution finished with no error |
| 6<br>SVIRQ | Security violation interrupt request<br>The Security Violation Interrupt Request indicates that there was an attempt to break the security measures of the system. This flag is set by a task with the completion status (TKCS) indicating the codes "1110" or "1111". In particular it is set by the Security Violation routine which is automaticaly called when the system wide security violation indication is active, also when the CR[FSV] is asserted or when there is an attempt to access the CAU3 Private DRAM content with the debug mode disabled DBGCSR[DDBGMC] = 1 or DBGCSR[DDBG] = 1. These routines ends with a STOP or STOPI instruction with operand [2:0]= "111" or "110". See Security Violation for details.<br>0b - No security violation<br>1b - Security violation |
| 5<br>DIADIRQ | DMEM illegal access interrupt request<br>The DMEM illegal access interrupt request is set when the CAU3 software executes an access (read or write) to an address of the DMEM which is greater than the maximum DMEM address, if an unaligned address is used, or when a 64-bit access is done to system memory region. In this case the CAU3 halts the software execution and enters the STOP state with a completion error indication. This flag is not set in case the Host CPU software access the DMEM through the IPS interface.<br>0b - no illegal address<br>1b - illegal address |
| 4 | IMEM Illegal address interrupt request |

*Table continues on the next page...*

| Field | Function |
|---|---|
| IIADIRQ | The IMEM Illegal Address Interrupt Request indicates if the CAU3 software tried to execute an instruction beyond the maximum allowed address of the IMEM RAM. In this case the CAU3 halts the software execution and enters the STOP state with a completion error indication. This flag is not set in case the Host CPU software access the IMEM through the IPS interface.<br>0b - no error<br>1b - illegal IMEM address detected |
| 3<br>ASREIRQ | AHB slave response error interrupt Request<br>The AHB Slave Response Error Interrupt Request indicates that the HRESP AHB Bus signal was set during an AHB access initiated by the CCore. In this case the CAU3 halts the software execution and enters the STOP state with a completion error indication. This bit is not set if the AHB access was initiated by the Host CPU through the IPS bus.<br>0b - no error<br>1b - AHB slave response error detected |
| 2<br>— | Reserved. |
| 1<br>ILLIRQ | Illegal instruction interrupt request<br>The Illegal Instruction Interrupt request is asserted when an illegal instruction is executed. This illegal instruction is not actually executed and the CAU3 core halts at (before) this instruction and enters the STOP state with a completion error indication.<br>0b - no error<br>1b - illegal instruction detected |
| 0<br>TCSEIRQ | Task completion with software error interrupt request<br>This flag indicates the end of a task execution that terminated with an error condition. This error is referred to as a software indicated error. It is set due to a STOP instruction execution with SR[TKCS]= "1010". It is cleared by the Host CPU application software by writing 1 to this bit.<br>0b - Task not finished or finished with no software error<br>1b - Task execution finished with software error |

## 45.5.6 Debug Control/Status Register (DBGCSR)

### 45.5.6.1 Offset

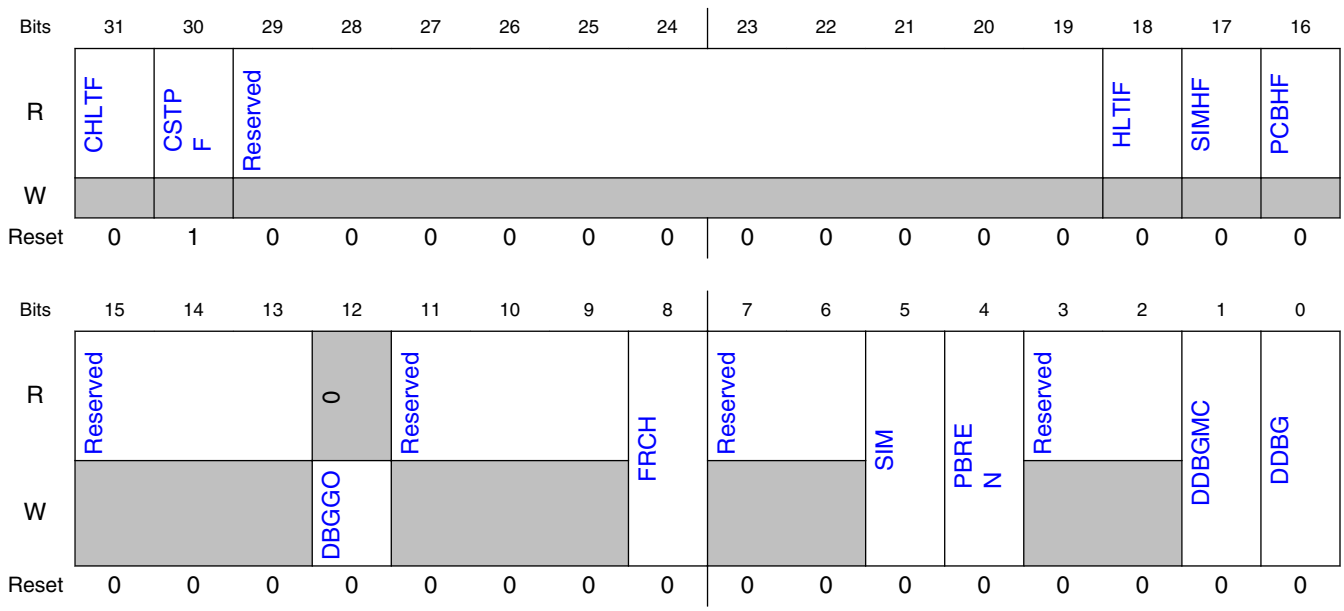
| Register | Offset |
|---|---|
| DBGCSR | 20h |

### 45.5.6.2 Function

This register contains the Debug Control and Status bits. These bits control the operation of the CAU3 CryptoCore in debug mode. This mode of operation provides software debug capabilities which means it allows access to the local private IMEM and DMEM as well as special configuration options in the CryptoCore. This mode does not provide

protection for secure information such as Cryptographic Keys. Any attempt to access this register out of debug mode, DBGCSR[DDBG] = 1, is not allowed and is terminated with error, therefore setting DBGCSR[DDBG] locks CAU3 out of debug mode. Accesses are also not allowed in low power, SR[MDISF]= 1, or if a security violation had occurred, SR[SVF]=1, or if the CryptoCore is running the initialization routine, i.e. it is in the initialization run state, when TKCS= '0000'.

## 45.5.6.3 Diagram



## 45.5.6.4 Fields

| Field | Function |
|---|---|
| 31<br>CHLTF | CryptoCore is Halted Status Flag<br>This flag bit indicates that the CryptoCore is halted.<br>0b - CryptoCore is not halted<br>1b - CryptoCore is halted |

| Field | Function |
|---|---|
| 1<br>DDBGMC | Disable Debug Memory Commands<br>This control bit disables IPS access to the local, private IMEM and DMEM. Any attempt to access these memories with this bit set has no effect and returns a transfer error. In particular, attempted accesses of the DBGMCMD, DBGMADR and DBGMDR registers are disabled when this indicator is set and are error terminated. This bit is sticky, meaning that once set to logic 1 it cannot be cleared by a subsequent write access. Only a hardware reset clears this bit. Even though not restricted by the hardware, this bit should only be changed when the CCore is in STOP state.<br>0b - IPS access to IMEM and DMEM are enabled<br>1b - IPS access to IMEM and DMEM are disabled |
| 0<br>DDBG | Debug Disable<br>This control bit, if set, disables all debug operations of the CAU3. If set to logic 1 it blocks the accesses to debug registers DBGCSR, DBGPBR, DBGMCMD, DBGMADR and DBGMDR. Attempts to access those registers when DBGCSR[DDBG] = 1 are terminated with an error. Even though not restricted by the hardware, this bit should only be changed when the CCore is in STOP state. This bit is sticky, meaning that once set to logic 1 it cannot be cleared since the DBGCSR register becomes unaccessible.<br>The CAU3's debug and non-debug modes of operation are defined by the combined DDBG and DDBGMC bits:<br>00 - debug mode: accesses for DBGMCMD, DBGMADR and DBGMDR registers are allowed;<br>01 - debug mode: accesses are blocked for DBGMCMD, DBGMADR and DBGMDR registers;<br>1x - non-debug: accesses are blocked for DBGMCMD, DBGMADR, DBGMDR, DBGPBR and DBGCSR registers<br>In non-debug mode PC breakpoints are disabled and HALT instructions are treated as invalid instructions. See section Debug Resources for details.<br>0b - debug is enabled<br>1b - debug is disabled |

## 45.5.7 Debug PC Breakpoint Register (DBGPBR)

### 45.5.7.1 Offset

| Register | Offset |
|---|---|
| DBGPBR | 24h |

### 45.5.7.2 Function

This register contains the Debug PC Breakpoint. If enabled by the DBGCSR[PBREN] control bit, a match between the Program Counter (PC) and PCBKPT forces the CryptoCore into halt state. The breakpoint recognition and subsequent entry into halt state occurs after the previous instruction has completed execution and before the

breakpointed instruction executes. Write accesses are not allowed in low power, SR[MDISF]= 1, or if a security violation had occurred, SR[SVF]=1.

### 45.5.7.3 Diagram

## 45.5.8 Debug Memory Command Register (DBGMCMD)

### 45.5.8.1 Offset

| Register | Offset |
|---|---|
| DBGMCMD | 30h |

### 45.5.8.2 Function

This register contains the Memory Debug Command. This command is to be used for indirect read/write accesses to the local private IMEM and DMEM. After configuring this register and DBGMADR with the address of the target memory block, the host performs writes or reads to the DBGDR register. Read or write accesses are not allowed if DBGCSR[DDBG]= 1 or DBGCSR[DDBGMC]= 1 or the CAU3 module is in low power, SR[MDISF]= 1, or if a security violation had occurred, SR[SVF]=1. Particularly if {DDBG,DDBGMC}!= "00" accesses to this register are interpreted as a security violation, see section Security Violation for details.

## 45.5.9 Debug Memory Address Register (DBGMADR)

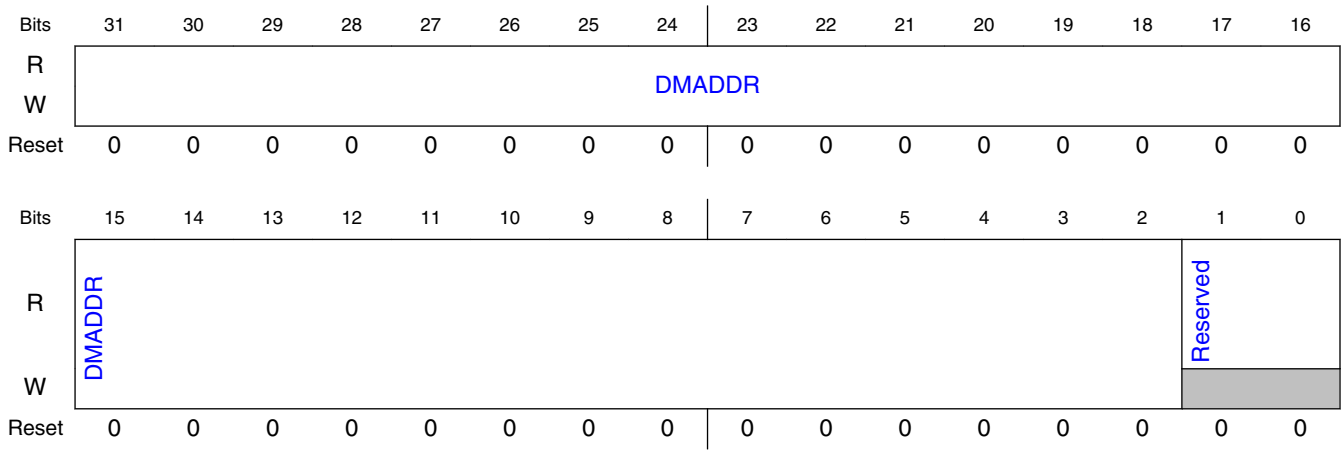
### 45.5.9.1 Offset

| Register | Offset |
|---|---|
| DBGMADR | 34h |

### 45.5.9.2 Function

This register contains the memory word address to be used for debug accesses. This address may be routed to the local private IMEM or DMEM depending on the DBGMCMD[DM] bit. Additionally, data accesses can also be made to the system RAM based on the address. The address is forced to be aligned on a 0-mod-4 byte boundary to match the access size of the CAU3. Read or write accesses are not allowed if DBGCSR[DDBG]=1 or DBGCSR[DDBGMC]= 1 or the CAU3 module is in low power, SR[MDISF]= 1, or if a security violation had occurred, SR[SVF]=1. Particularly if {DDBG,DDBGMC}!= "00" accesses to this register are interpreted as a security violation, see section Security Violation for details.

### 45.5.9.3 Diagram



### 45.5.9.4 Fields

|---|---|
| 31-2<br>DMADDR | Debug Memory Address<br>This address is used for write and read accesses to/from IMEM and DMEM as defined by the DBGMCMD[DM] control bit. If DBGMCMD[IA] is set then DMADDR is incremented by 1 after the access is done. If this address is used to access the DMEM.AHB space, the address range from 0x4000_0000 up to 0x5FFF_FFFF is blocked, meaning the access is terminated with an error. This restriction prevents IPS accesses of peripheral address space, which includes CAU3 address space, through the AHB master interface.<br>**NOTE:** DMADDR should only be changed in STOP or HALT states. |
| 1-0<br>— | Reserved |

## 45.5.10 Debug Memory Data Register (DBGMDR)

### 45.5.10.1 Offset

| Register | Offset |
|---|---|
| DBGMDR | 38h |

### 45.5.10.2 Function

This register contains the data related to the debug memory access. This register does not physically exist in the CAU3 module. Writes to this register are mapped to the memory location specified by DBGMCMD and DBGMADR registers. Reads of this register return the data from the memory address specified by the same two registers. Read or write accesses are not allowed if DBGCSR[DDBG]=1 or DBGCSR[DDBGMC]=1, or the CAU3 module is in low power, SR[MDISF]= 1, or if a security violation had occurred, SR[SVF]=1. Particularly if {DDBG,DDBGMC}!= "00" accesses to this register are interpreted as a security violation, see section Security Violation for details.

## 45.5.11 Semaphore Register (SEMA4)

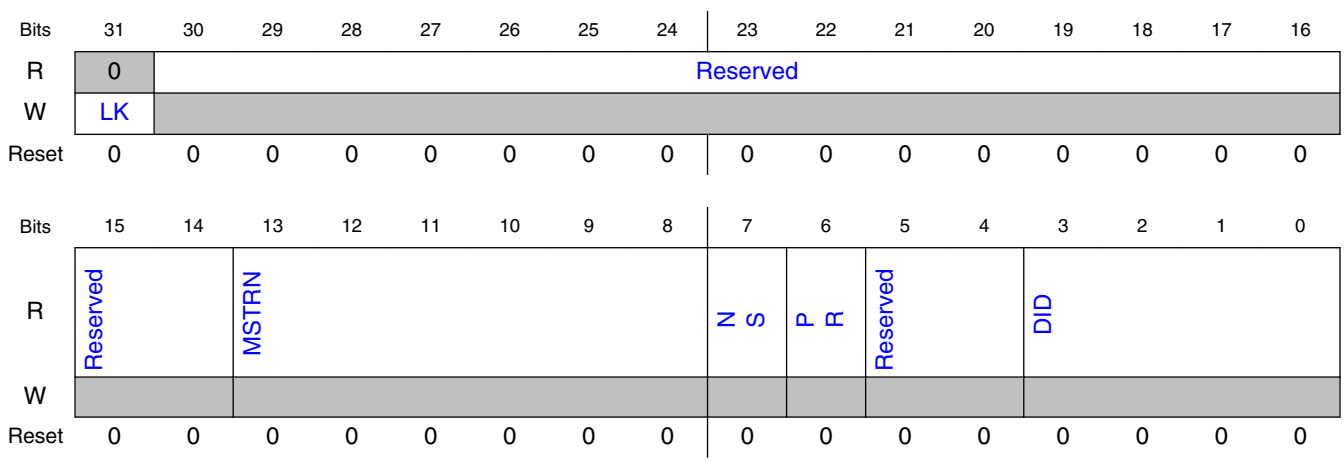
### 45.5.11.1 Offset

| Register | Offset |
|---|---|
| SEMA4 | F0h |

### 45.5.11.2 Function

The Semaphore Register is used when multiple host processors or associated bus mastering modules, for example, a DMA, need to use the shared CAU3 resources. The Semaphore Register is used by the software to take ownership of the CAU3. After writing 1 to the LK bit indicating that a host is trying to take ownership of the semaphore, the Semaphore Ownership Register, SMOWNR, can be read to verify that master is indeed the owner of the semaphore. In order to release the semaphore, the semaphore owner master writes 0 to the LK bit. Once semaphore ownership has been established, only host interface accesses from the owning master are allowed. Attempted accesses from any other master are blocked but are NOT terminated with an error. The MSTRN, NS, PR, DID fields are only visible by a secure, privileged bus master, else these fields are returned as zeros. In addition, accesses to this register are only allowed in STOP CCore state. Any attempt to write this register in a different CryptoCore state returns a transfer error. See section Semaphore Operation for details about the semaphore operation.

### 45.5.11.3 Diagram



### 45.5.11.4 Fields

| Field | Function |
|---|---|
| 31<br>LK | Semaphore Lock and Release Control |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This bit is write only and always reads as zero. If written as logic 1, this bit requests the locking of the semaphore for the accessing master. Writing logic zero means the master is releasing the semaphore, but only if it is the owning master.<br>0b - Semaphore release<br>1b - Semaphore lock |
| 30-14<br>— | Reserved |

| 5-4<br>— | Reserved |
| 3-0<br>DID | Domain ID of Locked Semaphore Owner<br>This bit field indicates the attribute ID of the locked semaphore. It is only visible for accesses with secure and privilege attributes, otherwise they are read as zero. |

## 45.5.12 Semaphore Ownership Register (SMOWNR)

### 45.5.12.1 Offset

| Register | Offset |
|---|---|
| SMOWNR | F4h |

## 45.5.12.2 Function

This read-only register indicates if the lock request was successful on locking the CAU3's semaphore. After attempting to claim ownership of the semaphore by seting the SEMA4[LK] bit, the host device reads the ownership register. The read data returns the semaphore state with 3 distinct values, allowing an easy single conditional branch resolution.See section Semaphore Operation for details about the semaphore operation.

## 45.5.13 Address Remap Register (ARR)

### 45.5.13.1 Offset

| Register | Offset |
|---|---|
| ARR | FCh |

### 45.5.13.2 Function

The Address Remap Register contains a register list for address remapping of host accesses to the CryptoCore's general-purpose registers. Once programmed with any non-zero data it becomes active. Each non-zero bit in the register corresponds to one of the CC_Rn registers, such that bit 0 corresponds to R0, bit 1 corresponds to R1 and so forth up to bit 31 corresponding to R31. For accesses in the CC_Rn (180h - 1FCh) address space with at least one non-zero ARR bit, instead of the register referenced by the actual bus address, a remapped address is generated based on the least significant non-zero bit in ARR. After the access is done, the corresponding ARR bit is cleared. The next access uses the next non-zero LSB in ARR for the remapping. The remapping is done while ARR is non-zero. Read or write accesses are not allowed if the CAU3 module is in low power, SR[MDISF]= 1, or if a security violation had occurred, SR[SVF]=1.

### 45.5.13.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.5.17 Program Counter (CC_PC)

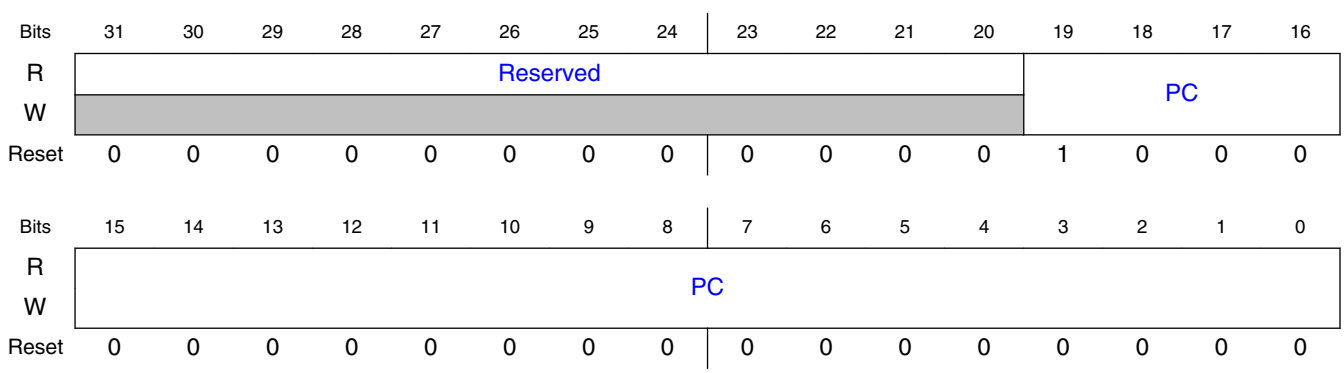
### 45.5.17.1 Offset

| Register | Offset |
|---|---|
| CC_PC | 200h |

### 45.5.17.2 Function

This register is mapped to the CryptoCore's Program Counter (PC) register. Reads and writes are only allowed in STOP or HALT states. Any attempt to read or write this register in a different CryptoCore state returns a transfer error. Accesses are also not allowed in low power, SR[MDISF]= 1, or if a security violation had occurred, SR[SVF]=1. In the error case, the register write is inhibited and the register read returns zeroes.

### 45.5.17.3 Diagram



### 45.5.17.4 Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved |
| 19-0<br>PC | Program Counter<br>The PC field is written prior to task execution with the appropriate index into the branch table based at address 0 of the IMEM. After task completion with a STOPPED status, the PC points to the address of the executed STOP instruction. For any type of illegal operation termination, the PC points to the instruction after, that is, PC+4 of the offending instruction. Since the CryptoCore implements a fixed 32-bit instruction length, the low-order 2 bits of the PC[19:0] field are hardwired to 00b, PC[1:0] = 00, making the PC a word address. Readings from PC[1:0] always return 00b. The PC reset value points to the IMEM.IROM base address: 0x80000. |

## 45.5.18 Start Command Register (CC_CMD)

### 45.5.18.1 Offset

| Register | Offset |
|---|---|
| CC_CMD | 204h |

### 45.5.18.2 Function

Accesses to this register are only allowed in STOP state. Any attempt to write this register in a different CryptoCore state returns a transfer error. Accesses are also not allowed in low power, SR[MDISF]= 1, or if a security violation had occurred, SR[SVF]=1. In the error case, the register write is ignored. In response to the register write, the CryptoCore performs two operations: first, it clears all pipeline state information, and second, it forces an instruction fetch to begin execution at the address programmed into the Program Counter register (CC_PC). Read accesses are terminated with an error.

| CC_CF | 208h |

### 45.5.19.2 Function

This read-only register is mapped to the CryptoCore's Condition Flags. Reads are only allowed in STOP or HALT states. Any attempt to read this register in a different CryptoCore state returns a transfer error. In the error case, the register read returns zeroes.

## 45.5.20 Mode Register (PublicKey) (MDPK)

### 45.5.20.1 Offset

| Register | Offset |
|---|---|
| MDPK | 400h |

### 45.5.20.2 Function

The Mode Register is used to define the public key operation that is being requested. The interpretation of this register is for public key operations (PKHA) only, and is described herein.

The bit assignments for the PKHA_MODE will be different depending on which of the four types of PKHA functions is being called. The four function types are: 1) Clear Memory, 2) Modular Arithmetic, 3) Elliptic Curve, and 4) Copy Memory. Detailed descriptions of their mode formats can be found in Table PKHA MODE: clear memory function, Table PKHA MODE: Arithmetic Functions, Table PKHA MODE: Elliptic Curve Functions, and Table PKHA MODE: copy memory functions.

## 45.5.35 Clock Linear Feedback Shift Register (CKLFSR)

### 45.5.35.1 Offset

| Register | Offset |
|---|---|
| CKLFSR | 608h |

### 45.5.35.2 Function

The Clock Linear Feedback Shift register provides access to a 32-bit LFSR used to add jitter to the PKHA clock signal. Initially software must write a 32-bit non-zero value random number into this register before using it, otherwise the LFSR remains locked at 0. Additionaly software may write a non-zero ramdom number into this register at any timer.

### 45.5.35.3 Diagram

## 45.5.36 PKHA A0 Register (PKA0_0 - PKA0_31)

### 45.5.36.1 Offset

For a = 0 to 31:

| Register | Offset |
|---|---|
| PKA0_a | 800h + (a × 4h) |

### 45.5.36.2 Function

The PKHA A0 Register contains a numeric value of up to 128 bytes, right-justified. The LSByte is in the base offset of the register. The PKHA A0 register is 1024 bits in length. Note that PKHA A3, A2, A1 and A0 Registers may be combined to contain a value of up to 4096 bits, with A0 containing the least-significant 128 bytes of this value. The value in the PKHA A0 Register (or {A3, A2, A1, A0}, if used as a single value) is limited by the PKHA A Size Register (PKASZ).

Note that the PKHA Registers can be read/written only when the Mode Register (PublicKey) (MDPK) does not contain a value enabling a PKHA operation. If the MDPK contains a PKHA operation mode value, then writes to PKHA Registers will be ignored, and reads of PKHA Registers will return a value of zero.

## 45.5.47 PKHA N3 Register (PKN3_0 - PKN3_31)

### 45.5.47.1 Offset

For a = 0 to 31:

| Register | Offset |
|---|---|
| PKN3_a | D80h + (a × 4h) |

### 45.5.47.2 Function

The PKHA N3 Register contains a numeric value of up to 128 bytes, right-justified. The LSByte is in the base offset of the register. The PKHA N3 register is 1024 bits in length. Note that PKHA N3, N2, N1 and N0 Registers may be combined to contain a value of up to 4096 bits, with N0 containing the least-significant 128 bytes of this value. The value in the PKHA N3 Register, if used as a separate value, is limited by the PKHA N Size Register (PKNSZ).

Note that the PKHA Registers can be read/written only when the Mode Register (PublicKey) (MDPK) does not contain a value enabling a PKHA operation. If the MDPK contains a PKHA operation mode value, then writes to PKHA Registers will be ignored, and reads of PKHA Registers will return a value of zero.

### 45.5.47.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | PKHA_N3 | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

## 45.5.48 PKHA E Register (PKE_0 - PKE_127)

### 45.5.48.1 Offset

For a = 0 to 127:

| Register | Offset |
|---|---|
| PKE_a | E00h + (a × 4h) |

### 45.5.48.2 Function

The PKHA E Register contains a numeric value of up to 512 bytes, right-justified. The LSByte is in offset E00h, in the right-most byte. The PKHA E register is 4096 bits in length. The value in the PKHA E Register is limited by the PKHA E Size Register (PKESZ).

Note that the PKHA E Register can be written only when the Mode Register (PublicKey) (MDPK) does not contain a value enabling a PKHA operation. If the MRPK contains a PKHA operation mode value, then writes to the PKHA E Register will be ignored.

### 45.5.48.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | | | | | | | | | | | | | | | | |
| W | PKHA_E | | | | | | | | | | | | | | | |

## 45.6 Functional description

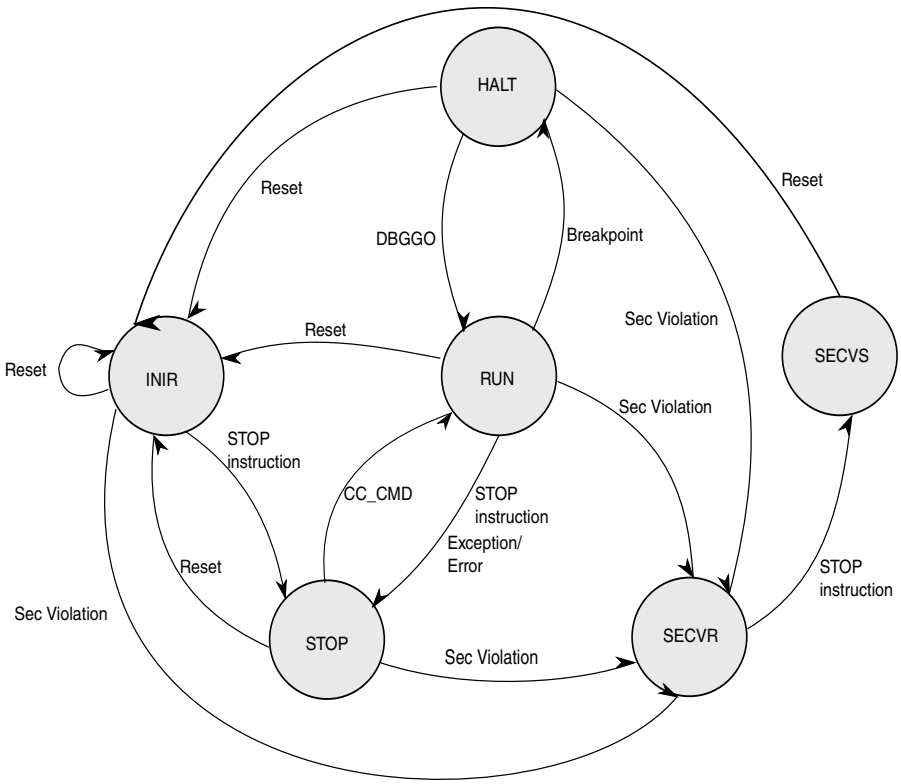
This section describes the programming model and operation of the CAU3 cryptographic core.

### 45.6.1 CryptoCore States

The CAU3 CryptoCore comes out of reset in the initialization run state (INIR). In this state it executes the initialization routine which initializes the DMEM.DRAM and the register file CC_Rn. TKCS='0000' indicates the INIR state. Once the CCore have transitioned to the STOP state indicated by TKCS='1001' it is ready to be programmed. After configuring all host interface (HIRC) registers and CryptoCore registers, a cryptographic routine is executed with a write to the CryptoCore Command (CC_CMD) register. At this point the CryptoCore transitions to the RUN state which blocks several HIRC registers from host CPU accesses. In RUN state the semaphore cannot be changed, from locked to unlocked and vice-versa. The CCore may then transition to STOP or HALT states: STOP state is reached when a STOP instruction is executed and HALT state is reached when a debug breakpoint occurs. In STOP or HALT states the access to HIRC registers are allowed and the semaphore can be locked and unlocked. The transition to HALT state is only allowed if the CryptoCore debug mode is enabled by the DBGCSR[DDBG] bit.

The figure below describes the CryptoCore states transitions.

**Figure 45-4. CryptoCore State Transition**



In case of a security violation, independent of the CCore state, it transitions to the security violation run state, SECVR, and after executing a special task stored in the IMEM.IROM it transitions to the security violation stop state, SECVS, staying at this state until a reset occurs, when it transitions to the INIR state. A hardware reset always re-initializes the CCore at INIR state. See specific section for use cases of the module reset CR[MRST].

## 45.6.2 Memory Map

The CAU3 is fully configured and programmed through the IPS interface. It provides access to the module registers within the range from (Base addr + 0x0) up to (Base addr + 0x1000). The CryptoCore resources directly accessed from the IPS interface are the configuration, debug, Register File and control/status registers. The CAU3 memory modules, IRAM, IROM and DRAM are accessed in an indirect manner, using the DBGMADR register.

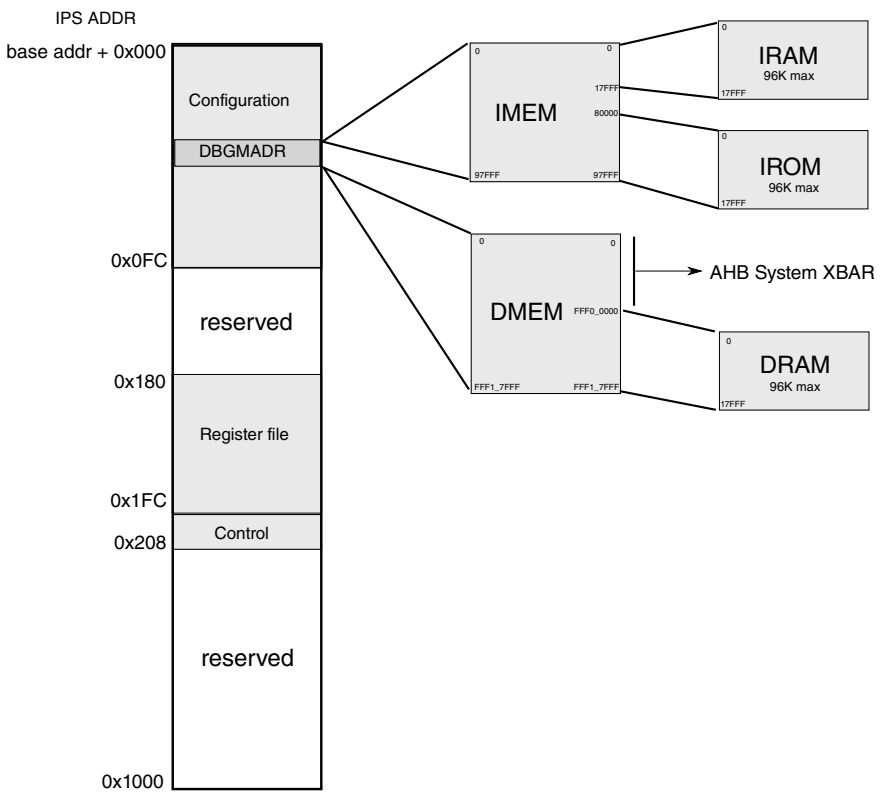
The DBGMADR is a 32-bit register that provides the address for the IMEM and DMEM memory regions. The selection of the target memory module from the IPS address bus is done by the Debug Memory Command Register (DBGMCMD). Before the access to the

memory is executed, the host programs the DBGMADR with the memory address. The DBGMADR is automatically incremented by the hardware after each access, if DBGMCMD[IA] bit is set, providing sequential addresses and allowing the programming of a contiguous memory region without the need for address reconfiguration in the DBGMADR register.

The physical memory modules in the IMEM address range are the IRAM and IROM. The DMEM address range is translated into the DRAM and AHB addresses.

The figure below depicts the address translation from the IPS address bus to the IRAM, IROM, DRAM and AHB addresses.

**Figure 45-5. IPS to physical memory address mapping**



## 45.6.3 Access to Cryptographic Routines

The CAU3 cryptographic routines are stored in the private IMEM. In order to execute those routines the host application software writes to the Program Counter (PC) register with the value corresponding to one element of a table stored at the beginning of the IMEM. The table elements are pointers to routines also stored in the IMEM. After that

the CMD register is written which causes the CryptoCore to start fetching instructions from the IMEM at the address specified by PC. Once initiated, the cryptographic routine runs until a STOP instruction is reached or until an exception occurs. See Handling Exceptions for details. The CryptoCore remains stopped allowing the host application software to access the results generated by the executed routine. These results are stored in the CryptoCore General Purpose Registers File (RGF). The process repeats with a new PC and CMD registers writes. The CryptoCore RGF is also initialized by the host application software before the cryptographic routine is executed.

### 45.6.4 Integrity checks

If an IPS access to a nonexistent memory location is attempted, the IPS bus cycle is terminated with a transfer error and no access is performed.

In case an illegal instruction is executed by the CryptoCore an error flag is set and the program execution is halted and the core transition to the STOP state. An illegal instruction is also provided in the CAU3 instruction set in order to allow the host application software to check if the illegal instruction behavior is correct.

IPS accesses are not allowed when a cryptographic routine is being executed. If a routine is being executed and an IPS access is attempted, the access is ignored and a termination error is indicated. This is to prevent security violations by the host application software when trying to access intermediary results stored in the CryptoCore registers.

The CAU3 provides a hardware semaphore to allow a master with locked semaphore to gain exclusive control of several CryptoCore registers. When the semaphore is locked, any attempt from another master, other than the one with matching master number (MSTRN), DID and with equal or higher privilege attributes, NS and PR, to access the CryptoCore semaphore protected registers is blocked and signaled with a transfer error. See Semaphore Operation for details.

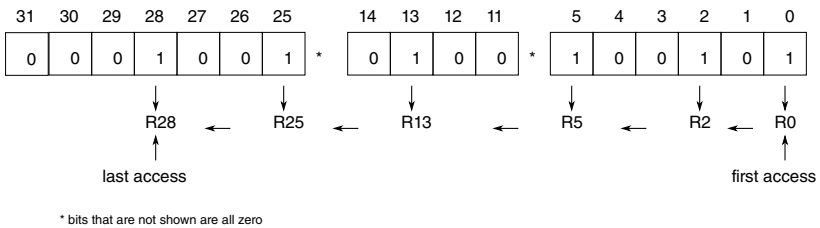
### 45.6.5 DMA and Address Remapping

The CAU3 implements a register address remapping in order to streamline the programming of the CryptoCore General Purpose Registers (CC_Rn). If the Address Remap Register (ARR) content is non-zero, accesses to CC_Rn address space, from 180h to 1FCh, are remapped to the CC_Rn pointed by ARR. After the access is done, the content of ARR is automatically modified by the CAU3 hardware in order to point to the next CC_Rn for the subsequent access. The remapping is done while ARR is non-zero.

Each ARR bit corresponds to one of the 32 CC_Rn registers. The least significant ARR bit , ARR[0], maps to the CC_R0. ARR[1] maps to CC_R1 and so forth. If ARR[0] = 1 then accessing any CC_Rn register will cause the access to be redirected to CC_R0 register. After the access is done, ARR[0] is cleared. If there is at least one non-zero bit in ARR, then the next access to CC_Rn is also remapped. The criteria for ARR bit selection is from the least to the most significant non-zero bit. If all ARR bits are zero then there is no address remapping and the IPS address is used to access the CC_Rn register.

The figure below describes the use of ARR remapping .

**Figure 45-6. ARR to CC_Rn Remapping**



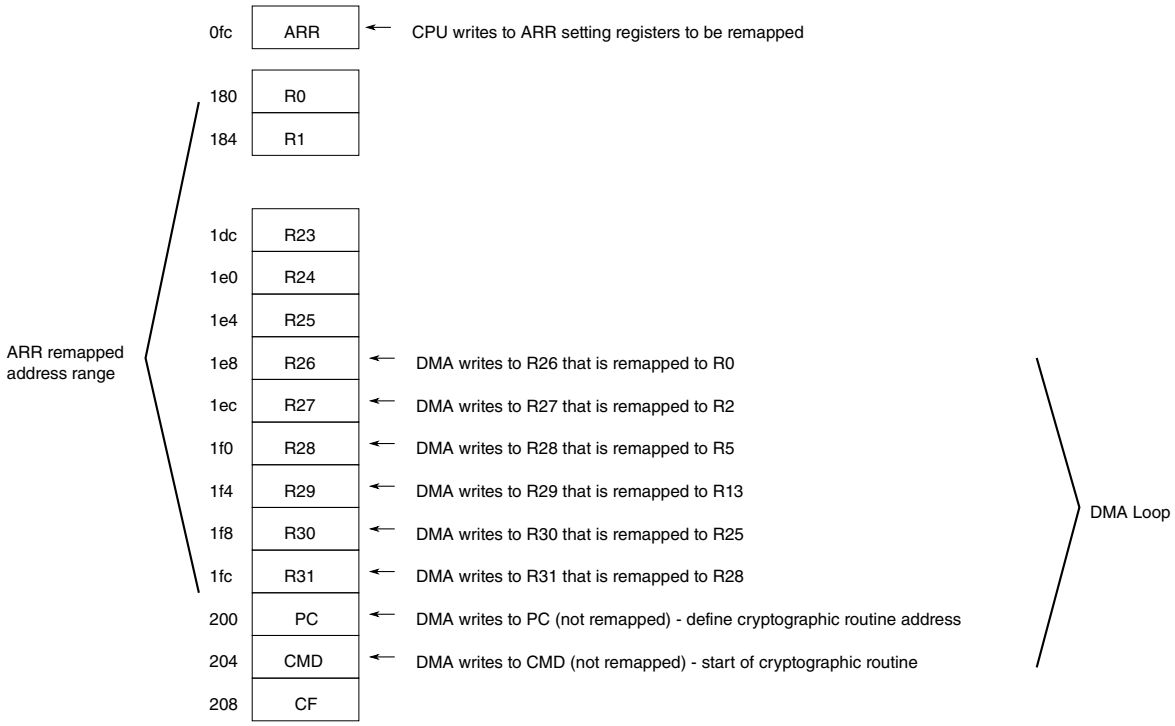
Consider the case where 6 register arguments must be written to the CryptoCore before beginning task execution. The host writes the bit map of the affected CC_Rn values into the ARR. Next, a sequential data transfer can be performed writing the appropriate register values into the CC_Rn registers using a starting offset address defined as 200h - 4*n, where n is the number of argument registers to be written.

If n = 6, then the starting offset address is 1E8h. The first writes at offset address {1E8h, 1ECh, 1F0h, 1F4h, 1F8h, 1FCh} are remapped to the appropriate CC_Rn registers based on the ARR.

The sequential CC_Rn programming allowed by using the ARR remapping is convenient for DMA transfers. After the CC_Rn registers are programmed the ARR content should be zero. The DMA then writes to the PC register defining the address of the selected cryptographic routine in the branch table to be executed and then writes to the CMD register to initiate the execution of the cryptographic routine.

The figure below describes an use case which considers the ARR programming of the previous figure.

**Figure 45-7. DMA ARR Use Case**

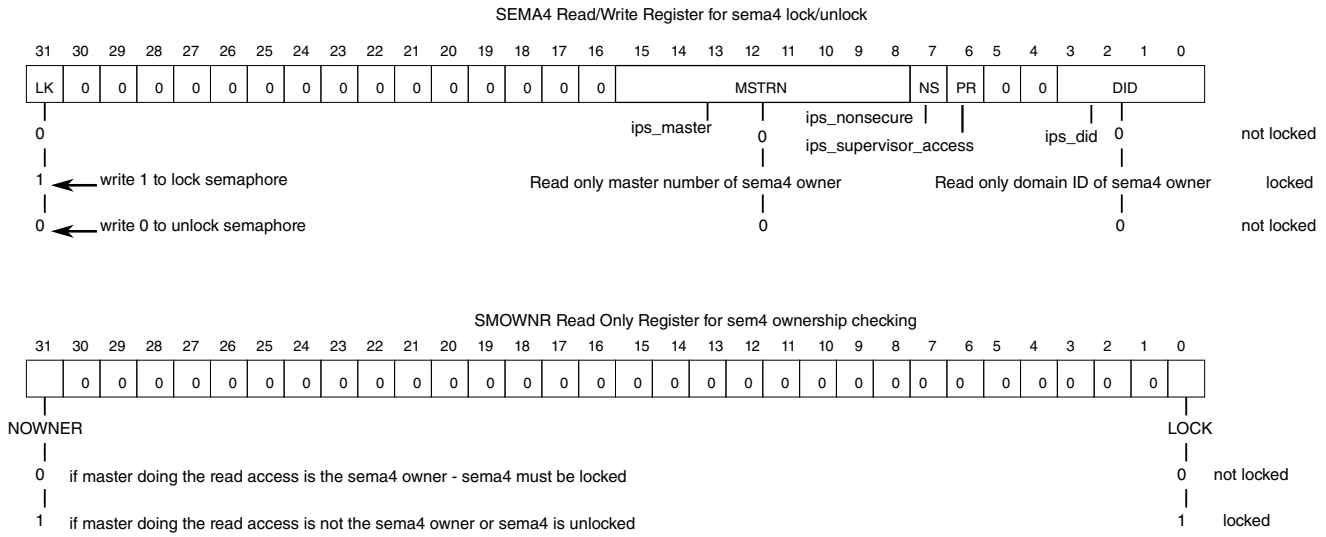


## 45.6.6 Semaphore Operation

The CAU3 module provides a hardware semaphore that allows multiple host processors or associated bus mastering modules, for example, a DMA, to take ownership of shared CAU3 resources. After locking the semaphore, by writing 1 to the SEMA4[LK] lock bit, the master host becomes the semaphore owner and then can access several CAU3 resources privately, meaning that, only host interface accesses with matching Master Number (MSTRN), Domain ID (DID) and with same or higher privilege as defined by the privilege and secure attribute signals NS and PR, compared to the semaphore register (SEMA4) fields, are allowed to access the semaphore protected registers. See section Access to Memory Mapped Registers for details about registers protected by semaphore.

Attempted accesses to the protected registers from any master other than the semaphore owner are terminated with an error. In order to release the semaphore, the semaphore owner master writes 0 to the SEMA4[LK] bit.

**Figure 45-8. Semaphore Operation**



The read data on the SMOWNR register returns the semaphore state with 3 distinct values, allowing an easy single conditional branch resolution:

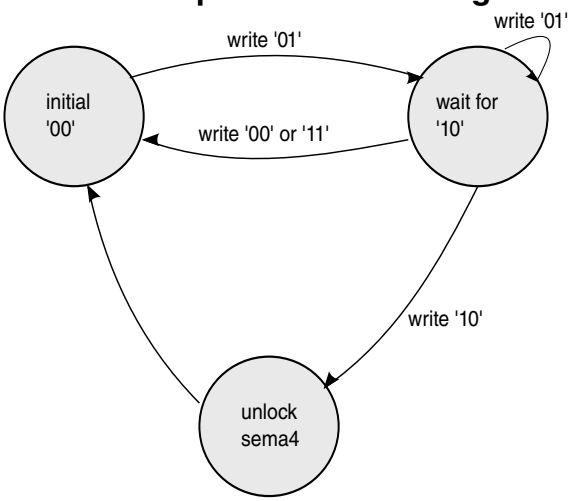
```
If (SMOWNR == 0x8000_0000) then
      semaphore is unlocked
else if (SMOWNR == 1) then
      semaphore is locked and master is the owner
else if (SMOWNR == 0x8000_0001) then
      semaphore is locked and master is not the owner
```

A master is considered the owner of a locked semaphore if the access attributes, MSTRN and DID, match with the SEMA4 register fields and the privilege/secure attributes, NS and PR, are the same or higher than the values stored in the SEMA4 register. See Privilege and Secure attributes precedence below for details.

A locked semaphore can be unlocked by the semaphore owner or by any other master using the CR[RSTSM4] bit, provided it has secure and privilege access attributes and the CryptoCore is in Stop state. In general the semaphore state can only be changed in Stop

state. The figure below describes a state machine based on CR[RSTSM4] values. It is initially in the '00' state. A write '01' moves the state to "wait for 10". Once in this state if '10' is written the "unlock sema4" state is reached and the semaphore is unlocked.

**Figure 45-9. Semaphore unlock using RSTSM4**



The Master and DID IPS sideband signals are also used for mastering of CAU3 AHB accesses. If the semaphore is locked, the Master Number and DID of the locked semaphore are used in the CAU3 AHB accesses. If the semaphore is not locked, the Master and DID of the IPS access of the Start Command (CC_CMD) register are used in the AHB accesses executed during the task execution.

### Semaphore operation and debug control signals

The DBGCSR[DDBG] and DBGCSR[DDBGMC] debug bits control the semaphore behavior:

- {DDBG,DDBGMC} = '00': semaphore is disabled
- {DDBG,DDBGMC} != '00': semaphore is enabled

### Privilege and Secure attributes precedence

The *Privileged* and *Nonsecure* attributes, PR and NS sideband signals of the IPS bus, define the privilege level of the master on accessing peripheral registers. From the highest to the lowest priority level the access privileges defined by {PR,NS} are as follows:

- PrivSecure (10) > PrivNonsecure (11) > UserSecure (00) > UserNonsecure (01)

## 45.6.7 Debug Resources

The CAU3 CryptoCore implements debug features to help the development of cryptographic routines. The debug features are:

- Breakpoint at a defined instruction address
- Code execution in step mode
- Resume program execution from breakpoint

There are two types of breakpoints: the hardware breakpoint using the Debug PC Breakpoint (DBGPBR) and the software breakpoint implemented by the HALT instruction.

### Hardware Breakpoint

Assuming the debug resources are enabled by DBGCSR[DDBG]=0, after the hardware breakpoint is enabled by DBGCSR[PBREN]=1, if the Program Counter (PC) matches the DBGPBR[PCBKPT] field, the program execution is halted before the instruction of the matching PC is executed. The program execution is resumed by setting the DBGCSR[DBGGO] bit. If the DBGCSR[SIM] bit is set, the next instruction is executed and the CryptoCore enters halt state again, implementing a step by step execution. If SIM is cleared and DBGGO is set, the program execution is resumed until the next breakpoint or a STOP instruction is executed.

### Software Breakpoint

The software breakpoint is implemented by replacing a regular instruction by the HALT instruction. After reaching a HALT instruction the program execution is halted and the program variables can be inspected or modified. After that the debug software replaces the HALT instruction with the actual instruction and resumes the program execution by setting the DBGCSR[DBGGO] bit. The instruction that replaced the HALT instruction is the first instruction to be executed after DBGGO is set. Note that if DBGGO is set and the HALT instruction is not replaced by any other instruction, the CryptoCore does not exit the breakpoint trap and remains at the same breakpoint address. The debug resources need to be enabled by DBGCSR[DDBG]=0. If a HALT instruction is reached and the DBGCSR[DDBG]=1, the HALT instruction is executed as an invalid instruction.

Once reaching a breakpoint the software has access to the CC_Rn registers, IMEM and DMEM through the IPS bus interface. Accesses to these resources while the CryptoCore is running are not allowed and return no valid data for IPS reads. Write accesses are not executed. In both cases a transfer error is issued.

In debug mode, if the CryptoCore is halted, the IMEM and DMEM can be accessed using the DBGMDR, DBGMCMD and DBGADR registers. If DBGCSR[DDBG] is set or if the CryptoCore is running, any attempt to access the IMEM and DMEM is blocked and the access is terminated with an error. The private memories content are not modified.

There are three status flags in the DBGCSR register that indicate the CryptoCore halt condition. The core could be halted due to a hardware breakpoint, HALT instruction or single step. In case there is more than one reason for halt, only one of the following flags are set at a time, highest priority on top:

1. SIMHF, single step
2. HLTIF, HALT instruction
3. PCBHF, hardware breakpoint

### 45.6.8 Virtual External Registers

SoC devices with the CAU3 include a 256-bit secret key as an input to the accelerator core. The 256-bit input vector can be treated as two separate 128-bit keys or a single 256-bit key. These inputs can be used as a Key Encryption Key (KEK) for unwrapping user-defined key blobs containing additional keys, or they can be used for encryption and decryption operations directly.

Regardless of the intended use case(s), care must be taken in the management of these SoC input keys. Note there can be various implementations at the SoC level for storing the KEK values. For example, they might be stored in the flash IFR, or implemented in eFuses, etc. In any case, the 256 bits of input key information is routed to the CAU3 over direct point-to-point connections. This input vector must not be generally accessible in any user-accessible programming model or on-chip memory.

Within the CAU3, the handling of the SoC input key(s) is made via the definition of an alternate read-only external (as viewed from the CryptoCore) “virtual” registers. This read-only external register space is only accessible via the MVXTR (MoVe eXternal To Register) instruction. This virtual register space includes the 256 bits of SoC input key as well as specific HIRC programming model registers to provide information on CAU3 configuration, control and status.

The memory map for this virtual read-only register space is defined as:

| RegID | Register |
|---|---|
| 0 | Processor Core Type (PCT) |
| 1 | Memory Configuration (MCFG) |
| 2 | Control Register (CR) |
| 3 | Status Register (SR) |
| 4 | RAZ, RFU |
| 5 | RAZ, RFU |
| 6 | RAZ, RFU |
| 7 | RAZ, RFU |

*Table continues on the next page...*

| RegID | Register |
|---|---|
| 8 | key0_w0 in BE format, i.e., byte-reversed input0[ 31: 0] |
| 9 | key0_w1 in BE format, i.e., byte-reversed input0[ 63: 32] |
| 10 | key0_w2 in BE format, i.e., byte-reversed input0[ 95: 64] |
| 11 | key0_w3 in BE format, i.e., byte-reversed input0[127: 96] |
| 12 | key1_w0 in BE format, i.e., byte-reversed input1[ 31: 0] |
| 13 | key1_w1 in BE format, i.e., byte-reversed input1[ 63: 32] |
| 14 | key1_w2 in BE format, i.e., byte-reversed input1[ 95: 64] |
| 15 | key1_w3 in BE format, i.e., byte-reversed input1[127: 96] |

It should be noted that the SoC key inputs are defined as a 16- or 32-element little-endian byte array. As a result, the logical mapping of the byte array to the input vectors is defined as:

| |
|---|
| soc_input_key0[ 31: 0] = key0_w0 = {k0[ 3], k0[ 2], k0[ 1], k0[ 0]} |
| soc_input_key0[ 63: 32] = key0_w1 = {k0[ 7], k0[ 6], k0[ 5], k0[ 4]} |
| soc_input_key0[ 95: 64] = key0_w2 = {k0[11], k0[10], k0[ 9], k0[ 8]} |
| soc_input_key0[127: 96] = key0_w3 = {k0[15], k0[14], k0[13], k0[12]} |

The second 128 bits of input key can be viewed as either a continuation of the k0 byte array or as a second key (k1) byte array:

| |
|---|
| soc_input_key1[ 31: 0] = key0_w4 = {k0[19], k0[18], k0[17], k0[16]} |
| soc_input_key1[ 63: 32] = key0_w5 = {k0[23], k0[22], k0[21], k0[20]} |
| soc_input_key1[ 95: 64] = key0_w6 = {k0[27], k0[26], k0[25], k0[24]} |
| soc_input_key1[127: 96] = key0_w7 = {k0[31], k0[30], k0[29], k0[28]} |

Or

| |
|---|
| soc_input_key1[ 31: 0] = key1_w0 = {k1[ 3], k1[ 2], k1[ 1], k1[ 0]} |
| soc_input_key1[ 63: 32] = key1_w1 = {k1[ 7], k1[ 6], k1[ 5], k1[ 4]} |
| soc_input_key1[ 95: 64] = key1_w2 = {k1[11], k1[10], k1[ 9], k1[ 8]} |
| soc_input_key1[127: 96] = key1_w3 = {k1[15], k1[14], k1[13], k1[12]} |

The MVXTR instruction has two operand arguments: the destination RGF register in which the external register content is going to be loaded and the pointer to the external register to select one of the 16 possible inputs.

### 45.6.9 Security Violation

The CAU3 detects and responds to security threats by the assertion of an interrupt request and optionally the assertion of the *cau3_security_violation* output signal. The SoC is responsible for processing the security violation indication and in response generate the appropriate actions in order to protect the system against intruders. In particular the CAU3 receives a *soc_security_violation* input signal that, once asserted, forces the CCore to branch to a *security violation routine* stored in the IMEM.IROM. The execution of this routine clears all data stored in the DMEM.DRAM and CC_Rn registers in order to avoid the intruder to steal information stored in these memory locations.

There are specific events within the CCore that cause the assertion of the *cau3_security_violation* signal:

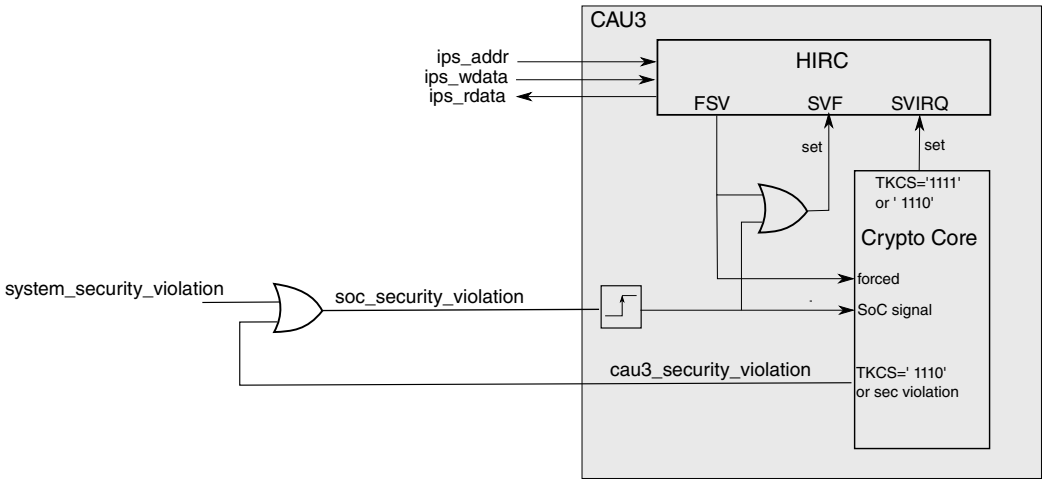
- Attempt to access CAU3 private memories, IMEM.IRAM or DMEM.DRAM, through the registers DBGMCMD, DBGMADR and DBGMDR if {DDBG,DDBGMC} != "00"
- Software setting security violation by executing STOP or STOPI instruction with status = "110"

Once the *cau3_security_violation* output signal is asserted it is up for the SoC logic to respond to this event by asserting the *soc_security_violation* signal.

If CAU3 is executing a task when the *soc_security_violation* signal asserts, it immediately branches to the *security violation routine*. If in STOP state, the CCore initiates the execution of the security routine. An especial case is when CAU3 is in low power mode, controlled by the assertion of CR[MDIS] bit. In this case, the module exits low power and executes the *security violation routine*. After that, it stays in security violation stop state , *SECVS*, out of low power mode, remaining at this state until a hardware reset is issued.

The figure below describes the CAU3 interface with the *soc_security_violation* signal and flag control logic.

**Figure 45-10. Security Violation Hardware Support**



The software can test the security violation logic by setting the *force security violation* control bit, CR[FSV] . In this case the behavior of the CCore is similar to the *SoC security violation* with the exception that a module reset, CR[MRST] can also be used, in addition to the hardware reset, to bring the module to normal mode of operation. If *soc_security_violation* is set, it is not possible to use CR[MRST] to reset the CCore to initialization run state (INIR).

The detection of the *soc_security_violation* signal transitioning to logic 1, or the set of CR[FSV] bit, sets the security violation flag, SR[SVF], immediately. Those events also trigger the execution of the *security violation routine*.

After SR[SVF] is set only accesses to PCT, MCFG, CR and SR registers are allowed. Accesses to other registers return an error.

The execution of any task may assert the *cau3_security_violation* signal and/or the SR[SVIRQ] flag, and consequently an interrupt request. Using the task completion status SR[TKCS]="1111", sets the SR[SVIRQ] flag. The task completion status SR[TKCS]="1110", asserts the *cau3_security_violation* signal and also sets the SR[SVIRQ] flag.

## 45.6.10 Module Reset

The module reset CR[MRST] provides for the application software the capability to reinitialize the CCore, in some circumstances, by forcing the execution of a STOP instruction. A typical scenario that would require the use of a module reset is when a task enters in an infinite loop due to a programming error. This task can then be terminated by CR[MRST], forcing the execution of a STOP instruction.

The MRST does not break any instruction being executed, meaning that, if there is an AHB transaction waiting for an *hready* acknowledgement, this instruction needs to complete, i.e. *hready* is asserted, before the STOP instruction is forced.

MRST is completely asynchronous to the task execution, therefore there is no way to synchronize the forced STOP with any task instruction.

The use of MRST should be possible in any scenario with the exception of the following, in which case setting this bit is ignored by the hardware:

- CCore at security violation run (SECVR) state
- CCore at security violation stop (SECVS) state if *soc_security_violation* was asserted
- CCore is running the initialization routine (INIR)
- CCore is already in STOP state

In all other cases when CR[MRST] is set, a STOP instruction execution is forced and the CCore transitions to STOP state. The task completion status (TKCS) corresponding to the forced STOP is "1001", indicating an error free task completion.

## 45.6.11 Handling Exceptions

This section describes the CAU3 exceptions, such as errors occurred during the execution of a task. It is also described the behavior of the interruptions that signal events to the host CPU.

CAU3 implements two interrupt signals to the host CPU to signal an *error free end of task* and an *end of task with error*. These interruptions are mutually exclusive, meaning that only one of these interrupt signals is asserted by a task and it is done at the end of the task. Also the interruptions do not assert when a task is executing. If enabled, they assert at the end of a task when the CCore is at the STOP state.

The *end of task with error* asserts at the occurrence of the following events:

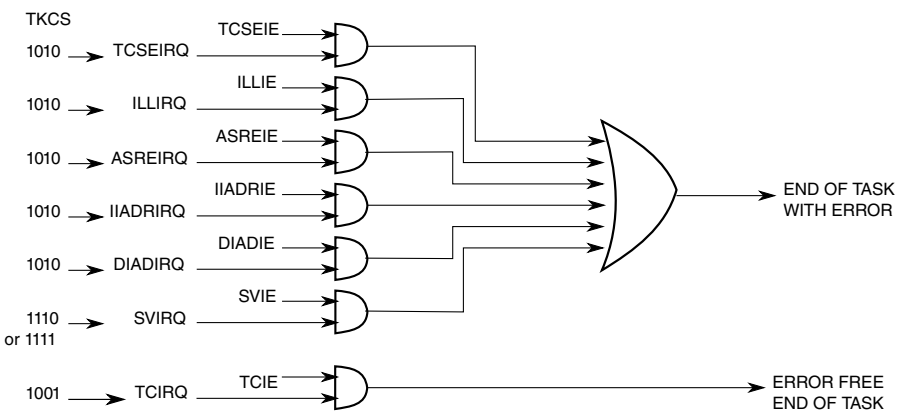
- DMEM illegal address
- IMEM illegal address
- AHB access error
- Execution of an illegal instruction

- Task termination error indicated by SR[TKCS] = "1010"
- Security violation task termination error indicated by SR[TKCS]= "1110" or "1111"

Several flags in the Status Register give the required resolution for the events signaled by the interruptions. The SR[TKCS] field is the main status indication of the most recent executed task and also the current state of the CryptoCore. In addition, there are individual flags to signal each completion status. Each flag controls the interrupt signals assertion. Error indication flags control the *end of task with error*. Task completion with no error flag set controls the *error free end of task* interrupt.

The figure below describes the logic behind the interrupt request signals.

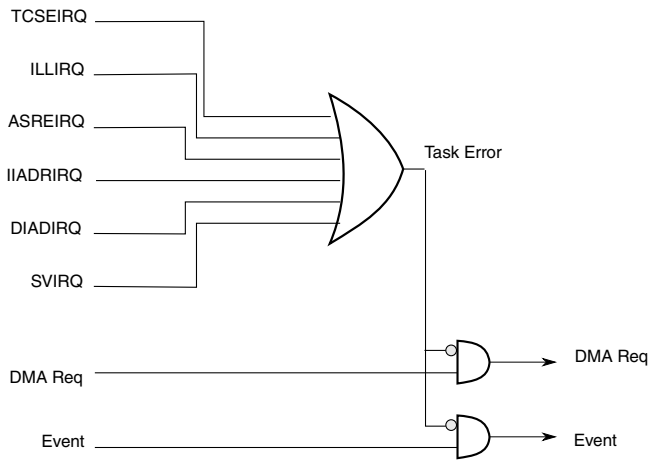
**Figure 45-11. Interrupt request logic**



Note that depending on the completion status, TKCS, the corresponding flag is set and if enabled , the interrupt signal is asserted. Clearing the flag, or flags, causes the interrupt to de-assert. TKCS and flags are independent registers, thus clearing the flags does not clear TKCS.

In case the task completion configuration, TCCFG, selects to signal a task completion by a DMA request (TCCFG='100') or assert the task completion event signal (TCCFG='010') and any error indication flag is set, then neither DMA request nor task completion event signal are asserted. The figure below describes this logic.

**Figure 45-12. DMA request and Task Completion Event signal logic**



### Instructions accessing illegal DMEM addresses

If a Load/Store instruction accesses an illegal DMEM address, the instruction is not executed and the task is terminated with an error. Also SR[DIADIRQ] flag is set.

## 45.6.12 Access to Memory Mapped Registers

This section describes the restrictions when accessing CAU3 memory mapped registers considering CryptoCore mode (debug enabled or not), access attributes and semaphore state. Also the state of the core (initialization run, running, stop, halted and security violation) is considered for the accesses as well as the low power mode.

The DBGCSR[DDBG] and DBGCSR[DDBGMC] debug bits define if the semaphore is enabled or disabled:

- {DDBG,DDBGMC} = '00': semaphore is disabled
- {DDBG,DDBGMC} != '00': semaphore is enabled

In the table below the access restriction is defined for all registers. The following convention is used:

- PS: requires PrivSec attributes- fail to comply with this requirement generates an error for reads and writes . Read accesses return zeroed data
- Y: access is allowed

- Yw: access is allowed only for the semaphore owner- fail to comply with this requirement generates an error for reads and writes . Read accesses return zeroed data
- Y(ro): access is allowed for read only - writes generate an error

**NOTE**

Y(ro) is used to identify read/write registers that become read only in specific scenarios. Please check the register definition section for information about registers access types for all registers.

- N: access is blocked - reads and writes generate an error

**Table 45-1. Semaphore and register access restrictions**

| Register | Attrib | Semaphore state | | | | CryptoCore State | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| name | Access mode | disabled unlocked | disabled locked | enabled unlocked | enabled locked | RUN[1] | STOP | HALT | LP | SEC VIOL |
| PCT | PS | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| MCFG | PS | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| CR | PS | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| SR | - | Y | Y | Y | Y | Y | Y | Y | Y(ro)[2] | Y |
| SEMA4 | - | Y | Y | Y | Yw[3] | N | Y | N | N | N |
| SMOWNR | - | Y | Y | Y | Y | Y | Y | Y | N | N |
| ARR | - | Y | Yw | N | Yw | N | Y | Y | N | N |
| CC_Rn | - | Y | Yw | N | Yw | N | Y | Y | N | N |
| CC_PC | - | Y | Yw | N | Yw | N | Y | Y | N | N |
| CC_CMD | - | Y | Yw | N | Yw | N | Y | N | N | N |
| CC_CF | - | Y | Yw | N | Yw | N | Y | Y | N | N |
| DBGCSR[4] | PS | Y | Y | Y | Y | Y | Y | Y | N | N |
| DBGPBR[5] | PS | Y | Y | Y | Y | N | Y | Y | N | N |
| DBGMCMD | PS | Y | Y | N | N | N | Y | Y | N | N |
| DBGMADR | PS | Y | Y | N | N | N | Y | Y | N | N |
| DBGMDR | PS | Y | Y | N | N | N | Y | Y | N | N |

1. **Initialization RUN is also included.**
2. This register is read/write and becomes read only in low power mode.
3. Writes by non owners do not generate errors, but have no effect. Reads return zeros if the master has no PS attribute, otherwise return correct register data.
4. DBGCSR is not accessible if DBGCSR[DDBG]=1, in Initialization and security violation RUN states.
5. DBGPBR is not accessible if DBGCSR[DDBG]=1.

In order to evaluate if a register is accessible in a particular semaphore configuration and CryptoCore state, it is required to extract the previous table row elements for the desired register inferring an AND operation between the semaphore and CryptoCore state elements. Consider the following equations to determine the register access allowances:

```
Y AND Y = Y (register is accessible)
Y AND Yw = Yw (register is accessible only by the semaphore owner)
Y AND N = N (register is not accessible)
Yw AND N = N (register is not accessible)
```

The Privilege Secure attributes are extracted from column 2. Below there is an example for the ARR register with the semaphore enabled and locked and the CryptoCore at STOP state:

```
ARR_access_permission = Yw AND Y (no PrivSec attributes required) = Yw
```

In this case ARR can be accessed by the semaphore owner only (more restrictive) and no privilege secure attributes are required.

Below there is an example for the DBGPBR with semaphore disabled and unlocked and CryptoCore at RUN state:

```
DBGPBR_access_permission = Y AND N (PrivSec attributes required) = N
```

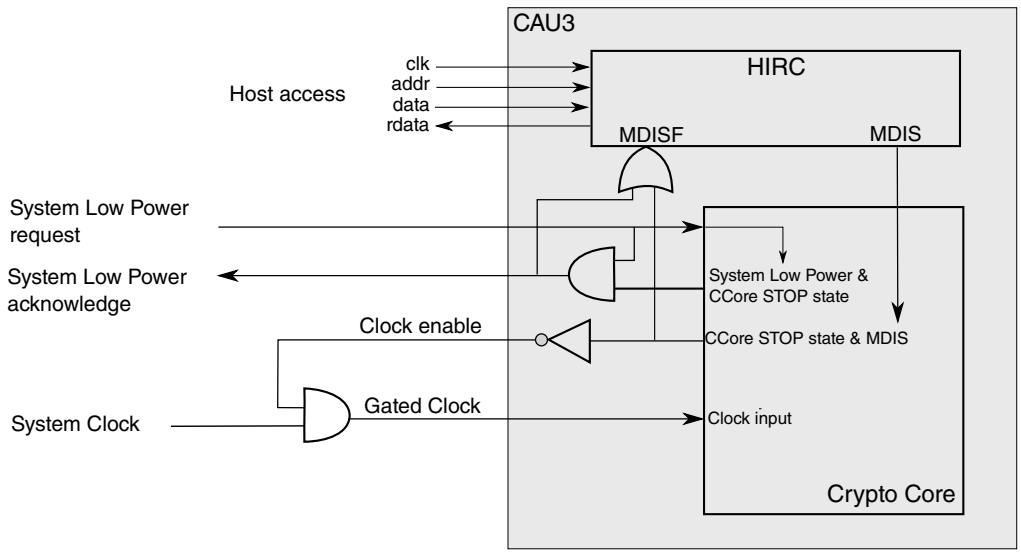
In this case DBGPBR is not accessible since it is blocked by the CryptoCore RUN state.

## 45.6.13 Low Power Operation

The CAU3's low power strategy is based on clock gating. In general, the internal clock to several registers is gated off if the register is not being updated at a specific clock cycle. The clock gating logic evaluates opportunities for gating off the clock on each clock cycle for each individual register. This strategy reduces the dynamic power but is not efficient if the entire module is not being used. In this case the clock for the whole

module should be gated off. This functionality is controlled by the CR[MDIS] bit. Once set, this bit turns the CryptoCore clock off and consequently blocks any activity in the module. The figure below describes the CAU3 clock gating control logic.

**Figure 45-13. Clock gating control logic**



**NOTE**

It is recommended to set the CR[MDIS] bit when the CryptoCore is already at STOP state, even though it would be possible to set it at any state. This procedure would avoid race conditions in the signals controlling the clock gating logic

Once set, the CR[MDIS] bit allows the CryptoCore clock to be gated off if the CryptoCore is at STOP state. At any other state the clock remains active until the STOP state is reached.

There is a second mechanism to turn the CryptoCore clock off which is the *system low power request*. This signal indicates an SoC request for the CryptoCore to enter the low power mode. If the CryptoCore is at STOP state the *system low power acknowledge* signal is asserted and the system clock is allowed to be gated off. Note that the CAU3 clock enable signal is not used in this process. When *system low power acknowledge* signal is asserted the clock enable signal is don't care.

**NOTE**

The system clock gating logic details are not described in the figure above. This logic is implemented at the SoC level.

The SR[MDISF], module disable flag, indicates that the CAU3 is at low power mode. This flag is set if the low power mode was entered by setting the CR[MDIS] bit or by the *system low power request* signal. In order to distinguish between the *system low power*

*mode* and MDIS low power mode, the CR[MDIS] should be considered. If CR[MDIS] is cleared and SR[MDISF] is set then CAU3 is in *system low power mode*. If CR[MDIS] and SR[MDISF] are both set, then CAU3 is in MDIS low power mode, but could also be in *system low power mode* at the same time.

In order to exit MDIS low power mode this bit should be cleared. The clock to CAU3 should be re-stored immediately after CR[MDIS]=0, assuming *system low power request* and *acknowledge* signals are not asserted. In case these signals are asserted the low power mode is under control by the SoC logic.

If a task is already running and the Host CPU software wants to set CAU3 CryptoCore in low power mode, then firstly the task needs to be terminated by a software reset, CR[MRST] = 1, and then the low power mode is enabled by setting CR[MDIS]=1. Since these two bits are in the CR register, they can be set at the same time.

**NOTE**

CAU3 does not enter low power mode if it is stopped with security violation flag set, CS[SVF]=1.

In order to avoid inconsistencies with DMA and Interrupt request signals, the interrupt and DMA request are de-asserted when CAU3 enters low power mode, either by CR[MDIS] =1 or by a system low power request signal assertion.

## 45.7 Public-key hardware accelerator (PKHA) functionality

The PKHA module is capable of performing a number of different operations used in public-key cryptography, including modular arithmetic functions such as addition, subtraction, multiplication, exponentiation, reduction, and inversion. All of these functions are provided in both integer and polynomial-binary field versions, except modular subtraction, which is the same as addition for binary polynomials. There are also elliptic-curve functions for point addition, point doubling, and point multiplication the standard prime and binary curves. Most of these functions can be performed timing-equalized to thwart timing-related side-channel attacks. PKHA also includes a Miller-Rabin primality test function for detecting prime numbers.

The PKHA internally performs modular multiply operations using "Montgomery multiplication". For efficiency, many of these functions have a variant which allows either inputs or outputs in Montgomery form. Some have variants to supply the Montgomery conversion factor. These save time over the variations without. Internally, the PKHA operates on digits of these values. Different versions of the PKHA may have a different digit size. This PKHA has a digit size of 16 bits. This has implications for the inputs and outputs of certain functions. See the discussion on Montgomery arithmetic.

Because the numbers used in public-key cryptography are typically quite large and often referenced many times during a function, the inputs to PKHA are loaded into registers. PKHA has four of these labeled A, B, E, and N. A and B are for operands and results. E is for "keys", and N holds the modulus. For ECC functions, A and B are divided up into equal-size quadrants to accommodate the greater number of inputs required.

PKHA also has two other types of functions for manipulating the data in the registers. These are the Clear Memory and Copy Memory functions. The Clear Memory function allows all or any combination of the registers to be overwritten with zeros. The Copy Memory functions can be used to copy data from any of the A, B or N registers or register quadrant to any register A, B, E or N.

PKHA requires that all data for a given function be loaded before the Mode Register is written to invoke a function. This convention indicates to PKHA that all needed data has been loaded, and the function can now be launched. The required data includes:

- PKHA A, B, E and N registers, as required per the function to be executed.
- PKHA A Size, PKHA B Size, PKHA E Size and PKHA N Size, as required.

Note that the PKHA A, B, E and N registers can be accessed only when the Mode Register is not programmed to any PKHA operation. Once the Mode Register contains any PKHA operation value, writes to the PKHA registers will be ignored, and reads will return zero data. After the PKHA operation is complete, the results can be read from the PKHA registers only after the Mode Register is cleared.

### 45.7.1 Modular math

Almost all math operations require with a modulus value in the N Memory. Math operations involving multiplication (multiplication, exponentiation, prime test, and ECC functions) are performed internally using Montgomery values.

### 45.7.2 About Montgomery values

The PKHA contains a Modular Arithmetic Unit. Multiplication is always modular multiplication:

$A * B \bmod N$.

The PKHA performs this computation with a Montgomery multiplier. A Montgomery multiplier can be more efficient than a multiply-then-reduce calculation because the modular reduction is done as part of the multiplication and the working product never gets larger than the modulus. In a normal multiplication, the product, before reduction, would be the size of the sum of the factors, so usually twice the size of the modulus. The

factors in a Montgomery multiplication each have an R factor, and, as part of the multiplication and modular reduction, one R is removed. Thus, the computation performed is:

*(AR * BR) / R* mod *N*.

The equivalent of "division by *R*" occurs even if one of the inputs does not have an *R* factor.

A number of PKHA functions accept inputs in Montgomery form instead of normal values. Some instead take $R^2$ mod *N* as an input. These functions can be faster than their normal-value alternatives if several operations are performed in a row or if these values are known in advance. This is because, before being used, ($R^2$ mod *N* needs to be computed and) normal values need to be converted internally to Montgomery form.

The Montgomery form of a value is *value*R* mod *N*, referred to here as $\underline{value}$. The term $R = 2^{SD}$ is the Montgomery factor, where D is the digit size (of a digit in the PKHA arithmetic unit), in bits, and S is the minimum number of digits needed to hold the value in N. R is therefore dependent on N and D.

To use the PKHA to convert a normal value to a Montgomery value, one must first compute (or know) $R^2$ mod *N*, the Montgomery Conversion Factor. The following steps can be used to convert a value from a normal value into its Montgomery form (A and B inputs may be reversed):

$R^2$ = MOD_R2(*N*)

$\underline{A}$ = MOD_MUL_IM_OM(*A*, B=$R^2$, *N*)

The equivalent F2M function can be used for binary polynomial values.

Eventually, the value needs to be converted out of Montgomery form. This can be done by performing another multiply ($R^2$ is not needed for this).

```
A = MOD_MUL_IM_OM(A=A, B=1, N)
```

Another method is to cause the PKHA to perform a multiplication and conversion to normal form. Internally, there are two multiplications: first the two inputs, then the product by one.

```
AB mod N = MOD_MUL_IM(A=A, B=B, N)
```

A third method is to have just one factor (either one) in Montgomery form:

```
AB mod N = MOD_MUL_IM_OM(A=A, B=B, N)
```

The following operations can be used to convert a value from a normal value into its Montgomery form (A and B inputs may be reversed):

The equivalent F2M functions can be used for binary polynomial values.

It is possible to add and subtract Montgomery values, if *R* mod *N* is the same. Do not mix and match Montgomery and normal values for addition or subtraction. 5 + 3R => *5/R + 3R* or *5/R + 3*; neither is likely the desired result.

## 45.7.3 Non-modular Math

Although addition, subtraction, and multiplication functions require a modulus, it is possible to perform these calculations without any reduction: the modulus must be larger than the expected result.

For addition and subtraction, this is easily done. For multiplication, the MOD_MUL function may be used, but it is not the most efficient, as internally first $R^2$ mod N will be computed, then two multiplications will be performed (first to convert one factor into Montgomery, then to compute the product, not in Montgomery).

For non-modular multiplication, MUL_IM_OM is much more efficient, as only one multiplication will be performed. This can be used if the factors are not in Montgomery form, i.e., if the product to be calculated is *A*B* instead of *A*B mod N*. Since the multiplier always "divides by *R*', a special modulus value in Nram is required which will make *R* have the value 1. This is done by creating a modulus *N = R-1* so that *R mod N* will have the value one. This way, normal values are the same as Montgomery values; no conversion is necessary and the multiplier will quietly "divide by one" to no effect.

As an example, on a PKHA with a digit size of 32 bits and a product which will be no more than six bytes long, $R = 2^{SD} = 2^{2*32} = 2^{64}$. Therefore the modulus must be 0xFFFFFFFFFFFFFFFF.

For computation with binary polynomials, the equivalent F2M functions may be used.

## 45.7.4 Elliptic-Curve Math

The PKHA provides point math operations on different types of elliptic curves. These include the ability to add two points (+ operator), double a point, and multiply a point by an integer (scalar) value (x operator).

The input points are assumed to be valid points on the curve. If non-point coordinates or invalid curve parameters are used an input, then a non-point set of coordinates are likely to be returned as output.

The minimum modulus is 1 byte. The maximum modulus is 1024 bits, 128 in length, or one quadrant.

If xx is the Point at Infinity, *P*and *Q* are points on the curve, and *j* and *k* are integers, then the following identities, as well as others easily derived by taking advantage of associative and commutive properites, hold:

- $P + Q = Q + P$
- $P = xx + P$
- $xx = 0 \times P$
- $(j + k)P = (j \times P) + (k \times P)$

There may be times when the negative of a point is necessary:

- When subtracting points $P_A - P_B$
- When multiplying by a negative integer: -abs(k) x $P_A$

To subtract, one can negate the second term and perform an addition, i.e.

$P_C = P_A - P_B = P_A + (-P_B)$

When multiplying by a negative value, one can either negate the starting point or the ending point. The multiplication value is the absolute value of the scalar, i.e., when *k* is negative

$P_C = k \times P_A = -abs(k) \times P_A = abs(k) \times (-1P_A) = -(abs(k) \times P_A)$

### 45.7.4.1 Point math over a prime field ($F_p$)

The ECC_MOD family of functions perform Add, Double, and scalar Multiply operations on points on a curve defined by the equation:

$E: y^2 = x^3 + ax + b \bmod p$

where p is the a prime integer > 3. These operations are available in Affine Coordinates (*x,y*).

The modulus (value in N memory) for these operations is *p*, also referred to as *q*.

The equality for the negative of a point *P*, in affine coordinates, is $-P = -(x,y) = (x, -y)$

The operations will not provide useful outputs if the inputs are not valid points on the curve, i.e., if they are not solutions to the curve equation E.

The representation of the point at infinity, in affine coordinates, depends upon the type of curve and the value of the *b* term of the curve's equation:

- Where *b* is equal to 0: (0, 1)
- Where *b* is not equal to 0: (0, 0)
- the equality for the negative of a point is $(X, -Y, Z) = (X, Y, Z)$

### 45.7.4.2 Point math over a binary field ($F_{2^m}$)

The ECC_F2M family of functions perform add, double, and scalar multiply operations on points on a curve defined by the equation:

E: $y^2 + xy = x^3 + ax^2 + b$

These operations are available in Affine Coordinates $(x,y)$. All inputs and output values of polynomial values are in polynomial basis. For example, $x^5+x+1$ is represented as 23h

The modulus (value in N memory) for these functions is $q$, the field-defining irreducible polynomial for the curve. Other documents use other symbols, including $p(t)$, $f(t)$, and $f$.

The equality for the negative of a point, in affine coordinates, is $-P = -(x,y) = (x, x+y)$.

The operations will not provide useful outputs if the inputs are not valid points on the curve, i.e., if they are not solutions to the curve equation E.

Because of the way the point operations are performed over a binary field, these functions require as an input the value $c$ rather than $b$. The relationship between these two values is:

$b = c^4 \bmod q$

and

$c = b^{2^{m-2}} \bmod q$, where $m$ is the degree (the power of its highest-power term) of $q$.

This $c$ value is referred to as $b'$ in the ECC Public-Key protocols for ECDSA sign, and so on. The calculation of $c$ is expensive, so it is obviously an advantage to calculate it only once or have it precomputed. See Special values for common ECC domains for these values for common ECC domains.

The representation of the point at infinity, in affine coordinates, is:

- (0, 0)

For $F_{2^m}$ curves,

- the curve equation is $E: Y^2 + XYZ = X^3 + aX^2Z^2 + bZ^6$
- the equality for the negative of a point is $(X, X + Y, Z) = (X, Y, Z)$

All computations must be performed with the proper MOD or F2M operation, with the curve's modulus as the modulus of the function.

#### 45.7.4.3 Point math over a Montgomery-form curve ($F_p$)

The ECM_MOD family of functions perform scalar Multiply operations on the affine x value of points on a curve defined by the equation:

$E: By^2 = x^3 + Ax^2 + x \bmod p$

where p is the a prime integer.

The modulus (value in N memory) for these operations is $p$. The curve coefficient $B$ is not used in x-only multiply operations.

The operations will not provide useful outputs if the inputs are not valid points on the curve, i.e., if $x$ is not part of a solution to the curve equation E.

The equality for the negative of a point $P$, in affine coordinates, is $-P = -(x,y) = (x, -y)$

With the values left in registers after an x-only multiply, it is possible to compute the y which would correspond to the result of a (x,y) multiply.

#### 45.7.4.4 Point math over an Edwards-form curve prime field ($F_p$)

The ECT_MOD family of functions perform Add and scalar Multiply operations on points on a curve defined by the equation:

$E: ax^2 + y^2 = 1 + d^2x^2y^2 \bmod p$

where p is the a prime integer. These operations are available in Affine Coordinates.

These functions can also be used on the following curves, when $c^2$ is one:

- $E: x^2 + y^2 = c^2 + d^2x^2y^2 \bmod p$
- $E: x^2 + y^2 = c^2(1 + d^2x^2y^2) \bmod p$
- $E: ax^2 + y^2 = c^2(1 + d^2x^2y^2) \bmod p$

The modulus (value in N memory) for these operations is $p$.

The equality for the negative of a point $P$, in affine coordinates, is $-P = -(x,y) = (-x, y)$

The operations will not provide useful outputs if the inputs are not valid points on the curve, i.e., if they are not solutions to the curve equation E.

### 45.7.5 PKHA Mode Register

The following tables list the valid PKHA_MODE values for all PKHA functions:

PKHA Modular Arithmetic functions: Table 45-6

PKHA Elliptic Curve functions: PKHA MODE: Elliptic Curve Functions

PKHA Copy Memory functions: Table 45-14

**NOTE**

Use of any PKHA_MODE value not listed in these tables results in an invalid mode error.

### 45.7.5.1 PKHA MODE: clear memory function

**Table 45-2. PKHA Mode register format for clear memory function**

| 19 | 18 | 17 | 16 | | 11-10 | 9 | 8 | 7 | 6 | 5-0 |
|---|---|---|---|---|---|---|---|---|---|---|
| Aram | Bram | Eram | Nram | . | Reserved | Q3 | Q2 | Q1 | Q0 | Function |
| *PKHA_MODE_MS* | | | | . | *PKHA_MODE_LS* | | | | | |

If the Function field in PKHA MODE specifies the clear memory function, PKHA expects to be in the format shown in Table 45-2. The PKHA RAMs to be cleared may be selected in any combination. Selecting one or more Quadrants for clearing will cause only the specified quadrants (of the specified RAMs) to be cleared. If no Quadrants are selected, then the whole RAM will be cleared.

**Table 45-3. PKHA mode register field descriptions for clear memory function**

| Bits | Description |
|---|---|
| 19 | Aram<br>This bit selects the A RAM for zeroization.<br>0: A not selected<br>1: A selected. |
| 18 | Bram<br>This bit selects the B RAM for zeroization.<br>0: B not selected<br>1: B selected |
| 17 | Eram<br>This bit selects the E RAM for zeroization.<br>0: E not selected<br>1: E selected |
| 16 | Nram<br>This bit selects the N RAM for zeroization.<br>0: N not selected<br>1: N selected |
| 11-10 | Reserved |

*Table continues on the next page...*

**Table 45-3. PKHA mode register field descriptions for clear memory function (continued)**

| Bits | Description |
|---|---|
| 9 | Quadrant 3<br>This bit selects the Quadrant 3 RAM for zeroization.<br>0: not selected<br>1: selected. Clearing will be only specified quadrant(s). Not valid if E RAM is selected. |
| 8 | Quadrant 2<br>This bit selects the Quadrant 2 RAM for zeroization.<br>0: not selected<br>1: selected. Clearing will be only specified quadrant(s). Not valid if E RAM is selected. |
| 7 | Quadrant 1<br>This bit selects the Quadrant 1 RAM for zeroization.<br>0: not selected<br>1: selected. Clearing will be only specified quadrant(s). Not valid is E RAM is selected. |
| 6 | Quadrant 0<br>This bit selects the Quadrant 0 RAM for zeroization.<br>0: not selected<br>1: selected. Clearing will be only specified quadrant(s). Not valid if E RAM is selected. |
| 5-0 | Function<br>The Function value for clearmemory is 000001. |

## 45.7.5.2 PKHA MODE: Arithmetic Functions

**Table 45-4. PKHA Mode Register Format for Arithmetic Functions**

| 19 | 18 | 17 | 16 | | 11 | 10 | 9-8 | 7-6 | 5-0 |
|---|---|---|---|---|---|---|---|---|---|
| inM | outM | F2m | R2 | . . | Reserved | Teq | OutSel | Reserved | Function |
| *PKHA_MODE_MS* | | | | . | *PKHA_MODE_LS* | | | | |

**Table 45-5. PKHA Mode register, format for arithmetic operation**

| Bits | Description |
|---|---|
| 19<br>inM | Inputs in Montgomery form. Indicates whether the inputs are in Montgomery form.<br>If inM=0 : Normal value representation<br>If inM=1 : Montgomery form. (Not valid for all functions.) |
| 18<br>outM | Outputs in Montgomery form. Indicates whether the outputs are to be left in Montgomery form or converted to normal values.<br>If outM=0 : Normal value representation<br>If outM=1 : Montgomery form. (Not valid for all functions.) |

*Table continues on the next page...*

**Table 45-5. PKHA Mode register, format for arithmetic operation (continued)**

| Bits | Description |
|---|---|
| 17<br>F2m | F2m. Indicates whether to use integer or binary polynomial arithmetic in executing the function.<br>If F2m=0 : Integer<br>If F2m=1 : Binary polynomial. (Not valid for all functions.) |
| 16<br>R2 | (R2 mod N). Indicates whether the term (R2 mod N) must be supplied as an input or will be calculated by the routine.<br>If R2=0 : ($R^2$ mod N) is calculated and applied, if needed<br>If R2=1 : ($R^2$ mod N) is an input. (Not valid for all functions.) |
| 11<br>Reserved | Reserved |
| 10<br>Teq | Timing Equalized. Indicates that a timing equalized version of the function should be executed.<br>If Teq=0 : No timing equalization<br>If Teq=1 : Timing equalization. (Not valid for all functions.) |
| 9-8<br>OutSel | Output destination select. Indicates which memory should contain the output of the selected function.<br>If OutSel=00b : B<br>If OutSel=01b : A<br>If OutSel=10b : Reserved<br>If OutSel=11b : Reserved |

1. PKHA_MODE_MS concatenated with 0h concatenated with PKHA_MODE_LS

These functions are grouped here because they do not fall into one of the previous categories of PKHA functions.

### 45.7.5.3 PKHA MODE: Elliptic Curve Functions

**NOTE**

Note that the elliptic curve functions with outputs going to the A RAM are identical to those with outputs going to the B RAM. The only difference is the output destination.

Elliptic Curve Functions over a prime field (ECC_MOD), where prime p > 3.

**Table 45-8. List of mode values for Prime Field ($F_p$) Elliptic Curve Arithmetic Functions**

| Function name | Brief description | Output reg | Teq | Bits 19-0, including PKHA_MODE and reserved bits[1] (Hex) | Detailed description |
|---|---|---|---|---|---|
| ECC_MOD_ADD | ECC prime field point add - affine coordinates | B | 0 | 00009 | ECC $F_p$ Point Add, Affine Coordinates (ECC_MOD_ADD) Function |
| | | A | 0 | 00109 | |
| ECC_MOD_ADD_R2 | ECC prime field point add - affine coordinates, R2 input | B | 0 | 10009 | ECC $F_p$ Point Add, Affine Coordinates, $R^2$ Mod N Input (ECC_MOD_ADD_R2) Function |
| | | A | 0 | 10109 | |

1. PKHA_MODE_MS concatenated with 0h concatenated with PKHA_MODE_LS

## 45.7.5.4 PKHA MODE: copy memory functions

**Table 45-12. PKHA Mode register, format for copy memory functions**

| 19-17 | 16 | 11-10 | 9-8 | 7-6 | 5-0 |
|---|---|---|---|---|---|
| Source Register | Destination Register | | Source Segment | Destination Segment | Function |
| *PKHA_MODE_MS* | *PKHA_MODE_LS* | | | | |

**Table 45-13. PKHA Mode register, field descriptions for copy memory functions**

| Bits | Description |
|---|---|
| 19-17<br>Source Register | Source Register. Specifies the register to be copied from.<br>If Source Register=000 : A<br>If Source Register=001 : B<br>If Source Register=011 : N<br>All other values are currently reserved. |
| 16<br>Destination Register<br>11-10 | Destination Register. Specifies the register to be copied to.<br>If Destination Register=000 : A<br>If Destination Register=001 : B<br>If Destination Register=010 : E<br>If Destination Register=011 : N<br>All other values are currently reserved.<br>**NOTE:** The source register and destination register fields must not be the same. |
| 9-8<br>Source Segment | Source Segment. Used when copying a register segment to specify which segment in the source register to copy from.<br>If Source Segment=00 : Segment 0<br>If Source Segment=01 : Segment 1<br>If Source Segment=10 : Segment 2<br>If Source Segment=11 : Segment 3 |

*Table continues on the next page...*

## Table 45-13. PKHA Mode register, field descriptions for copy memory functions (continued)

| Bits | Description |
|---|---|
| 7-6<br>Destination Segment | Destination Segment. Used when copying a register segment to specify which segment in the Destination Register to copy to.<br>If Destination Segment=00 : Segment 0<br>If Destination Segment=01 : Segment 1<br>If Destination Segment=10 : Segment 2<br>If Destination Segment=11 : Segment 3<br>**NOTE:** These bits must be zero when E is the destination register. |
| 5-0<br>Function | Function. Indicates which copy function to execute.<br>If Function=010000 : Copy Memory N-Size (copies the same number of words as are in the modulus.)<br>If Function=010001 : Copy Memory SRC-Size (copies the number of words specified in the source's size register) |

This table gives the encodings for the PKHA memory-to-memory copy functions. The top encoding in each cell is for Copy Memory, N-Size, and the bottom encoding is for Copy Memory, Source-Size ( Copy memory, N-Size and Source-Size (COPY_NSZ and COPY_SSZ)).

The encoding is in bits 19-0, including PKHA_MODE (i.e. PKHA_MODE_MS concatenated with 0h concatenated with PKHA_MODE_LS) and reserved bits. (Hex)

## Table 45-14. Mode values for PKHA copy memory functions

| | Destination Memory | | | |
|---|---|---|---|---|
| **Source Memory** | **A** | **B** | **N** | **E** |
| A | | 00410<br>00411 | 00C10<br>00C11 | 00810<br>00811 |
| B | 20010<br>20011 | | 20C10<br>20C11 | 20810<br>20811 |
| N | 60010<br>60011 | 60410<br>60411 | | 60810<br>60811 |

This table gives the encodings for the PKHA memory-to-memory copy functions, when segments are involved. The top encoding in each cell is for Copy Memory, N-Size, and the bottom encoding is for Copy Memory, Source-Size ( Copy memory, N-Size and Source-Size (COPY_NSZ and COPY_SSZ)).

The encoding is in bits 19-0, including PKHA_MODE (i.e. PKHA_MODE_MS concatenated with 0h concatenated with PKHA_MODE_LS) and reserved bits. (Hex)

## Table 45-15. Mode values for PKHA copy memory by segment functions

| | Destination Quadrant | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| **Source Quadrant** | **A0** | **A1** | **A2** | **A3** | **B0** | **B1** | **B2** | **B3** | **N0** | **N1** | **N2** | **N3** |
| A0 | | | | | 00410 | 00450 | 00490 | 004D0 | 00C10 | 00C50 | 00C90 | 00CD0 |

*Table continues on the next page...*

## 45.7.6 PKHA functions

The various PKHA functions are described in the following subsections. The following information applies to all PKHA functions.

- Mode Register bits that may be either 1's or 0's for the given function are represented with *x*.
- For convenience, in all the descriptions below the output is shown as the default B, although the actual output destination can be specified via the Class 1 Mode Register[OutSel] field to be either the B RAM or the A RAM.

- The descriptions specify the output register(s) and any other registers that might be modified. Note that the default output register is still modified but the output is placed into the specified destination register(s).
- Note that any parameter underlined is in Montgomery form (for example, $\underline{A}$ = AR mod N).
- It is important to note that the PKHA mathematical functions work in terms of "digits"; that is, the arithmetic unit is pipelined to work on a digit of data at a time. For PKHA-16 a digit = 16 bits (2 bytes) of data, PKHA-32 a digit = 32 bits (4 bytes) of data, for PKHA-64 a digit = 64 bits (8 bytes), and for PKHA-128 a digit = 128 bits (16 bytes). Therefore, the term 'digit' refers to 16, 32, 64, or 128 bits of data in the input and/or output values used by the PKHA arithmetic unit.

### 45.7.6.1 Clear Memory (CLEAR_MEMORY) function

This function clears the specified registers or quadrants of registers in the PKHA. This includes the A, B, N and E. All registers or quadrants of registers are written with zeros.

A detailed description may be found in PKHA MODE: clear memory function.

**Table 45-16. CLEAR_MEMORY function properties**

| Property | Notes |
|---|---|
| Mode value | *ABEN*_0000_00 *QQ_QQ* 00_0001, with the following restrictions on the combinations of ABEN and QQQQ: At least one of ABEN must be on. If E is on, all Q must be zero. Some example encodings are in the table below. |
| Input | None |
| Output | A = 0, B = 0, E = 0, N = 0, or some quadrant(s) thereof, as specified by ABEN and QQQQ. Each *Q* specifies a quadrant, in order from 3 through 0. |
| Requirements | The Mode Register specifies which registers or quadrants of registers to clear.<br>If no quadrants are selected, then all quadrants of the specified register(s) are cleared. |
| Side effects | None |
| Errors reported | Invalid Mode, if no registers are selected, or E with one or more quadrants is selected |
| Flags set | None |

**Table 45-17. Example mode values for PKHA clear memory functions**

| Function name | Register selects | | | | Quadrant selects | | | | Brief description | Bits 19-0, including PKHA_MODE and reserved bits[1] (Hex) |
|---|---|---|---|---|---|---|---|---|---|---|

## 45.7.6.2 Arithmetic Functions

### 45.7.6.2.1 Integer Modular Addition (MOD_ADD) function

**Table 45-18. MOD_ADD function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_0010 ( output placed in B )<br>0000_0000_000***1***_0000_0010 ( output placed in A ) |
| Input | • N = modulus and data size, any integer<br>• A = first addend, any integer less than N<br>• B = second addend, any integer less than N |
| Output | B (or A, if selected) = (A + B) mod N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and B are each < N. |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N.<br><br>If (A + B) >= N, N will be subtracted just once from the sum. That is, if (A + B) >= 2N, then the result will not be mod N. |
| Flags set | |

### 45.7.6.2.2 Integer Modular Subtraction (MOD_SUB_1) function

Modular subtraction can be described as follows. If A ≥ B or A = B = 0, then B = A - B. Otherwise, if A < B, then B = A + N - B. The result is always positive and less than N.

**Table 45-19. MOD_SUB_1 function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_0011 ( output placed in B )<br>0000_0000_000***1***_0000_0011 ( output placed in A ) |
| Input | • N = modulus, any integer<br>• A = minuend, any integer less than N<br>• B = subtrahend, any integer less than N |
| Output | B (or A, if selected) = (A - B) mod N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and B are less than N. |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N. |
| Flags set | |

### 45.7.6.2.3 Integer Modular Subtraction (MOD_SUB_2) function

**Table 45-20. MOD_SUB_2 function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_0100 ( output placed in B )<br>0000_0000_000***1***_0000_0100 ( output placed in A ) |
| Input | • N = modulus, any integer<br>• B = minuend, any integer less than or equal to N<br>• A = subtrahend, any integer less than or equal to N |
| Output | B (or A, if selected) = (B - A) mod N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and B are < N |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N. |
| Flags set | |

### 45.7.6.2.4 Integer Modular Multiplication (MOD_MUL)

The (AB) mod N computation is provided to assist in algorithms and protocols where a single modular multiplication is required and not as a chaining of multiplications. In the latter case, Montgomery form multiplication routines (that is, MOD_MUL_IM or MOD_MUL_IM_OM) are more efficient. This function first computes $R^2$ mod N, then multiples one factor to produce AR, then multiplies AR*B to produce AB.

**Table 45-21. MOD_MUL function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_0101 ( output placed in B )<br>0000_0000_000***1***_0000_0101 ( output placed in A ) |
| Input | • N = modulus, any odd integer<br>• A = multiplicand, any integer less than N<br>• B = multiplier, any integer less than N |
| Output | B (or A, if selected) = (AxB) mod N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and B are < N. |
| Side effects | A and E are modified. |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N.<br>• Divide-By-Zero Error is set if the most significant digit of the modulus is all zeros. |
| Flags set | |

### 45.7.6.2.5 Integer Modular Multiplication with Montgomery Inputs (MOD_MUL_IM)

This function takes its inputs, integers, in Montgomery form, multiplies them modulo the value in the N register and returns the result as a field value. To do this, it performs two multiplications: AR*BR => ABR and ABR*1 => AB.

**Table 45-22. MOD_MUL_IM function properties**

| Property | Notes |
|---|---|
| Mode value | 1000_0000_000***0***_0000_0101 ( output placed in B )<br>1000_0000_000***1***_0000_0101 ( output placed in A ) |
| Input | • N = modulus, any odd integer<br>• A = multiplicand, a value in Montgomery form<br>• B = multiplier, a value in Montgomery form |
| Output | B (or A if selected) = A x B mod N, the non-Montgomery product of the inputs |
| Requirements | • Minimum modulus size = 1 byte |

*Table continues on the next page...*

**Table 45-22. MOD_MUL_IM function properties (continued)**

| Property | Notes |
|---|---|
| | • Maximum modulus size = 512 bytes<br>• A and B are less than modulus N |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N. |
| Flags set | |

### 45.7.6.2.6 Integer Modular Multiplication with Montgomery Inputs and Outputs (MOD_MUL_IM_OM) Function

This function performs the calculation A*B/R mod N, where R is the Montgomery factor for N. This can be used in several ways:

- If one value is a normal value, and the other is R2 mod N, then the result is the normal value converted to Montgomery.
- If A and B are both Montgomery values, then the result is the product of A and B as a Montgomery value.
- If only one of (A,B) is a Montgomery value, then the result is the product as a normal value.
- If one of (A,B) is a Montgomery value and the other is the value one, then the result is Montgomery value converted to a normal value.

**Table 45-23. MOD_MUL_IM_OM function properties**

| Property | Notes |
|---|---|
| Mode value | 1100_0000_000***0***_0000_0101 ( output placed in B )<br>1100_0000_000***1***_0000_0101 ( output placed in A ) |
| Input | • N = modulus, any odd integer<br>• A = multiplicand, a value in Mongomery format 0 ≤ A < N<br>• B = multiplier, a value in Mongomery format 0 ≤ B < N |
| Output | B (or A, if selected) = (AxB) mod N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N. |
| Flags set | |

#### 45.7.6.2.7 Integer Modular Exponentiation (MOD_EXP and MOD_EXP_TEQ)

This function is commonly used to perform a single-step RSA operation. It computes $R^2$ mod N and converts A to Montgomery form before beginning the exponentiation. MOD_EXP_TEQ performs the same operation as MOD_EXP but with an added timing equalization security feature. The exponentiation run-time of MOD_EXP_TEQ, for a given modulus and size of exponent, is constant. In general MOD_EXP will run faster than MOD_EXP_TEQ, but will never run slower.

**Table 45-24. MOD_EXP and MOD_EXP_TEQ function properties**

| Property | Notes |
|---|---|
| Mode value for MOD_EXP | 0000_0000_0**0**0***0***_0000_0110 ( output placed in B )<br>0000_0000_0**0**0***1***_0000_0110 ( output placed in A ) |
| Mode value for MOD_EXP_TEQ | 0000_0000_0**1**0***0***_0000_0110 ( output placed in B )<br>0000_0000_0**1**0***1***_0000_0110 ( output placed in A ) |
| Input | • N = modulus, any odd integer<br>• A = an integer 0 ≤ A < N<br>• E = exponent, any integer |
| Output | B (or A, if selected) = ($A^E$) mod N, a an integer 0 ≤ A < N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• Maximum key (exponent) size = 512> bytes<br>• A < N |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• Key Size Error is set if size of E = 0 or size of E > 512.<br>• A Size Error is set if the size of A is greater than size of N. |
| Flags set | |

#### 45.7.6.2.8 Integer Modular Exponentiation, Montgomery Input (MOD_EXP_IM and MOD_EXP_IM_TEQ) Function

This function is commonly used to perform a single-step RSA operation. It computes $\underline{A}$ = AR (mod N), where R is the Montgomery constant). The input data (base) to be exponentiated must be provided in the Montgomery form. The result will be returned in normal integer (non-Montgomery) representation. MOD_EXP_IM_TEQ performs the same operation as MOD_EXP_IM but with an added timing equalization security feature. The exponentiation run-time of MOD_EXP_IM_TEQ is constant for a given modulus and size of exponent. In general MOD_EXP_IM will run faster than MOD_EXP_IM_TEQ, but will never run slower.

**Table 45-25. MOD_EXP_IM and MOD_EXP_IM_TEQ function properties**

| Property | Notes |
|---|---|
| Mode value for MOD_EXP_IM | 1000_0000_0**0**0***0***_0000_0110 ( output placed in B )<br>1000_0000_0**0**0***1***_0000_0110 ( output placed in A ) |
| Mode value for MOD_EXP_IM_TEQ | 1000_0000_0**1**0***0***_0000_0110 ( output placed in B )<br>1000_0000_0**1**0***1***_0000_0110 ( output placed in A ) |
| Input | • N = modulus, any odd integer<br>• A = a value 0 ≤ A < N, in Montgomery form<br>• E = exponent, any integer (normal integer representation) |
| Output | B (or A, if selected) = ($A^E$) mod N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• Maximum key (exponent) size = 512 bytes<br>• A < N |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• Key Size Error is set if size of E = 0 or size of E > 512.<br>• A Size Error is set if the size of A is greater than size of N. |
| Flags set | |

### 45.7.6.2.9 Integer Modular Square Root (MOD_SQRT)

The modular square root function computes output result B, such that ( B x B ) mod N = input A. If no such B result exists, the result will be set to 0 and the PKHA "prime" flag will be set. Input values A and B are limited to a maximum size of 128 bytes. Note that two such square root values may exist. This algorithm will find either one of them, if any exist. The second possible square root (B') can be found by calculating B' = N - B.

**Table 45-26. MOD_SQRT function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0001_0111 ( output placed in B )<br>0000_0000_000***1***_0001_0111 ( output placed in A ) |
| Input | • N0 (N RAM, 1st quadrant) = modulus, any odd integer<br>• A0 (A RAM, 1st quadrant) = input value, for which a square root is to be calculated |
| Output | B0 (or A0, if selected) is calculated such that ( B0 x B0 ) mod N = A mod N. If no such B exists, then B is set to 0. |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and B are < N. |
| Side effects | All of the following PKHA RAM quadrants are modified: E2, E3, N1, N2, N3, B1, B2, B3, A1, A2, A3. |
| Errors reported | N Size Error is set if the size of N is greater than 128. |
| Flags set | |

### 45.7.6.2.10 Integer Modulo Reduction (MOD_AMODN)

MOD_AMODN computes the remainder of A divided by N. A and N can be of any size and it is not required that A > N, but N must be non-zero.

**Table 45-27. MOD_AMODN function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_0111 ( output placed in B )<br>0000_0000_000***1***_0000_0111 ( output placed in A ) |
| Input | • N = modulus, any non-zero integer<br>• A = any integer |
| Output | B (or A, if selected) = A mod N, A reduced modulo N |
| Requirements | • N = non-zero value<br>• Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Divide By Zero Error is set if N = 0. |
| Flags set | |

### 45.7.6.2.11 Integer Modular Inversion (MOD_INV)

MOD_INV computes the inverse of A, if an inverse exists. If the modulus, N, is prime, then all values of A, 1 ≤ A < N, are guaranteed to have an inverse mod N. If N is not prime, A may or may not have an inverse. It will have one only if GCD(A, N) == 1.

**Table 45-28. MOD_INV function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_1000 ( output placed in B )<br>0000_0000_000***1***_0000_1000 ( output placed in A ) |
| Input | • N = modulus, any non-zero integer<br>• A = any non-zero integer lass than N |
| Output | B (or A, if selected) = $A^{-1}$ mod N, an integer, the multiplicative inverse of A |
| Requirements | • Neither A or N can be zero.<br>• A must be less than N.<br>• Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes |
| Side effects | A and E are modified. |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• A Size Error is set if the size of A is greater than size of N.<br>• Divide-By-Zero Error is set if N or A = 0, or if the most significant digit of N = 0, or if there is no inverse. |
| Flags set | None |

### 45.7.6.2.12 Integer Montgomery Factor Computation (MOD_R2)

This function is used to compute a constant to assist in converting operands into the Montgomery residue system representation. The constant $R^2$(mod N) is dependent upon the digit size of the PKHA and the value in N.

MUL, EXP, and ECC functions that do not have "IM" (Montgomery inputs) or an R2 input will internally invoke this routine to determine the constant and do the conversions before other operations.

If the modulus N is a protocol- or system-wide parameter that does not change frequently, such as in ECC operations for a specific curve, save this computed constant, because this routine takes a not-insignificant amount of time to complete.

**Table 45-29. MOD_R2 function properties**

| Property | Notes |
|---|---|
| Mode value | 1000_0000_000***0***_0000_1100 ( output placed in B )<br>1000_0000_000***1***_0000_1100 ( output placed in A ) |
| Input | N = modulus, any odd integer |
| Output | B (or A, if selected) = R2 mod N, where R = $2^{SD}$ where S is size of a digit in bits and D is the number of digits of N; in other words, D = ceiling [sizeof(N) in bits / S] |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even. |
| Flags set | None |

### 45.7.6.2.13 Integer $R_E R_P$ mod P (MOD_RR)

This function is used to compute a constant to assist in converting operands into the Montgomery residue system representation specifically for Chinese Remainder Theorem while performing RSA with a CRT implementation where a modulus E=P x Q, and P and Q are prime numbers. Although labeled $R_E R_P$ mod P, this routine (function) can also compute $R_E R_Q$ mod Q.

To use this routine, the size of the prime number (either P or Q) in bytes must be written into the Data Size Register, and the size of the modulus E = P x Q in bytes must be written into the Key Size Register. Next, the prime modulus (either P or Q) is written into N-memory.

**Table 45-30. MOD_RR function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_1101 ( output placed in B )<br>0000_0000_000***1***_0000_1101 ( output placed in A ) |
| Input | • N = modulus P or Q of CRT, an odd integer<br>• Key size = number of bytes of E = P x Q (this size must be given, though content of E itself is not used) |
| Output | B (or A, if selected) = $R_E R_P$ mod P, where $R_E = 2^{SD(E)}$, and $R_P = 2^{SD(P)}$, where S is the size of a digit (in bits). D(E), D(P) are the number of digits of E, P respectively; in other words, D(E or P) = ceiling [size of (E or P) in bits / S] |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• Maximum key size (P-size + Q-size) = 512 bytes<br>• Key size > modulus size |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• Key Size Error is set if size of E = 0 or size of E > 512. |
| Flags set | None |

## 45.7.6.2.14 Integer Greatest Common Divisor (MOD_GCD)

MOD_GCD finds the greatest common divisor of two integers.

**Table 45-31. MOD_GCD function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_1110 ( output placed in B )<br>0000_0000_000***1***_0000_1110 ( output placed in A ) |
| Input | • N = any integer. The most-significant digit of N must be non-zero.<br>• A = any integer less than or equal to N |
| Output | B (or A, if selected) = GCD(A,N), an integer less than or equal to A that divides both A and N<br>If the output is placed in B, the MOD_INV result is available in A. |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and N may not both be zero |
| Side effects | A is modified |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• A Size Error is set if the size of A is greater than size of N.<br>• Divide-By-Zero Error is set if N or A = 0, or if the most significant digit of N = 0. |
| Flags set | |

### 45.7.6.2.15 Miller_Rabin Primality Test (PRIME_TEST)

**Table 45-32. PRIME_TEST function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_1111 ( output placed in B )<br>0000_0000_000***1***_0000_1111 ( output placed in A ) |
| Input | • N[1] = Candidate prime integer<br>• A = An initial random seed for the base value of exponentiation; can be any integer 2 < A < N - 2<br>• B = "t" parameter, which is the number of trial runs. By default, it is set at 1 or B[7:0], whichever is greater. Only the lowest byte of the supplied value is used. |
| Output | B (or A, if selected) = 1 if candidate is believed to be prime, otherwise 0 |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and N may not both be zero |
| Side effects | N and A are modified |
| Errors reported | • N Size Error is set if size of N = 0 or size of N > 512.<br>• B Size Error is set if B[7:5] is nonzero and N size > 256.<br>• Divide-By-Zero Error is set if no seed can be found that is in the legal range of 2 < A < N-2. This occurs if N = 1 or N = 3. |
| Flags set | |

1. If the most significant digit of N is zero, the result is always composite, the output is the value zero, regardless of the primality of the value of N.

### 45.7.6.2.16 Binary Polynomial ($F_{2^m}$) Addition (F2M_ADD) function

This function performs binary polynomial modular addition without any modulo reduction, as the value in the N register is ignored. Only its size is used, to determine the size of the result.

This type of addition is the equivalent of a bitwise XOR and this function may be used for that purpose.

This function could as easily be labeled F2M_SUB, as it is mathematically equivalent.

**Table 45-33. F2M_ADD function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_0010 ( output placed in B )<br>0000_0000_000***1***_0000_0010 ( output placed in A ) |
| Input | • Size of N (modulus size)<br>• A = first addend, a binary polynomial<br>• B = second addend, a binary polynomial |
| Output | B (or A, if selected) = A xor B, a binary polynomial |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• The N need not be written, because its contents are ignored, but the size of N must be written. This size is needed because inputs A and B are considered binary polynomials modulo some irreducible polynomial N. |

*Table continues on the next page...*

**Table 45-33. F2M_ADD function properties (continued)**

| Property | Notes |
|---|---|
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N. |
| Flags set | |

### 45.7.6.2.17 Binary Polynomial ($F_{2^m}$) Modular Multiplication (F2M_MUL)

The (AB) mod N computation is provided to assist in algorithms and protocols where a single modular multiplication is required and not as a chaining of multiplications. In the latter case, Montgomery form multiplication routines (that is, F2M_MUL_IM or F2M_MUL_IM_OM) are more efficient. This function first computes $R^2$ mod N, then multiples $A*R^2$ to produce AR, then multiplies AR*B to produce AB.

**Table 45-34. F2M_MUL function properties**

| Property | Notes |
|---|---|
| Mode value | 0010_0000_000***0***_0000_0101 ( output placed in B )<br>0010_0000_000***1***_0000_0101 ( output placed in A ) |

| Flags set | |

### 45.7.6.2.18 Binary Polynomial ($F_{2^m}$) Modular Multiplication with Montgomery Inputs (F2M_MUL_IM) Function

This function takes its inputs, binary polynomials, in Montgomery form, multiplies them modulo the value in the N register, used as a reduction polynomial, and returns the result as a field value. To do this, it performs two multiplications: AR*BR => ABR and ABR*1 => AB.

**Table 45-35. F2M_MUL_IM function properties**

| Property | Notes |
|---|---|
| Mode value | 1010_0000_000***0***_0000_0101 ( output placed in B )<br>1010_0000_000***1***_0000_0101 ( output placed in A ) |
| Input | • N = modulus, an "odd" binary polynomial of order m<br>• A = multiplicand, a binary polynomial < $2^m$, in Montgomery form<br>• B = multiplicand, a binary polynomial < $2^m$, in Montgomery form |
| Output | B (or A, if selected) = (AxB) mod N, a a binary polynomial < $2^m$, non-Montgomery form |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and B are field elements in Montgomery form and must be modulo reduced by irreducible polynomial N. |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N. |
| Flags set | |

### 45.7.6.2.19 Binary Polynomial ($F_{2^m}$) Modular Multiplication with Montgomery Inputs and Outputs (F2M_MUL_IM_OM) Function

This function performs the calculation A*B/R mod N, where R is the Montgomery factor for N. This can be used in several ways:

- If one value is a normal value, and the other is R2 mod N, then the result is the normal value converted to Montgomery.
- If A and B are both Montgomery values, then the result is the product of A and B as a Montgomery value.
- If only one of (A,B) is a Montgomery value, then the result is the product as a normal value.
- If one of (A,B) is a Montgomery value and the other is the value one, then the result is Montgomery value converted to a normal value.

**Table 45-36. F2M_MUL_IM_OM function properties**

| Property | Notes |
|---|---|
| Mode value | 1110_0000_000***0***_0000_0101 ( output placed in B )<br>1110_0000_000***1***_0000_0101 ( output placed in A ) |
| Input | • N = modulus, an "odd" binary polynomial of order m<br>• A = a binary polynomial 0 < $2^m$, in Montgomery form.<br>• B = a binary polynomial 0 < $2^m$, in Montgomery form. |
| Output | B (or A, if selected) = (AxB) mod N, in Montgomery form |
| Requirements | • Minimum modulus size = 1 byte |

*Table continues on the next page...*

**Table 45-36. F2M_MUL_IM_OM function properties (continued)**

| Property | Notes |
|---|---|
| | • Maximum modulus size = 512 bytes<br>• A and B are field elements in Montgomery form. |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error is set if the size of B is greater than size of N. |

### 45.7.6.2.20 Binary Polynomial ($F_{2^m}$) Modular Exponentiation (F2M_EXP and F2M_EXP_TEQ)

This function is similar to MOD_EXP but works on binary polynomials. It is provided mainly to assist in the computation of elliptic curve parameter "c", where c = $b^{2^{m-2}}$ mod $n$) given an elliptic curve parameter "b" and the field-defining polynomial in N. It computes $R^2$ mod N and converts A to Montgomery form before beginning the exponentiation. F2M_EXP_TEQ performs the same operation as F2M_EXP but with an added timing equalization security feature. Its exponentiation run-time, for a given modulus and size of exponent, is constant. In general F2M_EXP will run faster than F2M_EXP_TEQ, but will never run slower.

**Table 45-37. F2M_EXP function properties**

| Property | Notes |
|---|---|
| Mode value for F2M_EXP | 0010_0000_0**00*0***_0000_0110 ( output placed in B )<br>0010_0000_0**00*1***_0000_0110 ( output placed in A ) |
| Mode value for F2M_EXP_TEQ | 0010_0000_0**10*0***_0000_0110 ( output placed in B )<br>0010_0000_0**10*1***_0000_0110 ( output placed in A ) |
| Input | • N = modulus, an "odd" binary polynomial of order m<br>• A = a binary polynomial < $2^m$<br>• E = exponent, any integer |
| Output | B (or A, if selected) = ($A^E$) mod N, a binary polynomial |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• Maximum key (exponent) size = 512 bytes |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• Key Size Error is set if size of E = 0 or size of E > 512.<br>• A Size Error is set if the size of A is greater than size of N. |
| Flags set | |

### 45.7.6.2.21 Binary Polynomial ($F_{2^m}$) Simultaneous Modular Exponentiation (F2M_SML_EXP)

F2M_SML_EXP performs two modular exponentiations on binary polynomials, and multiplies the results. This is faster than doing them separately. It is useful for DSA Verification.

**Table 45-38. F2M_SML_EXP function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0001_0110 ( output placed in B )<br>0000_0000_000***1***_0001_0110 ( output placed in A ) |
| Input | • N = modulus, any odd integer<br>• A0 = a field element, first base<br>• E = an integer, first exponent<br>• A2 = a field element, second base<br>• B = an integer, second exponent |
| Output | B (or A if selected) = $A0^E * A2^B$ mod N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 1/2 RAM<br>• Maximum key (exponent) size and B size = 1/4 RAM size<br>• A0 < N<br>• A2 < N<br>• The values in A0 and A2 must be the same number of bytes, matching the A SIZE register, and should be the same size as N |
| Side effects | A, B, and E are modified. |
| Errors reported | • N size error is set if N size > half RAM<br>• A size error is set if A size > half RAM<br>• B size error is set if B size > quarter-RAM<br>• E size error is set if E size > quarter-RAM |
| Flags set | PIZ is set if the result is zero.<br>PIO is set if the result is one. |

### 45.7.6.2.22 Binary Polynomial ($F_{2^m}$) Modulo Reduction (F2M_AMODN)

F2M_AMODN computes the remainder of A divided by N. This is the equivalent of the MOD_AMODN function applied to a binary polynomial. A and N can be of any size and it is not required that A > N, but N must be non-zero.

**Table 45-39. F2M_AMODN function properties**

| Property | Notes |
|---|---|
| Mode value | 0010_0000_000***0***_0000_0111 ( output placed in B )<br>0010_0000_000***1***_0000_0111 ( output placed in A ) |
| Input | • N = modulus, any non-zero polynomial<br>• A = any polynomial |
| Output | B (or A, if selected) = A mod N, a polynomial, binary element modulo N |

*Table continues on the next page...*

**Table 45-39. F2M_AMODN function properties (continued)**

| Property | Notes |
|---|---|
| Requirements | • N = non-zero value<br>• Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Divide By Zero Error is set if N = 0. |
| Flags set | |

### 45.7.6.2.23 Binary Polynomial ($F_{2^m}$) Modular Inversion (F2M_INV)

F2M_INV computes the multiplicative inverse of a binary polynomial.

**Table 45-40. F2M_INV function properties**

| Property | Notes |
|---|---|
| Mode value | 0010_0000_000***0***_0000_1000 ( output placed in B )<br>0010_0000_000***1***_0000_1000 ( output placed in A ) |
| Input | • N = modulus, an irreducible polynomial<br>• A = a field element |
| Output | B (or A, if selected) = $A^{-1}$ mod N, a field element, the multiplicative inverse of A |
| Requirements | • A is an element of the binary polynomial field.<br>• Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes |
| Side effects | A and E are modified. |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if the size of A is greater than size of N.<br>• Divide-By-Zero Error is set if N or A = 0, or if the most significant digit of N = 0. |
| Flags set | None |

### 45.7.6.2.24 Binary Polynomial ($F_{2^m}$) $R^2$ Mod N (F2M_R2) Function

This function is used to compute the Montgomery Conversion Factor, which is used to convert operands into the Montgomery residue system representation. The constant $R^2$(mod N) is dependent upon the digit size of the PKHA and the value of N. If this value is not available, then this routine (function) is called to determine the constant before other operations. If N contains a protocol- or system-wide parameter that does not change frequently, such as in ECC operations for a specific curve, save this computed constant, because this routine takes a considerable amount of time to complete.

**Table 45-41. F2M_R2 function properties**

| Property | Notes |
|---|---|
| Mode value | 0010_0000_000***0***_0000_1100 ( output placed in B )<br>0010_0000_000***1***_0000_1100 ( output placed in A ) |
| Input | N = modulus, an irreducible polynomial |
| Output | B (or A, if selected) = R2 mod N, where R = $2^{SD}$ where S is size of a digit in bits and D is the number of digits of an irreducible polynomial, in other words D = ceiling [sizeof(N) in bits / S] |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes |
| Side effects | None |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• Modulus Even Error is set if N is even. |
| Flags set | None |

### 45.7.6.2.25 Binary Polynomial ($F_{2^m}$) Greatest Common Divisor (F2M_GCD) Function

MOD_GCD finds the greatest common divisor of two binary polynomials.

**Table 45-42. F2M_GCD function properties**

| Property | Notes |
|---|---|
| Mode value | 0010_0000_000***0***_0000_1110 ( output placed in B )<br>0010_0000_000***1***_0000_1110 ( output placed in A ) |
| Input | • N = any polynomial. The most-significant digit of N must be non-zero.<br>• A = any polynomial with degree less than or equal to N |
| Output | B (or A, if selected) = BINARY_GCD(A,N), a polynomial with degree less than or equal to polynomial A that divides both A and N |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 512 bytes<br>• A and N may not both be zero |
| Side effects | A is modified |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 512.<br>• A Size Error is set if the size of A is greater than size of N.<br>• Divide-By-Zero Error is set if N or A = 0, or if the most significant digit of N = 0. |
| Flags set | |

## 45.7.6.3 Elliptic Curve Functions

#### 45.7.6.3.1 ECC $F_p$ Point Add, Affine Coordinates (ECC_MOD_ADD) Function

ECC_MOD_ADD performs an addition of two points on an elliptic curve. The inputs and output are in affine coordinates.

**Table 45-43. ECC_MOD_ADD function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_1001 ( output placed in B )<br>0000_0000_000***1***_0000_1001 ( output placed in A ) |
| Input | • N = modulus, a prime number. The most significant digit of N must be non-zero The most significant digit of N must be non-zero<br>• [A0, A1] = first addend in affine coordinates<br>• A2 = ignored<br>• A3 = elliptic curve "a" parameter<br>• B0 = elliptic curve "b" parameter<br>• [B1, B2] = second addend in affine coordinates<br>• B3 = ignored |
| Output | [B1, B2] (or [A0, A1], if A output selected) = [A0, A1] + [B1, B2], where "+" represents an elliptic curve point addition. Output is in affine coordinates. |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 128 bytes<br>• Point coordinates A0, A1, B1 and B2, and elliptic curve parameters A3 and B0 are elements of the prime field and therefore are less than the modulus N. |
| Side effects | A0, A1, A2, A3 and B3 are modified. |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 128.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error will be set if size of B is greater than size of N.<br>• Divide-By-Zero Error is set if the most-significant digit of N = 0. |
| Flags set | None |

#### 45.7.6.3.2 ECC $F_p$ Point Add, Affine Coordinates, $R^2$ Mod N Input (ECC_MOD_ADD_R2) Function

ECC_MOD_ADD_R2 performs an addition of two points on an elliptic curve. The addends are input and the sum is output in affine coordinates. Since ECC_MOD_ADD_R2 has $R^2$ mod N as an additional input, this function is more efficient than ECC_MOD_ADD, which first must compute $R^2$ mod N before performing the addition.

**Table 45-44. ECC_MOD_ADD_R2 function properties**

| Property | Notes |
|---|---|
| Mode value | 0001_0000_000***0***_0000_1001 ( output placed in B )<br>0001_0000_000***1***_0000_1001 ( output placed in A ) |

*Table continues on the next page...*

**Table 45-44. ECC_MOD_ADD_R2 function properties (continued)**

| Property | Notes |
|---|---|
| Input | • N = modulus, a prime number. The most significant digit of N must be non-zero The most significant digit of N must be non-zero<br>• [A0, A1] = first addend point in affine coordinates (x,y)<br>• A2 = ignored<br>• A3 = elliptic curve "a" parameter<br>• B0 = elliptic curve "b" parameter<br>• [B1, B2] = second addend point in affine coordinates (x,y)<br>• B3 = R2 ($R^2$ mod N) input |
| Output | [B1, B2] (or [A0, A1], if A output selected) = [A0, A1] + [B1, B2], where "+" represents an elliptic curve point addition. Output is in affine coordinates. |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 128 bytes<br>• Point coordinates A0, A1, B1 and B2, and elliptic curve parameters A3 and B0 are elements of the prime field formed by N. |
| Side effects | A0, A1, A2, A3 and B3 are modified. |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 128.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if the size of A is greater than size of N.<br>• B Size Error will be set if size of B is greater than size of N.<br>• Divide-By-Zero Error is set if the most-significant digit of N = 0. |
| Flags set | None |

### 45.7.6.3.3 ECC $F_p$ Point Double, Affine Coordinates (ECC_MOD_DBL) Function

ECC_MOD_DBL computes the double (B + B) of a point B on an elliptic curve. The input and output are in affine coordinates.

**Table 45-45. ECC_MOD_DBL function properties**

| Property | Notes |
|---|---|
| Mode value | 0000_0000_000***0***_0000_1010 ( output placed in B )<br>0000_0000_000***1***_0000_1010 ( output placed in A ) |
| Input | • N = modulus, a prime number. The most significant digit of N must be non-zero.<br>• [A0, A1, A2] = ignored<br>• A3 = elliptic curve "a" parameter<br>• B0 = elliptic curve "b" parameter<br>• [B1, B2] = input point in affine coordinates<br>• B3 = ignored |
| Output | [B1, B2] (or [A0, A1], if A output selected) = [B1, B2] + [B1, B2], where "+" represents an elliptic-curve point addition. Output is in affine coordinates (x, y). |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 128 bytes<br>• Point coordinates B1 and B2, and elliptic curve parameters A3 and B0 are elements of the prime field formed by N. |
| Side effects | A0, A2, A3 and B3 are modified. |

*Table continues on the next page...*

**Table 45-45. ECC_MOD_DBL function properties (continued)**

| Property | Notes |
|---|---|
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 128.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if size of A is greater than size of N.<br>• B Size Error is set if size of B is greater than size of N.<br>• Divide-by-Zero Error is set if the most significant digit of N = 0. |
| Flags set | |

### 45.7.6.3.4 ECC $F_p$ Point Multiply, Affine Coordinates (ECC_MOD_MUL and ECC_MOD_MUL_TEQ) Function

ECC_MOD_MUL computes the scalar multiplication of a point on an elliptic curve. The input and output are in affine coordinates. ECC_MOD_MUL_TEQ computes the same function, but with an added timing equalization security feature. Its computation run-time is, for a given curve (N, A3, B0), constant for a given size of E. ECC_MOD_MUL in general will run faster than ECC_MOD_MUL_TEQ, but will never run slower.

**Table 45-46. ECC_MOD_MUL and ECC_MOD_MUL_TEQ function properties**

| Property | Notes |
|---|---|
| Mode value for ECC_MOD_MUL | 0000_0000_0**0**0***0***_0000_1011 ( output placed in B )<br>0000_0000_0**0**0***1***_0000_1011 ( output placed in A ) |
| Mode value for ECC_MOD_MUL_TEQ | 0000_0000_0**1**0***0***_0000_1011 ( output placed in B )<br>0000_0000_0**1**0***1***_0000_1011 ( output placed in A ) |
| Input | • N = modulus, a prime number. The most significant digit of N must be non-zero<br>• E = scalar multiplier (k), any integer<br>• [A0, A1] = multiplicand, an input point in affine coordinates (x,y)<br>• A2 = ignored<br>• A3 = elliptic curve "a" parameter<br>• B0 = elliptic curve "b" parameter<br>• B1 = ignored<br>• B2 = ignored<br>• B3 = ignored<br>• A0-A3 and B0-B3 are four equal-size segments of A and B memory locations. |
| Output | • P[B1, B2] (or P[A0, A1], if A output selected) = E x P[A0, A1], where "x" denotes elliptic curve scalar point multiplication. Output is in affine coordinates (x,y).<br>• B0 = undefined<br>• B3 = undefined |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 128 bytes<br>• The point (A0, A1) must be on the elliptic curve formed by (N, A3, B0). |
| Side effects | A0, A1, A2, A3 and B3 are modified. |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 128.<br>• Key Size Error is set if size of E = 0 or size of E > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if size of A is greater than size of N. |

*Table continues on the next page...*

**Table 45-46. ECC_MOD_MUL and ECC_MOD_MUL_TEQ function properties (continued)**

| Property | Notes |
|---|---|
| | • B Size Error is set if size of B is greater than size of N.<br>• Divide-by-Zero Error is set if the most significant digit of N = 0. |
| Flags set | |

The following special cases should be noted:

- For k = 0, this function returns a point at infinity; that is (0,0) if curve parameter "b" is nonzero and (0,1) otherwise.
- For k < 0, (that is, a negative scalar multiplication is required), its absolute value should be provided to the PKHA; that is, k = abs(-k). After the computation is complete, the formula -P= (x,-y) can be used to compute the "y" coordinate of the effective final result, and other coordinates are the same.

### 45.7.6.3.5 ECC $F_p$ Point Multiply, $R^2$ Mod N Input, Affine Coordinates (ECC_MOD_MUL_R2 and ECC_MOD_MUL_R2_TEQ) Function

ECC_MOD_MUL_R2 computes a scalar multiplication of a point on an elliptic curve. The input point and the output point are in affine coordinates. Since ECC_MOD_MUL_R2 has $R^2$ mod N as an additional input, this function is more efficient than ECC_MOD_MUL, which first must compute $R^2$ mod N before performing the multiplication. ECC_MOD_MUL_R2_TEQ computes the same function, but with an added timing equalization security feature. Its computation run-time is, for a given curve (N, A3, B0), constant for a given size of E. ECC_MOD_MUL_R2 in general will run faster than ECC_MOD_MUL_R2_TEQ, but will never run slower.

**Table 45-47. ECC_MOD_MUL_R2 and ECC_MOD_MUL_R2_TEQ function properties**

| Property | Notes |
|---|---|

### 45.7.6.3.7 ECC $F_{2^m}$ Point Add, Affine Coordinates, $R^2$ Mod N Input (ECC_F2M_ADD_R2) Function

ECC_F2M_ADD_R2 performs an addition of two points on an elliptic curve. The inputs and output are in affine coordinates. Since this function takes $R^2$ mod N as an additional input, ECC_F2M_ADD_R2 is more efficient than ECC_F2M_ADD, which first must compute $R^2$ mod N before performing the addition.

**Table 45-49. ECC_F2M_ADD_R2 function properties**

### 45.7.6.3.9 ECC $F_{2^m}$ Point Multiply, Affine Coordinates (ECC_F2M_MUL and ECC_F2M_MUL_TEQ) Function

ECC_F2M_MUL computes the scalar multiplication of a point on an elliptic curve. The input and output are in affine coordinates. ECC_F2M_MUL_TEQ performs the same operation as ECC_F2M_MUL but with an added timing equalization security feature. Its computation run-time is, for a given curve (N, A3, B0), constant for a given size of E. In general ECC_F2M_MUL will run faster than ECC_F2M_MUL_TEQ, but will never run slower.

**Table 45-51. ECC_F2M_MUL and ECC_F2M_MUL_TEQ function properties**

| Output | • P[B1, B2] (or P[A0, A1], if A output selected) = E x P[A0, A1], where "x" denotes elliptic curve scalar point multiplication. Output is in affine coordinates (x,y).<br>• B0 = undefined<br>• B3 = undefined |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 128 bytes (irreducible polynomial of maximum degree 1023<br>• Point coordinates A0 and A1 and elliptic curve parameters A3 and B0 must be elements of the binary polynomial field. |
| Side effects | A0, A1 and B3 are modified. |
| Errors reported | • Data Size Error is set if size of N = 0or size of N > 128.<br>• Key Size Error is set if size of E = 0 or size of E > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if size of A is greater than size of N.<br>• B Size Error is set if size of B is greater than size of N.<br>• Divide-by-Zero Error is set if the most significant digit of N = 0.<br>• C is Zero Error if B3 is zero. |
| Flags set | |

The following special cases should be noted:

- For E = 0, this function returns a point at infinity (0,0).
- For E < 0, (that is, a negative scalar multiplication is required), its absolute value should be provided to the PKHA; that is, k = -E). After the multiplication is

complete, the formula -P= (x, x+y) can be used to compute the *y* coordinate of the effective final result; the *x* coordinate stays the same.

### 45.7.6.3.10 ECC $F_{2^m}$ Point Multiply, $R^2$ Mod N Input, Affine Coordinates (ECC_F2M_MUL_R2 and ECC_F2M_MUL_R2_TEQ) Function

ECC_F2M_MUL_R2 computes the scalar multiplication of a point on an elliptic curve. The input and output are in affine coordinates. Since this function takes $R^2$ mod N as an additional input, ECC_F2M_MUL_R2 is more efficient than ECC_F2M_MUL, which first must compute $R^2$ mod N before performing the multiplication.
ECC_F2M_MUL_R2_TEQ performs the same operation as ECC_F2M_MUL_R2 but with an added timing equalization security feature. Its computation run-time is, for a given curve (N, A3, B0), constant for a given size of E. In general ECC_F2M_MUL_R2 will run faster than ECC_F2M_MUL_R2_TEQ, but will never run slower.

The following special cases should be noted:

- For k = 0, this function returns a point at infinity (0,0).
- For k < 0, (that is, a negative scalar multiplication is required), its absolute value should be provided to the PKHA; that is, k = abs(- k). After the computation is complete, the formula -P = (x, x+y) can be used to compute the "y" coordinate of the effective final result, and other coordinate is the same.

### 45.7.6.3.11 ECM Modular Multiplication (ECM_MOD_MUL and ECM_MOD_MUL_TEQ) Function

ECM_MOD_MUL computes the scalar multiplication of a point on an elliptic curve in Montgomery form. The input and output are just the x coordinates of the points. ECM_MOD_MUL_TEQ computes the same function, but with an added timing equalization security feature. Its computation run-time is, for a given curve (N, A3), constant for a given size of E. ECM_MOD_MUL in general will run faster than ECM_MOD_MUL_TEQ, but will never run slower.

This function computes a point multiplication on a Montgomery curve, using Montgomery values, by means of a Montgomery ladder. At the end of the ladder, P2 = P3 + P1, where P1 is the input and P3 is the result.

**Table 45-53. ECM_MOD_MUL and ECM_MOD_MUL_TEQ function properties**

### 45.7.6.3.13 ECT Modular Multiplication (ECT_MOD_MUL and ECT_MOD_MUL_TEQ) Function

ECT_MOD_MUL computes the scalar multiplication of a point on an elliptic curve. The input and output are in affine coordinates. ECT_MOD_MUL_TEQ computes the same function, but with an added timing equalization security feature. Its computation run-time is, for a given curve (N, A3, B0), constant for a given size of E. ECT_MOD_MUL in general will run faster than ECT_MOD_MUL_TEQ, but will never run slower.

**Table 45-55. ECT_MOD_MUL and ECT_MOD_MUL_TEQ function properties**

| Property | Notes |
|---|---|
| Mode value for ECT_MOD_MUL | 0000_0000_0**00*0***>_1000_1011 ( output placed in B )<br>0000_0000_0**00*0***_1000_1011 ( output placed in A ) |
| Mode value for ECT_MOD_MUL_TEQ | 0000_0000_0**10*0***_1000_1011 ( output placed in B )<br>0000_0000_0**10*1***_1000_1011 ( output placed in A ) |
| Input | • N = modulus, a prime number. The most significant digit of N must be non-zero<br>• E = scalar multiplier (k), any integer<br>• [A0, A1] = multiplicand, an input point in affine coordinates (x,y)<br>• A2 = ignored<br>• A3 = elliptic curve "a" parameter<br>• B0 = elliptic curve "b" *(or should this be "d")* parameter<br>• B1 = ignored<br>• B2 = ignored<br>• B3 = ignored<br>• A0-A3 and B0-B3 are four equal-size segments of A and B memory locations. |
| Output | • P[B1, B2] (or P[A0, A1], if A output selected) = E x P[A0, A1], where "x" denotes elliptic curve scalar point multiplication. Output is in affine coordinates (x,y).<br>• B0 = undefined<br>• B3 = undefined |
| Requirements | • Minimum modulus size = 1 byte<br>• Maximum modulus size = 128 bytes<br>• The point (A0, A1) must be on the elliptic curve formed by (N, A3, B0). |
| Side effects | A0, A1, A2, A3 and B3 are modified. |
| Errors reported | • Data Size Error is set if size of N = 0 or size of N > 128.<br>• Key Size Error is set if size of E = 0 or size of E > 512.<br>• Modulus Even Error is set if N is even.<br>• A Size Error is set if size of A is greater than size of N.<br>• B Size Error is set if size of B is greater than size of N.<br>• Divide-by-Zero Error is set if the most significant digit of N = 0. |
| Flags set | |

The following special cases should be noted:

- For k = 0, this function returns a point at infinity; that is (0,0) if curve parameter "b" is nonzero and (0,1) otherwise.
- For k < 0, (that is, a negative scalar multiplication is required), its absolute value should be provided to the PKHA; that is, k = abs(-k). After the computation is complete, the formula -P= (x,-y) can be used to compute the "y" coordinate of the effective final result, and other coordinates are the same.

### 45.7.6.3.14 ECT $F_p$ Point Multiply, $R^2$ Mod N Input, Affine Coordinates (ECT_MOD_MUL_R2 and ECT_MOD_MUL_R2_TEQ) Function

ECT_MOD_MUL_R2 computes a scalar multiplication of a point on an elliptic curve. The input point and the output point are in affine coordinates. Since ECT_MOD_MUL_R2 has $R^2$ mod N as an additional input, this function is more

efficient than ECT_MOD_MUL, which first must compute $R^2$ mod N before performing the multiplication. ECT_MOD_MUL_R2_TEQ computes the same function, but with an added timing equalization security feature. Its computation run-time is, for a given curve (N, A3, B0), constant for a given size of E. ECT_MOD_MUL_R2 in general will run faster than ECT_MOD_MUL_R2_TEQ, but will never run slower.

#### 45.7.6.3.16 ECT $F_p$ Point Add, Affine Coordinates, $R^2$ Mod N Input (ECT_MOD_ADD_R2) Function

ECT_MOD_ADD_R2 performs an addition of two points on an elliptic curve. The addends are input and the sum is output in affine coordinates. Since ECT_MOD_ADD_R2 has $R^2$ mod N as an additional input, this function is more efficient than ECT_MOD_ADD, which first must compute $R^2$ mod N before performing the addition.

### 45.7.6.4 Copy memory, N-Size and Source-Size (COPY_NSZ and COPY_SSZ)

These functions copy data from a PKHA register (or register quadrant) specified as a source, to another PKHA register (or register quadrant) specified as a destination. COPY NSZ copies the amount of data specified by the N Size register. COPY_SSZ copies the amount of data specified in the source register's size register. The source and destination are specified in the Mode Value. The source can be A, B or N. The destination can be A, B, E or N, but not the same as the source.

In a quadrant copy, when NSZ/SSZ exceeds the length of a quadrant, the copy will carry on into the next (higher-numbered) quadrant(s).

When the copy operation has completed, the destination register's size register will be updated to contain the number of bytes copied.

**Table 45-59. COPY_NSZ and COPY_SSZ function properties**

1. If the destination register is E, the source and destination seqments must be 00b.

## 45.7.7 Special values for common ECC domains

Software can sometimes use the PKHA more effectively if the Montgomery Conversion Factor ($R^2$ mod N) is either provided or previously used to convert other inputs into Montgomery form. For convenience, the conversion factors for common ECC domains have been computed and published here. Some of the other domain values are provided to aid in definite identification of the domain, in the case that the name is not found or is not an exact match.

The following tables give these values for the *q* and *r* modulus values found in ECC domains. These associated Montgomery values are dependent upon the PKHA digit size (16, 32, 64, 128). These tables are for a PKHA with a 16-bit digit.

ECC $F_{2^m}$ requires a *c* (also called *b'*) parameter for the elliptic curve in place of the *b* value. Table 45-61 provides these values in addition to the Montgomery values. The *b'* values are universal and do not change with PKHA digit size.

The following variable definitions apply to both tables. Variable names (*q, r, b, c*) follow the conventions of IEEE Std 1363.

**Name**

The names in these tables are associated with, or named in, various published standards. Neither the names nor the domains are guaranteed to be complete. Two values of the domain parameters are provided for purposes of identification.

- Those beginning with "P-", "K-", and "B-" are in FIPS 186 from NIST, found at www.csrc.nist.gov
- Those beginning with "ansix9" are names from ANS X9.62-2005; those beginning with "prime" or "c2pnb" are from an earlier ANSI document
- Those beginning with "sec" are from SEC 2 from the Standards for Efficient Cryptography group, found at www.secg.org
- Those beginning with "wtls" are taken from Wireless Transport Layer Security / Wireless Access Protocol, Version 06-Apr-2001, WAP-261-WTLS-20010406-a. Not all software libraries agree with the mapping of these names to values; care has been taken to identify the values based upon the source documentation.
- Those beginning with "ECDSA", "ECP", "EC2N", "ecp_group", and "Oakley" are from various RFCs found at www.ietf.org
- Those beginning with "GOST" are from the Russian standard GOST R 3410-2001
- Those beginning with "brainpool" are from ECC Brainpool, found at www.ecc-brainpool.org and republished in RFC 5639

**R**

*R* is the Montgomery factor. Its value is $2^{SD}$, where *D* is the PKHA digit size in bits, and *S* is the minimum number of digits needed to hold the modulus. As an example, for a modulus of nine bytes (72 bits), *R* would be

- $2^{80}$ for a PKHA with digit size of 16 bits
- $2^{96}$ for a PKHA with digit size of 32 bits
- $2^{128}$ for a PKHA with digit size of 64 or 128 bits

**q**

This is the *field-defining* value for the elliptic curve. For $F_p$ curves, it is the prime number used as the modulus for all point arithmetic; it is named *p* in some other publications. For $F_{2^m}$ curves, it is the irreducible binary polynomial used as the modulus for all point arithmetic. It is not, as usually defined, $q = 2^m$, i.e. the size of the field.

**L**

This is the number of bytes needed to hold *q* and each of its associated values: *R2modq*, *a*,*b*,*c*, the point coordinates *x* and *y*, the result of an ECDH key agreement, etc.

**R2modq**

This is $R^2 \bmod q$, the Montgomery Conversion Factor when *q* is the modulus.

**r**

This is the (usually prime) number which is the order of *G*, the generator point. It is also usually used as the modulus for the non-ECC-related arithmetic in an ECC primitive. This variable is named *n* in some other publications.

**N**

This is the number of bytes needed to hold *r* and each of its associated values: *R2modr*, private keys, each of the two components of an ECDSA signature, etc.

**R2modr**

This is $R^2 \ mod \ r$, the Montgomery Conversion Factor when *r* is the modulus.

**b / c (b')**

*b* is the coefficient for the $x^0$ (ones) term in an $F_{2^m}$ elliptic curve equation. Its relationship with *c* is $b = c^4$. *c* is sometimes referred to as *b'* in NXP documentation.

**A / a24**

*a24* is the special value derived from the A coefficient for the $y^2$term in a Montgomery-form elliptic curve equation. Its relationship with *A* is *a24 = (A+2)/4*.

The domains in the table are ordered by size.

## 45.8 Application/initialization information

This section discusses how to initialize and use the CAU3 module.

### 45.8.1 Code example

A code fragment is shown below as an example of how the CAU3 is used. This example shows the AES decrypting a single 16-byte block

```
//*****************************************************************************
// AES: Decrypts a single 16-byte block
//   arguments
//          *in         pointer to 16-byte block of input chiphertext
//          *key_sch    pointer to key schedule (44, 52, 60 longwords)
//           nr         number of AES rounds (10, 12, 14 = f(key_schedule))
//          *out        pointer to 16-byte block of output plaintext
//
//   NOTE   Input and output blocks may overlap
//
//   calling convention
//   void   cau_aes_decrypt (const unsigned char *in,
//                           const unsigned char *key_sch,
//                           const int            nr,
//                           unsigned char       *out)

  .equ        p_in,       R4
  .equ        p_key_sch,  R5

# Chapter 46
# Analog-to-Digital Converter (ADC)

## 46.1 Chip-specific LPADC information

### 46.1.1 LPADC0 channel assignments

The following table shows the channel assignments for the LPADC0 module.

**Table 46-1. LPADC0 channel assignments**

| Channel name | LPADC channel (CMDLn[ADCH]) | Input signal | Direct connection |
|---|---|---|---|
| CH0A | 000000 | LPADC0_SE0 | via LPADC0MUX0 |
| CH1A | 000001 | LPADC0_SE1 | via LPADC0MUX0 |
| CH2A | 000010 | LPADC0_SE2 | via LPADC0MUX0 |
| CH3A | 000011 | LPADC0_SE3 | via LPADC0MUX0 |
| CH4A | 000100 | LPADC0_SE4 | via LPADC0MUX1 |
| CH5A | 000101 | LPADC0_SE5 | via LPADC0MUX1 |
| CH6A | 000110 | LPADC0_SE6 | via LPADC0MUX1 |
| CH7A | 000111 | LPADC0_SE7 | via LPADC0MUX1 |
| CH8A | 001000 | LPADC0_SE8 | via LPADC0MUX2 |
| CH9A | 001001 | LPADC0_SE9 | via LPADC0MUX2 |
| CH10A | 001010 | LPADC0_SE10 | via LPADC0MUX2 |
| CH11A | 001011 | LPADC0_SE11 | via LPADC0MUX2 |
| CH12A | 001100 | LPADC0_SE12 | via LPADC0MUX2 |
| CH13A | 001101 | LPADC0_SE13 | via LPADC0MUX2 |
| CH14A | 001110 | LPADC0_SE14 | via LPADC0MUX2 |
| CH15A | 001111 | LPADC0_SE15 / $V_{REF_OUT}$ | Direct Connection |
| CH16A | 010000 | LPADC0_SE16 / DAC0_OUT | Direct Connection |
| CH17A | 010001 | Reserved | — |
| CH18A | 010010 | LPADC0_SE18 | via LPADC0MUX6 |

*Table continues on the next page...*

## Table 46-1. LPADC0 channel assignments (continued)

| Channel name | LPADC channel (CMDLn[ADCH]) | Input signal | Direct connection |
|---|---|---|---|
| CH19A | 010011 | LPADC0_SE19 | via LPADC0MUX6 |
| CH20A | 010100 | LPADC0_SE20 | via LPADC0MUX6 |
| CH21A | 010101 | LPADC0_SE21 | via LPADC0MUX6 |
| CH22A | 010110 | LPADC0_SE22 | via LPADC0MUX6 |
| CH23A | 010111 | LPADC0_SE23 | via LPADC0MUX6 |
| CH24A | 011000 | Reserved | — |
| CH25A | 011001 | Reserved | — |
| CH26A | 011010 | Reserved | — |
| CH27A | 011011 | Reserved | — |
| CH28A | 011100 | Reserved | — |
| CH29A | 011101 | Reserved | — |
| CH30A | 011110 | Reserved | — |
| CH31A | 011111 | Reserved | — |
| CH0B | 100000 | Reserved | — |
| CH1B | 100001 | Reserved | — |
| CH2B | 100010 | Reserved | — |
| CH3B | 100011 | Reserved | — |
| CH4B | 100100 | Reserved | — |
| CH5B | 100101 | Reserved | — |
| CH6B | 100110 | Reserved | — |
| CH7B | 100111 | Reserved | — |
| CH8B | 101000 | Reserved | — |
| CH9B | 101001 | Reserved | — |
| CH10B | 101010 | Reserved | — |
| CH11B | 101011 | Reserved | — |
| CH12B | 101100 | Reserved | — |
| CH13B | 101101 | Reserved | — |
| CH14B | 101110 | Reserved | — |
| CH15B | 101111 | Reserved | — |
| CH16B | 110000 | $V_{DDIO1}$ | via LPADC0MUX2 |
| CH17B | 110001 | $V_{DDIO2}$ | via LPADC0MUX6 |
| CH18B | 110010 | VBAT_DIV4 | via LPADC0MUX6 |
| CH19B | 110011 | Reserved | — |
| CH20B | 110100 | Reserved | — |
| CH21B | 110101 | $V_{DD_CORE}$ | via LPADC0MUX7 |
| CH22B | 110110 | Reserved | — |
| CH23B | 110111 | Reserved | — |
| CH24B | 111000 | Reserved | — |
| CH25B | 111001 | Reserved | — |

*Table continues on the next page...*

**Table 46-1. LPADC0 channel assignments (continued)**

| Channel name | LPADC channel (CMDLn[ADCH]) | Input signal | Direct connection |
|---|---|---|---|
| CH26B | 111010 | Temperature Sensor | via LPADC0MUX7 |
| CH27B | 111011 | Bandgap[1] | via LPADC0MUX7 |
| CH28B | 111100 | Reserved | — |
| CH29B | 111101 | $V_{REFH}$/LPADC0_SE29 | via LPADC0MUX7 |
| CH30B | 111110 | $V_{REFL}$/LPADC0_SE30 | via LPADC0MUX7 |
| CH31B | 111111 | DCDC | via LPADC0MUX7 |

1. This is the System Power Management (SPM) bandgap 1V reference voltage. Prior to reading from this LPADC channel, ensure that the bandgap buffer is enabled by setting the SPM_CORELPCNFG[BGBEN] bit. Refer to the device data sheet for the bandgap voltage (VBG) specification.

## 46.1.2 Triggers

The LPADC supports both software and hardware triggers. The primary hardware mechanism for triggering the LPADC is the Trigger Multiplexor (TRGMUX). The TRGMUX takes all of the hardware triggers and multiplexes them onto the trigger inputs of the system modules. This allows a broader range of triggers to be used to initiate autonomous action. Because many of the modules which use triggers to initiate actions also have trigger outputs when those actions have completed, sequences that involve multiple peripherals can be created through the proper chaining of the triggers through the TRGMUX.

The following table shows the trigger inputs to the LPADC and where they are generated.

**Table 46-2. LPADC0 trigger inputs**

| Trigger | Source |
|---|---|
| 0 | TRGMUX_LPADC0_trigger0 |
| 1 | TRGMUX_LPADC0_trigger1 |
| 2 | TRGMUX_LPADC0_trigger2 |
| 3 | TRGMUX_LPADC0_trigger3 |

For operation of triggers in different modes, refer to Power Management chapter.

## 46.1.3 Voltage reference options

The LPADC0 supports the following high voltage references which can be configured by :

- Option 1: $V_{REFH}$ - Voltage Reference High
- Option 2: $V_{REF_OUT}$ - Internal Voltage Reference Output
- Option 3: $V_{DDA}$ - Analog Voltage Supply

The high voltage reference source is selected by setting the LPADC0_CFG [REFSEL] field. Option 1 is connected to the $V_{REFH}$ pin. Option 2 is connected to the $V_{REF_OUT}$ pin. Option 3 is connected to the $V_{DDA}$ pin.

The LPADC0 supports the following low voltage references:

- $V_{REFL}$ - Voltage Reference Low ($V_{REFL}$)

### 46.1.4 Functional clock options

The LPADC0 has multiple functional clock sources that can be selected for use during data conversion. These sources includes multiple external clocks and an internal clock source. The clocks are controlled by the System Clock Generator (SCG) and the Peripheral Clock Control (PCC) modules. For information on configuring and enabling these external clocks, please see the SCG chapter. For information on selecting and enabling the LPADC's internal and external functional clocks, please refere to the PCC chapter.

The internal clock source is a 2 MHz Internal Resistor Capacitor Oscillator (LPADCIRC) and is provided so that the LPADC can function in low-power modes when all other clock sources are disabled. The 2 MHz LPADCIRC is controlled through the internal and selected by PCC.

### 46.1.5 Direct Memory Access (DMA) support

Customers may require continuous sampling of the LPADC for certain applications. As the sample rate increases, a larger load is placed on the processor core to move the data from the LPADC peripheral to memory. To eliminate this loading, the LPADC supports data transfers from the LPADC FIFOs to the system memory through DMA. A DMA request can be enabled to trigger when the FIFO exceeds a programmable watermark.

## 46.2 Introduction

The 12-bit analog-to-digital converter (LPADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

**NOTE**

For the chip specific modes of operation, see the power management information of the device.

**Note**

Hexadecimal values are designated by a preceding 0x, binary values designated by a preceding 0b, and decimal values have no preceding character.

## 46.2.1 Features

Following are the features of the LPADC module.

- Linear successive approximation algorithm
  - single-ended operation with 12-bit resolution
- Channel support for up to 64 analog input channels for conversion of external pins and from internal sources
  - Measurement of on-chip analog sources such as DAC, temperature sensor or bandgap
- Configurable analog input sample time
- Configurable speed options to accommodate operation in low power modes of the device.
- Trigger detect with up to 4 trigger sources with priority level configuration. Software or hardware trigger option for each.
- 15 command buffers allow independent options selection and channel sequence scanning.
- Automatic compare for less-than, greater-than, within range, or out-of-range with "store on true" and "repeat until true" options
- 16-entry conversion result data FIFO with configurable watermark and overflow detection
- Interrupt, DMA or polled operation

## 46.2.2 Block diagram

The following figure is the LPADC module block diagram.

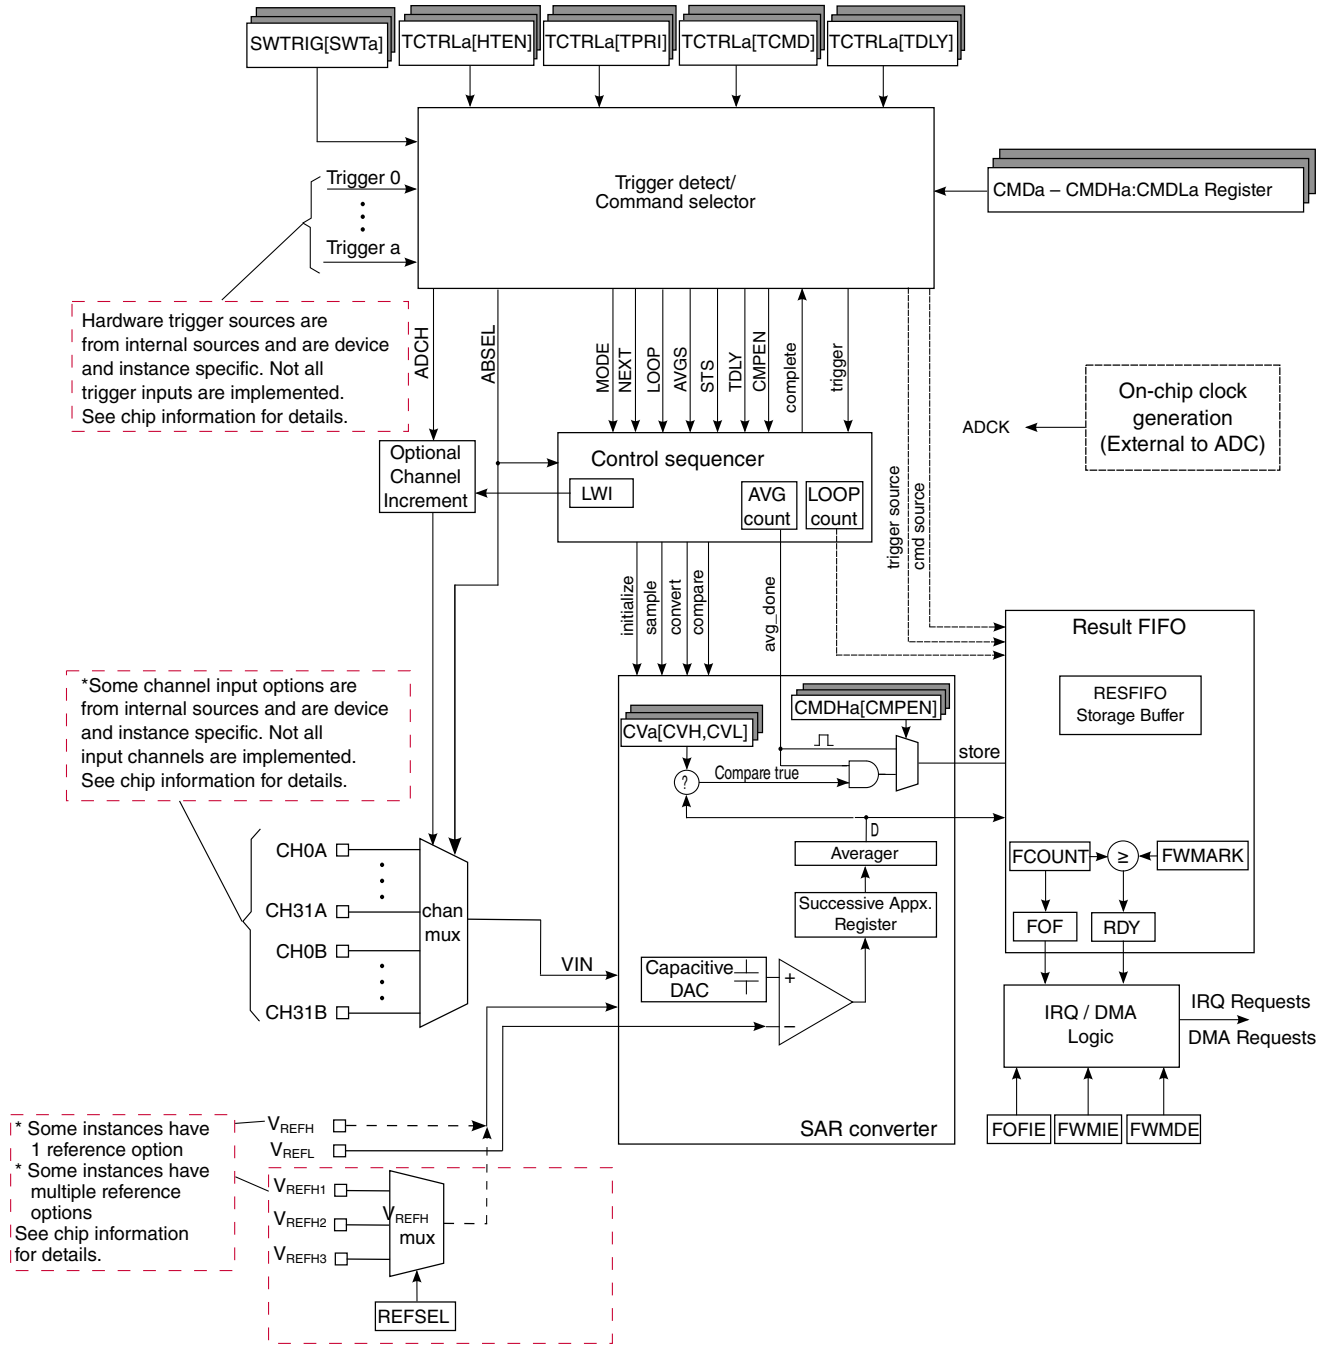

**Figure 46-1. LPADC block diagram**

## 46.2.3 Modes of operation

The table below shows the operation of LPADC module in various chip modes.

**Table 46-3. Chip modes supported by the ADC module**

| Chip mode | LPADC Operation |
|---|---|
| Run | Normal operation |
| Stop/Wait | Can continue operating provided the Doze Enable bit (CTRL[DOZEN]) is clear and the module is using an external or internal clock source which remains operating during stop/wait modes. When the CTRL[DOZEN] bit is set, the module will wait for the current averaging iteration/FIFO storage to complete before acknowledging stop or wait mode entry. |
| Low Leakage Stop | The Doze Enable (CTRL[DOZEN]) bit is ignored and the ADC will wait for the current transfer to complete any pending operation before acknowledging low-leakage mode entry. |

## 46.3 Signal descriptions

The LPADC module supports up to 64 analog channel inputs. The module also requires supply and ground connections.

**Table 46-4. LPADC signal descriptions**

| Signal | Description | I/O |
|---|---|---|
| $V_{DDA}$ | Analog Power Supply | I |
| $V_{SSA}$ | Analog Ground | I |
| CH31A–CH0A | A-side Analog Channel Inputs | I |
| CH31B–CH0B | B-side Analog Channel Inputs | I |

**NOTE**

The voltage reference high ($V_{REFH}$) used by the LPADC is supplied from either an on-chip voltage reference source or from an off-chip source supplied through external pins. $V_{REFL}$ is always from an external pin and must be at the same voltage potential as $V_{SSA}$. See the chip configuration information on the voltage reference options specific to this packaged device.

**NOTE**

This block supports a programmable selection of the Voltage Reference High used for ADC conversions (via the CFG[REFSEL] field). See the chip configuration information on the voltage reference options specific to this packaged device.

### 46.3.1 Analog Power ($V_{DDA}$)

The ADC analog portion uses $V_{DDA}$ as its power connection. In some packages, $V_{DDA}$ is connected internally to $V_{DD}$. If externally available, connect the $V_{DDA}$ pin to the same voltage potential as $V_{DD}$. External filtering may be necessary to ensure clean $V_{DDA}$ for good results.

### 46.3.2 Analog Ground ($V_{SSA}$)

The ADC analog portion uses $V_{SSA}$ as its ground connection. In some packages, $V_{SSA}$ is connected internally to $V_{SS}$. If externally available, connect the $V_{SSA}$ pin to the same voltage potential as $V_{SS}$.

### 46.3.3 Analog Channel Inputs (CH*n*A and CH*n*B)

The CMDL*a*[ADCH] and CMDL*a*[ABSEL] bitfields control selection of a input channel. Each ADC command independently makes a channel selection.

**NOTE**

Some of the input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of the ADC module. Some of the input channel options in the bitfield-setting descriptions may not be available for your device. Refer to ADC configuration section in the chip configuration chapter for the channels supported on this device.

## 46.4 LPADC register descriptions

This section describes the LPADC registers.

### 46.4.1 LPADC Memory map

LPADC0 base address: 4004_A000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID Register (VERID) | 32 | RO | 0100_0708h |
| 4h | Parameter Register (PARAM) | 32 | RO | 0F04_1004h |
| 10h | LPADC Control Register (CTRL) | 32 | RW | 0000_0000h |

## 46.4.2 Version ID Register (VERID)

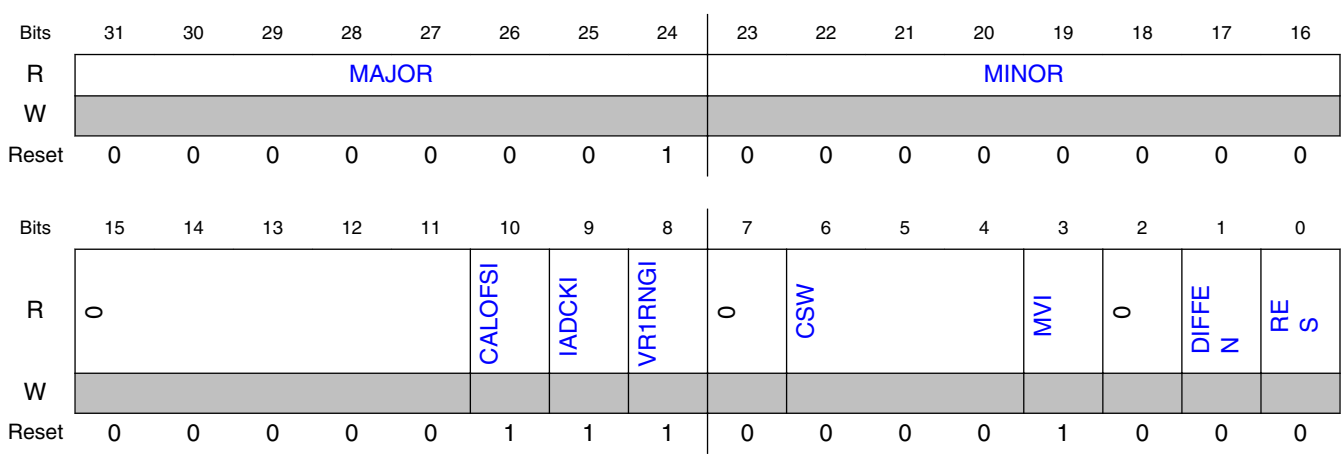
### 46.4.2.1 Offset

| Register | Offset |
|---|---|
| VERID | 0h |

### 46.4.2.2 Function

The Version ID register indicates the version integrated for this instance on the device and also indicates inclusion/exclusion of several optional features.

### 46.4.2.3 Diagram



### 46.4.2.4 Fields

| Field | Function |
|---|---|
| 31-24<br>MAJOR | Major Version Number<br>This read-only field returns the major version number for the module specification. |
| 23-16<br>MINOR | Minor Version Number<br>This read-only field returns the minor version number for the module specification. |
| 15-11<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 10<br>CALOFSI | Calibration Offset Function Implemented<br>This read-only field indicates if a calibration function and trimming control register are implemented. When supported, the CFG[CALOFS] and OFSTRIM[OFSTRIM] fields are available in support of this function.<br>0b - Offset calibration and offset trimming not implemented.<br>1b - Offset calibration and offset trimming implemented. |
| 9<br>IADCKI | Internal LPADC Clock implemented<br>This read-only field indicates if this implementation of the LPADC includes an internal clock source. When supported, the CFG[ADCKEN] field is available and documented for enabling the clock source. When available, this clock source is used in clock selection logic external to the module for use within the system.<br>0b - Internal clock source not implemented.<br>1b - Internal clock source (and CFG[ADCKEN]) implemented. |
| 8<br>VR1RNGI | Voltage Reference 1 Range Control Bit Implemented<br>This read-only field indicates if a control bit is implemented for selecting the input voltage range on Voltage Reference Option 1.When range control is required, the CFG[VREF1RNG] field is available and documented for controlling the Voltage Reference Option 1.<br>0b - Range control not required. CFG[VREF1RNG] is not implemented.<br>1b - Range control required. CFG[VREF1RNG] is implemented. |
| 7<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 6-4<br>CSW | Channel Scale Width<br>This read-only field indicates if channel scaling is supported by this implementation. When supported, each command buffer has a control field (CMDLa[CSCALE]) for setting input scaling.<br>000b - Channel scaling not supported.<br>001b - Channel scaling supported. 1-bit CSCALE control field.<br>110b - Channel scaling supported. 6-bit CSCALE control field. |
| 3<br>MVI | Multi Vref Implemented<br>This read-only field indicates if multiple Voltage Reference High inputs are supported by this implementation. When multiple voltage references are supported, the CFG[REFSEL] field is available and documented for selecting the Voltage Reference High options.<br>0b - Single voltage reference high (VREFH) input supported.<br>1b - Multiple voltage reference high (VREFH) inputs supported. |
| 2<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 1<br>DIFFEN | Differential Supported |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This read-only field indicates if differential operation is supported by this implementation. When supported, each command buffer has control fields (CMDLa[DIFF] and CMDLa[ABSEL]) for configuring for differential operation and expanding the number of supported channels from 32 to 64.<br>0b - Differential operation not supported.<br>1b - Differential operation supported. CMDLa[DIFF] and CMDLa[ABSEL] control fields implemented. |
| 0<br>RES | Resolution<br>This read-only field indicates the maximum accuracy supported by this implementation. When RES=1, each command buffer has a control field (CMDLa[MODE]) for selecting resolution of conversions for the associated command.<br>0b - Up to 13-bit differential/12-bit single ended resolution supported.<br>1b - Up to 16-bit differential/15-bit single ended resolution supported. |

## 46.4.3 Parameter Register (PARAM)

### 46.4.3.1 Offset

| Register | Offset |
|---|---|
| PARAM | 4h |

### 46.4.3.2 Function

The Parameter register indicates the size of several variable integration options for this instance on the device.

### 46.4.3.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 46.4.5.4 Fields

| Field | Function |
|---|---|
| 31-28<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 27-24<br>CMDACT | Command Active<br>CMDACT is a read-only status field indicating the command that is actively being processed.<br>0000b - No command is currently in progress.<br>0001b - Command 1 currently being executed.<br>0010b - Command 2 currently being executed.<br>0011-1111b - Associated command number is currently being executed. |
| 23-18<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 17-16 | Trigger Active |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TRGACT | TRGACT is a read-only status field indicating the trigger associated with the command actively being processed. TRGACT only has meaning when CMDACT is non-zero.<br>00b - Command (sequence) associated with Trigger 0 currently being executed.<br>01b - Command (sequence) associated with Trigger 1 currently being executed.<br>10b - Command (sequence) associated with Trigger 2 currently being executed.<br>11b - Command (sequence) associated with Trigger 3 currently being executed. |
| 15-9 | Reserved |
| — | This read-only field is reserved and always has the value 0. |
| 8 | Reserved |
| — | This read-only field is reserved and always has the value 0. |
| 7-2 | Reserved |
| — | This read-only field is reserved and always has the value 0. |
| 1 | Result FIFO Overflow Flag |
| FOF | Indicates that more data has been written to the Result FIFO than it can hold. The newer data is not stored and the FIFO remains holding the original contents. This field asserts regardless of the value of IE[FOFIE]. However, an interrupt request is issued only if IE[FOFIE] is set. This flag is cleared by writing a 1.<br>0b - No result FIFO overflow has occurred since the last time the flag was cleared.<br>1b - At least one result FIFO overflow has occurred since the last time the flag was cleared. |
| 0 | Result FIFO Ready Flag |
| RDY | Indicates when the number of valid datawords in the result FIFO is greater than the watermark level set in the FCTRL[FWMARK] bitfield. This field asserts regardless of the value of FWMIE. However, an interrupt request or DMA request occurs only when the associated control bit (IE[FWMIE] and DE[FWMDE]) is set. This flag is cleared when the FCOUNT (which decrements on each read of the RESFIFO register) is less than or equal to the watermark level set in the FCTRL[FWMARK] bitfield.<br>0b - Result FIFO data level not above watermark level.<br>1b - Result FIFO holding data above watermark level. |

## 46.4.6 Interrupt Enable Register (IE)

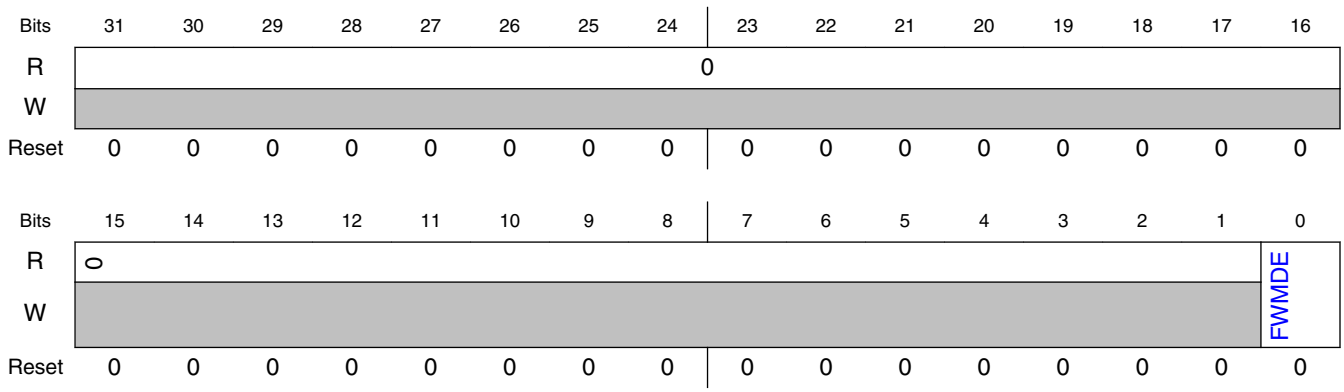
## 46.4.7 DMA Enable Register (DE)

### 46.4.7.1 Offset

| Register | Offset |
|---|---|
| DE | 1Ch |

### 46.4.7.2 Diagram



### 46.4.7.3 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 0<br>FWMDE | FIFO Watermark DMA Enable<br>Configures ADC to generate DMA requests when RDY flag is asserted.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |

## 46.4.8 LPADC Configuration Register (CFG)

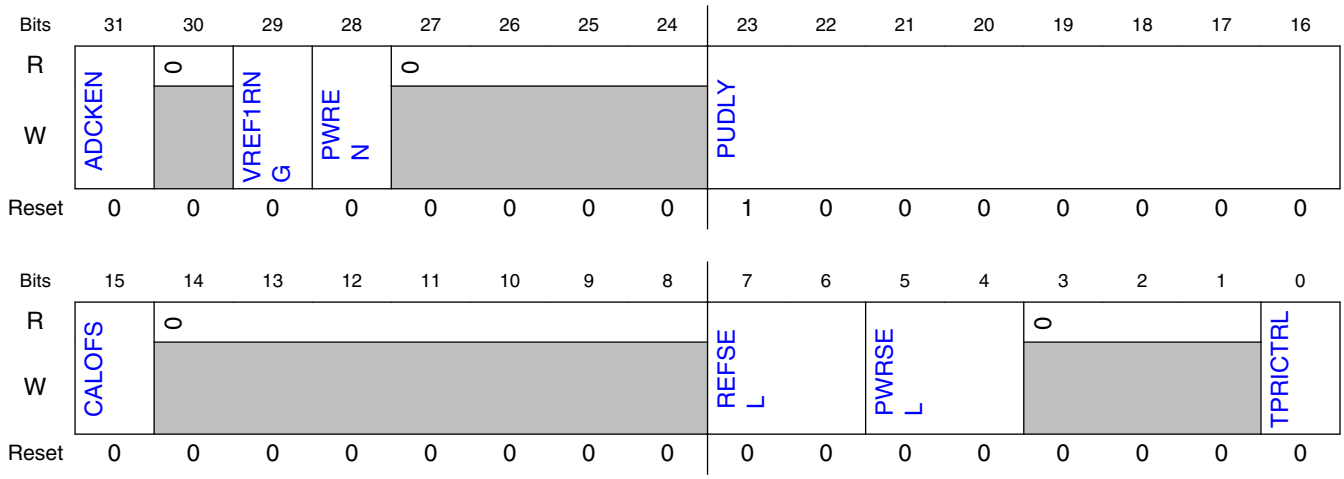
### 46.4.8.1 Offset

| Register | Offset |
|---|---|
| CFG | 20h |

### 46.4.8.2 Function

The Configuration Register controls ADC functions that are common to all commands. The CFG cannot be changed while the CTRL[ADCEN] bit is set. Writes to CFG while CTRL[ADCEN] is set are ignored.

### 46.4.8.3 Diagram



### 46.4.8.4 Fields

| Field | Function |
|---|---|
| 31<br>ADCKEN | LPADC asynchronous clock enable<br>Enables the internally generated clock source. The clock source is used in clock selection logic at the chip level and is optionally used for the LPADC clock source, depending on chip-level clock select definition.<br>0b - LPADC internal clock is disabled<br>1b - LPADC internal clock is enabled |
| 30<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 29<br>VREF1RNG | Enable support for low voltage reference on Option 1 Reference<br>The VREF1RNG control bit should be set when Reference Option 1 is used and the reference is below 1.8V. When the reference is above 1.8V, the VREF1RNG control bit should be clear.<br>0b - Configuration required when Voltage Reference Option 1 input is in high voltage range<br>1b - Configuration required when Voltage Reference Option 1 input is in low voltage range |
| 28<br>PWREN | LPADC Analog Pre-Enable<br>Enables the LPADC analog circuits. When setting CFG[PWREN], user code should delay for a period exceeding the analog startup time of $t_{ADCSTUP}$ before enabling the LPADC for operation. The module is still operational even when CFG[PWREN] is left clear but command execution start is delayed for a period defined by CFG[PUDLY]. Refer to the device datasheet for LPADC idle and LPADC active power consumption parameters.<br>0b - LPADC analog circuits are only enabled while conversions are active. Performance is affected due to analog startup delays.<br>1b - LPADC analog circuits are pre-enabled and ready to execute conversions without startup delays (at the cost of higher DC current consumption). When PWREN is set, the power up delay is enforced such that any detected trigger does not begin ADC operation until the power up delay time has passed. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 27-24<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 23-16<br>PUDLY | Power Up Delay<br>When CFG[PWREN]=0b0, the LPADC analog circuits are only powered while the module is active and there is a counted delay defined by CFG[PUDLY] after an initial trigger transitions the LPADC from its Idle state to allow time for the analog circuits to stabilize. The startup delay count of (PUDLY*4) ADCK cycles must result in a longer delay than the analog startup time of $t_{ADCSTUP}$. Accuracy of the initial conversion after activation is degraded if CFG[PUDLY] is set to too small a value.<br>When CFG[PWREN]=0b1 prior to LPADC activation, the analog circuits are pre-enabled and the activation delay defined by CFG[PUDLY] is bypassed. |
| 15<br>CALOFS | Configure for offset calibration function<br>When CALOFS is set, the LPADC is configured to perform a calibration function anytime the module executes a conversion. Any channel selected is ignored and the value returned in the RESFIFO is a signed value between -31 and 31. -32 is not a valid and is never a returned value. Software should copy the lower 6-bits of the conversion result stored in the RESFIFO after a completed calibration conversion to the OFSTRIM[OFSTRIM] field. The OFSTRIM field is used in normal operation for offset correction.<br>0b - Calibration function disabled<br>1b - Configure for offset calibration function |
| 14-8<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 7-6<br>REFSEL | Voltage Reference Selection<br>Selects the voltage reference high used for conversions.<br>**NOTE:** See the chip configuration information on the voltage reference options specific to this packaged device.<br>00b - (Default) Option 1 setting.<br>01b - Option 2 setting.<br>10b - Option 3 setting.<br>11b - Reserved |
| 5-4<br>PWRSEL | Power Configuration Select<br>Configures the module for power and performance. In the highest power setting, the highest conversion rates are possible. Refer to the device datasheet for power and performance capabilities for each setting. The highest power setting corresponds to 0b11 with decreasing power down to 0b00.<br>00b - Level 1 (Lowest power setting)<br>01b - Level 2<br>10b - Level 3<br>11b - Level 4 (Highest power setting) |
| 3-1<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 0<br>TPRICTRL | LPADC trigger priority control<br>This bitfield controls how higher priority triggers are handled. See Trigger detect and command execution for a detailed explanation trigger event handling.<br>0b - If a higher priority trigger is detected during command processing, the current conversion is aborted and the new command specified by the trigger is started.<br>1b - If a higher priority trigger is received during command processing, the current conversion is completed (including averaging iterations if enabled) and stored to the RESFIFO before the higher priority trigger/command is initiated. Note that compare until true commands can be interrupted prior to resulting in a true conversion. |

## 46.4.9 LPADC Pause Register (PAUSE)

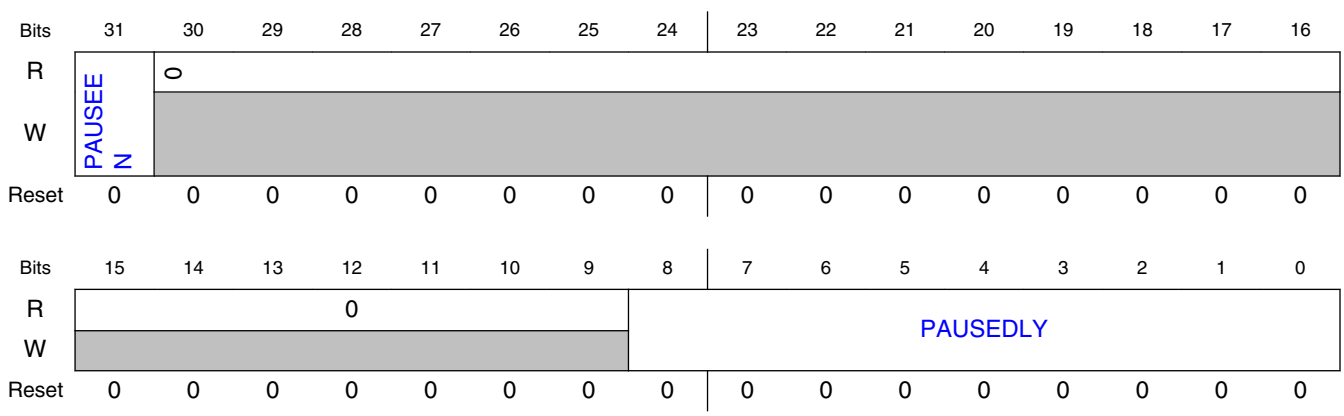
### 46.4.9.1 Offset

| Register | Offset |
|---|---|
| PAUSE | 24h |

### 46.4.9.2 Function

The Pause Register controls an optional inserted delay between conversions. PAUSE cannot be changed while the CTRL[ADCEN] bit is set. Writes to PAUSE while CTRL[ADCEN] is set are ignored.

### 46.4.9.3 Diagram



### 46.4.9.4 Fields

| Field | Function |
|---|---|
| 31<br>PAUSEEN | PAUSE Option Enable<br>Enables the LPADC pausing function. When enabled, a programmable delay is inserted during command execution sequencing between LOOP iterations, between commands in a sequence, and between conversions when command is executing in for "Compare Until True" configuration.<br>0b - Pause operation disabled<br>1b - Pause operation enabled |

*Table continues on the next page...*

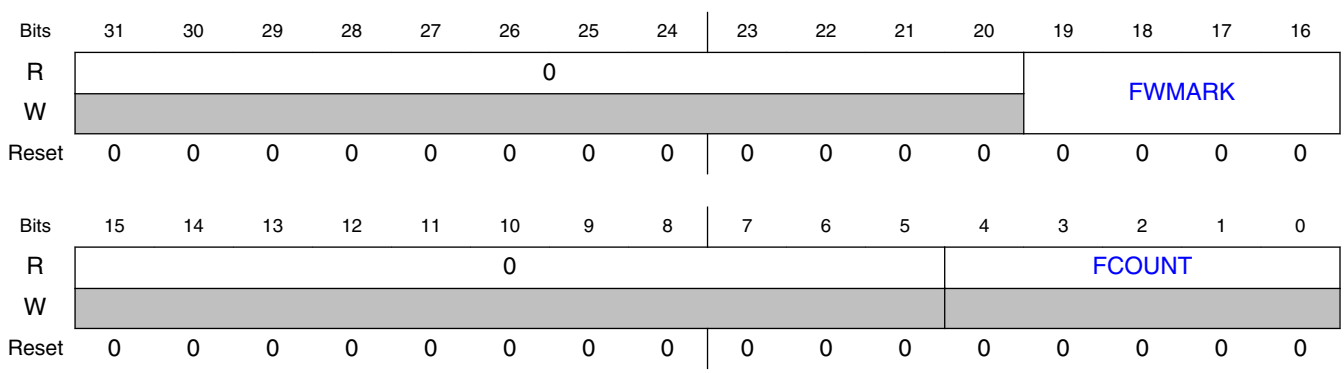
| Field | Function |
|---|---|
| 30-9<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 8-0<br>PAUSEDLY | Pause Delay<br>When PAUSEEN is set, the PAUSEDLY field controls the duration of pausing during command exection sequencing. The pause delay is a count of (PAUSEDLY*4) ADCK cycles. |

## 46.4.10 LPADC FIFO Control Register (FCTRL)

### 46.4.10.1 Offset

| Register | Offset |
|---|---|
| FCTRL | 30h |

### 46.4.10.2 Diagram



### 46.4.10.3 Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 19-16<br>FWMARK | Watermark level selection<br>FWMARK is a programmable threshold setting. When the number of datawords stored in the ADC Result FIFO is greater than the value in this field, the STAT[RDY] flag is asserted to indicate stored data has |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | reached the programmable threshold. When IE[FWMIE] is set, an interrupt request is generated. When DE[FWMDE] is set, a DMA request is generated. |
| 15-5<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 4-0<br>FCOUNT | Result FIFO counter<br>This read-only field indicates the number of datawords that are stored in the result FIFO. This value may be used in conjunction with PARAM[FIFOSIZE] to calculate how much room is left in the result FIFO. FCOUNT is incremented with each store of new data to the result FIFO and decrements with each read of the result FIFO. The FIFO is reset by writing to the CTRL[RSTFIFO] bit, resulting in FCTRL[FCOUNT] initialized to 0x0. |

## 46.4.11 Software Trigger Register (SWTRIG)

### 46.4.11.1 Offset

| Register | Offset |
|---|---|
| SWTRIG | 34h |

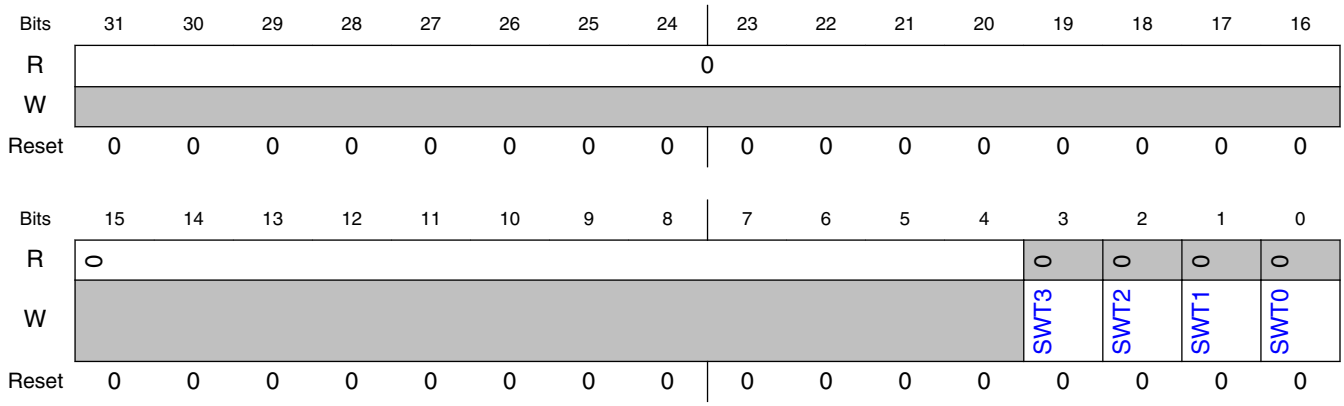
### 46.4.11.2 Function

The Software Trigger Register (SWTRIG) is written to initiate software triggered conversions. Writes to SWTRIG register are ignored while CTRL[ADCEN] is clear.

**NOTE**

There is a synchronization delay of 3 ADCK clock cycles when writing to set CTRL[ADCEN]. Writes to SWTRIG will continue to be ignored ultil CTRL[ADCEN] can propagate into the ADCK domain.

## 46.4.11.3 Diagram



## 46.4.11.4 Fields

| Field | Function |
|---|---|
| 31-4<br>— | Reserved<br>This read-only field is reserved and always has the value 0. |
| 3<br>SWT3 | Software trigger 3 event<br>Write 1 to SWT3 generates a trigger 3 event. Writing 1 to SWT3 is ignored while the trigger 3 event is being serviced or is pending.<br>0b - No trigger 3 event generated.<br>1b - Trigger 3 event generated. |

| 1<br>SWT1 | Software trigger 1 event<br>Write 1 to SWT1 generates a trigger 1 event. Writing 1 to SWT1 is ignored while the trigger 1 event is being serviced or is pending.<br>0b - No trigger 1 event generated.<br>1b - Trigger 1 event generated. |
| 0<br>SWT0 | Software trigger 0 event<br>Write 1 to SWT0 generates a trigger 0 event. Writing 1 to SWT0 is ignored while the trigger 0 event is being serviced or is pending.<br>0b - No trigger 0 event generated.<br>1b - Trigger 0 event generated. |

## 46.4.12 LPADC Offset Trim Register (OFSTRIM)

### 46.4.12.1 Offset

| Register | Offset |
|---|---|
| OFSTRIM | 40h |

### 46.4.12.2 Function

The Offset Trim register is used to trim for offset. The LPADC supports a calibration step in which the module is configured to perform a calibration operation to determine the value needed in the OFSTRIM register.

To determine the value to put in the OFSTRIM register, set the CFG[CALOFS] and trigger a conversion using standard triggering methods. Any selected channel is ignored and the conversion result stored in the RESFIFO after a completed conversion is a signed value between -31 and 31. To minimize the offset during normal operation, software should read the conversion result from the RESFIFO calibration operation and write the lower 6 bits to the OFSTRIM register.

## 46.4.13 Trigger Control Register (TCTRL0 - TCTRL3)

### 46.4.13.1 Offset

| Register | Offset |
|---|---|
| TCTRL0 | C0h |
| TCTRL1 | C4h |
| TCTRL2 | C8h |
| TCTRL3 | CCh |

### 46.4.13.2 Function

The Trigger Control (TCTRL*a*) register implements control fields associated with each implemented trigger source. When the LPADC is actively executing commands, only one of the TCTRL*a* registers is actively controlling ADC conversions. The actively controlling TCTRL*a* register cannot be updated while the LPADC is active. A write to a TCTRL*a* registers while that trigger control register is controlling the ADC operation is ignored.

# 46.4.14 LPADC Command Low Buffer Register (CMDL1 - CMDL 15)

## 46.4.14.1 Offset

For a = 1 to 15:

| Register | Offset |
|---|---|
| CMDLa | F8h + (a × 8h) |

## 46.4.14.2 Function

There are 15 command buffers (CMD*a*), each constructed from two 32-bit registers (CMDL*a*:CMDH*a*) that can be configured for different channel select and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of the TCTRL*a*[TCMD] bitfield. When the LPADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer cannot be updated while the LPADC is active. A write to a CMD buffer while that CMD buffer is controlling the ADC operation is ignored.

## 46.4.17 Compare Value Register (CV1 - CV4)

### 46.4.17.1 Offset

| Register | Offset |
|---|---|
| CV1 | 200h |
| CV2 | 204h |
| CV3 | 208h |
| CV4 | 20Ch |

### 46.4.17.2 Function

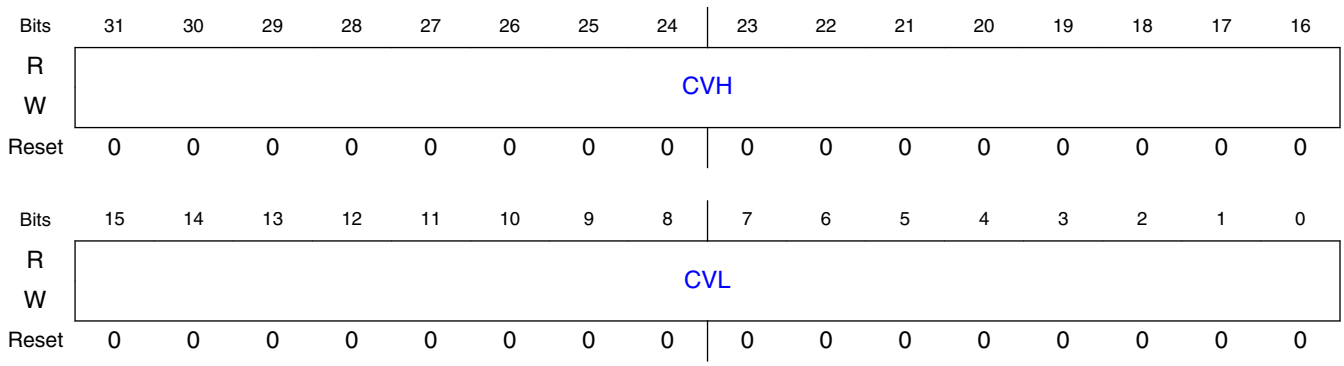
The compare value registers (CV*a*) contain values used to compare the conversion result when the compare function is enabled. This register is formatted in the same way as the D field in the RESFIFO registers in different modes of operation for both bit position definition and value format using unsigned or signed 2's complement. There is a direct association of each compare value register to a specific command buffer register (i.e., CV1 is only used during execution of CMD1 command).

**NOTE**

Not all Command Buffers have an associated Compare Value register. The compare function is only available on Command Buffers that have a corresponding Compare Value register.

When the LPADC is actively executing commands, the CV*a* register associated with the active command (CMD*a*) cannot be updated and writes to associated CV*a* register during this time are ignored.

### 46.4.17.3 Diagram



### 46.4.17.4 Fields

| Field | Function |
|---|---|
| 31-16<br>CVH | Compare Value High.<br>The compare function can be configured to check whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVH is used. |
| 15-0<br>CVL | Compare Value Low.<br>The compare function can be configured to check whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. See Compare function for a description on how CVL is used. |

## 46.4.18 LPADC Data Result FIFO Register (RESFIFO)

### 46.4.18.1 Offset

| Register | Offset |
|---|---|
| RESFIFO | 300h |

### 46.4.18.2 Function

The data result FIFO register (RESFIFO) is a 16 entry FIFO that stores the data result of ADC conversions. In addition, several tag fields of source command and trigger information are stored along with the data. FCTRL[FCOUNT] indicates how many valid datawords are stored in the RESFIFO. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCOUNT. The FIFO can be emptied by successive reads of RESFIFO. The FIFO is reset by writing 0b1 to the CTRL[RSTFIFO] bit.

The following table describes the format of data in the result FIFO.

**Table 46-5. Data result register format description**

| Conversion mode | D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 | Format |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 12-bit single-ended | 0 | D | D | D | D | D | D | D | D | D | D | D | D | 0 | 0 | 0 | Unsigned, zero in D[15] and D[2:0] |

**NOTE**

| 15-0<br>D | Data result<br>The formatting for the data in D is summarized in Table 46-5. |

## 46.5 Functional description

The LPADC module performs analog-to-digital conversions on any of the software selectable analog input channels by a successive approximation algorithm. The module initializes to its lowest power state during reset and in Low-Power Stop mode. The LPADC analog circuits can optionally be pre-enabled for faster starts to conversions at the expense of higher idle currents. Conversions are initiated by selectable trigger events

from software or hardware sources. The trigger detect logic includes a configurable enable and priority scheme for the available trigger sources. The module includes multiple command buffers that provide configurable flexibility for channel scanning and independent channel selections for different trigger sources. Multiple command buffers also allow variable option selection such as sample time and averaging on a per-channel basis.

This module optionally averages the result of multiple conversions on a channel before storing the calculated result. The hardware average function is enabled by setting CMDH*a*[AVGS] bitfield to a non-zero value and operates in any of the conversion modes and configurations.

When the conversion and averaging loops are completed, the resulting data is placed in a FIFO data buffer along with other tag information associated with the result. A configurable watermark level supports interrupt or DMA requests when the number of stored datawords exceeds the setting.

The LPADC module optionally compares the result of a conversion with the contents of two value registers for less-than, greater-than, inside-range or outside-range detection. The compare function operates in any of the conversion modes and configurations.

The sequencing of an ADC command is summarized in the flow diagram shown below.

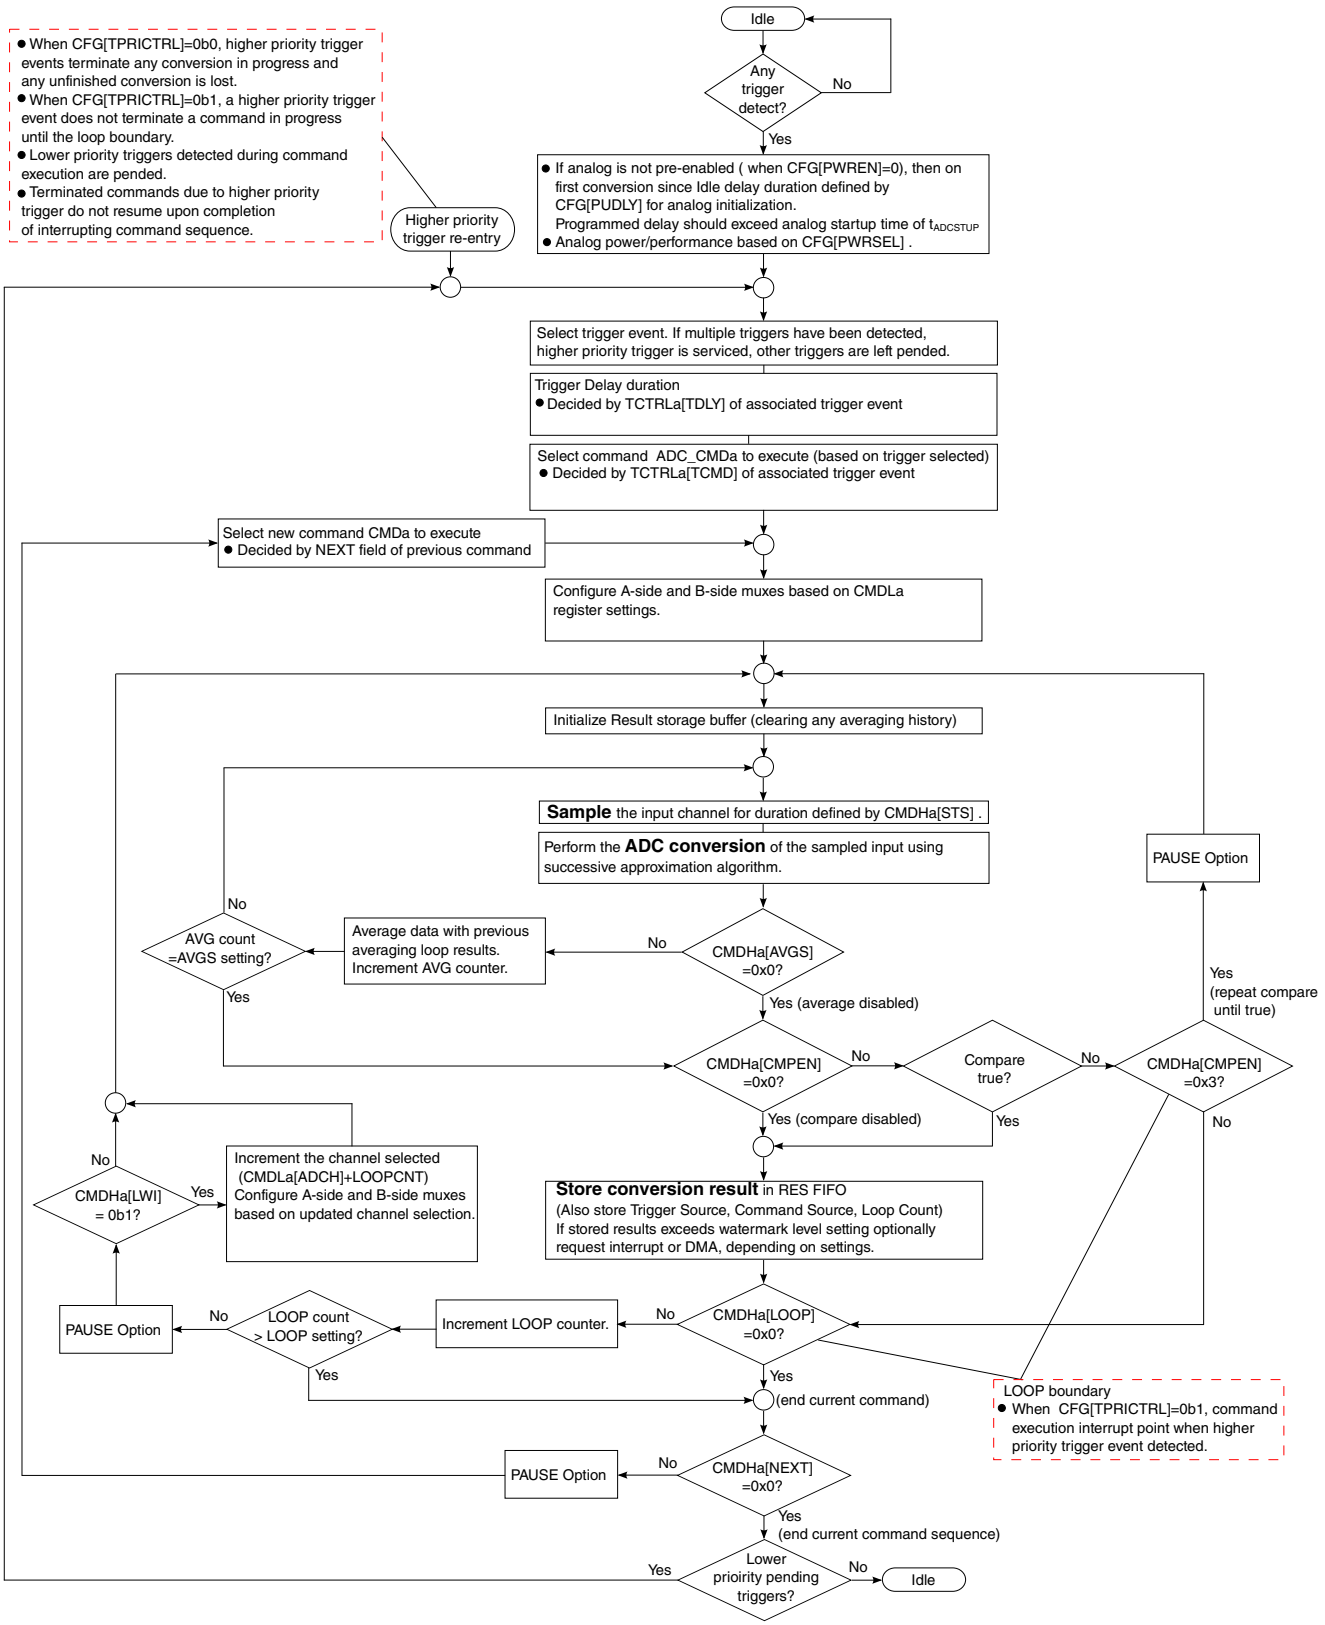

**Figure 46-2. ADC command execution flow diagram**

### 46.5.1 Voltage reference

The voltage reference high ($V_{REFH}$) used by the LPADC is supplied from either an on-chip voltage reference source or from an off-chip source supplied through external pins. $V_{REFL}$ is always from an external pin and must be at the same voltage potential as $V_{SSA}$. See the chip configuration information on the voltage reference options specific to this packaged device.

This block supports a programmable selection of the Voltage Reference High used for ADC conversions (via the CFG[REFSEL] field). See the chip configuration information on the voltage reference options specific to this packaged device.

### 46.5.2 Power control

The default setting for the ADC analog circuits is disabled while the LPADC is in its Idle state. When a trigger is detected and ADC command processing is initiated, the analog circuits are enabled and require a period of initialization before the first conversion cycle. The CFG[PUDLY] should be programmed such that a delay duration longer than $t_{ADCSTUP}$ is incurred. Accuracy of the initial conversion(s) after activation is degraded if CFG[PUDLY] is set to too small a value.

Faster conversion startup times can be achieved by optionally setting the CFG[PWREN] field to pre-enable the analog circuits of the LPADC at the expense of power consumption even while the module is in an idle state. When CFG[PWREN] is set, the Power Enable timer is activated and enforces the minimum startup (controlled by the PUDLY register field) before detected triggers are allowed to initiate ADC conversions.

This module also has configuration options for controlling power and performance summarized in the table below. See the device datasheet for specification of the available power modes.

**Table 46-6. Power option settings**

| CFG[PWRSEL] | Description |
|---|---|
| 0b00 (Default) | Level 1. Slowest speed/Lowest power setting. |
| 0b01 | Level 2. |
| 0b10 | Level 3. |
| 0b11 | Level 4. Fastest speed/highest power setting. |

In the two highest power mode settings (CFG[PWRSEL]=0x2 or CFG[PWRSEL]=0x3) the LPADC will delay start of sampling for 16 ADC clock cycles on the initial conversion since being in its Idle state. This delay is in addition to any configured Power Up delay or trigger delay.

### 46.5.3 Clock operation

The LPADC operates from the ADCK clock input provided from an on-chip clock select block and is used by the SAR conversion control sequencing logic and the FIFO storage buffer. The ADCK frequency must fall within the specified frequency range for ADCK and will vary based on configuration of CFG[PWRSEL]. See the device datasheet for supported frequency ranges.

The LPADC continues operating in stop and wait modes provided the Doze Enable bit (CTRL[DOZEN]) is clear and the on-chip clock select block continues to supply an ADCK clock source. When the CTRL[DOZEN] bit is set, the module will wait for the current averaging iteration/FIFO storage to complete before acknowledging stop or wait mode entry.

### 46.5.4 Trigger detect and command execution

See Figure 46-2 for a flow diagram of command execution sequencing.

LPADC command execution is initiated from up to 4 trigger sources. Each trigger can be software generated by writing 0b1 to the corresponding SWTRIG[SWT*n*] bitfield. Alternatively, hardware triggers can be generated from asynchronous input sources at the periphery of the module. The number and sources of hardware triggers implemented is device-specific. See the chip configuration information for description of available hardware trigger sources for this device.

Each hardware trigger source is enabled by setting the associated enable bit (TCTRL*a*[HTEN]). Each trigger source is assigned a priority via the associated priority control field (TCTRL*a*[TPRI]). Each of the trigger sources is configurably associated with a command in the command buffer via the associated command select field (TCTRL*a*[TCMD]).

When a hardware trigger input is enabled, hardware trigger events are detected on the rising-edge of the associated hardware trigger source.

If a trigger event occurs that is configured for a higher priority than the trigger source associated with the currently executing command, the current command is handled in one of two ways depending on the CFG[TPRICTRL] bitfield setting. When

CFG[TPRICTRL]=0b0, a higher priority trigger causes an immediate command abort and the new command specified by the trigger is immediately started. When CFG[TPRICTRL]=0b1, a higher priority triggers allows the current conversion to complete (including averaging and compare functions) before the higher priority command is initiated.

If a lower priority trigger occurs (i.e., a trigger event occurs that is configured for a lower priority than the trigger source associated with the currently executing command), the trigger detect is pended until completion of the current command sequence.

At the completion of a command, the LPADC does not resume a previously interrupted command (or series of commands). The module begins command execution associated with the processing of lower priority pending triggers. If no trigger events are pending, the LPADC transitions to its idle state.

When a conversion is completed (including hardware averaging when AVGS is non-zero), the result is placed in the RESFIFO buffer. When an ADC command selects looping (when LOOP is non-zero) a command will store multiple conversion results to the FIFO during execution of that command.

At the end of command execution, the NEXT field of the command selects the next command to be executed. Multiple commands can be executed sequentially by configuration of each command's NEXT field. Setting the next command to 0x0 causes conversions to terminate at the completion of the command. Unending circular command execution is allowed by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Lower priority trigger events cannot be serviced until a higher priority triggered command (or command sequence) completes.

Disabling the LPADC by writing 0b0 to the CTRL[ADCEN] bitfield terminates any active ADC command processing. Writing 0b0 to the CTRL[ADCEN] bitfield causes the current command (or command sequence) to terminate, clears any pending triggers, and sends the module to an Idle state.

### 46.5.5 Pause option

When the maximum conversion rate is not required by an application the effective conversion rate can be reduced by implementing periodic trigger events to initiate ADC conversions or by selecting a reduced frequency clock as the ADACK source. Both of these options are chip specific and are dependent on ADC triggering and clocking options external to the LPADC module. The latency associated with ADC analog power up delays results in a limit on the maximum conversion rate when using periodic triggering.

Another means of reducing conversion rates is by inserting a pause of a programmable duration between LOOP iterations, between commands in a sequence, and between conversions when command is executing in the "Compare Until True" configuration. When PAUSE[PAUSEEN] is set, the PAUSE[PAUSEDLY] field controls the duration of pausing during command exection sequencing. The pause delay is a count of (PAUSEDLY*4) ADCK cycles. The PAUSE register cannot be changed while the CTRL[ADCEN] bit is set. Writes to the PAUSE register while CTRL[ADCEN] is set are ignored.

See Figure 46-2 for the places during command execution sequencing where the pause is optionally inserted.

### 46.5.6 Result FIFO operation

The LPADC includes a 16 entry FIFO in which the result of ADC conversions are stored. In addition, a valid indicator bit, the trigger source, the source command and the loop count are also stored along with the data. FCTRL[FCOUNT] indicates how many valid datawords are stored in the RESFIFO.

A programmable watermark threshold supports configurable notification of data availability. When FCOUNT is greater than FCTRL[FWMARK], the STAT[RDY] flag is asserted. When IE[FWMIE] is set, a watermark interrupt request is issued. When DE[FWMDE] is set, a DMA request is issued. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCOUNT. When FCOUNT falls equal to or below FWMARK, the RDY flag is cleared.

The FIFO can be emptied by successive reads of RESFIFO. When the RESFIFO[VALID] bit is 1, the associated FIFO entry is valid. Reading RESFIFO when the FIFO is empty (when RESFIFO[VALID] is clear and FCOUNT=0x0) provides an undefined dataword. The FIFO is reset by writing 0b1 to the CTRL[RSTFIFO] bit.

If the LPADC attempts to store a dataword to the FIFO when the FIFO is full, the FIFO overflow flag (FCTRL[FOF]) is set. When IE[FOFIE] is set, an overflow interrupt request is issued. The STAT[FOF] flag is cleared by writing 1 to FOF. On overflow events, no new data is stored and the data associated with the store that triggered the overflow is lost, the current ADC command (sequence) is aborted and all pending trigger events are discarded. No new triggers are detected until the overflow flag is cleared.

## 46.5.7 Compare function

After the input is sampled and converted and any averaging iterations are performed, the CMDH*a*[CMPEN] field guides operation of the automatic compare function to optionally only store when the compare operation is true. There are multiple options on command sequencing related to the compare function as summarized in the table below.

**NOTE**

Not all Command Buffers have an associated Compare Value register. The compare function is only available on Command Buffers that have a corresponding Compare Value register.

**Table 46-7. Compare modes**

| CMDH*a*[CMPEN] | Compare Function | Description |
|---|---|---|
| 0b00 | Compare disabled | Do not perform compare operation. Always store the conversion result to the FIFO. |
| 0b01 | Reserved | |
| 0b10 | Store on true | Perform compare operation. Store conversion result to FIFO at end of averaging only if compare is true. If compare is false, do not store the result to the FIFO. In either the true or false condition, the LOOP setting is considered and increments the LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required. |
| 0b11 | Repeat compare until true | Perform compare operation. Store conversion result to FIFO at end of averaging only if compare is true. Once the true condition is found the LOOP setting is considered and increments the LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required. If the compare is false do not store the result to the FIFO. The conversion is repeated without consideration of LOOP setting and does not increment the LOOP counter. |

Depending on CV*a*[CVH] and CV*a*[CVL] values programmed, the compare operation checks whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. The compare values are used as described in the following table.

**Table 46-8. Compare operations**

| CV*a*[CVL] vs. CV*a*[CVH] | Operation | Description |
|---|---|---|
| set CVL < CVH | Outside range (General form) | Compare true if the result is less than CVL value or greater than CVH value. |
| set CVH to max value<br>set CVL to compare point | Less than | Compare true if the result is less than CVL value. |
| set CVL to min value<br>set CVH to compare point | Greater than | Compare true if the result is greater than CVH value. |

*Table continues on the next page...*

**Table 46-8. Compare operations (continued)**

| CV*a*[CVL] vs. CV*a*[CVH] | Operation | Description |
|---|---|---|
| set CVL > CVH | Inside range | Compare true if the result is less than CVL value and greater than CVH value. |

**Note**

In low power modes where the LPADC continues to operate, the compare function can monitor the voltage and only wake the device when the compare condition is met.

# Low Power Comparator (LPCMP)

## 47.1 Chip-specific LPCMP information

### 47.1.1 LPCMP input connections

The following table shows the fixed internal connections to the LPCMP.

**Table 47-1. LPCMP input connections**

| LPCMP Inputs | LPCMP0 | LPCMP1 |
|---|---|---|
| IN0 | LPCMP0_IN0 | LPCMP1_IN0 |
| IN1 | LPCMP0_IN1 | LPCMP1_IN1 |
| IN2 | LPCMP0_IN2 | LPCMP1_IN2 |
| IN3 | LPCMP0_IN3 / DAC0_OUT (12-bit) | LPCMP1_IN3 / DAC0_OUT (12-bit) |
| IN4 | — | LPCMP1_IN4 |
| IN5 | LPCMP0_IN5 / VREF Output | LPCMP1_IN5 / VREF Output |
| IN6 | PMC 1 V Bandgap | PMC 1 V Bandgap |
| IN7 | DAC0 Reference (6-bit) | DAC1 Reference (6-bit) |

### 47.1.2 LPCMP external references

The 6-bit DAC sub-block supports the selection of two reference sources. For this device, the references are:

- $V_{REFH_EXT}$ - $V_{DDIO1}$ (LPCMP0), $V_{DDIO2}$ (LPCMP1). LPCMPx[VRSEL] = 1
- $V_{REFH_INT}$ -$V_{SS_BULK}$, LPCMPx[VRSEL] = 0

## 47.2 Introduction

The low power comparator (LPCMP) module provides a circuit for comparing two analog input voltages. It comprises a comparator (CMP), a DAC and an analog mux (ANMUX).

The CMP circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The DAC is a 64-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. The 64-tap resistor ladder network divides the supply reference $V_{in}$ into 64 voltage levels. A 6-bit digital signal input selects the output voltage level, which varies from $V_{in}$ to $V_{in}/64$. $V_{in}$ can be selected from two voltage sources, vrefh_int and vrefh_ext. The DAC from a comparator is available as an on-chip internal signal only and is not available to output externally to a pin.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One channel is provided by the DAC. Refer to the chip-specific information section for details on which device resources are connected to other channels. The mux circuit is designed to operate across the full range of the supply voltage.

## 47.3 Features

The features of the LPCMP module include:

- Two 8-to-1 channel MUXes to select input signal from eight channels
- Multiple operation modes to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally Filtered
- Selectable performance levels: nano mode, normal mode, high speed mode
- Programmable hysteresis control
- Selectable inversion on comparator output
- External hysteresis can be used at the same time that the output filter is used for internal functions

- Interrupt and DMA support
- Includes a 6-bit resolution DAC
- Selectable supply reference source for DAC
- Configurable low power mode or high speed mode for DAC

## 47.4 LPCMP Block Diagram

The following figure shows the LPCMP block diagram includes the CMP, DAC, and ANMUX modules.

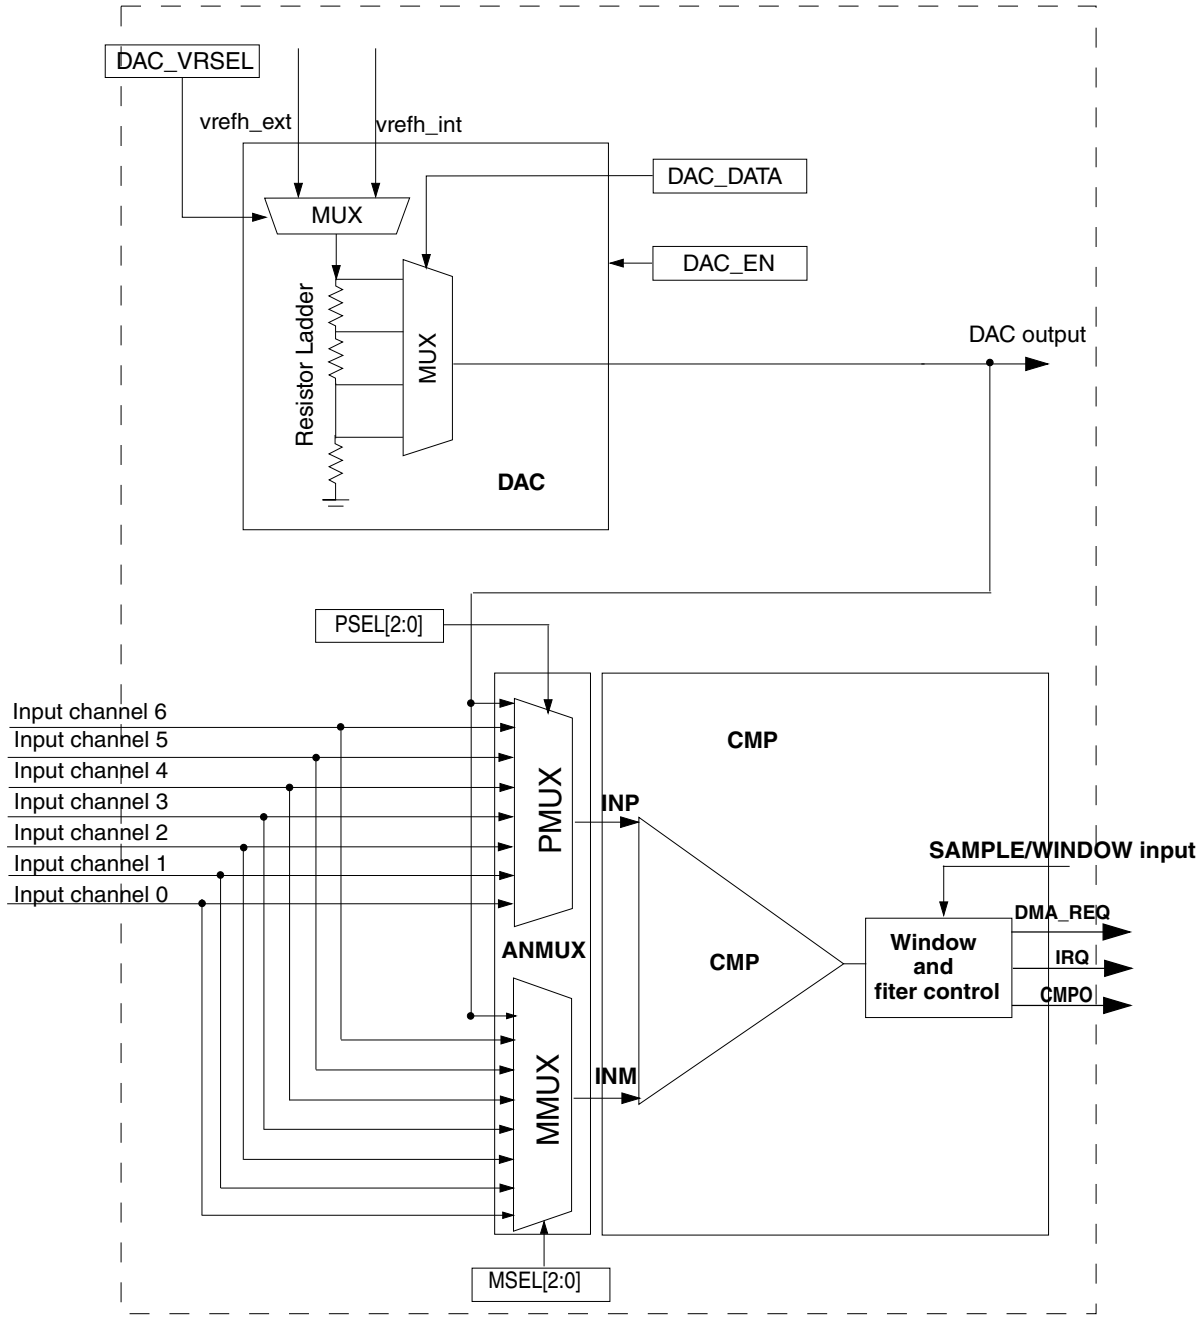

**Figure 47-1. LPCMP Block Diagram**

## 47.5 LPCMP0 register descriptions

The memory map comprises of 32-bit aligned registers which can be accessed via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error. Read access to reserved address will also generate a transfer error and the read data bus will show all 0s.

## 47.5.1 LPCMP0 Memory map

### 47.5.9.3 Fields

| Field | Function |
|---|---|
| 31-9<br>— | Reserved |
| 8<br>COUT | Analog Comparator Output<br>Returns the current value of the analog comparator output, when read. The field is reset to 0 and will read as CCR1[COUT_INV] when the analog comparator module is disabled, that is, when CCR0[CMP_EN] = 0. Writing to this field is ignored. |
| 7-2<br>— | Reserved |
| 1<br>CFF | Analog Comparator Flag Falling<br>The CFF bit is set when a falling edge on COUT has been detected. CFF is cleared by writing 1 to it when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag is automatically cleared when DMA is done. CFF is cleared when CCR0[CMP_EN] is not set.<br>0b - A falling edge has not been detected on COUT.<br>1b - A falling edge on COUT has occurred. |
| 0<br>CFR | Analog Comparator Flag Rising<br>The CFR bit is set when a rising edge on COUT has been detected. CFR is cleared by writing 1 to it when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag is automatically cleared when DMA is done. CFR is cleared when CCR0[CMP_EN] is not set.<br>0b - A rising edge has not been detected on COUT.<br>1b - A rising edge on COUT has occurred. |

## 47.6 LPCMP1 register descriptions

The memory map comprises of 32-bit aligned registers which can be accessed via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces are terminated with an error. Read access to reserved address will also generate a transfer error and the read data bus will show all 0s.

### 47.6.1 LPCMP1 Memory map

LPCMP1 base address: 4103_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID Register (VERID) | 32 | RO | 0000_0000h |
| 4h | Parameter Register (PARAM) | 32 | RO | 0000_0001h |

*Table continues on the next page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 8h | Comparator Control Register 0 (CCR0) | 32 | RW | 0000_0002h |
| Ch | Comparator Control Register 1 (CCR1) | 32 | RW | 0000_0000h |

| Field | Function |
|---|---|
| 31-9<br>— | Reserved |
| 8<br>COUT | Analog Comparator Output<br>Returns the current value of the analog comparator output, when read. The field is reset to 0 and will read as CCR1[COUT_INV] when the analog comparator module is disabled, that is, when CCR0[CMP_EN] = 0. Writing to this field is ignored. |
| 7-2<br>— | Reserved |
| 1<br>CFF | Analog Comparator Flag Falling<br>The CFF bit is set when a falling edge on COUT has been detected. CFF is cleared by writing 1 to it when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag is automatically cleared when DMA is done. CFF is cleared when CCR0[CMP_EN] is not set.<br>0b - A falling edge has not been detected on COUT.<br>1b - A falling edge on COUT has occurred. |
| 0<br>CFR | Analog Comparator Flag Rising<br>The CFR bit is set when a rising edge on COUT has been detected. CFR is cleared by writing 1 to it when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag is automatically cleared when DMA is done. CFR is cleared when CCR0[CMP_EN] is not set.<br>0b - A rising edge has not been detected on COUT.<br>1b - A rising edge on COUT has occurred. |

## 47.7 LPCMP Function Description

### 47.7.1 Functional Block Diagram

The following figure shows the functional block diagram.

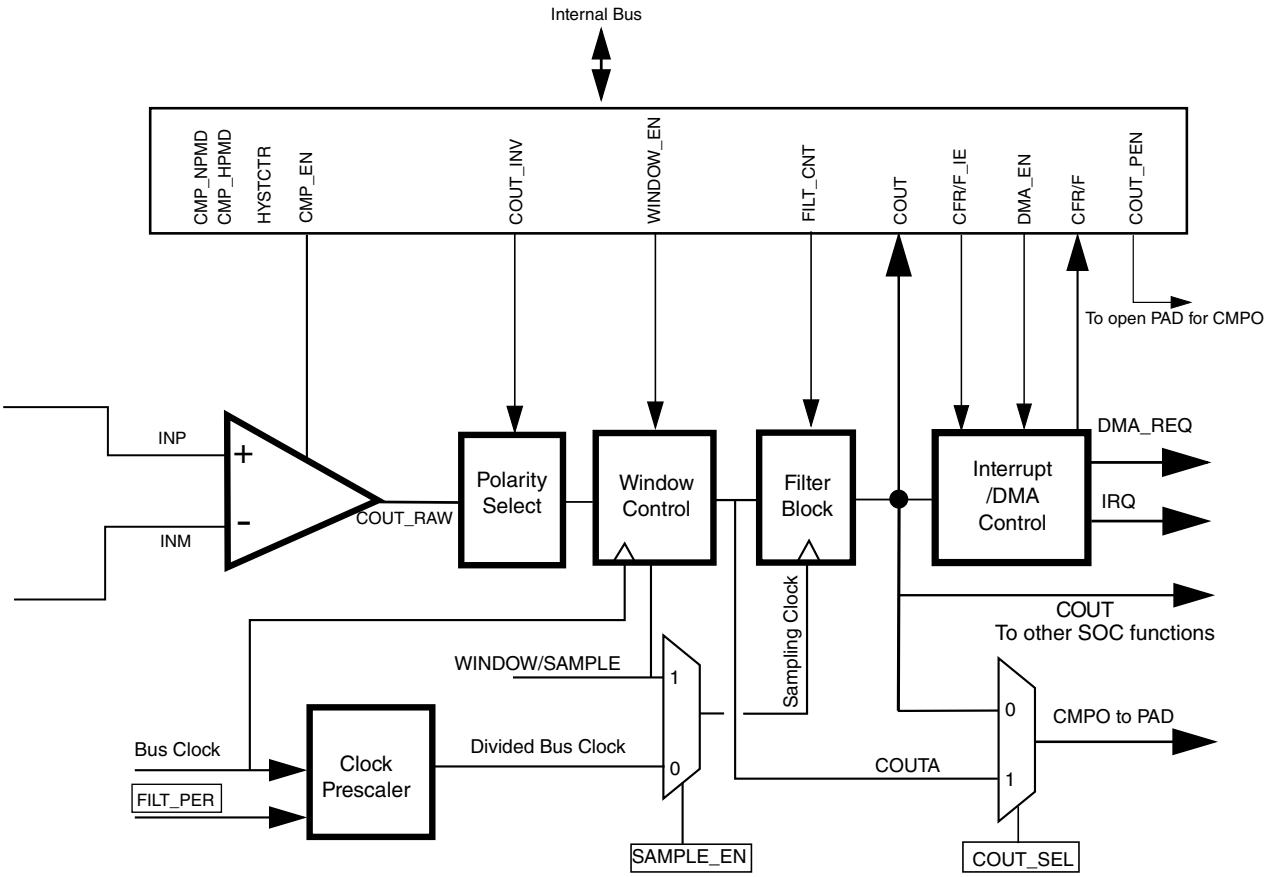

**Figure 47-2. Functional Block Diagram**

In the block diagram:

- Two analog input voltages applied to INP and INM are compared. COUT_RAW is high when the INP input voltage is greater than the INM input, and is low when the INP input voltage is less than the INM input.
- This COUT_RAW signal can be inverted if CCR1[COUT_INV] is enabled.
- If CCR1[WINDOW_EN] is enabled, the optionally inverted comparator output COUT_RAW is sampled on every bus clock when window is enabled to generate COUTA. Sampling does NOT occur when window is disabled. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.
- The window control block can be bypassed if CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler if CCR1[FILT_CNT] is set to 0x01.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set greater than 0x01.

- If CCR1[SAMPLE_EN] = 1, the external SAMPLE input is used as the sampling clock.
- If CCR1[SAMPLE_EN] = 0, the divided bus clock is used as the sampling clock.

- The filter block can be bypassed when not in use.

```
Bypass_Filter_Block = ((FILT_CNT == 0x00) | (FILT_PER == 0x00)) & ~SAMPLE_EN
```

- Both COUTA and COUT can be configured as module output CMPO by configuring the CCR1[COUT_SEL] bit and are used for different purposes within the system.
- The optionally filtered COUT can be read directly through register bit CSR[COUT].

**NOTE**

See the chip configuration section for the source of SAMPLE/ WINDOW input.

## 47.7.2 Functional Modes

The comparator window and filter features can be combined as shown in the following table. Individual modes are discussed below the table.

**Table 47-2. Functional modes**

| Mode # | CMP_EN | WINDOW_EN | SAMPLE_EN | FILT_CNT | FILT_PER | Operation | Maximum latency[1] |
|---|---|---|---|---|---|---|---|
| 1 | 0 | X | X | X | X | See the Disabled Mode (#1). | N/A |
| 2A | 1 | 0 | 0 | 0x00 | X | See the Continuous Mode (#2A & 2B). | $T_{PD}$ |
| 2B | 1 | 0 | 0 | X | 0x00 | | |
| 3A | 1 | 0 | 1 | 0x01 | X | See the Sampled, Non-Filtered Mode (#3A & 3B). | $T_{PD} + T_{SAMPLE} + T_{per}$ |
| 3B | 1 | 0 | 0 | 0x01 | > 0x00 | | $T_{PD} + (FILT_PER * T_{per}) + T_{per}$ |
| 4A | 1 | 0 | 1 | > 0x01 | X | See the Sampled, Filtered Mode (#4A & 4B). | $T_{PD} + (FILT_CNT * T_{SAMPLE}) + T_{per}$ |
| 4B | 1 | 0 | 0 | > 0x01 | > 0x00 | | $T_{PD} + (FILT_CNT * FILT_PER \times T_{per}) + T_{per}$ |
| 5A | 1 | 1 | 0 | 0x00 | X | See the Windowed Mode (#5A & 5B). | $T_{PD} + 2T_{per}$ |
| 5B | 1 | 1 | 0 | X | 0x00 | | |
| 6 | 1 | 1 | 0 | 0x01 | > 0x00 | See the Windowed/ Resampled Mode (#6). | $T_{PD} + (FILT_PER * T_{per}) + 3T_{per}$ |
| 7 | 1 | 1 | 0 | > 0x01 | > 0x00 | See the Windowed/Filtered Mode (#7). | $T_{PD} + (FILT_CNT * FILT_PER \times T_{per}) + 3T_{per}$ |
| All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, FILT_PER are illegal. | | | | | | | |

1. $T_{PD}$ represents the intrinsic delay of the analog component plus the polarity select logic. $T_{SAMPLE}$ is the clock period of the external sample clock. $T_{per}$ is the period of the bus clock.

### 47.7.2.1 Disabled Mode (#1)

In disabled mode, the analog comparator is non-functional and consumes no power. CSR[COUT] and CMPO is same as CCR1[COUT_INV] in this mode.

### 47.7.2.2 Continuous Mode (#2A & 2B)

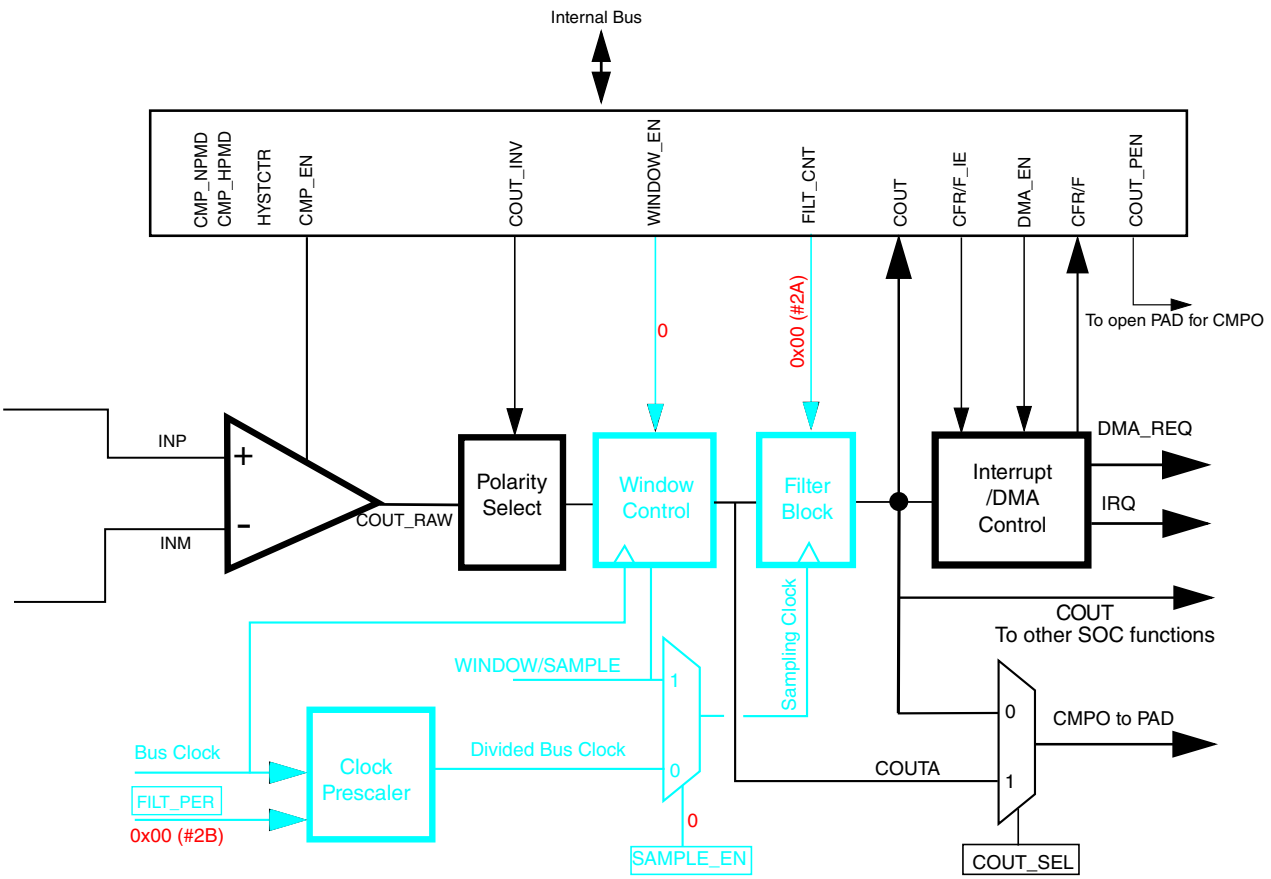

**Figure 47-3. Comparator Operation in Continuous Mode**

In this mode, COUT_RAW may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. CSR[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational(unclocked) mode. COUT and COUTA are identical.

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM, it should generally be configured to operate in continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

### 47.7.2.3 Sampled, Non-Filtered Mode (#3A & 3B)

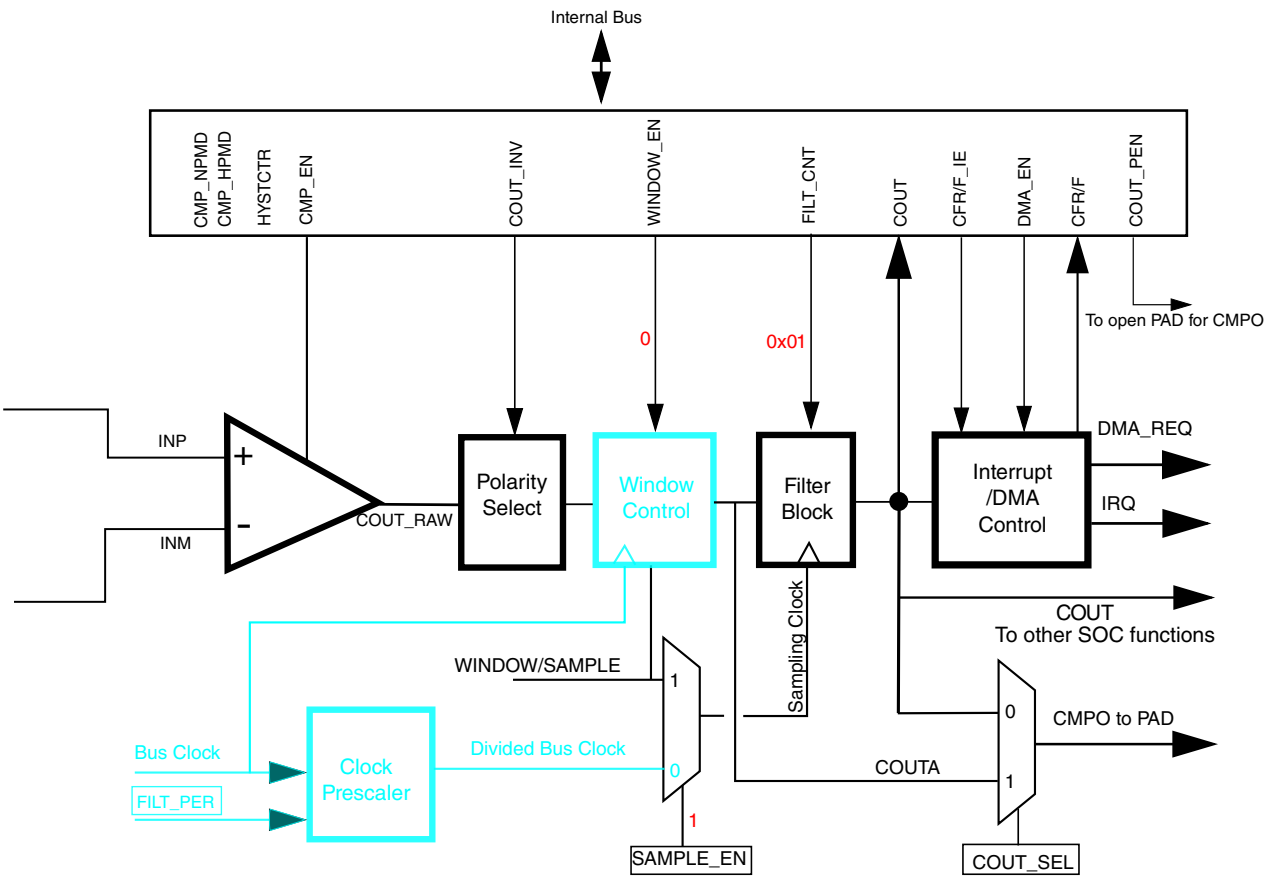

**Figure 47-4. Sampled, Non-Filtered (#3A): Sampling Point Externally Driven**

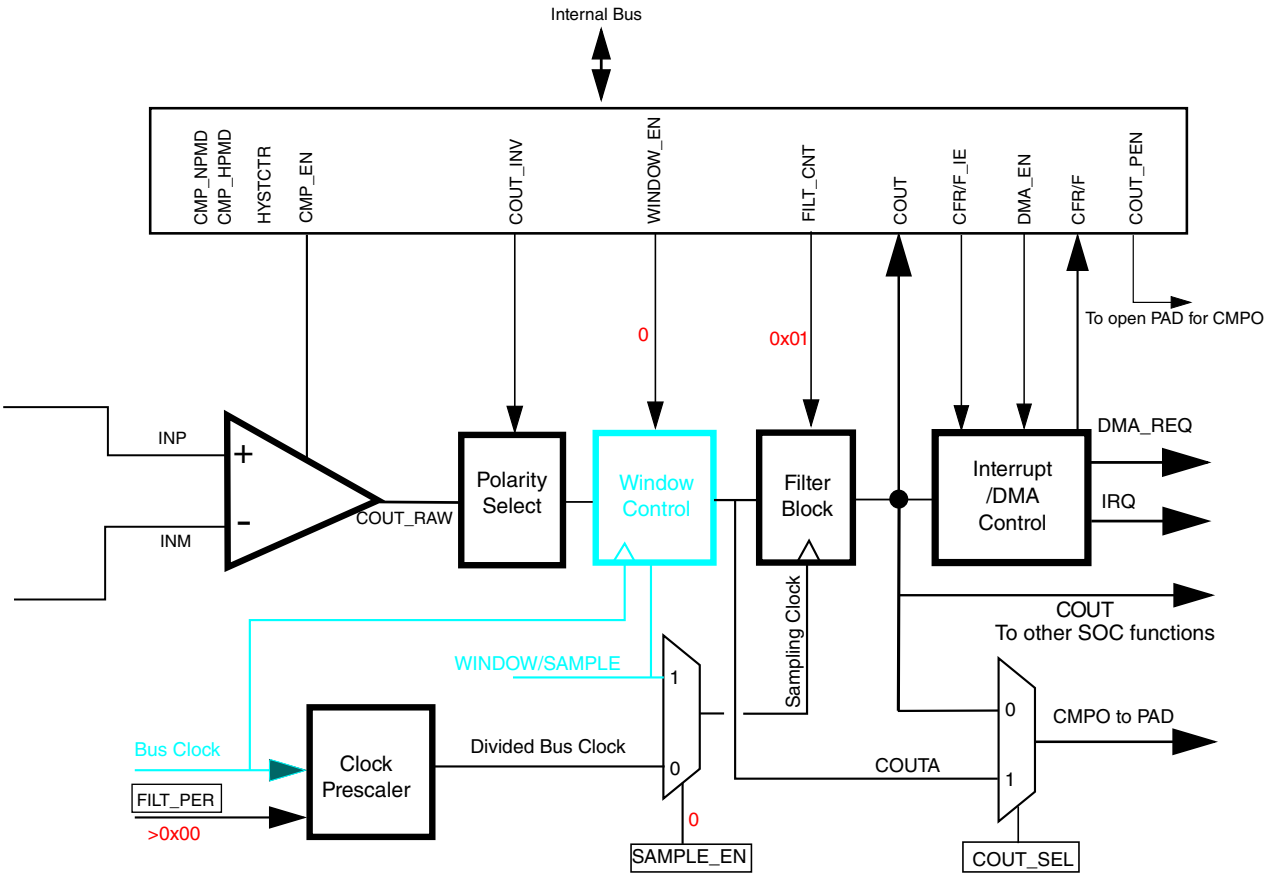

**Figure 47-5. Sampled, Non-Filtered (#3B): Sampling Interval Internally Derived**

In this mode, the path from analog inputs to COUTA is combinational(unclocked). Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) and sampled, non-filtered (#3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The filter block has no other function than sample/hold of the comparator output in this mode.

## 47.7.2.4 Sampled, Filtered Mode (#4A & 4B)

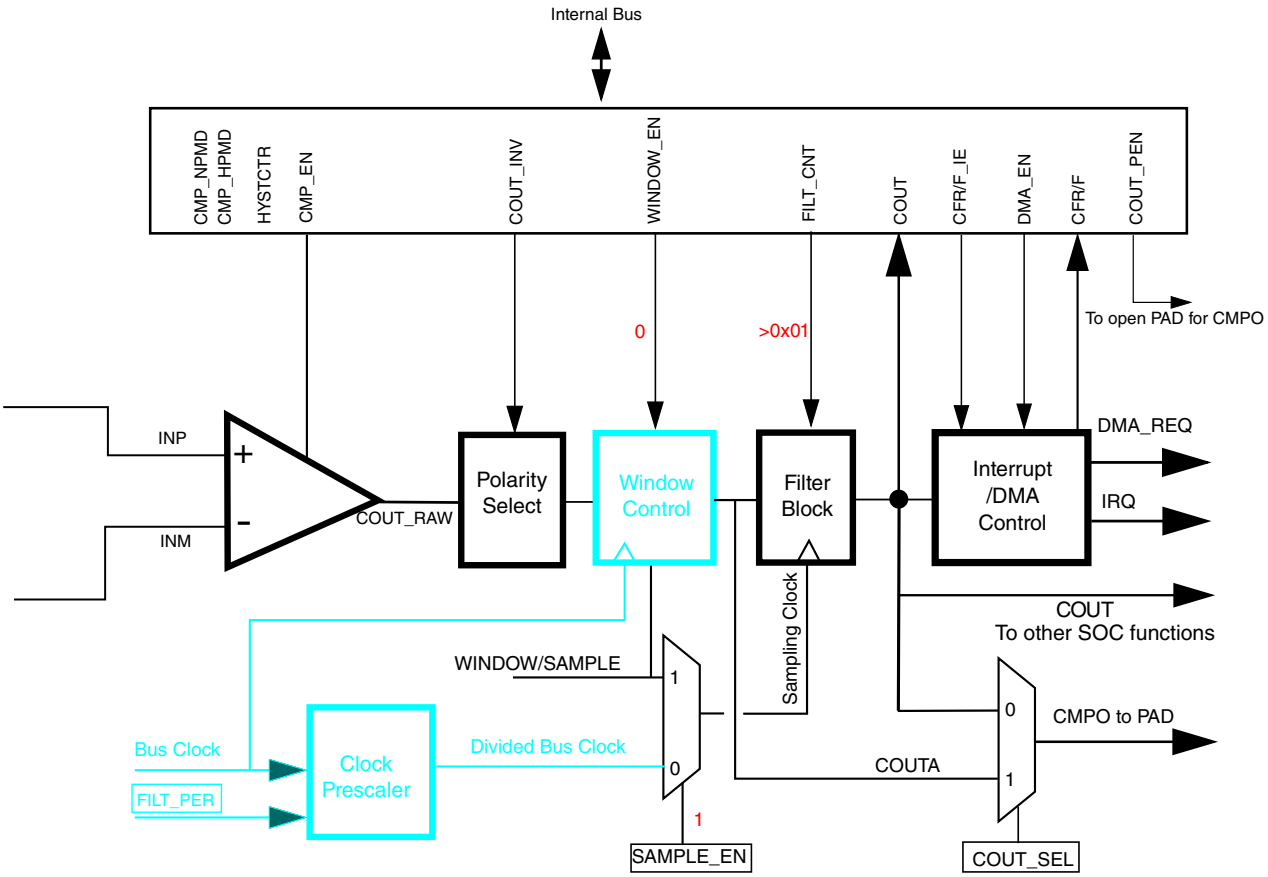

**Figure 47-6. Sampled, Filtered (#4A): Sampling Point Externally Driven**

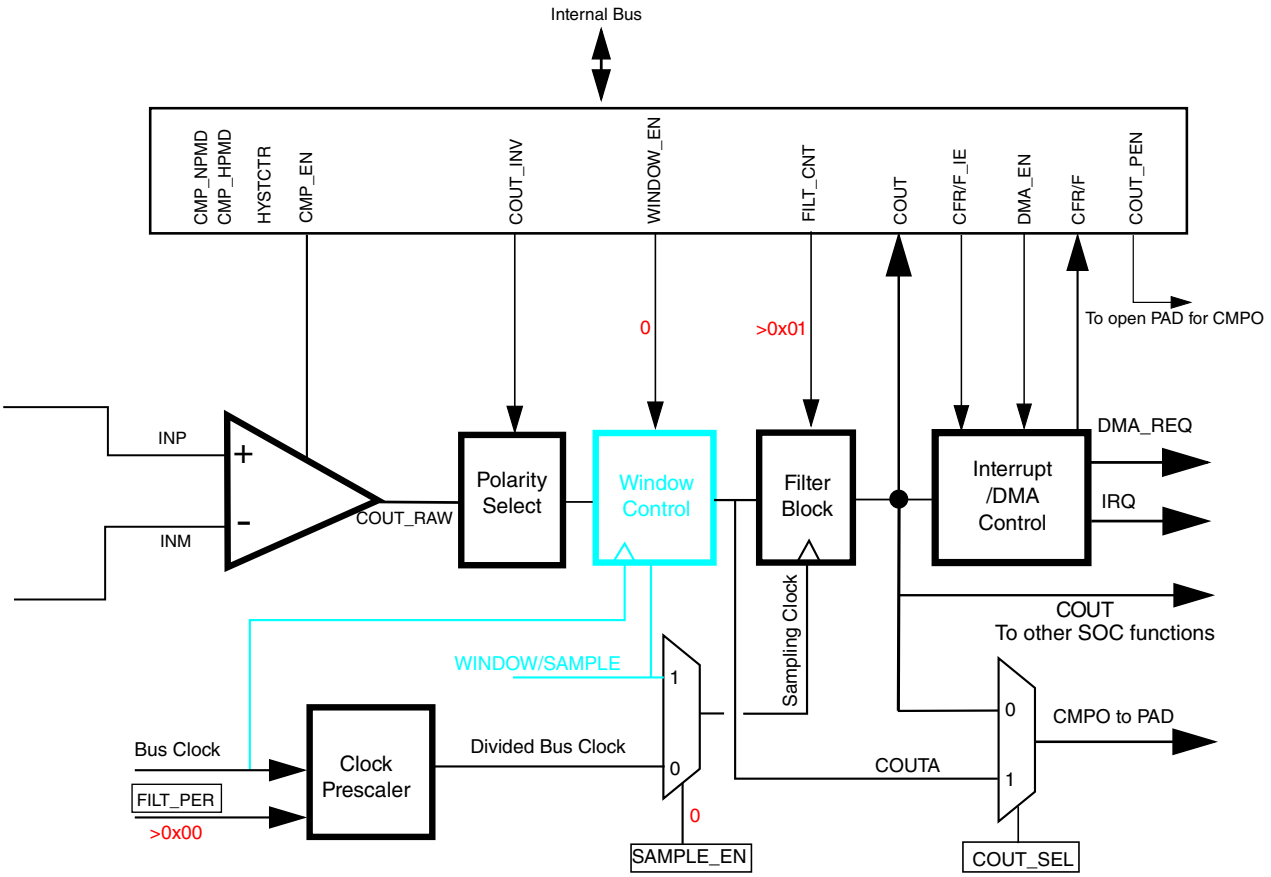

**Figure 47-7. Sampled, Filtered (#4B): Sampling Point Internally Derived**

In this mode, the path from analog inputs to COUTA is combinational(unclocked). Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) and sampled, filtered (#4A) is that, now, CCR1[FILT_CNT]>1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) and sampled, filtered (#4B) is that now, CCR1[FILT_CNT]>1, which activates filter operation.

## 47.7.2.5 Windowed Mode (#5A & 5B)

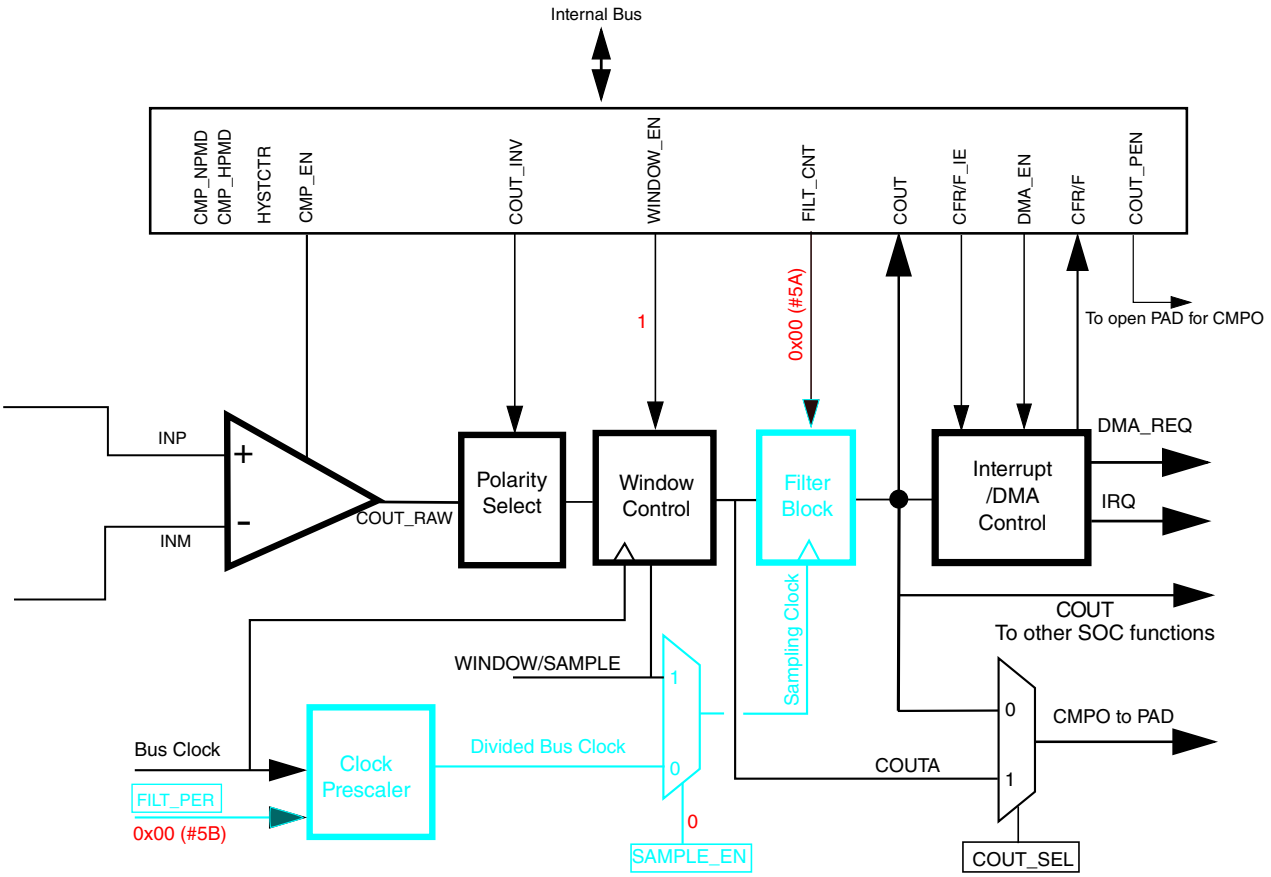

**Figure 47-8. Windowed Mode**

In this mode, COUTA is clocked by the bus clock whenever window is enabled. The last latched value is held when window is disabled. The filter block is bypassed.

The following figure illustrates comparator operation in this mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

In actual operation, COUTA may lag the analog inputs by up to two bus clock cycles plus the combinational path delay through the comparator and polarity select logic.

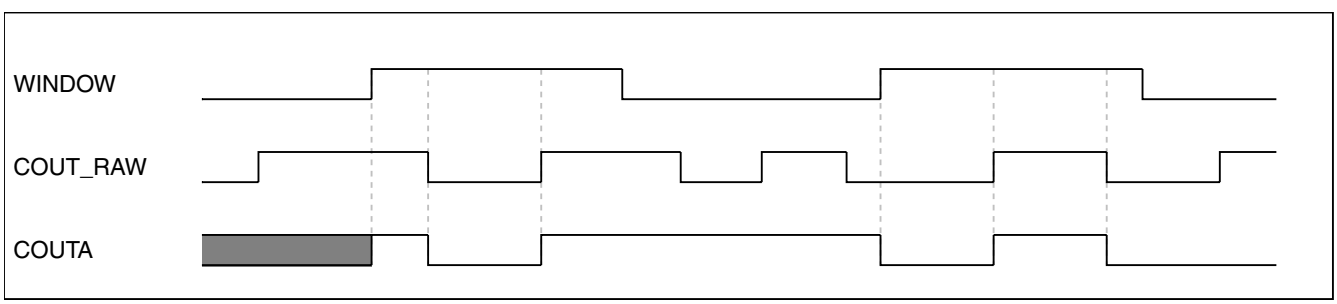

**Figure 47-9. Windowed Mode Timing Diagram**

### 47.7.2.6 Windowed/Resampled Mode (#6)

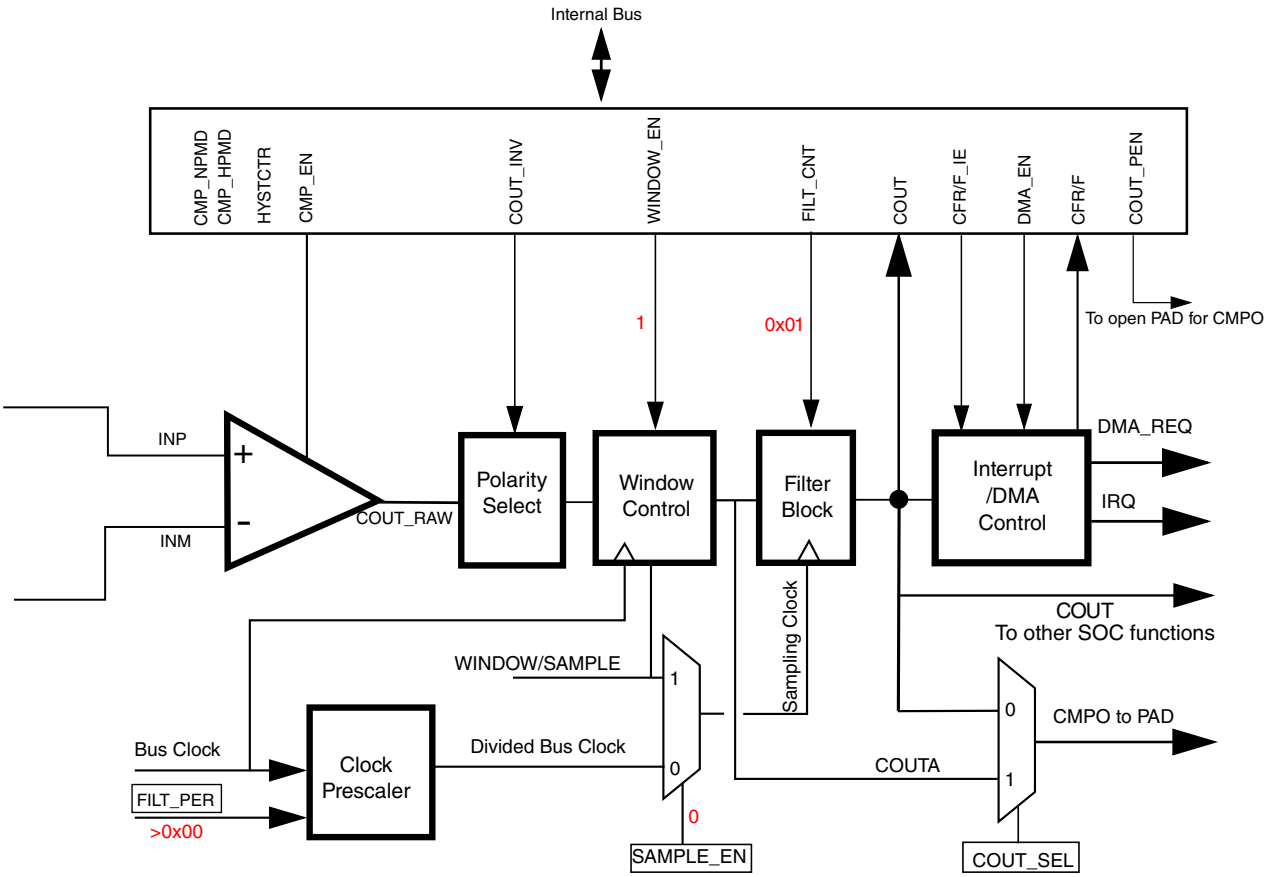

**Figure 47-10. Windowed/Resampled Mode**

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by CCR1[FILT_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the windowed/filtered mode shown in the next section. The only difference is that the value of CCR1[FILT_CNT] in this mode must be 1.

The following figure uses the same input stimulus shown in Figure 47-9, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

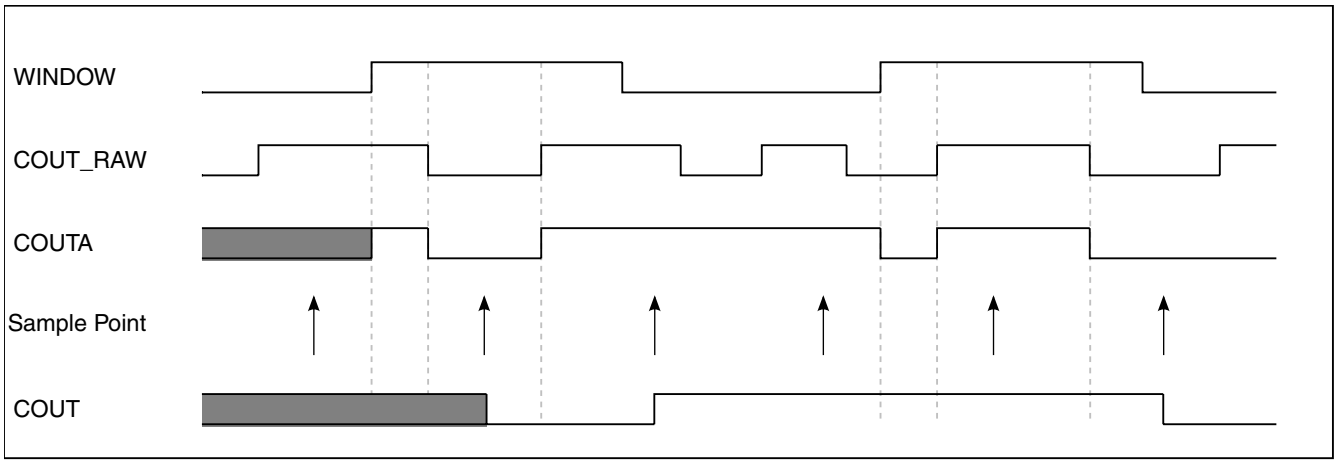

**Figure 47-11. Windowed/Resampled Mode Operation**

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

### 47.7.2.7 Windowed/Filtered Mode (#7)

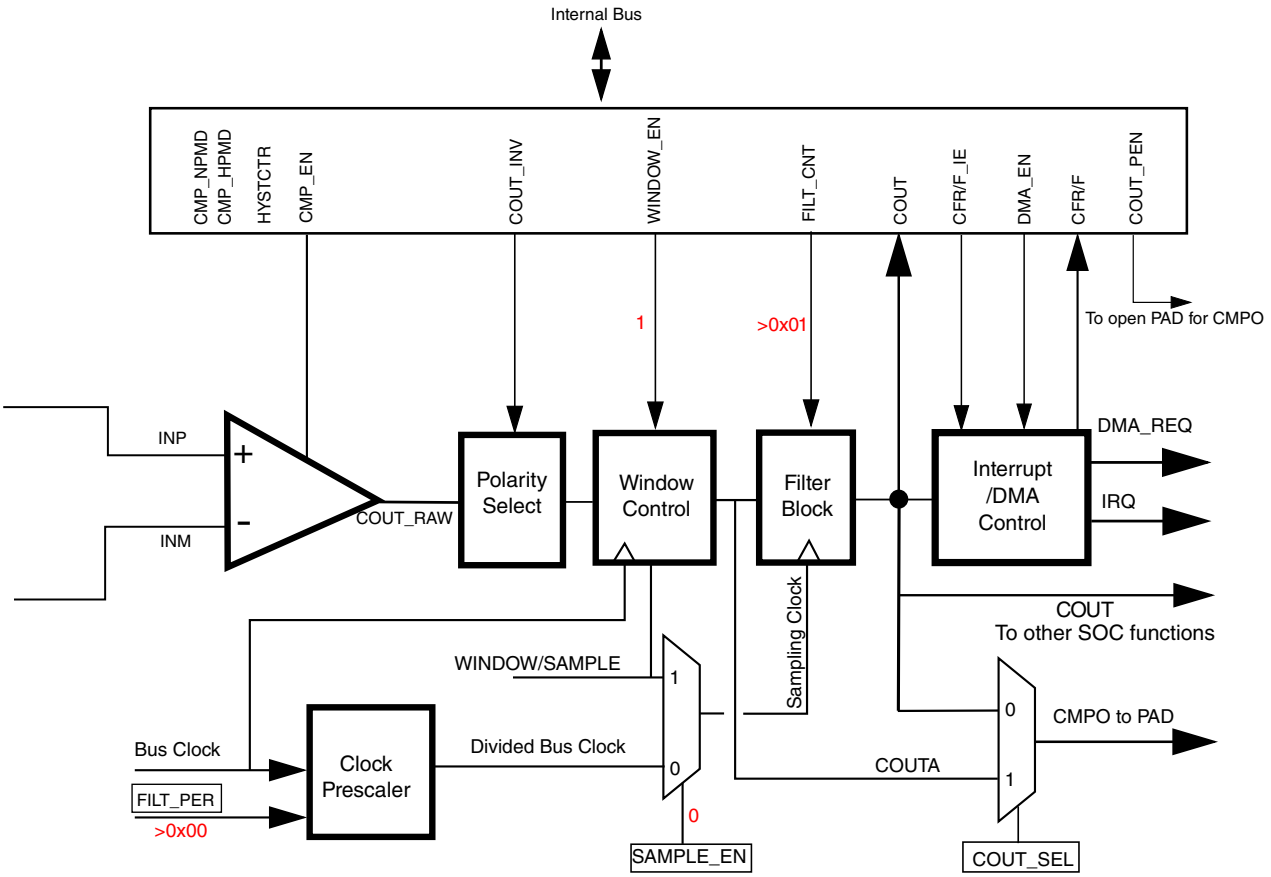

**Figure 47-12. Windowed/Filtered Mode**

The only difference in operation between Windowed/Resampled Mode (#6) and Windowed/Filtered Mode (#7) is that, now, CCR1[FILT_CNT]>1, which activates filter operation.

This is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] X CCR1[FILT_PER]) + 1) X peripheral clock for the filter function.

## 47.7.3 Hysteresis

The following diagram illustrates implementation of an external hysteresis resistor bridge between the asynchronous comparator output and the INP input of the Comparator. Since positive feedback is required, CCR1[COUT_INV] must be set to 0 when the hysteresis resistor bridge is added to the INP input of the comparator. CCR1[COUT_INV] must be set to 1 when the hysteresis resistor bridge is added to the INM input of the comparator.

The option of adding an external resistor bridge for the purpose of adding hysteresis to the comparator and the amount of hysteresis depends on the user's individual requirements. Hysteresis can be important in some system designs. In the absence of hysteresis, the continuous comparison of nearly identical analog inputs may add noise and waste power by generating high-frequency oscillations at CMPO.

If external hysteresis is added to the comparator, the bridge must be designed to consider other issues than simply how much hysteresis is needed. The resistor values must be sufficiently high so that they do not cause the drive strength of the digital output driver in the CMPO IO cell to be exceeded. Also, if any digital function other than CMPO must operate on the CMPO pad in the presence of such a bridge, the resistor values must be sufficiently high so that the IO cell can function appropriately in its digital role.

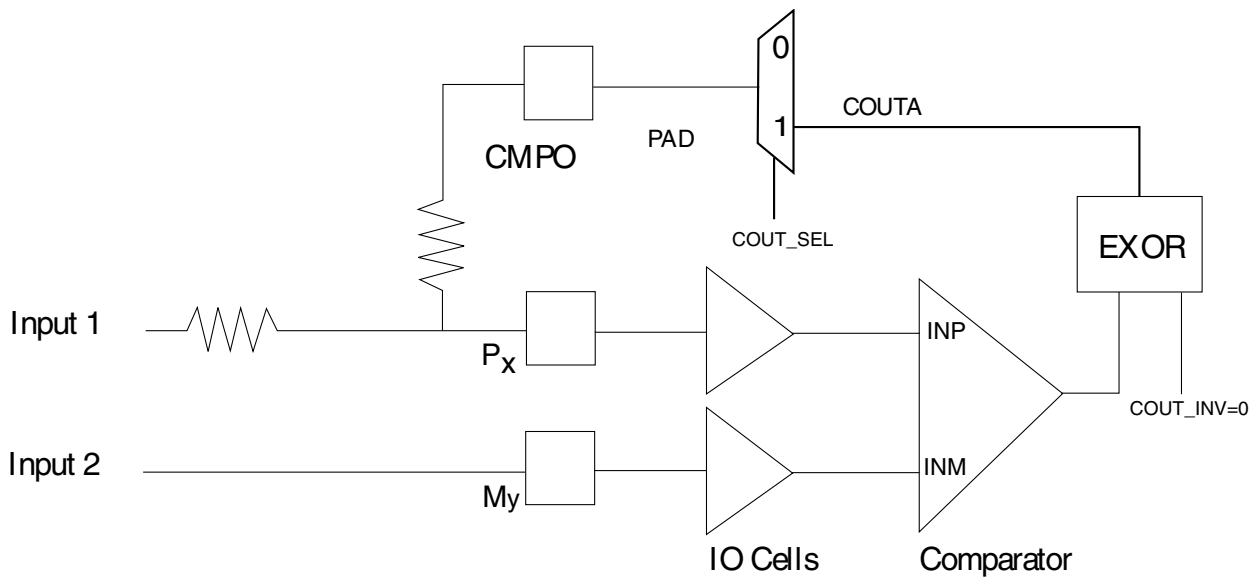

**Figure 47-13. External Hysteresis Circuit**

## 47.7.4 Initialization

To enable the LPCMP module, it is recommended to configure the control registers(CCR1, CCR2, DCR, etc) before setting the CCR0[CMP_EN] bit. To disable the module, just clear the CCR0[CMP_EN] bit. Switch operation modes or change control register bits on the fly(when CCR0[CMP_EN] is 1) may cause some noise on the COUT or COUTA. So it is recommended to disable the module before mode switch or any control bits change.

Interrupts should be disabled during power up, recovery from partial-power-down, and while re-enabling the module. Failure to do so could result in spurious interrupts.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter. See the datasheet for power-on delays of the comparators. The delay caused by windowing and filter function is specified in the Table 47-2.

During operation, the propagation delay of the selected data paths must always be considered. It can take many bus clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

When programmed for filtering modes, COUT will initially be equal to zero until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic one.

## 47.7.5 Low-Pass Filter

The low-pass filter operates on the unfiltered, optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT. Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by CCR1[FILT_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

### 47.7.5.1 Enabling Filter Modes

Filter modes can be enabled by:

- Setting CCR1[FILT_CNT] > 0x01 and
- Setting CCR1[FILT_PER] to a nonzero value or setting CCR1[SAMPLE_EN]=1

If using the divided bus clock to drive the filter, it samples COUTA every CCR1[FILT_PER] bus clock cycles.

The filter output is at logic zero when first initalized, and subsequently changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed. In other words, CMP_C0[COUT] is zero for some initial period, even when COUTA is at logic one.

If CCR1[SAMPLE_EN]=1, the filter samples COUTA on each positive transition of the SAMPLE input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

#### 47.7.5.2 Latency Issues

The value of CCR1[FILT_PER] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CCR1[FILT_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

The values of CCR1[FILT_PER] or SAMPLE period and CCR1[FILT_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 47-2 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency is restarted each time an actual output transition is masked by noise.

### 47.7.6 Interrupts

When corresponding interrupt enable register bit is set, flags CSR[CFR], CSR[CFF] can generate interrupt, assuming the DMA enable bit is not set. The interrupt is de-asserted by clearing either the flag or the interrupt enable register bit.

### 47.7.7 DMA Support

When DMA support is enabled by setting CCR1[DMA_EN] and the interrupt is enabled by setting IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has

completed the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flag to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes if CCR0[CMP_STOP_EN] is set. A DMA transfer request will wake up the system from STOP modes. After the data transfer has finished, the system will go back again to STOP modes. Refer to the DMA chapters in the device reference manual for the asynchronous DMA function for details.

## 47.7.8 Low Power Mode Operation

The following table shows the WAIT mode and the STOP mode operation of the LPCMP module.

**Table 47-3. Low Power Modes Operation**

| Modes of Operation | Description |
|---|---|
| WAIT | The LPCMP module can operate normally with window and filter function. |
| STOP | The LPCMP module can only operate in continuous mode. |

# Chapter 48
# 12-bit Low Power Digital-to-Analog Converter (LPDAC)

## 48.1 Chip-specific LPDAC information

### 48.1.1 12-bit LPDAC Overview

This device contains 1 instance of a 12-bit low-power digital-to-analog converter (LPDAC) with programmable reference generator output. The LPDAC includes a FIFO for DMA support.

### 48.1.2 12-bit LPDAC Output

The output of the LPDAC can be placed on an external pin or set as one of the inputs to the analog comparator or LPADC.

### 48.1.3 12-bit LPDAC Reference

For this device VREF_OUT and VDDA are selectable as the LPDAC reference. VREF_OUT is connected to the VREFH_INT input and VDDA is connected to the VREFH_EXT input. Use LPDAC_GCR[DACRFS] control bit to select between these two options.

Be aware that if the LPDAC and ADC use the VREF_OUT reference simultaneously, some degradation of ADC accuracy is to be expected due to LPDAC switching.

## 48.2 Introduction

The LPDAC is a low-power, 12-bit general-purpose digital-to-analog converter. The output of the LPDAC can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.

## 48.3 Features

The features of the LPDAC module include:

- On-chip programmable reference generator output. The voltage output range is from 1⁄4096 $V_{in}$ to $V_{in}$, and the step is 1⁄4096 $V_{in}$, where $V_{in}$ is the input reference voltage.
- $V_{in}$ can be selected from two reference sources.
- 16-word depth FIFO supported with configurable watermark.
- Multiple operation modes.
  - Buffer mode
  - FIFO mode
  - Swing back mode
- Software trigger and hardware trigger supported.
- Selectable performance levels: low power mode and high power mode.
- Interrupt and DMA support.

## 48.4 Block diagram

The block diagram of the LPDAC module is as follows:

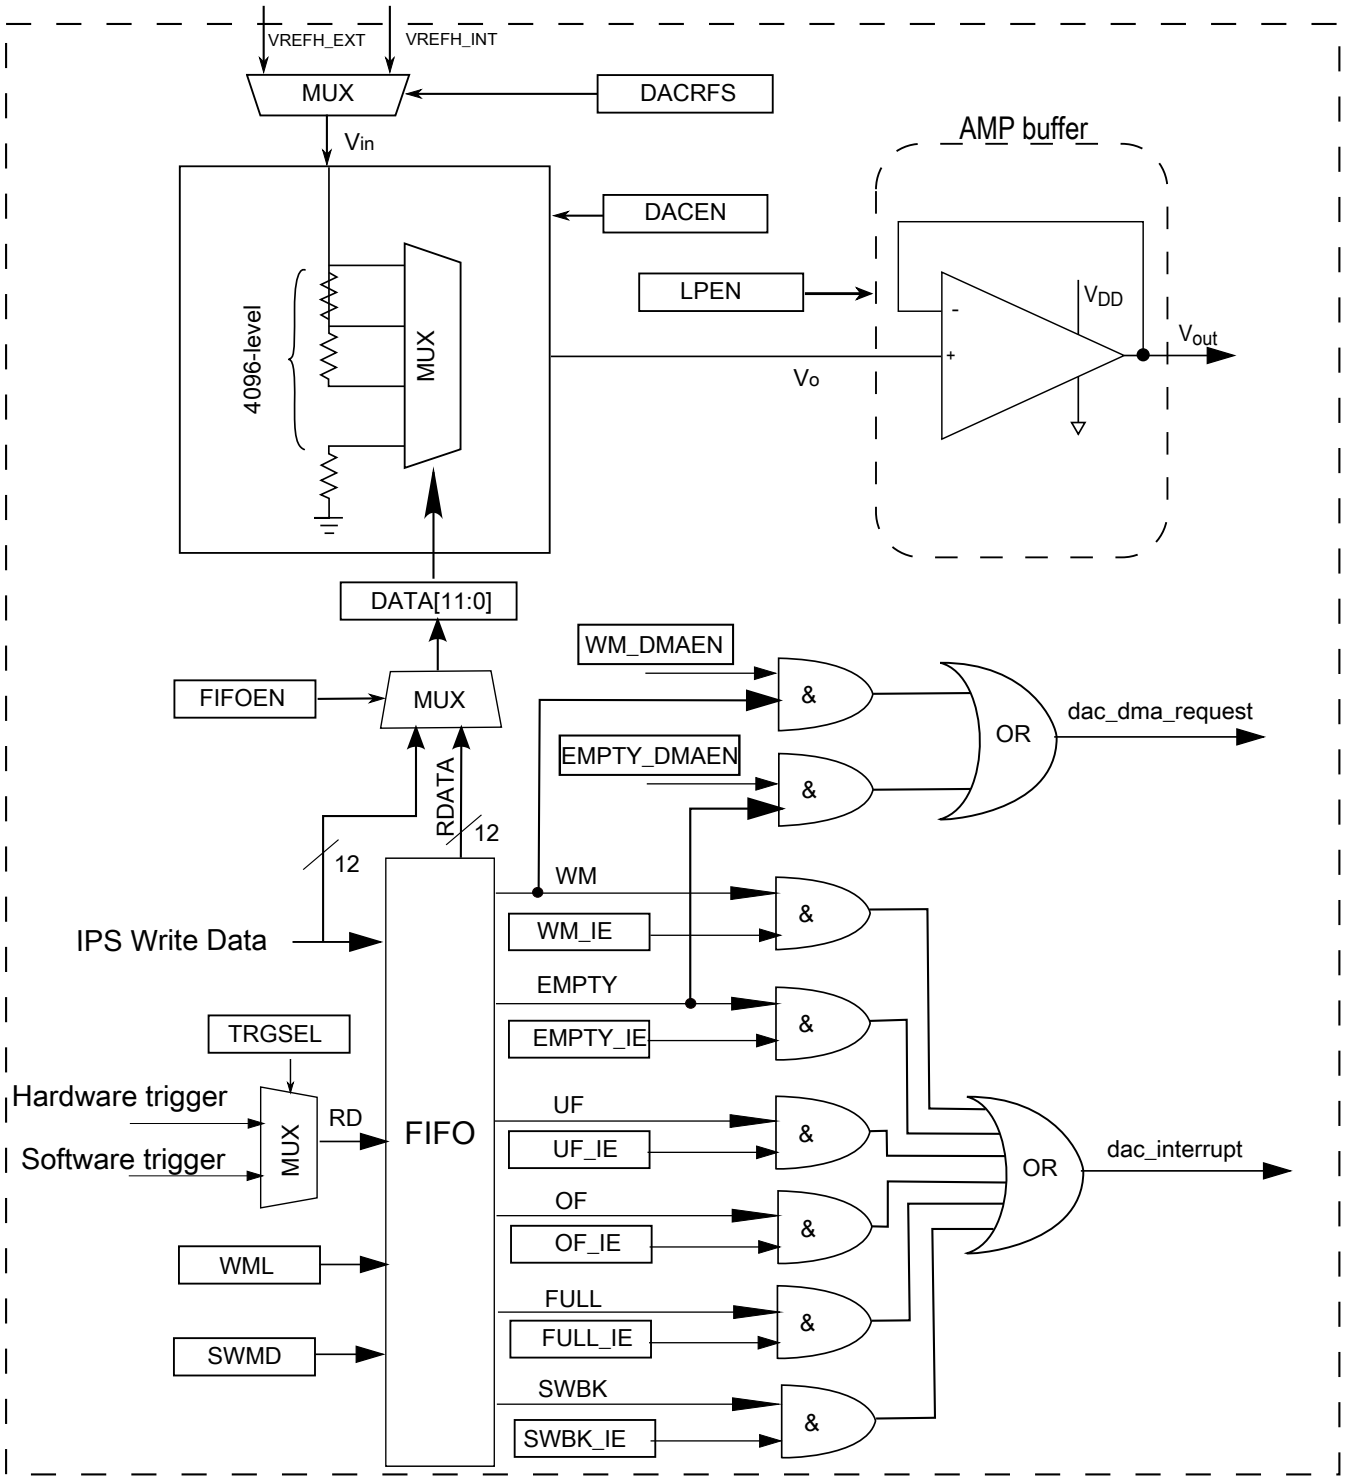

**Figure 48-1. LPDAC Block Diagram**

## 48.5 LPDAC register descriptions

Access to an address outside the valid memory map will generate a bus error.

## 48.6 Functional description

The LPDAC can select one of the two reference inputs — VREFH_INT and VREFH_EXT as the reference voltage, by GCR[DACRFS]. See the chip-specific LPDAC information to determine the source options for VREFH_INT and VREFH_EXT.

When enabled, the LPDAC converts a 12 bit data to a stepped analog output voltage. The output voltage range is from $V_{in}$ to $V_{in}/4096$, and the step is $V_{in}/4096$.

The LPDAC can be configured to FIFO mode, swing back mode or buffer mode.

**NOTE**

User should configure the LPDAC before any conversion. During conversion or FIFO write operation, user should not change the configuration or disable the GCR[DACEN] bit. If need to switch to another mode, user should first reset the LPDAC by writing a 1 to RCR[SWRST] or just clear the GCR[DACEN] bit.

### 48.6.1 Buffer mode

Buffer mode is enabled with GCR[DACEN].

In buffer mode, any write to the DATA[DATA] will push the data to analog conversion without trigger support.

**NOTE**

The data write speed should be not higher than the analog conversion speed.

### 48.6.2 FIFO mode

FIFO mode is enabled with GCR[FIFOEN] and GCR[DACEN].

In FIFO mode, for a 32/16-bit write to DATA[DATA], the data is put into the FIFO, and the write pointer is automatically incremented. For an 8-bit write, only if both the bytes are written, the write pointer will increase. User needs to ensure that an 8-bit write is done in pair, and both the upper and lower bytes are written. There is no priority for which byte is written to first.

When a software trigger or hardware trigger comes, the read pointer pointed data in FIFO will be pushed to analog conversion, and the read pointer is automatically incremented. If the trigger comes when FIFO is empty, the data to analog keeps unchanged and an underflow error flag is set.

### 48.6.3 Swing back mode

Swing back mode is enabled with GCR[FIFOEN], GCR[SWMD] and GCR[DACEN].

In swing back mode, the read pointer swings between the writer pointer and zero. That is, the trigger increases the read pointer till the writer pointer and decreases the read pointer till zero, and so on. The FIFO EMPTY/FULL/WM flags have no meaning and should be ignored during swing back mode.

**NOTE**

In swing back mode, the FIFO should first be written at least two data, otherwise this mode will not work correctly. User should not write the FIFO when in swing back process.

### 48.6.4 Interrupts

When corresponding interrupt enable register bit is set, warning flags and error flags can generate interrupt. The warning flags are EMPTY, FULL, WM, SWBK. The error flags are OF and UF.

### 48.6.5 DMA operation

When corresponding DMA enable register bit is set, DMA requests can be generated automatically when WM or EMPTY flag is set. When DMA is enabled, interrupt can only be generated from the error flags.

### 48.6.6 Low-power mode operation

The LPDAC can be functional with FIFO mode/swing back mode during STOP/WAIT modes, using the hardware trigger initiating the conversion.

# Chapter 49
# Voltage Reference (VREF)

## 49.1 Chip-specific VREF information

### 49.1.1 VREF Overview

This device includes a voltage reference (VREF) to supply an accurate 1.2 V or 2.1V voltage output.

The voltage reference can provide a reference voltage to external peripherals or a reference to analog peripherals, such as the LPADC, LPDAC, or LPCMP.

**NOTE**

SPM_CORELPCNFG[BGEN] bit must be set if the VREF regulator is required to remain operating in VLPx modes.

**NOTE**

For either an internal or external reference if the VREF_OUT functionality is being used, VREF_OUT signal must be connected to an output load capacitor. Refer the device data sheet for more details.

## 49.2 Introduction

The VREF can be used in applications to provide a reference voltage to external devices, or used internally in the device as a reference to analog peripherals (such as the ADC, DAC, or CMP). The Voltage Reference (VREF) can supply an accurate voltage output that can be trimmed in 0.5 mV steps (for 1.2 V output) or 1.5 mV steps (for 2.1 V output). The voltage reference has 3 operating modes that provide different levels of supply rejection and power consumption.

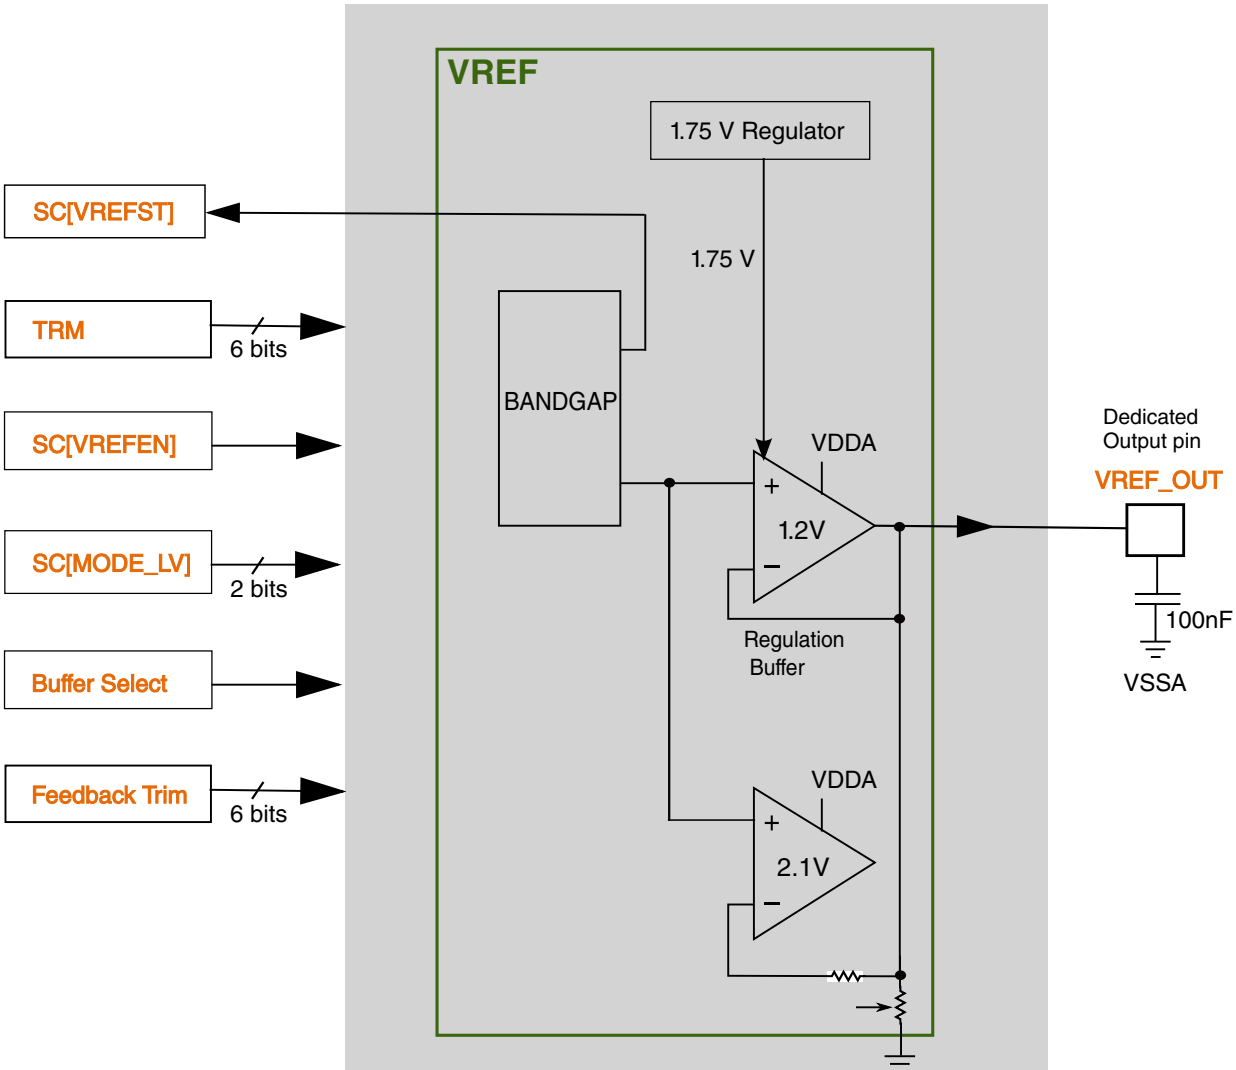

**Figure 49-1. Voltage reference block diagram**

## 49.2.1 Overview

The Voltage Reference provides a buffered reference voltage for use as an external reference, which can be set to either 1.2V or 2.1V. In addition, the buffered reference is available internally for use with on-chip peripherals (such as ADCs and DACs). Refer to the chip configuration details. When the VREF is enabled, the reference voltage is placed on a dedicated output pin.

- In 1.2V mode, the Voltage Reference output can be trimmed with 0.5mV resolution, using the TRM register TRIM[5:0] bitfield.
- In 2.1V mode, the Voltage Reference output can be trimmed with 1.5mV resolution, using the TRM register VREF_TRM4 TRIM2V1[5:0] bitfield.

## 49.2.2 Features

- Programmable trim register with 0.5 mV steps in 1.2V mode and 1.5mV steps in 2.1V mode; upon reset, the trim register is automatically loaded with a factory-trimmed value
- Programmable buffer mode selection:
  - Off
  - Bandgap enabled/standby (output buffer disabled)
  - Low power buffer mode (output buffer enabled)
  - High power buffer mode (output buffer enabled)
- Selectable 1.2V or 2.1V output at room temperature
- Dedicated output pin, VREF_OUT

## 49.2.3 Modes of Operation

The Voltage Reference continues normal operation in Run, Wait, and Stop modes. The Voltage Reference can also run in Very Low Power Run (VLPR), Very Low Power Wait (VLPW) and Very Low Power Stop (VLPS). If it is desired to use the VREF regulator and/or the chop oscillator in the very low power modes, the system reference voltage (also referred to as the bandgap voltage reference) must be enabled in these modes. Refer to the chip configuration details for information on enabling this mode of operation. Having the VREF regulator enabled does increase current consumption. In very low power modes it may be desirable to disable the VREF regulator to minimize current consumption. Note however that the accuracy of the output voltage will be reduced (by as much as several mVs) when the VREF regulator is not used.

**NOTE**

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

### 49.2.4 VREF Signal Descriptions

The following table shows the Voltage Reference signals properties.

**Table 49-1. VREF Signal Descriptions**

| Signal | Description | I/O |
|---|---|---|
| VREF_OUT | Internally-generated Voltage Reference output | O |

**NOTE**

When the VREF output buffer is disabled, the status of the VREF_OUT signal is high-impedence.

## 49.3 Memory Map and Register Definition

### 49.3.1 VREF register descriptions

#### 49.3.1.1 VREF Memory map

VREF base address: 4004_D000h

## 49.4 Functional Description

The Voltage Reference is a bandgap buffer system. Unity gain amplifiers are used.

The VREF_OUT signal can be used by both internal and external peripherals in low and high power buffer mode. A 100 nF capacitor must always be connected between VREF_OUT and VSSA if the VREF is being used.

The following table shows all possible function configurations of the Voltage Reference.

**Table 49-2. Voltage Reference function configurations**

| SC[VREFEN] | SC[MODE_LV] | Configuration | Functionality |
|---|---|---|---|
| 0 | X | Voltage Reference disabled | Off |
| 1 | 00 | Voltage Reference enabled, bandgap on only | Startup and standby |
| 1 | 01 | Voltage Reference enabled, high-power buffer on | VREF_OUT available for internal and external use. 100 nF capacitor is required. |
| 1 | 10 | Voltage Reference enabled, low power buffer on | VREF_OUT available for internal and external use. 100 nF capacitor is required. |
| 1 | 11 | Reserved | Reserved |

### 49.4.1 Voltage Reference Disabled, SC[VREFEN] = 0

When SC[VREFEN] = 0, the Voltage Reference is disabled, the VREF bandgap and the output buffers are disabled. The Voltage Reference is in off mode.

### 49.4.2 Voltage Reference Enabled, SC[VREFEN] = 1

When SC[VREFEN] = 1, the Voltage Reference is enabled, and different modes should be set by the SC[MODE_LV] bits.

#### 49.4.2.1 SC[MODE_LV]=00

The internal VREF bandgap is enabled to generate an accurate 1.2 V output that can be trimmed with the TRM register's TRIM[5:0] bitfield. The bandgap requires some time for startup and stabilization. SC[VREFST] can be monitored to determine if the stabilization and startup is complete when the chop oscillator is not enabled.

If the chop oscillator is being used, the internal bandgap reference voltage settles within the chop oscillator start up time, Tchop_osc_stup.

The output buffer is disabled in this mode, and there is no buffered voltage output. The Voltage Reference is in standby mode. If this mode is first selected and the low power or high power buffer mode is subsequently enabled, there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet.

#### 49.4.2.2 SC[MODE_LV] = 01

The internal VREF bandgap is on. The high power buffer is enabled to generate a buffered 1.2 V voltage to VREF_OUT. It can also be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from the standby mode (SC[MODE_LV] = 00, SC[VREFEN] = 1) there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet. If this mode is entered when the VREF module is enabled then you must wait the longer of Tstup or until SC[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, you must wait the time specified by Tchop_osc_stup (chop oscillator start up time) to ensure the VREF output has stabilized.

In this mode, a 100 nF capacitor is required to connect between the VREF_OUT pin and VSSA.

#### 49.4.2.3 SC[MODE_LV] = 10

The internal VREF bandgap is on. The low power buffer is enabled to generate a buffered 1.2 V voltage to VREF_OUT. It can also be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from the standby mode (SC[MODE_LV] = 00, SC[VREFEN] = 1) there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet. If this mode is entered when the VREF module is enabled then you must wait the longer of Tstup or until SC[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, you must wait the time specified by Tchop_osc_stup (chop oscillator start up time) to ensure the VREF output has stabilized.

In this mode, a 100 nF capacitor is required to connect between the VREF_OUT pin and VSSA.

#### 49.4.2.4 SC[MODE_LV] = 11

Reserved

### 49.4.3 Internal voltage regulator

The VREF module contains an internal voltage regulator that can be enabled to provide additional supply noise rejection. It is recommended that when possible, this regulator be enabled to provide the optimum VREF performance.

If the internal voltage regulator is being used, the chop oscillator must also be enabled. A specific sequence must be followed when enabling the internal regulator as follows:

1. Enable the chop oscillator (VREF_TRM[CHOPEN] = 1)
2. Configure the VREF_SC register to the desired settings with the internal regulator disabled, VREF_SC[REGEN] = 0
3. Wait > 300ns
4. Enable the internal regulator by setting VREF_SC[REGEN] to 1

## 49.5 Initialization/Application Information

The Voltage Reference requires some time for startup and stabilization. After SC[VREFEN] = 1, SC[VREFST] can be monitored to determine if the stabilization and startup is completed when the chop oscillator is not enabled. When the chop oscillator is enabled, the settling time of the internal bandgap reference is defined by Tchop_osc_stup (chop oscillator start up time). You must wait this time (Tchop_osc_stup) after the internal bandgap has been enabled to ensure the VREF internal reference voltage has stabilized.

When the Voltage Reference is already enabled and stabilized, changing SC[MODE_LV] will not clear SC[VREFST] but there will be some startup time before the output voltage at the VREF_OUT pin has settled. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet. Also, there will be some settling time when a step change of the load current is applied to the VREF_OUT pin. When the 1.75V VREF regulator is disabled, the VREF_OUT voltage will be more sensitive to supply voltage variation. It is recommended to use this regulator to achieve optimum VREF_OUT performance.

The TRM[CHOPEN], SC[REGEN] and SC[ICOMPEN] bits must be written to 1 to achieve the performance stated in the device data sheet.

**NOTE**

See section "Internal voltage regulator" for details on the required sequence to enable the internal regulator.

# Chapter 50
# Low Power Interrupt Timer (LPIT)

## 50.1 Introduction

### 50.1.1 Overview

LPIT is a low power periodic interval timer with multiple timer channels. After a timer reaches a programmed count, the respective timer channel will generate pre-trigger and trigger output signals, and these pre-trigger and trigger outputs can be used to trigger other modules on the device.

- Timers can be configured to be controlled using:
  - external triggers (triggers from outside the LPIT module)
  - or internal triggers (triggers from other timer channels inside the LPIT module).
- The timer channels can be chained together, to form a larger width timer.
- Depending on the timer modes, the timer channels may reload and count again, or stop after reaching the programmed count.

The next figure shows the interface of an LPIT module to the other modules on the SoC.

- The CPU interface provides the clock, reset, register read/write bus interface and handles interrupts from an LPIT.
- The trigger output signals from an LPIT may trigger other modules on the SoC, like the DMA, ADC, and other modules.
- Similarly, other timer modules may provide trigger inputs to an LPIT module, to control when an LPIT timer channel starts.

For the exact module interactions, see the SoC Configuration chapter in your device's hardware Reference Manual (RM).

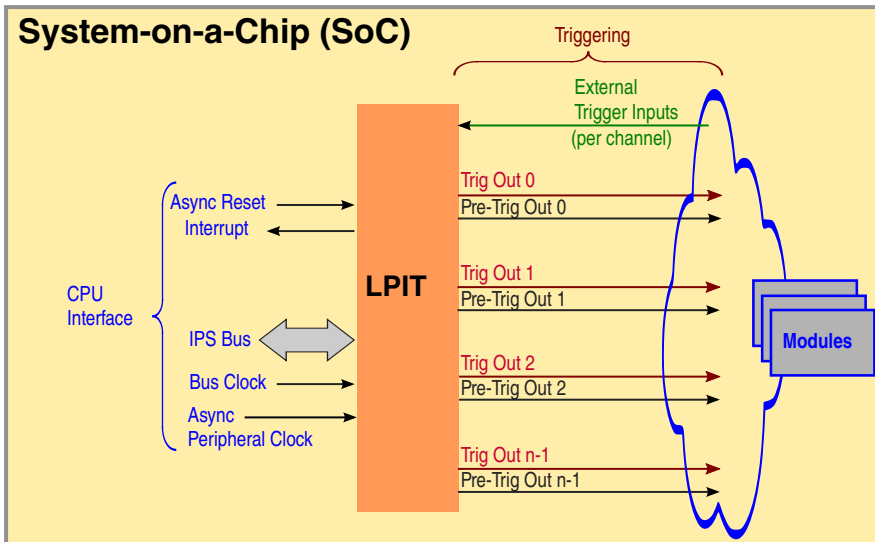

**Figure 50-1. LPIT Interface in SoC**

Each timer channel in LPIT can be configured to work in either compare modes or capture modes.

- **In compare mode:** the timers decrement when enabled and generate an output pre-trigger and trigger output. The trigger output is 1 clock cycle delayed of the pre-trigger pulse. Each timer channel start, reload and restart can be controlled via control bits. The timer can be configured to always decrement from a programmed start value, or decrement on selected trigger inputs or previous channel timeout (when channels are chained). By chaining timer channels, applications can achieve larger timeout durations.
- **In capture mode:** the timer can be used to perform measurements as the timer value is captured (in the timer value register) when a selected trigger input is asserted. The timer can support once-off or multiple measurements (like frequency measurements).

The timer channels operate on an asynchronous clock, which is independent from the register read/write access clock. Clock synchronization between the clock domains ensures normal operations.

## 50.1.2 Block Diagram

The next figure shows a detailed block diagram for an LPIT module. The programming model comprises of a global register set (common to all timer channels), and registers for each timer channel (that control their respective timer channels). Access to these registers gets synchronized to the asynchronous peripheral clock, then affects the timer channel registers.

- Each timer channel contains a 32-bit counter that loads the starting value and down counts on every peripheral clock's positive edge.

- After reaching a zero value (a channel timer timeout), a trigger output is generated.
- The counter enable is controlled using a timer enable register control bit, external or internal triggers or via previous channel timeout (when using timer chaining).
- After a channel timer timeout, an interrupt bit is also set, to tell the CPU about the timer timeout.

For more details, see the functional description section.

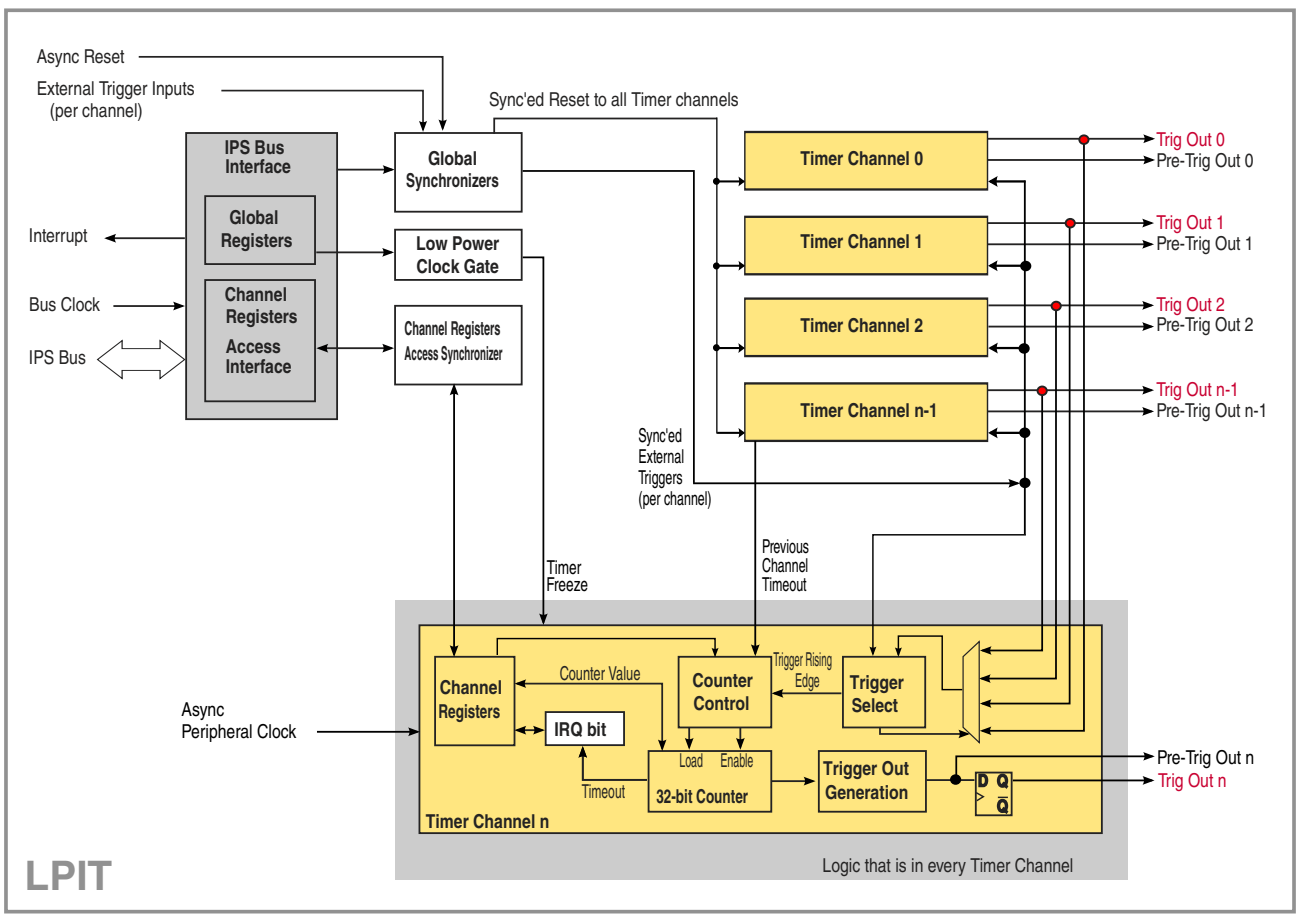

**Figure 50-2. Detailed Block Diagram**

## 50.2 Modes of operation

The LPIT module supports the following chip modes.

**Table 50-1. Chip modes supported by the LPIT module**

| Chip mode | LPIT Operation |
|---|---|
| Run | Normal operation |

*Table continues on the next page...*

**Table 50-1. Chip modes supported by the LPIT module (continued)**

| Chip mode | LPIT Operation |
|---|---|
| Stop/Wait | Can continue operating, if the Doze Enable bit (MCR[DOZE_EN]) is set and the LPIT is using an external or internal clock source that remains operating during stop/wait modes. |
| Low Power Stop (also called Low Leakage Stop or LLS) | The Doze Enable (MCR[DOZE_EN]) bit is ignored and the LPIT will be disabled for the duration of low power mode. |
| Debug | Can continue operating provided the Debug Enable bit (MCR[DBG_EN]) is set. |

# 50.3 Memory Map and Registers

## 50.3.1 LPIT0 register descriptions

The memory map comprises of 32-bit aligned registers, which can be accessed via 8-bit, 16-bit, or 32-bit accesses.

- Write access to reserved locations will generate a transfer error.
- Read access to reserved locations will also generate a transfer error, and the read data bus will show all 0s.

**NOTE**

- The Memory Map and complete module is in Big Endian format.
- The LPIT module will not check if programmed values in the registers are correct; software must ensure that correct programmed values are being written.

### 50.3.1.1 LPIT0 Memory map

## 50.3.1.7 Set Timer Enable Register (SETTEN)

### 50.3.1.7.1 Offset

| Register | Offset |
|---|---|
| SETTEN | 14h |

### 50.3.1.7.2 Function

The Set Timer Enable register allows the simultaneous enabling of timer channels.

- Timer channels can be enabled by
  - either by writing '1' to Timer Enable bit (T_EN) in the respective TCTRLn register,
  - or by setting the corresponding Set Timer Enable bit (SET_T_EN_*n*) in the Set Timer Enable register (SETTEN).

- To disable timer channels simultaneously, use the Clear Timer Enable register (CLRTEN).
- Writing a '0' to the Set Timer Enable register has no effect.

**NOTE**

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled)), reading or writing the Set Timer Enable register will generate a transfer error.

### 50.3.1.7.3 Diagram

## 50.3.1.9 Timer Value Register (TVAL0 - TVAL3)

### 50.3.1.9.1 Offset

For n = 0 to 3:

| Register | Offset |
|---|---|
| TVALn | 20h + (n × 10h) |

### 50.3.1.9.2 Function

- In compare modes: the Timer Value Registers (TVAL*n*) select the timeout period for the timer channels.
- In capture modes: the Timer Value Registers (TVAL*n*) are loaded with the value of the counter when the trigger asserts.

**NOTE**

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled), then reading or writing the TVALn register will generate a transfer error.

### 50.3.1.9.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 50.3.1.9.4 Fields

| Field | Function |
|---|---|
| 31-0<br>TMR_VAL | Timer Value<br>• In compare mode: Timer Value (TMR_VAL) is the timer channel start value.<br>  • The timer will count down until the timer reaches 0, then the timer will generate an interrupt and load the Timer Value register (TVAL*n*) value again.<br>  • Writing a new value to the Timer Value register (TVAL*n*) will not restart the timer channel; instead the new value will be loaded *after the timer expires*.<br>  • To abort the current timer cycle and start a timer period with a new value, the timer channel must be disabled and enabled *again*.<br>• In capture mode: whenever the trigger asserts, the Timer Value register stores the inverse of the counter value.<br><br>00000000000000000000000000000000b - Invalid load value in compare mode<br>00000000000000000000000000000001b - Invalid load value in compare mode<br>00000000000000000000000000000010-11111111111111111111111111111111b - In compare mode: the value to be loaded; in capture mode, the value of the timer |

## 50.3.1.10 Current Timer Value (CVAL0 - CVAL3)

### 50.3.1.10.1 Offset

For n = 0 to 3:

| Register | Offset |
|---|---|
| CVALn | 24h + (n × 10h) |

### 50.3.1.10.2 Function

The Current Timer Value registers indicate the current timer counter value.

#### 50.3.1.10.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

#### 50.3.1.10.4 Fields

| Field | Function |
|---|---|
| 31-0<br>TMR_CUR_VAL | Current Timer Value<br>Represents the current timer value, if the timer is enabled |

### 50.3.1.11 Timer Control Register (TCTRL0 - TCTRL3)

#### 50.3.1.11.1 Offset

For n = 0 to 3:

| Register | Offset |
|---|---|
| TCTRLn | 28h + (n × 10h) |

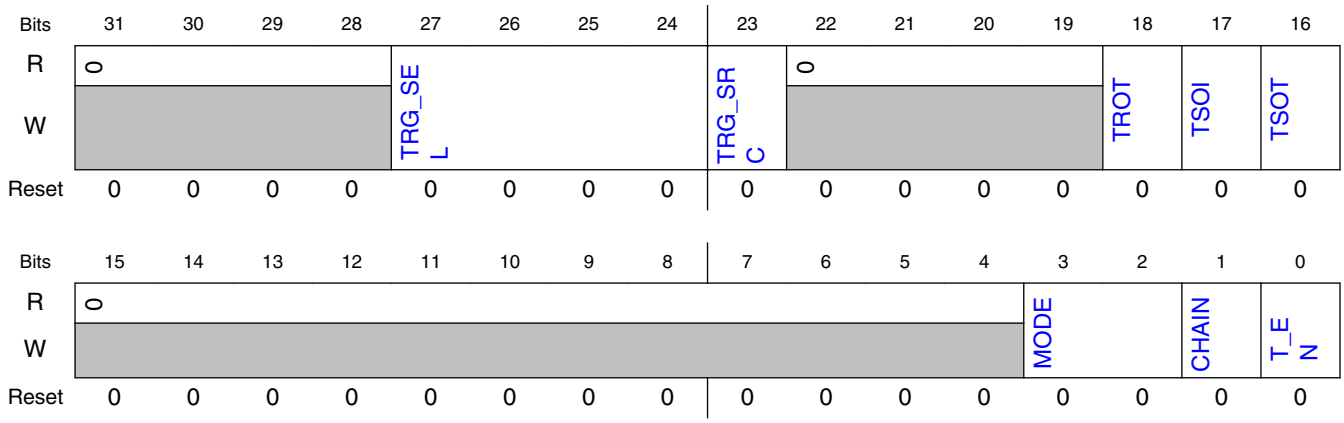
#### 50.3.1.11.2 Function

The Timer Control registers contain the control bits for each timer channel.

**NOTE**

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled), reading or writing the Timer Control register will generate a transfer error.

## 50.3.1.11.3 Diagram



## 50.3.1.11.4 Fields

The channel timer runs independently.<br>1b - Channel Chaining is enabled. The timer decrements on the previous channel's timeout. |
| 0<br>T_EN | Timer Enable<br>Enables or disables the Timer Channel<br>0b - Timer Channel is disabled<br>1b - Timer Channel is enabled |

## 50.3.2 LPIT1 register descriptions

The memory map comprises of 32-bit aligned registers, which can be accessed via 8-bit, 16-bit, or 32-bit accesses.

- Write access to reserved locations will generate a transfer error.
- Read access to reserved locations will also generate a transfer error, and the read data bus will show all 0s.

**NOTE**

- The Memory Map and complete module is in Big Endian format.
- The LPIT module will not check if programmed values in the registers are correct; software must ensure that correct programmed values are being written.

### 50.3.2.1 LPIT1 Memory map

| 31-4<br>— | This read-only field is reserved and always has the value 0 |
| 3<br>TIE3 | Channel 3 Timer Interrupt Enable<br>Enables interrupt generation when:<br>• the Channel 3 Timer Interrupt Enable bit (TIE3) is set to 1<br>• and if the corresponding Timer Interrupt Flag (MSR[TIF3]) is asserted (=1, timeout has occurred)<br>0b - Disabled<br>1b - Enabled |
| 2<br>TIE2 | Channel 2 Timer Interrupt Enable<br>Enables interrupt generation when:<br>• the Channel 2 Timer Interrupt Enable bit (TIE2) is set to 1<br>• and if the corresponding Timer Interrupt Flag (MSR[TIF2]) is asserted (=1, timeout has occurred)<br>0b - Disabled<br>1b - Enabled |
| 1<br>TIE1 | Channel 1 Timer Interrupt Enable<br>Enables interrupt generation when:<br>• the Channel 1 Timer Interrupt Enable bit (TIE1) is set to 1<br>• and if the corresponding Timer Interrupt Flag (MSR[TIF1]) is asserted (=1, timeout has occurred)<br>0b - Disabled<br>1b - Enabled |
| 0<br>TIE0 | Channel 0 Timer Interrupt Enable<br>Enables interrupt generation when:<br>• the Channel 0 Timer Interrupt Enable bit (TIE0) is set to 1<br>• and if the corresponding Timer Interrupt Flag (MSR[TIF0]) is asserted (=1, timeout has occurred)<br>0b - Disabled<br>1b - Enabled |

## 50.3.2.7 Set Timer Enable Register (SETTEN)

### 50.3.2.7.1 Offset

| Register | Offset |
|---|---|
| SETTEN | 14h |

### 50.3.2.7.2 Function

The Set Timer Enable register allows the simultaneous enabling of timer channels.

- Timer channels can be enabled by
  - either by writing '1' to Timer Enable bit (T_EN) in the respective TCTRLn register,
  - or by setting the corresponding Set Timer Enable bit (SET_T_EN_*n*) in the Set Timer Enable register (SETTEN).
- To disable timer channels simultaneously, use the Clear Timer Enable register (CLRTEN).
- Writing a '0' to the Set Timer Enable register has no effect.

**NOTE**

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled)), reading or writing the Set Timer Enable register will generate a transfer error.

## 50.3.2.9 Timer Value Register (TVAL0 - TVAL3)

### 50.3.2.9.1 Offset

For n = 0 to 3:

| Register | Offset |
|---|---|
| TVALn | 20h + (n × 10h) |

### 50.3.2.9.2 Function

- In compare modes: the Timer Value Registers (TVAL*n*) select the timeout period for the timer channels.
- In capture modes: the Timer Value Registers (TVAL*n*) are loaded with the value of the counter when the trigger asserts.

**NOTE**

Unless the Module Clock Enable bit (MCR[M_CEN]) is set (=1, peripheral clock to timers is enabled), then reading or writing the TVALn register will generate a transfer error.

### 50.3.2.9.3 Diagram

# 50.4 Functional description

## 50.4.1 LPIT programming model

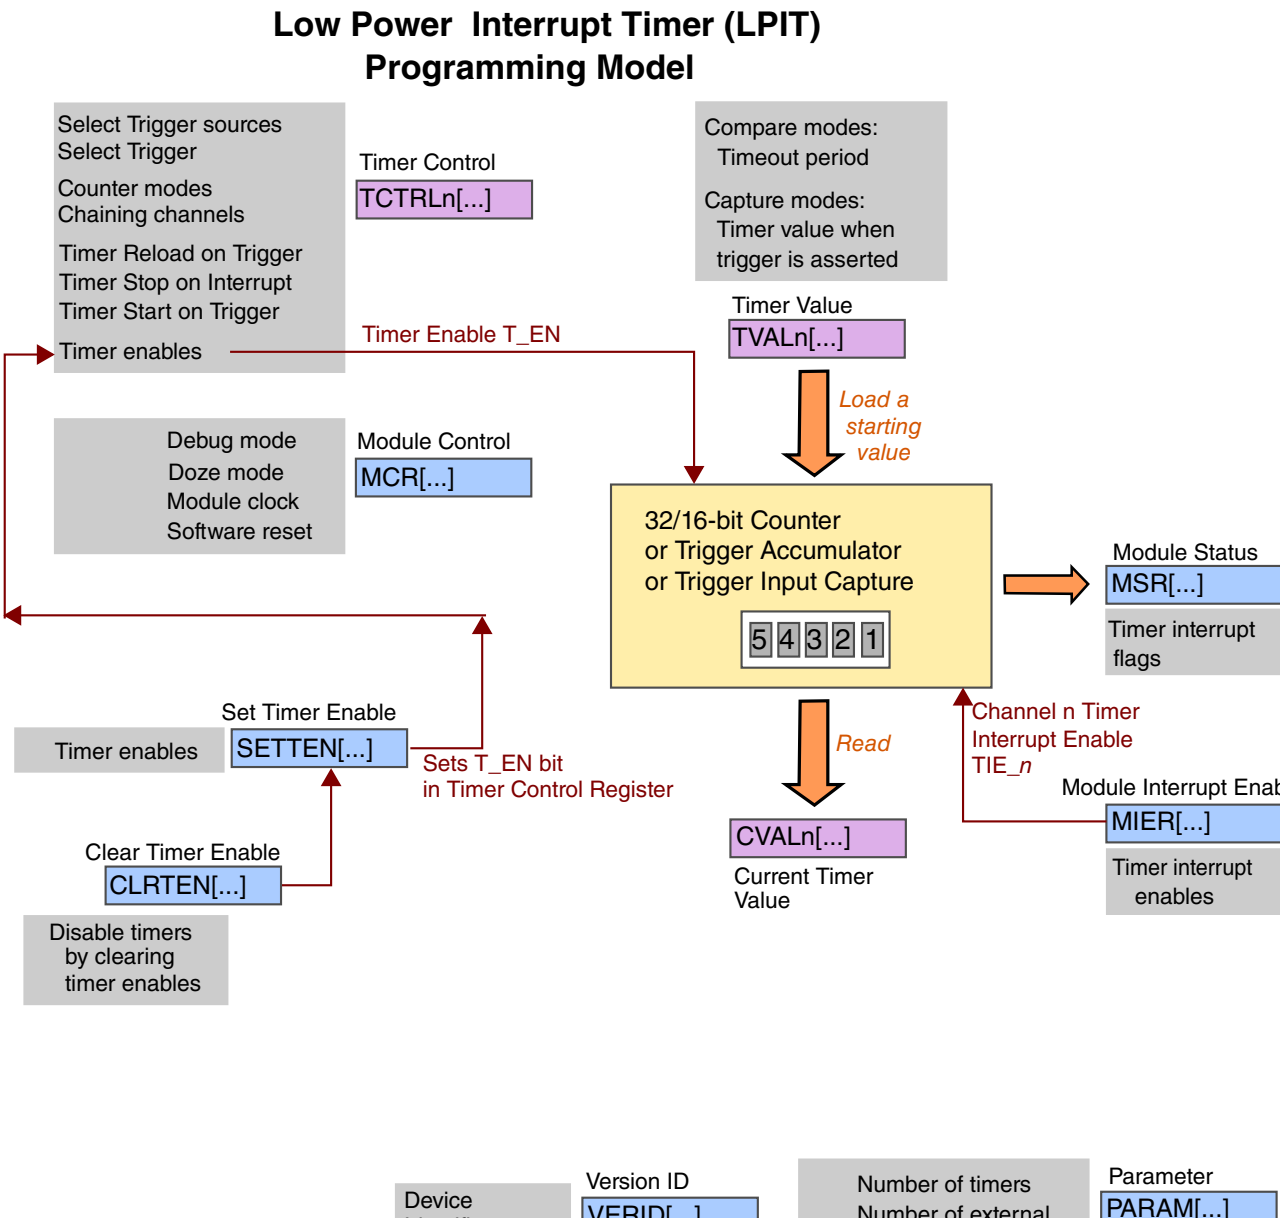

**Figure 50-3. Programming Model**

Global registers need only be set once:

- Version ID Register (VERID)
- Parameter Register (PARAM)
- Module Control Register (MCR)
- Module Status Register (MSR)
- Module Interrupt Enable Register (MIER)

- Set Timer Enable Register (SETTEN)
- Clear Timer Enable Register (CLRTEN)

Channel registers must be set for each channel:

- Timer Value Register (TVAL0 - TVAL3)
- Current Timer Value (CVAL0 - CVAL3)
- Timer Control Register (TCTRL0 - TCTRL3)

## 50.4.2 Initialization

**Table 50-2. Initializing the LPIT module**

| Step | | How? Why? |
|---|---|---|
| 1 | Enable the peripheral clock | by setting the Module Clock Enable bit (M_CEN) in the Module Control Register (MCR) register.<br>**NOTE:**<br>• Writing to certain registers (MSR, SETTEN, CLRTEN, TVAL, and TCTRL) while M_CEN = 0 will lead to assertion of a transfer error for that bus access.<br>  • Writing to CVAL and Reserved registers will generate a transfer error, regardless of the value of the Module Clock Enable bit (M_CEN) bit.<br>  • Reads to CVAL and Reserved registers can happen regardless of the M_CEN bit value.<br>• There might be additional clock gating bits in the device that gate the peripheral clock to this module. When enabling the clock to this module, ensure that software is configuring those additional clock gating bits (in addition to M_CEN bit). |
| 2 | Wait for 4 peripheral clock cycles | to allow time for clock synchronization and reset de-assertion. |
| 3 | Configure timer control bits | for each timer channel that is to be enabled:<br>• timer mode of operation bits TCTRLn[MODE]<br>• trigger source selection bits TCTRLn[TRG_SEL, TRG_SRC]<br>• trigger control bits TCTRLn[TROT, TSOT, TSOI] |
| 4 | Configure the channels that are to be chained | by setting the CHAIN bit in the corresponding channel's TCTRLn register. |
| 5 | Set the timer timeout value | for channels configured in Compare Mode, by programming the appropriate value in TVAL register for those channels. |
| 6 | Configure TIEn bits in MIER register | for those channels that are required to generate interrupts on timer timeouts. |
| 7 | Configure the low power modes of the module | by setting the DBG_EN and DOZE_EN bits in the MCR register. This is common to all timer channels. |
| 8 | Enable the channel timers | by setting the corresponding T_EN bit in the corresponding channel's TCRTLn register. |

*Also:*

- For channels configured in Capture Mode, the timer value can be read from TVALn register when a channel timeout occurs.

- At any time, the current value of the timer for any channel can be read by reading the corresponding channel's CVALn register.
- The timer interrupt flag bits (TIFn) in MSR register get asserted on timer timeout. To clear these timer interrupt flag bits, write '1' to them.

## 50.4.3 Timer Modes

The timer mode is configured by setting an appropriate value in the MODE bits in TCTRLn register.

**Table 50-3. Timer modes that are supported**

| Timer Mode | Operation |
|---|---|
| 32-bit Periodic Counter | • The counter will load, decrement down to 0<br>• which will set the timer interrupt flag and assert the output pre-trigger. |
| Dual 16-bit Periodic Counter | • The counter will load, then the lower 16-bits will decrement down to 0<br>• which will assert the output pre-trigger.<br>• The upper 16-bits will then decrement down to 0<br>• which will set the timer interrupt flag and then negate the output pre-trigger. |
| 32-bit Trigger Accumulator | • The counter will load on the 1st trigger rising edge and then decrement down to 0 on each trigger rising edge<br>• which will set the timer interrupt flag and assert the output pre-trigger. |
| 32-bit Trigger Input Capture | • The counter will load with 0xFFFF_FFFF and then decrement down to 0.<br>• If a trigger rising edge is detected,<br>  • then it will store the inverse of the current counter value in the timer value register<br>  • which will set the timer interrupt flag and assert the output pre-trigger. |

The timer operation is controlled by Trigger Control bits (TSOT, TSOI, TROT) which control the timer load, reload, start and restart of the timers.

**NOTE**

- The trigger output is asserted one Peripheral Timer Clock cycle later than pre-trigger output. The trigger output and the pre-trigger output de-assert at the same time.
- The pre-trigger output is asserted for 2 clock cycles and the trigger output is asserted for 1 clock cycle (except in 16-bit Periodic Counter mode, where both pre-trigger and trigger are asserted for many cycles depending on TMR_VAL[31:16]).
- Timer changes *that are based on external triggers* take effect after 4 peripheral clocks after the actual external trigger assertion (due to clock synchronization, rise edge detection and timer update).

### 50.4.4 Trigger Control for Timers

Various programmable bits control how the trigger inputs and the timer operate. TRG_SEL and TRG_SRC select the timer triggers:

- Trigger Select (TRG_SEL) selects the input trigger for the channel from all of the other channel's trigger outputs.
- Trigger Source (TRG_SRC) selects between the internal trigger and the external trigger inputs to the channel.

The selected trigger affects how the timer operates, using the configuration of the TROT, TSOI and TSOT bits.

**Table 50-4. How bits control timer operations**

| If | = | Then |
|---|---|---|
| TSOI<br>*Timer Stop On Interrupt* | 1 | then the counter stops on a Timer Interrupt flag (MSR[TIFn]) assertion. To reload and decrement, it requires:<br>• a trigger (if TSOT = 1)<br>• a T_EN rising edge (if TSOT = 0) |
| | 0 | then the counter does not stop after timeout |
| TROT<br>*Timer Reload On Trigger* | 1 | then the counter is loaded on each trigger |
| | 0 | then the counter is loaded on every T_EN rising edge or timeout rising edge (timeout not used in Capture modes) |
| TSOT<br>*Timer Start On Trigger* | 1 | then the counter will start to decrement on a trigger. Subsequent triggers are ignored until the counter times out. |
| | 0 | then the counter decrements immediately on the next clock edge. When channel is Chained or in Capture mode, TSOT has no effect. |

In different timer modes, these programmable bits affect the timer operation differently:

**Table 50-5. Time modes and programmable bits**

| Mode | Which programmable bits affect timer operations |
|---|---|
| 32-bit Periodic Counter | All bits (TSOT, TSOI, TROT) affect the timer operation as described previously. |
| Dual 16-bit Periodic Counter | |
| 32-bit Trigger Accumulator | • Only the TSOI bit controls the timer function.<br>• TROT and TSOT bits have no effect on timer operations. |
| 32-bit Input Trigger Capture | • Only TSOI and TROT bits control the timer function.<br>• TSOT bit has no effect on timer operations. |

## 50.4.5 Channel Chaining

Individual timer channels can be chained together to achieve a larger value of timeout. Chaining the timer channel causes them to work in a *'nested loop'* manner thereby leading to an effective timeout value of $TVAL_{CHn} \times (TVAL_{CHn-1} + 1)$.

The channels are chained by setting the CHAIN bit in corresponding channel's $TCTRL_{CHn}$ register. When a channel is chained, that channel's timer decrements on previous channel's timeout pulse, regardless of the timer mode (MODE bits). The TSOT bit does not have any effect if the channel timer (Channel 'n') is chained to previous channel's timer (Channel 'n-1').

## 50.4.6 Detailed timing

**NOTE**

The timing diagrams in these sections are not *cycle-accurate* (i.e., some cycles may not be shown), but the timing diagrams do show the timer channel behavior across several clock cycles.

**Table 50-6. Timing diagrams list**

| Mode | | Timing Diagram | TSOT | TROT | TSOI | CHAIN |
|---|---|---|---|---|---|---|

### 50.4.6.1 Mode=00: 32-bit periodic counter (compare mode)

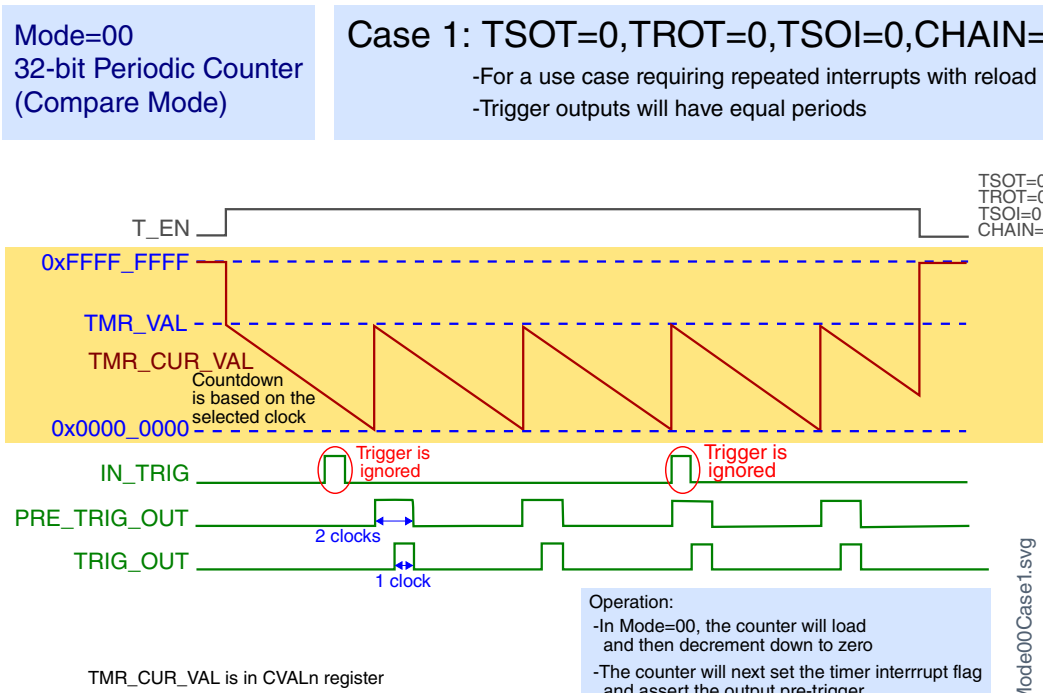

**Figure 50-4. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0**

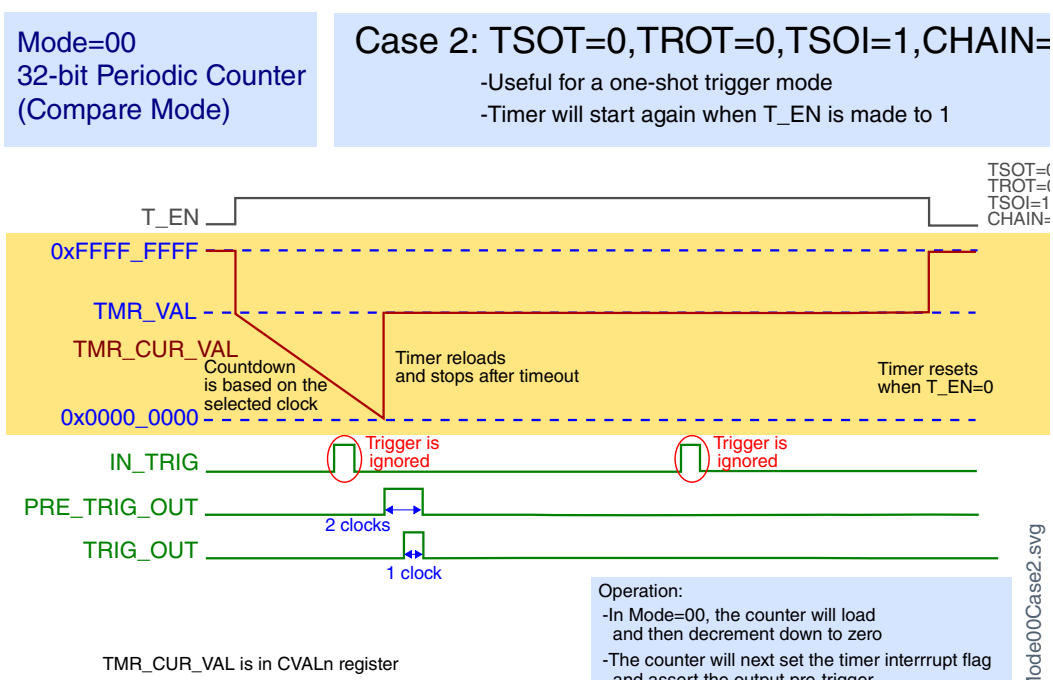

**Figure 50-5. Case 2: TSOT = 0, TROT = 0, TSOI = 1, CHAIN = 0**

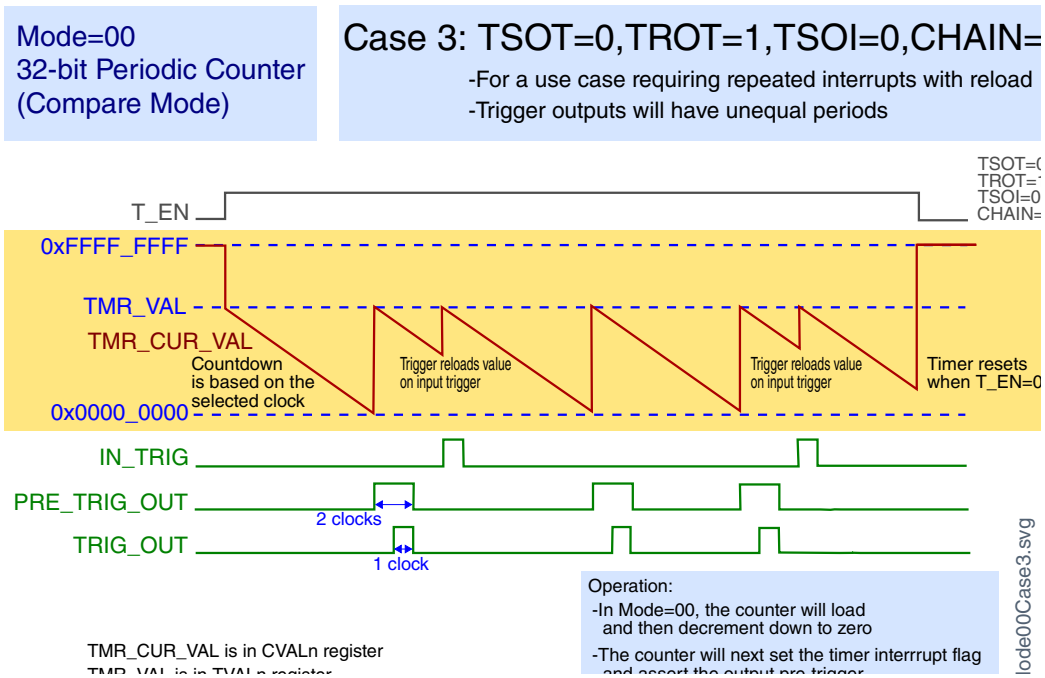

**Figure 50-6. Case 3: TSOT = 0, TROT = 1, TSOI = 0, CHAIN = 0**

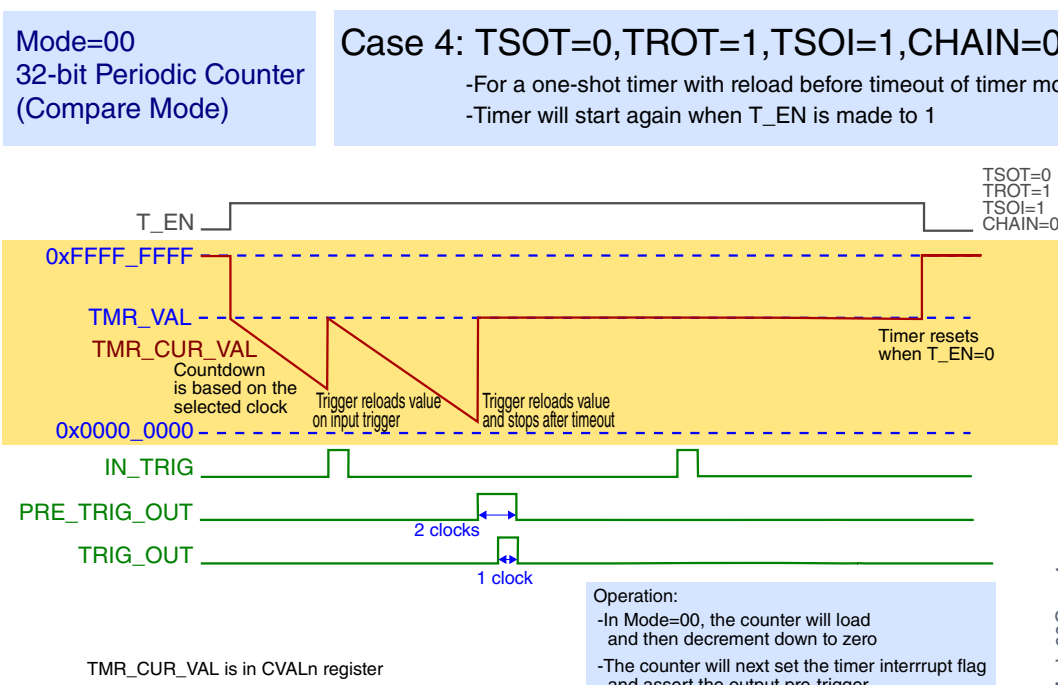

**Figure 50-7. Case 4: TSOT = 0, TROT = 1, TSOI = 1, CHAIN = 0**

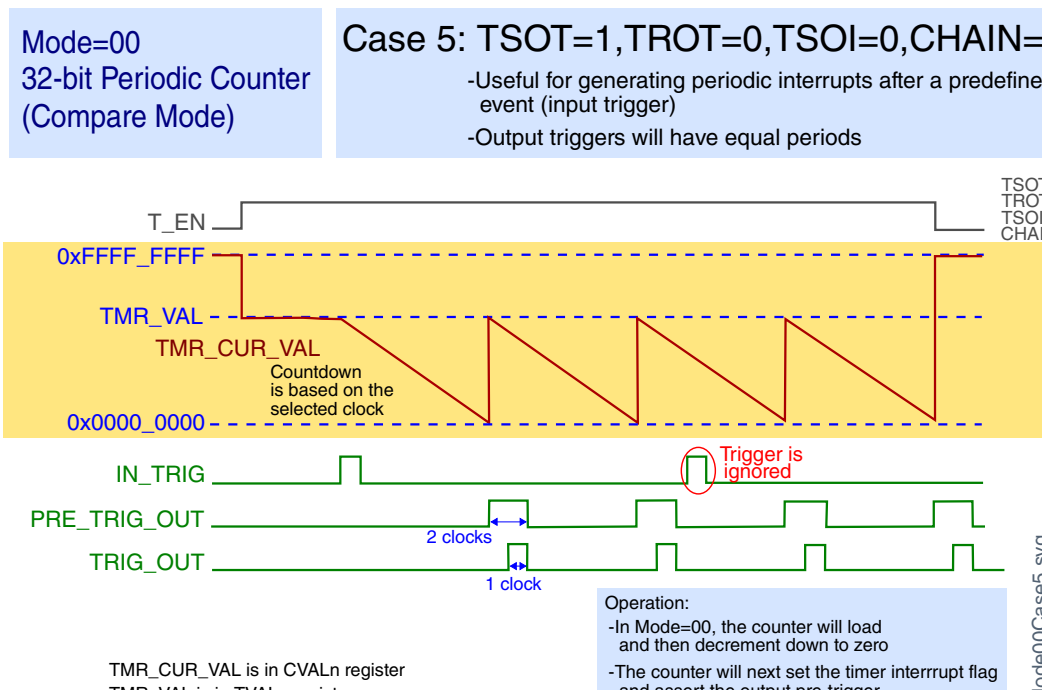

**Figure 50-8. Case 5: TSOT = 1, TROT = 0, TSOI = 0, CHAIN = 0**

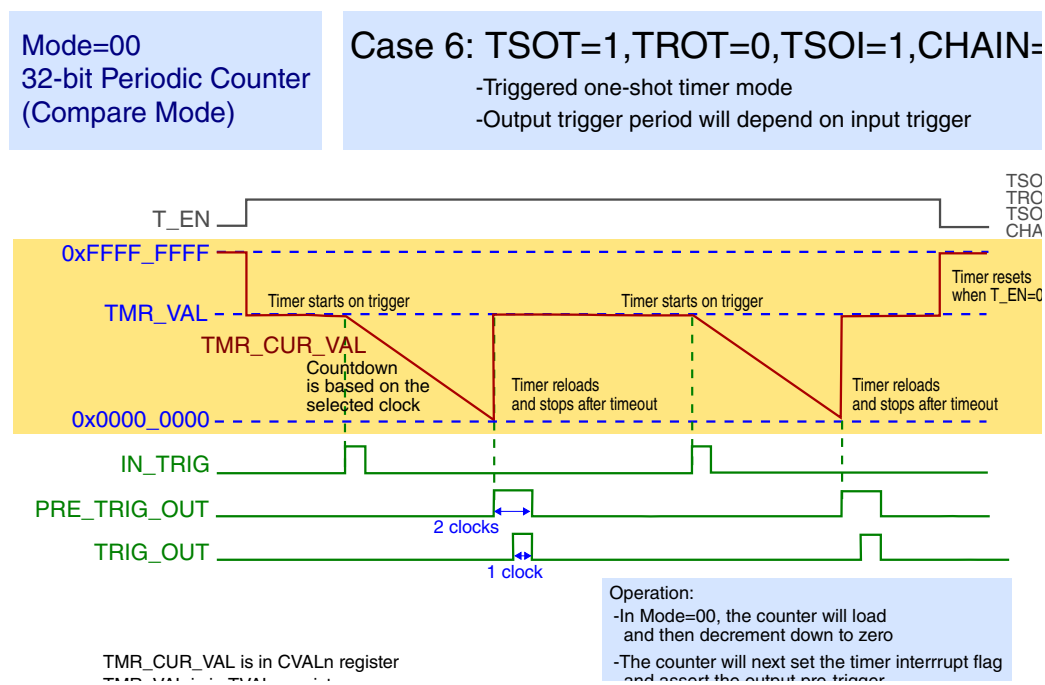

**Figure 50-9. Case 6: TSOT = 1, TROT = 0, TSOI = 1, CHAIN = 0**

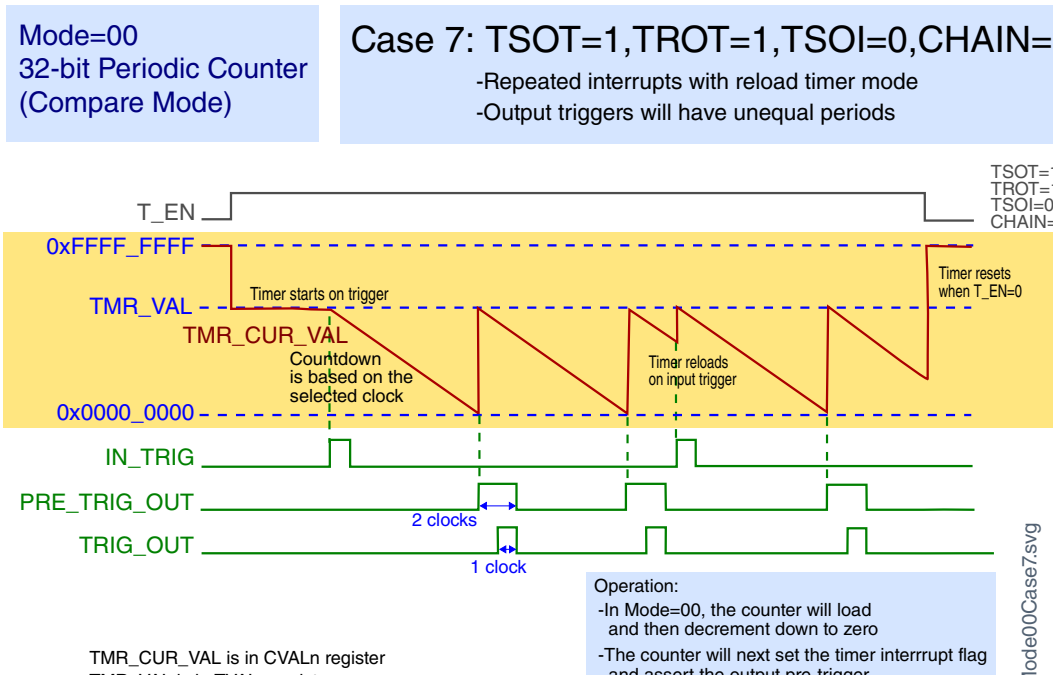

**Figure 50-10. Case 7: TSOT = 1, TROT = 1, TSOI = 0, CHAIN = 0**

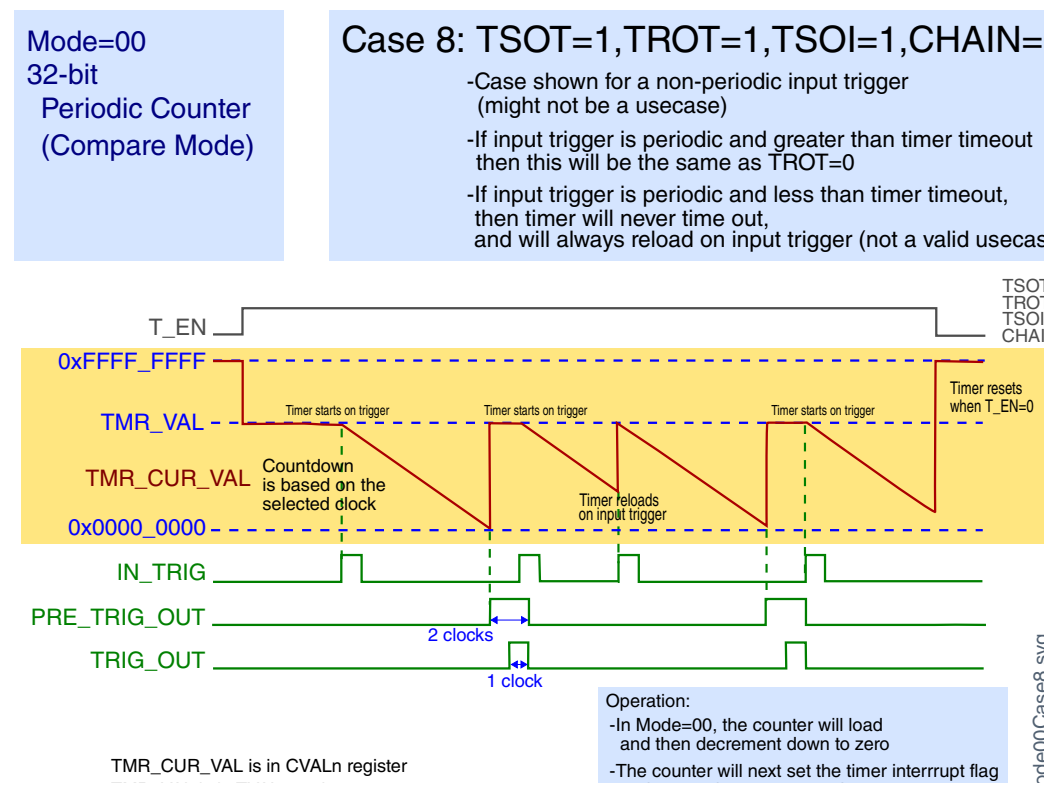

**Figure 50-11. Case 8: TSOT = 1, TROT = 1, TSOI = 1, CHAIN = 0**

### 50.4.6.2 Mode=01: 16-bit dual periodic counter (compare mode)

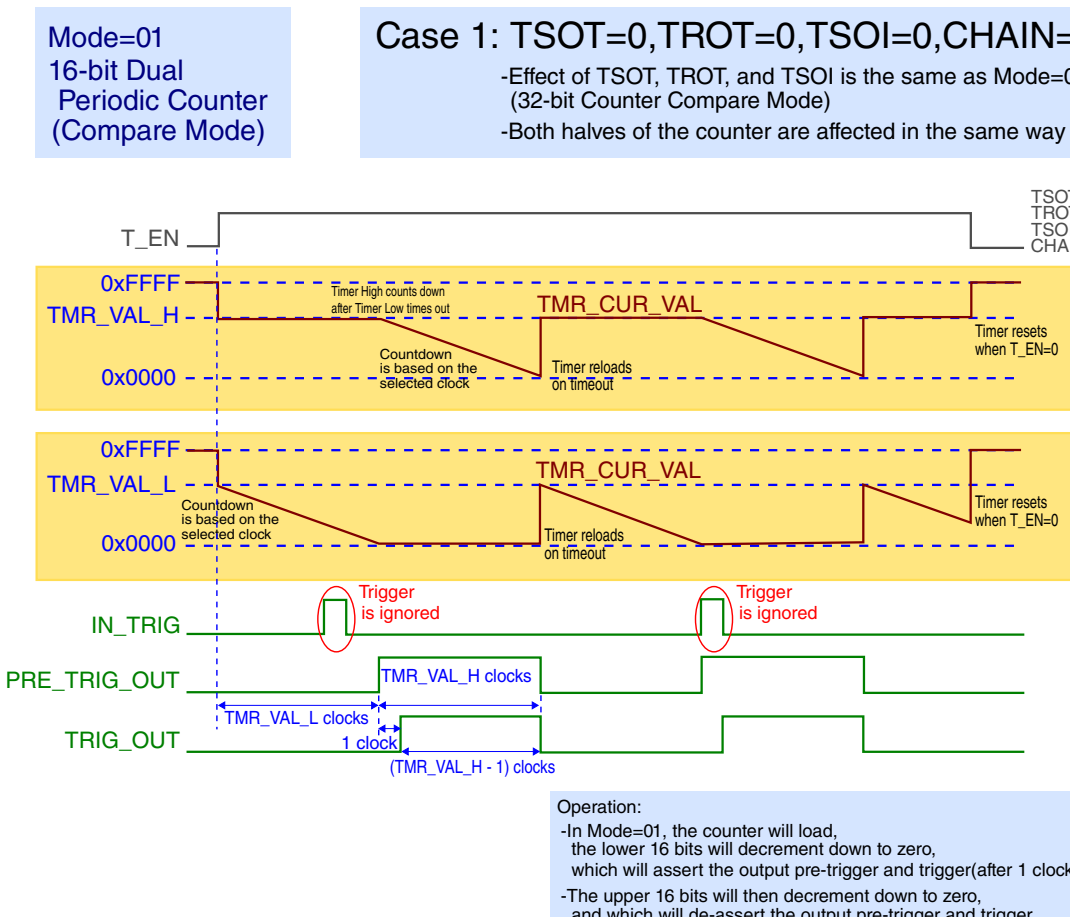

**Figure 50-12. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0**

## Effect of Timer Control Bits in Mode=01:

- Effect of timer control bits are the same as for Mode=00. Refer to the individual figures of Mode=00.
- The Timer Interrupt (timeout) asserts when {TMR_H,TMR_L} = 0x0000_0000.
- Behavior for Mode = 01 is explained in the next table.

**Table 50-7. Mode=01 timer control bits**

| TSOT | TROT | TSOI | Function | Effect on Timer |
|---|---|---|---|---|
| 0 | 0 | 0 | • For repeated interrupts with reload<br>• Trigger outputs will have equal periods | Similar to Figure 50-12. |
| 0 | 0 | 1 | One-shot mode | • Both timers stop after first count down and then time out<br>• Timers will not count again until T_EN is made 1 again<br>• Similar to Figure 50-5. |

*Table continues on the next page...*

## Table 50-7. Mode=01 timer control bits (continued)

| TSOT | TROT | TSOI | Function | Effect on Timer |
|---|---|---|---|---|
| 0 | 1 | 0 | • For repeated interrupts with reload<br>• Trigger outputs will have unequal periods | • Both timers will reload TMR_VAL on trigger rise edge<br>• Output triggers will clear on reload, if asserted<br>• Similar to Figure 50-6. |
| 0 | 1 | 1 | Reloadable one-shot mode | • If a trigger occurs before timeout, then both timers reload and count down (as shown); the timers stop after timeout<br>• A trigger assertion after timeout simply reloads TMR_VAL into the timers<br>• The timers will not count again until T_EN is set to 1 again<br>• Similar to Figure 50-7. |
| 1 | 0 | 0 | • For generating periodic interrupts after a predefined event (input trigger)<br>• Output triggers will have equal periods | After T_EN rises, the timers do not start until the first trigger's rising edge<br>• Subsequent triggers will have no effect<br>• Similar to Figure 50-8. |
| 1 | 0 | 1 | • Triggered one-shot timer mode<br>• Output trigger period will depend on input trigger | After T_EN rises, the timers do not start until the first trigger's rising edge.<br>• The timer stops counting after a timeout assertion (a timeout is asserted)<br>• The timer does not start counting again until a new trigger's rising edge is detected<br>• Similar to Figure 50-9. |
| 1 | 1 | 0 | • For repeated interrupts with reload timer mode<br>• Output triggers will have unequal periods | After T_EN rises, the timers do not start until the first trigger's rising edge<br>• Subsequent triggers will cause the timer to reload TMR_VAL into both counters<br>• The output triggers will clear after a reload, if asserted<br>• Similar to Figure 50-10. |
| 1 | 1 | 1 | • For a non-periodic input trigger<br>• If input trigger is periodic and greater than timer timeout, then this will be the same as TROT=0 (which is triggered one-shot timer mode; output trigger period will depend on input trigger) | After T_EN rises, the timers do not start until the first trigger's rising edge<br>• The timers stops counting after a timeout assertion (a timeout is asserted)<br>• A trigger's rising edge will cause the timers to reload and then count down<br>• Similar to Figure 50-11. |

### 50.4.6.3 Mode=10: 32-bit trigger accumulator mode

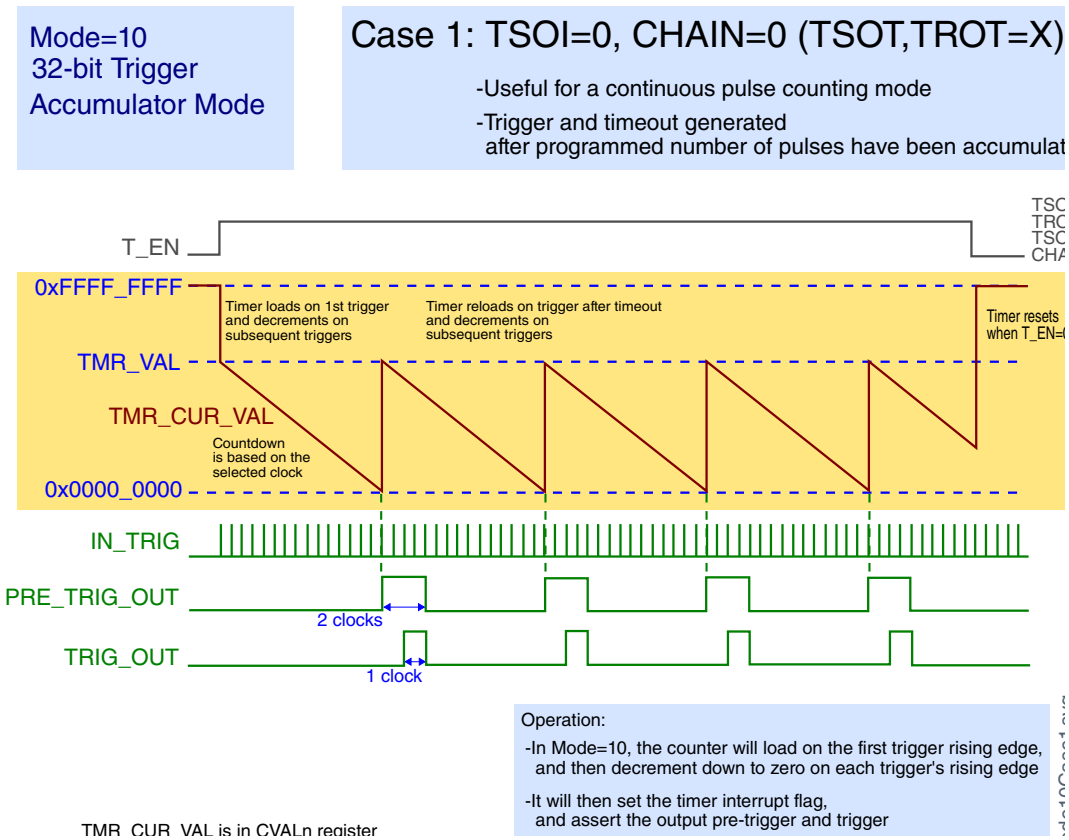

**Figure 50-13. Case 1: TSOT = X, TROT = X, TSOI = 0, CHAIN = 0**

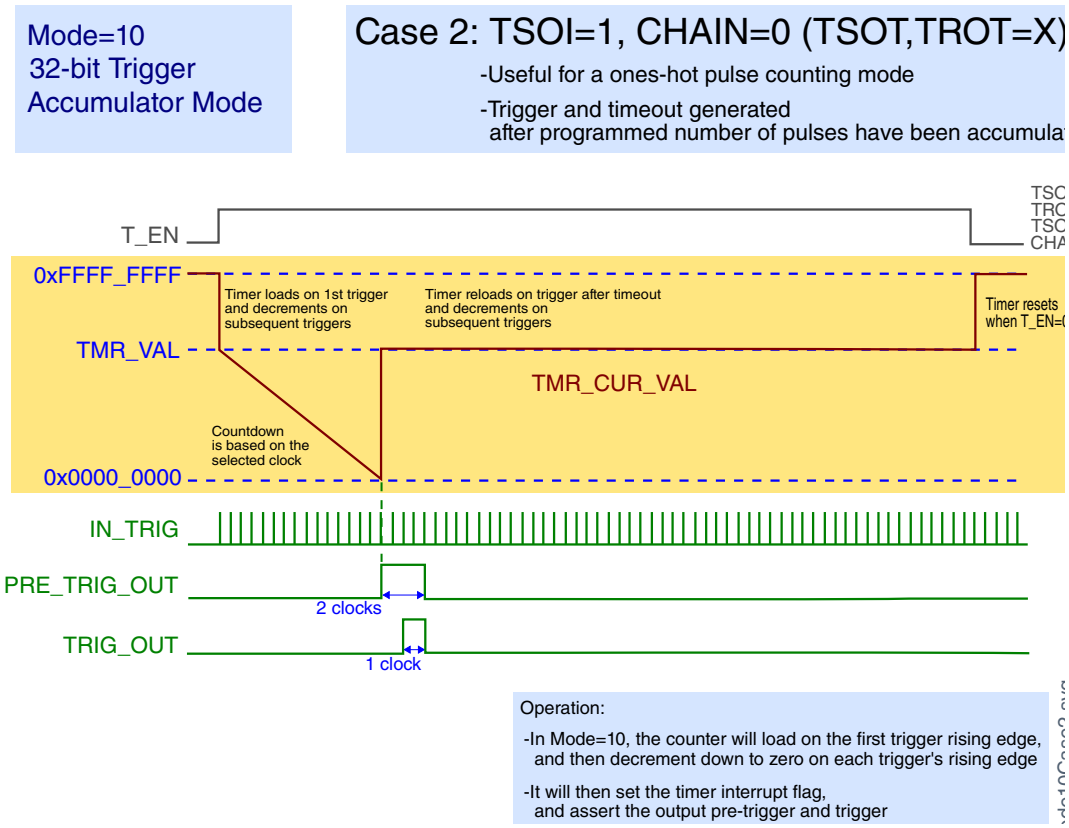

**Figure 50-14. Case 2: TSOT = X, TROT = X, TSOI = 1, CHAIN = 0**

### 50.4.6.4 Mode=11: 32-bit trigger capture mode

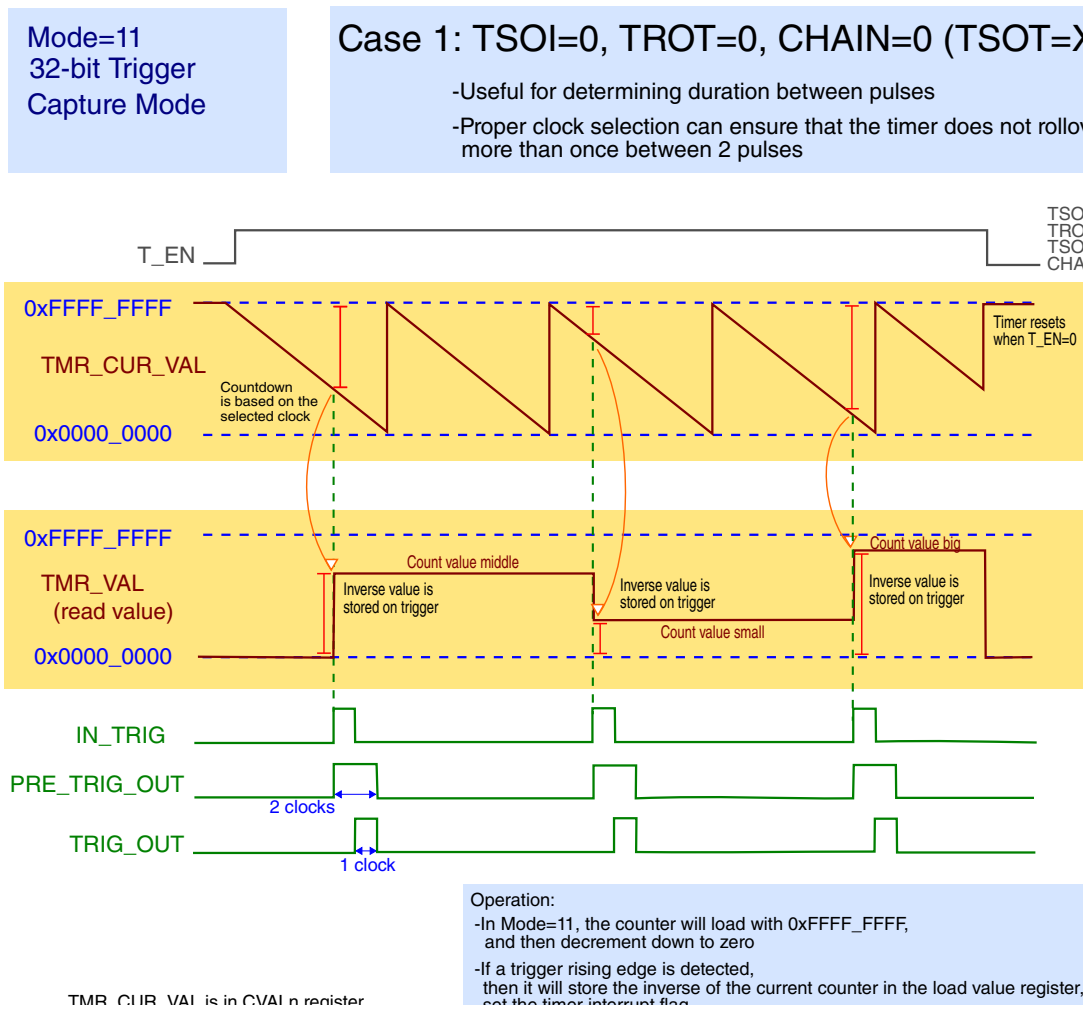

**Figure 50-15. Case 1: TSOT = X, TROT = 0, TSOI = 0, CHAIN = 0**

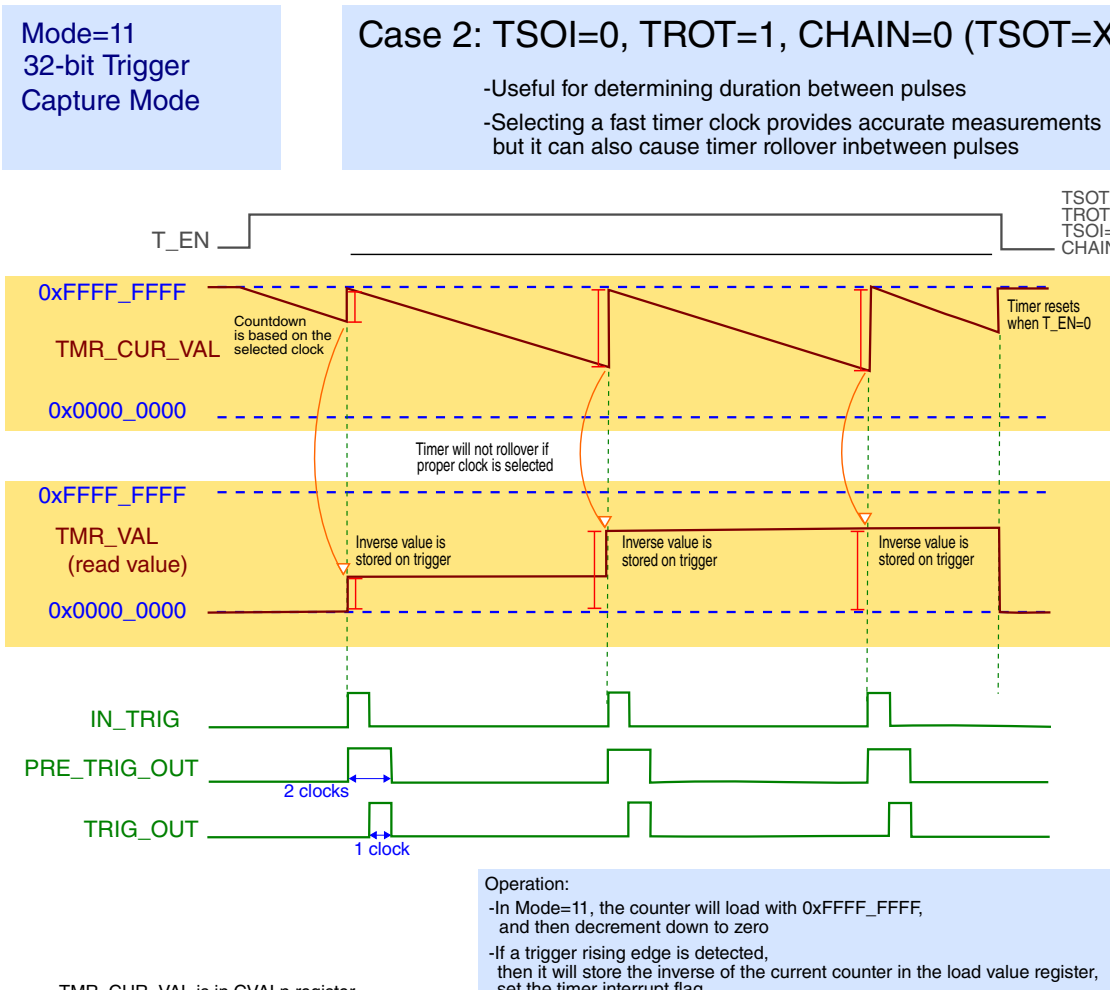

**Figure 50-16. Case 2: TSOT = X, TROT = 1, TSOI = 0, CHAIN = 0**

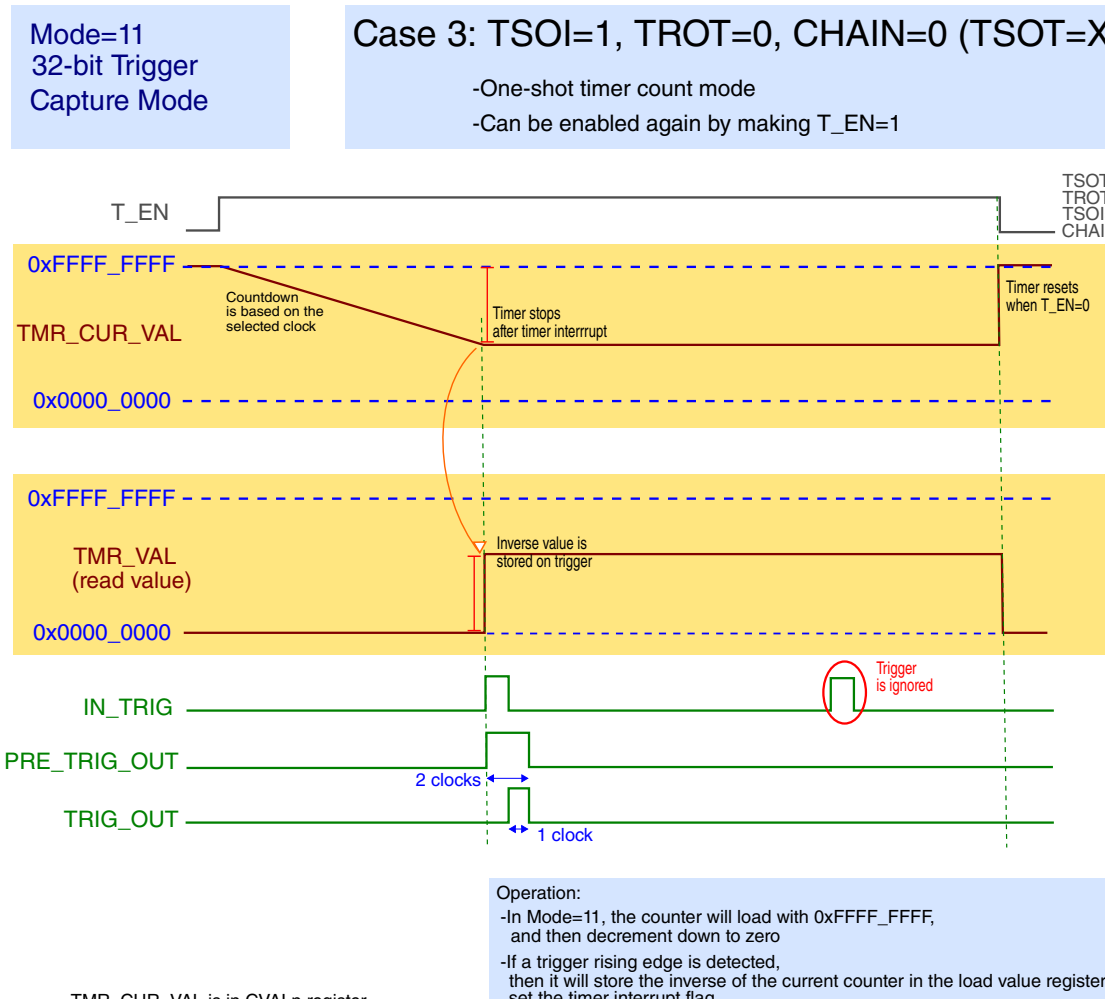

**Figure 50-17. Case 3: TSOT = X, TROT = 0, TSOI = 1, CHAIN = 0**

## Case 4: TSOT = X, TROT = 1, TSOI = 1, CHAIN = 0

Same as previous case (Case 3), except that the timer reloads to 0xFFFF_FFFF and then stops. The timer does not start until T_EN is made 1 again. Case 4 is not a very useful case, because Case 3 covers this.

### 50.4.6.5 Timer chaining

| Effect of Chaining | -Chaining causes Timer “n” to decrement on every timeout pulse (trigger output pulse) from Timer “n – 1”, regardless of what mode is configured in Timer “n”<br>-Timers “n” and “n – 1” effectively form a larger width timer (64-bits)<br>-More than 2 timer channels (or all timer channels) can be chained<br>-It is preferred to have the same trigger source and timer controls configured for chained channels |
|---|---|

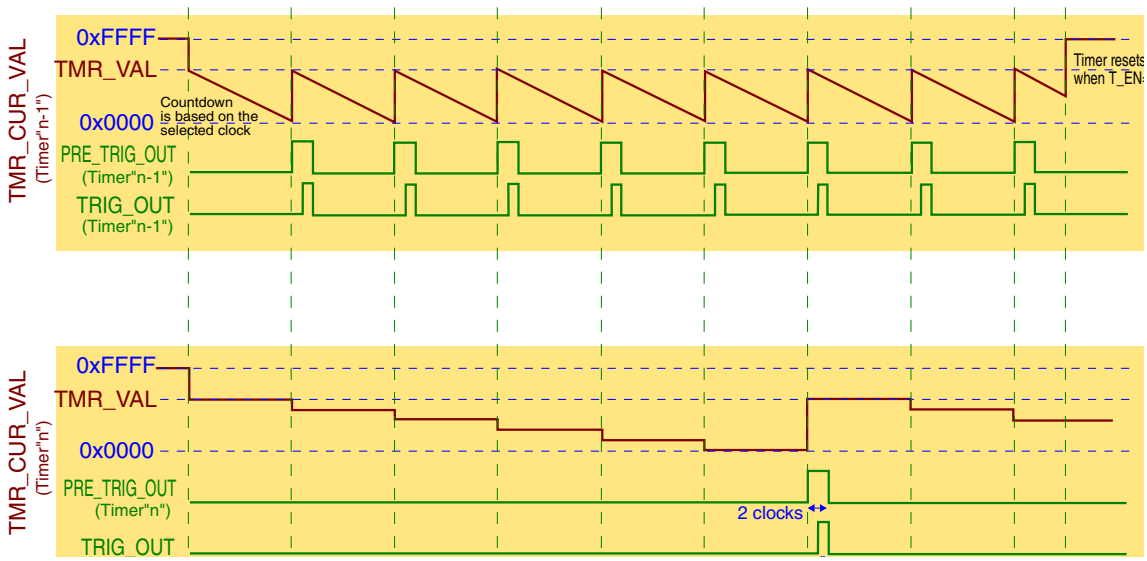

**Figure 50-18. Chaining Effects**

# Chapter 51
# Timer/PWM Module (TPM)

## 51.1 Chip-specific TPM information

### 51.1.1 TPM Instantiation Information

This device contains 4 TPM modules. All TPM modules in the device are configured with basic TPM functionality with no quadrature decoder function and all can be functional in Stop/VLPS mode. The clock source is either external or internal in Stop/VLPS mode.

The following table shows how these modules are configured.

**Table 51-1. TPM configuration**

| TPM instance | Number of channels | Features/usage |
|---|---|---|
| TPM0 | 6 | Basic TPM,functional in Stop/VLPS mode |
| TPM1 | 2 | Basic TPM,functional in Stop/VLPS mode |
| TPM2 | 6 | Basic TPM,functional in Stop/VLPS mode |
| TPM3 | 2 | Basic TPM,functional in Stop/VLPS mode |

### 51.1.2 Global Timebase

Each TPM has a global timebase feature controlled by the TPMx_CONF[GTBEEN] bit. TPM1 is configured as the global time when this option is enabled.

### 51.1.3 TPM Interrupts

The TPM has multiple sources of interrupt. However, these sources are OR'd together to generate a single interrupt request to the interrupt controller. When a TPM interrupt occurs, read the TPM status registers to determine the exact interrupt source.

## 51.2 Introduction

The TPM (Timer/PWM Module) is a 2- to 8-channel timer which supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications.

The counter, compare and capture registers are clocked by an asynchronous clock that can remain enabled in low power modes. An example of using the TPM with the asynchronous DMA is described in AN4631:Using the Asynchronous DMA features of the Kinetis L Series .

### 51.2.1 TPM Philosophy

The TPM is built upon a very simple timer (HCS08 Timer PWM Module – TPM) used for many years on 8-bit microcontrollers. The TPM extends the functionality to support operation in low power modes by clocking the counter, compare and capture registers from an asynchronous clock that can remain functional in low power modes.

### 51.2.2 Features

The TPM features include:

- TPM clock mode is selectable
  - Can increment on every edge of the asynchronous counter clock
  - Can increment on rising edge of an external clock input synchronized to the asynchronous counter clock
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- TPM includes a 16-bit counter
  - It can be a free-running counter or modulo counter
  - The counting can be up or up-down

- Includes 6 channels that can be configured for input capture, output compare, edge-aligned PWM mode, or center-aligned PWM mode
  - In input capture mode the capture can occur on rising edges, falling edges or both edges
  - In output compare mode the output signal can be set, cleared, pulsed, or toggled on match
  - All channels can be configured for edge-aligned PWM mode or center-aligned PWM mode
- Support the generation of an interrupt and/or DMA request per channel
- Support the generation of an interrupt and/or DMA request when the counter overflows
- Support selectable trigger input to optionally reset or cause the counter to start incrementing.
  - The counter can also optionally stop incrementing on counter overflow
- Support the generation of hardware triggers when the counter overflows and per channel

## 51.2.3 Modes of operation

During debug mode, the TPM can can be configured to temporarily pause all counting until the core returns to normal user operating mode or to operate normally. When the counter is paused, trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state.

During doze mode, the TPM can be configured to operate normally or to pause all counting for the duration of doze mode. When the counter is paused, trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state.

During stop mode, the TPM counter clock can remain functional and the TPM can generate an asynchronous interrupt to exit the MCU from stop mode.

## 51.2.4 Block diagram

The TPM uses one input/output (I/O) pin per channel, CHn (TPM channel (n)) where n is the channel number.

The following figure shows the TPM structure. The central component of the TPM is the 16-bit counter with programmable final value and its counting can be up or up-down.

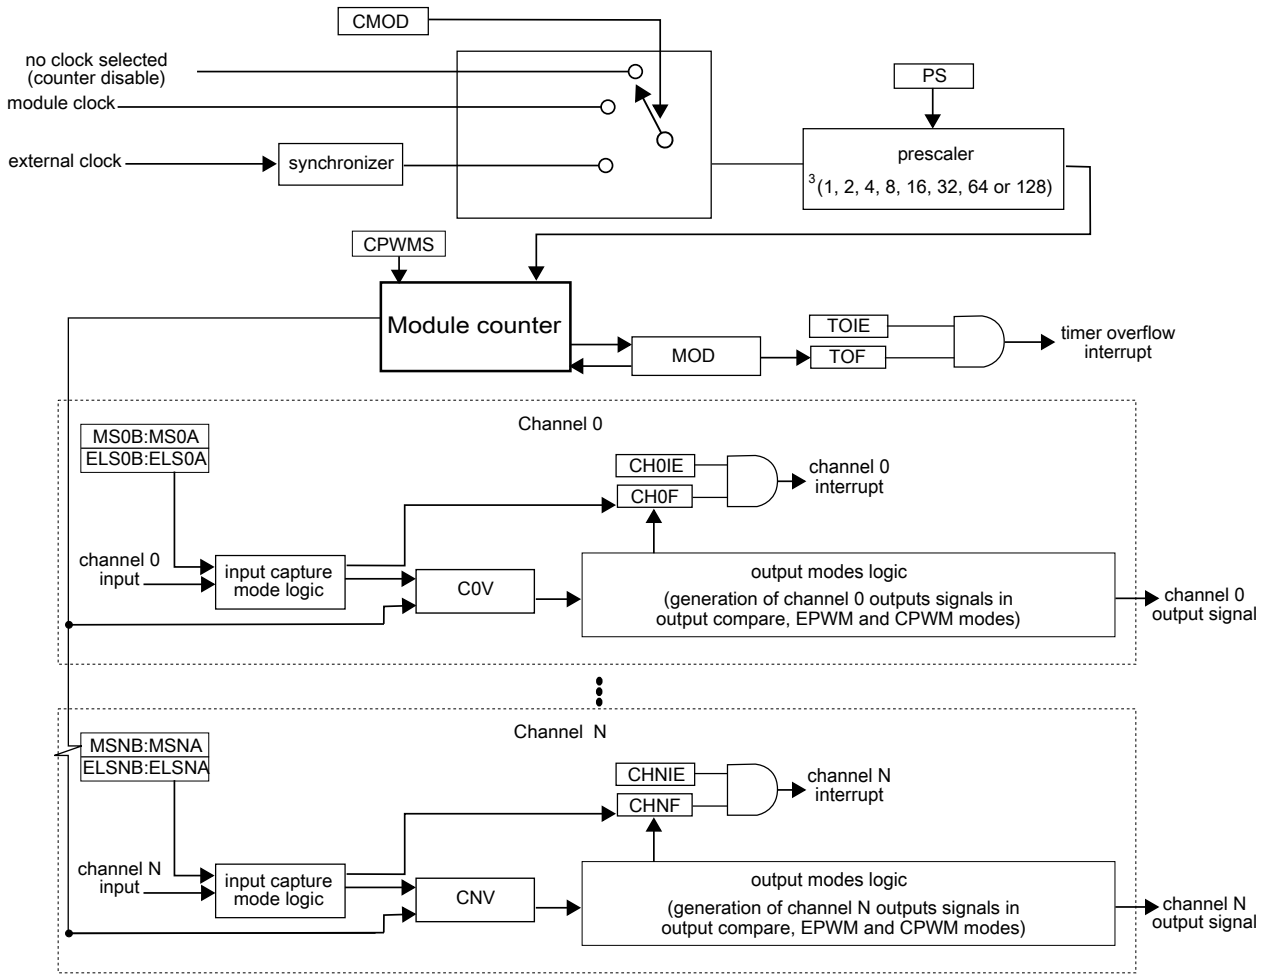

**Figure 51-1. TPM block diagram**

## 51.3 TPM Signal Descriptions

Table 51-2 shows the user-accessible signals for the TPM.

**Table 51-2. TPM signal descriptions**

| Signal | Description | I/O |
|---|---|---|
| TPM_EXTCLK | External clock. TPM external clock can be selected to increment the counter on every rising edge synchronized to the counter clock. | I |
| TPM_CHn | TPM channel (n = 5 to 0). A TPM channel pin is configured as output when configured in an output compare or PWM mode and the TPM counter is enabled, otherwise the TPM channel pin is an input. | I/O |

### 51.3.1 TPM_EXTCLK — TPM External Clock

The rising edge of the external input signal is used to increment the TPM counter if selected by CMOD[1:0] bits in the SC register. This input signal must be less than half of the TPM counter clock frequency. The TPM counter prescaler selection and settings are also used when an external input is selected.

### 51.3.2 TPM_CHn — TPM Channel (n) I/O Pin

Each TPM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.

## 51.4 Memory Map and Register Definition

This section provides a detailed description of all TPM registers.

Attempting to access a reserved register location in the TPM memory map will generate a bus error.

### 51.4.1 TPM0 register descriptions

#### 51.4.1.1 TPM0 Memory map

TPM0 base address: 4003_5000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|

## 51.4.1.6 Counter (CNT)

### 51.4.1.6.1 Offset

| Register | Offset |
|---|---|
| CNT | 14h |

### 51.4.1.6.2 Function

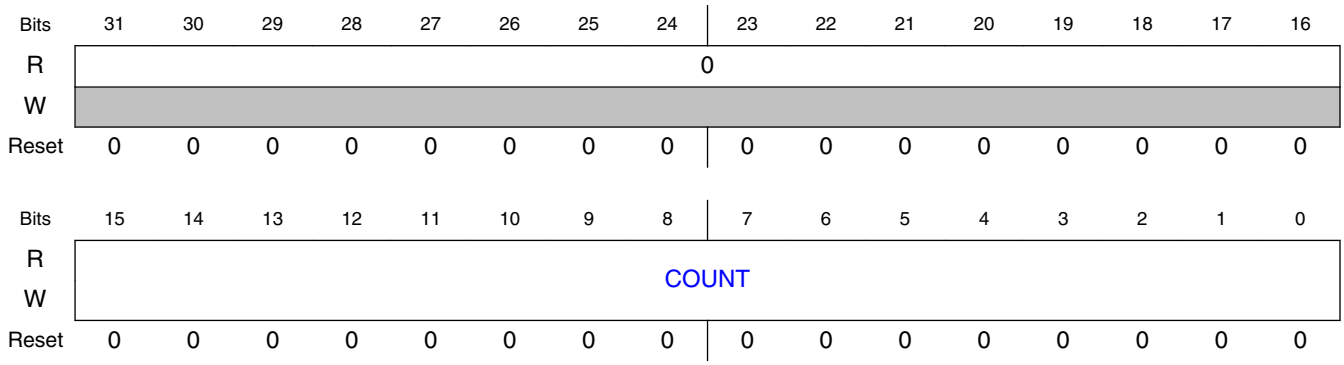
The CNT register contains the TPM counter value.

Reset clears the CNT register. Writing any value to COUNT will trigger a reload of the counter, this will force PWM outputs to their reload state..

When debug is active, the TPM counter does not increment unless configured otherwise.

Reading the CNT register adds two wait states to the register access due to synchronization delays.

#### 51.4.1.6.3 Diagram



#### 51.4.1.6.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>COUNT | Counter value |

### 51.4.1.7 Modulo (MOD)

#### 51.4.1.7.1 Offset

| Register | Offset |
|---|---|
| MOD | 18h |

#### 51.4.1.7.2 Function

The Modulo register contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, the overflow flag (TOF) is set and the next value of TPM counter depends on the selected counting method (see Counter ).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to MOD Register Update . Additional writes to the MOD write buffer are ignored until the register has been updated.

It is recommended to initialize the TPM counter (write to CNT) before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

| 15-0<br>MOD | Modulo value<br>This field must be written with single 16-bit or 32-bit access. |

### 51.4.1.8 Capture and Compare Status (STATUS)

#### 51.4.1.8.1 Offset

| Register | Offset |
|---|---|
| STATUS | 1Ch |

#### 51.4.1.8.2 Function

The STATUS register contains a copy of the status flag, CnSC[CHnF] for each TPM channel, as well as SC[TOF], for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by writing all ones to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. Writing a 1 to CHF clears it. Writing a 0 to CHF has no effect.

If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

## 51.4.1.10 Channel (n) Value (C0V - C5V)

### 51.4.1.10.1 Offset

For a = 0 to 5:

| Register | Offset |
|---|---|
| CaV | 24h + (a × 8h) |

### 51.4.1.10.2 Function

These registers contain the captured TPM counter value for the input modes or the match value for the output modes.

In input capture mode, any write to a CnV register is ignored.

In compare modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to CnV Register Update . Additional writes to the CnV write buffer are ignored until the register has been updated.

### 51.4.1.10.3 Diagram

## 51.4.1.12 Channel Trigger (TRIG)

### 51.4.1.12.1 Offset

| Register | Offset |
|---|---|
| TRIG | 6Ch |

### 51.4.1.12.2 Function

In input capture mode, configures the trigger input that is used by the channel to capture the counter value. In output compare or PWM mode, configures the trigger input used to modulate the channel output. When modulating the output, the output is forced to the channel initial value whenever the trigger is not asserted. Note that the even numbered channels share the first input trigger source and the odd numbered channels share the second input trigger source.

### 51.4.1.12.3 Diagram

Deadtime insertion is disabled when CH0FVAL is zero, otherwise deadtime insertion for channel 0 is configured as (CH0FVAL * 4) clock cycles. |

## 51.4.1.15 Quadrature Decoder Control and Status (QDCTRL)

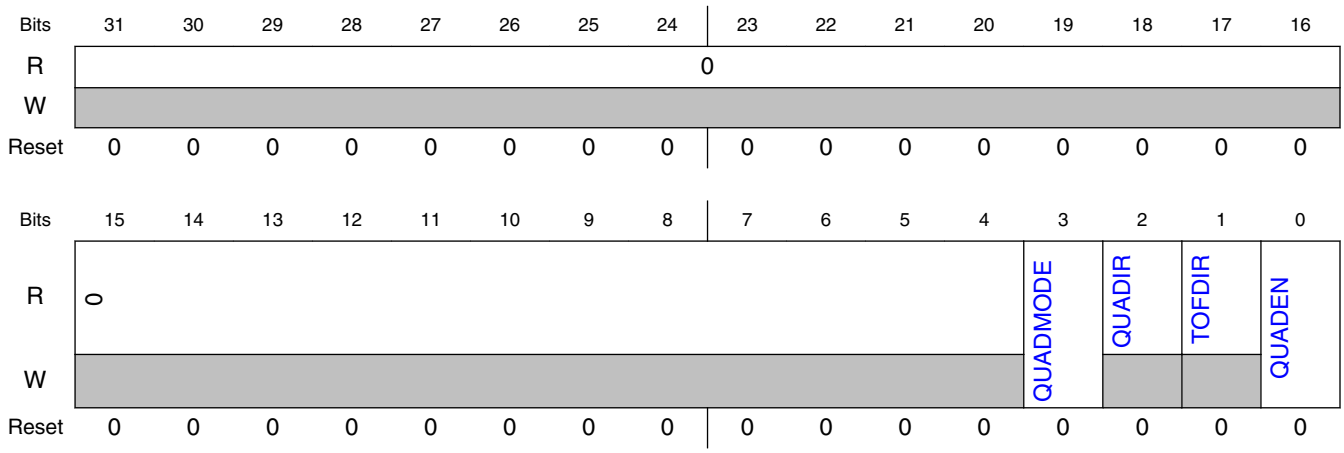
### 51.4.1.15.1 Offset

| Register | Offset |
|---|---|
| QDCTRL | 80h |

### 51.4.1.15.2 Function

This register has the control and status bits for the quadrature decoder mode.

## 51.4.1.15.3 Diagram



## 51.4.1.15.4 Fields

| Field | Function |
|---|---|
| 31-4<br>— | Reserved |
| 3<br>QUADMODE | Quadrature Decoder Mode<br>Selects the encoding mode used in the quadrature decoder mode.<br>0b - Phase encoding mode.<br>1b - Count and direction encoding mode. |
| 2<br>QUADIR | Counter Direction in Quadrature Decode Mode<br>Indicates the counting direction.<br>0b - Counter direction is decreasing (counter decrement).<br>1b - Counter direction is increasing (counter increment). |
| 1<br>TOFDIR | TOFDIR<br>Indicates if the TOF bit was set on the top or the bottom of counting.<br>0b - TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (zero) to its maximum value (MOD register).<br>1b - TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (zero). |
| 0<br>QUADEN | QUADEN<br>Enables the quadrature decoder mode. In this mode, the channel 0 and channel 1 inputs control the TPM counter direction and can only be used for software compare. The quadrature decoder mode has precedence over the other modes.<br>0b - Quadrature decoder mode is disabled.<br>1b - Quadrature decoder mode is enabled. |

## 51.4.1.16 Configuration (CONF)

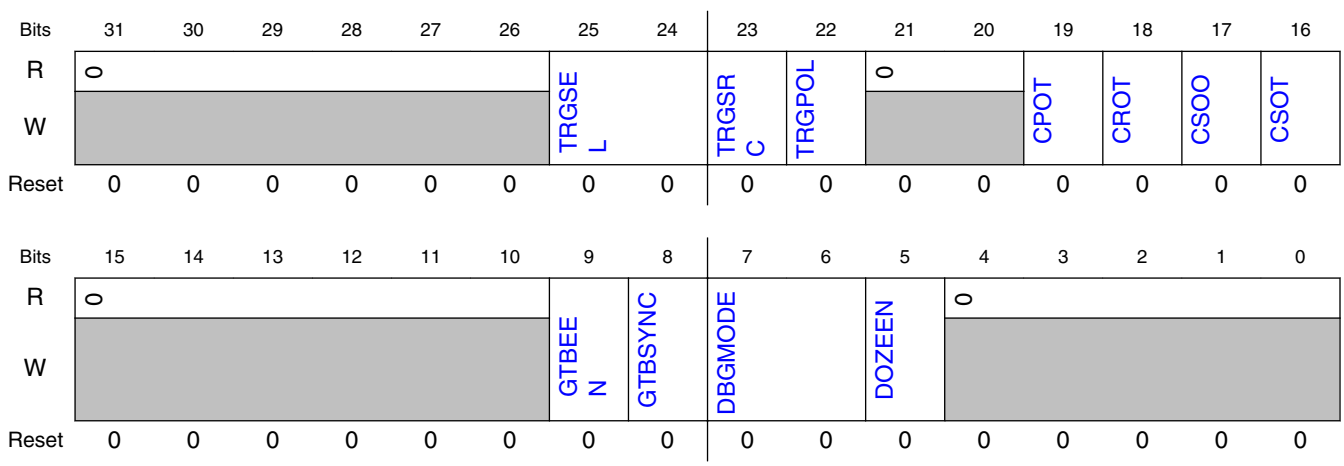
### 51.4.1.16.1 Offset

| Register | Offset |
|---|---|
| CONF | 84h |

### 51.4.1.16.2 Function

This register selects the behavior in debug and wait modes and the use of an external global time base.

### 51.4.1.16.3 Diagram



### 51.4.1.16.4 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-24<br>TRGSEL | Trigger Select<br>Selects the input trigger to use for starting, reloading and/or pausing the counter. The source of the trigger (external or internal to the TPM) is configured by the TRGSRC field. This field should only be changed when the TPM counter is disabled.<br>Refer to chip configuration section for available external trigger options.<br>The available internal trigger sources are listed below.<br>01b - Channel 0 pin input capture<br>10b - Channel 1 pin input capture |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 11b - Channel 0 or Channel 1 pin input capture |
| 23<br>TRGSRC | Trigger Source<br>Selects between internal (channel pin input capture) or external trigger sources.<br>When selecting an internal trigger, the channel selected should be configured for input capture. Only a rising edge input capture can be used to initially start the counter using the CSOT configuration; either rising edge or falling edge input capture can be used to reload the counter using the CROT configuration; and the state of the channel input pin is used to pause the counter using the CPOT configuration. The channel polarity register can be used to invert the polarity of the channel input pins.<br>This field should only be changed when the TPM counter is disabled.<br>0b - Trigger source selected by TRGSEL is external.<br>1b - Trigger source selected by TRGSEL is internal (channel pin input capture). |
| 22<br>TRGPOL | Trigger Polarity<br>Selects the polarity of the external trigger source. This field should only be changed when the TPM counter is disabled.<br>0b - Trigger is active high.<br>1b - Trigger is active low. |
| 21-20<br>— | Reserved |
| 19<br>CPOT | Counter Pause On Trigger<br>When enabled, the counter will pause incrementing while the trigger remains asserted (level sensitive). While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state.<br>The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled. |
| 18<br>CROT | Counter Reload On Trigger<br>When set, the TPM counter will reload with zero (and set PWM outputs to their reload state) when a rising edge is detected on the selected trigger input.<br>The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled.<br>0b - Counter is not reloaded due to a rising edge on the selected input trigger<br>1b - Counter is reloaded when a rising edge is detected on the selected input trigger |
| 17<br>CSOO | Counter Stop On Overflow<br>When set, the TPM counter will pause incrementing once the counter equals the MOD value and increments (this also sets the TOF). Reloading the counter with 0 due to writing to the counter register or due to a trigger input does not cause the counter to stop incrementing. Once the counter has stopped incrementing, the counter will not start incrementing unless it is disabled and then enabled again, or a rising edge on the selected trigger input is detected when CSOT is set. While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state.<br>This field should only be changed when the TPM counter is disabled.<br>0b - TPM counter continues incrementing or decrementing after overflow<br>1b - TPM counter stops incrementing or decrementing after overflow. |
| 16<br>CSOT | Counter Start on Trigger<br>When set, the TPM counter will pause incrementing when it is enabled until a rising edge on the selected trigger input is detected. If the TPM counter is paused due to an overflow, a rising edge on the selected trigger input will also cause the TPM counter to start incrementing again. While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state. |

*Table continues on the next page...*

| Field | Function |
|---|---|

## 51.4.2.6 Counter (CNT)

### 51.4.2.6.1 Offset

| Register | Offset |
|---|---|
| CNT | 14h |

### 51.4.2.6.2 Function

The CNT register contains the TPM counter value.

Reset clears the CNT register. Writing any value to COUNT will trigger a reload of the counter, this will force PWM outputs to their reload state..

When debug is active, the TPM counter does not increment unless configured otherwise.

Reading the CNT register adds two wait states to the register access due to synchronization delays.

### 51.4.2.6.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 51.4.2.6.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>COUNT | Counter value |

## 51.4.2.7 Modulo (MOD)

### 51.4.2.7.1 Offset

| Register | Offset |
|---|---|
| MOD | 18h |

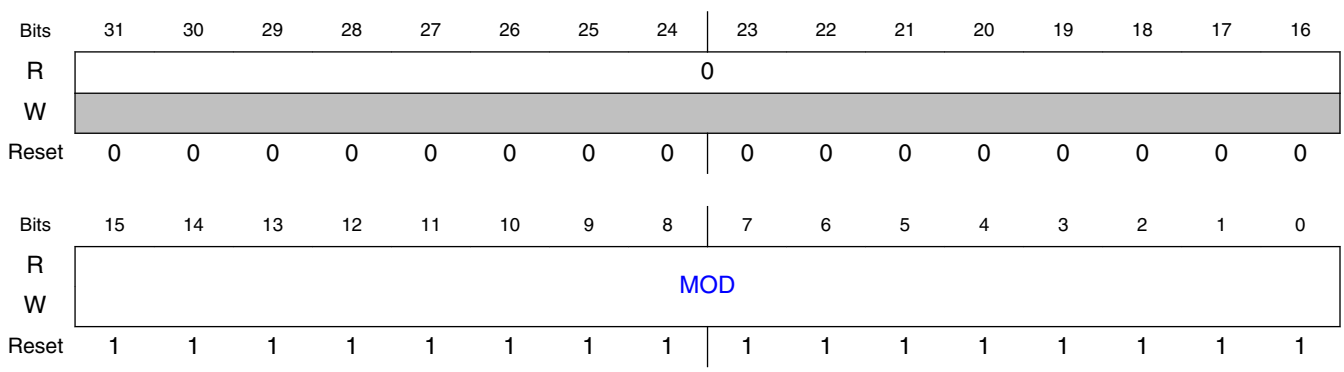
### 51.4.2.7.2 Function

The Modulo register contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, the overflow flag (TOF) is set and the next value of TPM counter depends on the selected counting method (see Counter ).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to MOD Register Update . Additional writes to the MOD write buffer are ignored until the register has been updated.

It is recommended to initialize the TPM counter (write to CNT) before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

### 51.4.2.7.3 Diagram



### 51.4.2.7.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0 | Modulo value |

| Field | Function |
|---|---|
| MOD | This field must be written with single 16-bit or 32-bit access. |

## 51.4.2.8 Capture and Compare Status (STATUS)

### 51.4.2.8.1 Offset

| Register | Offset |
|---|---|
| STATUS | 1Ch |

### 51.4.2.8.2 Function

The STATUS register contains a copy of the status flag, CnSC[CHnF] for each TPM channel, as well as SC[TOF], for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by writing all ones to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. Writing a 1 to CHF clears it. Writing a 0 to CHF has no effect.

If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

### 51.4.2.8.3 Diagram

## 51.4.2.10 Channel (n) Value (C0V - C1V)

### 51.4.2.10.1 Offset

For a = 0 to 1:

| Register | Offset |
|---|---|
| CaV | 24h + (a × 8h) |

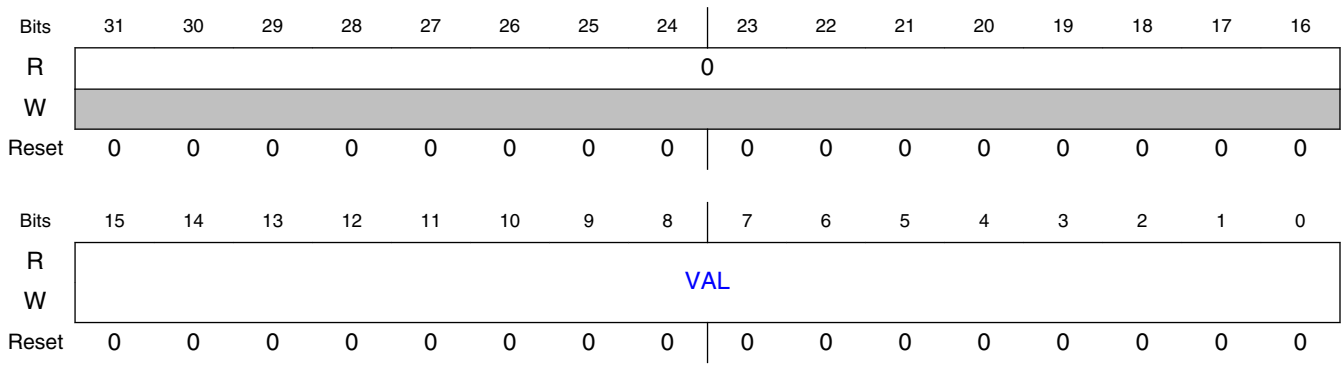
### 51.4.2.10.2 Function

These registers contain the captured TPM counter value for the input modes or the match value for the output modes.

In input capture mode, any write to a CnV register is ignored.

In compare modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to CnV Register Update . Additional writes to the CnV write buffer are ignored until the register has been updated.

### 51.4.2.10.3 Diagram



### 51.4.2.10.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>VAL | Channel Value<br>Captured TPM counter value of the input modes or the match value for the output modes. This field must be written with single 16-bit or 32-bit access. |

## 51.4.2.11 Combine Channel Register (COMBINE)

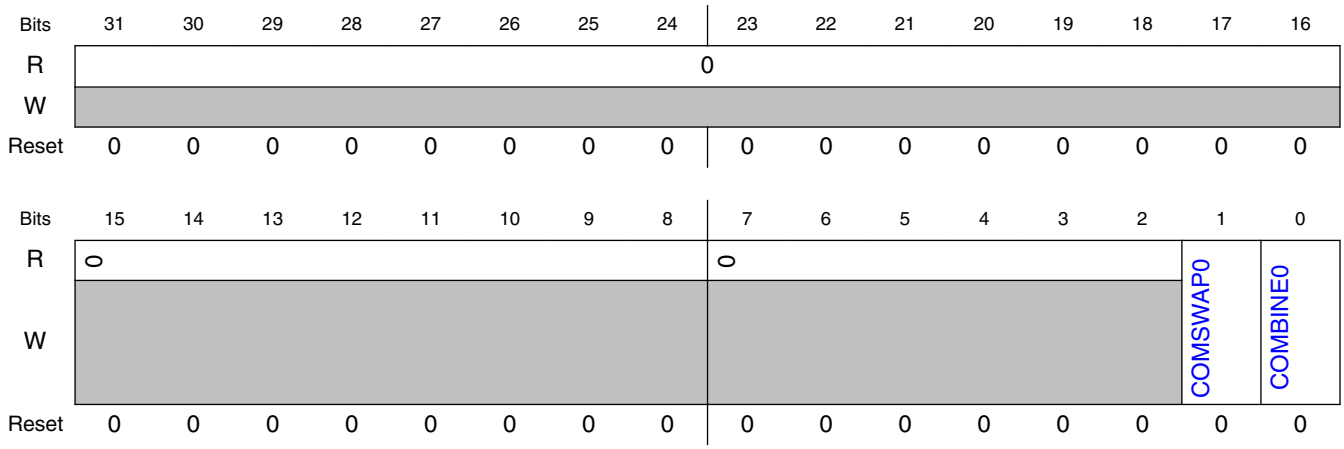
### 51.4.2.11.1 Offset

| Register | Offset |
|---|---|
| COMBINE | 64h |

### 51.4.2.11.2 Function

This register contains the control bits used to configure the combine channel modes for each pair of channels (n) and (n+1), where n is all the even numbered channels.

### 51.4.2.11.3 Diagram



### 51.4.2.11.4 Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7-2<br>— | Reserved |
| 1<br>COMSWAP0 | Combine Channel 0 and 1 Swap<br>When set in combine mode, the even channel is used for the input capture and 1st compare, the odd channel is used for the 2nd compare.<br>0b - Even channel is used for input capture and 1st compare.<br>1b - Odd channel is used for input capture and 1st compare. |
| 0<br>COMBINE0 | Combine Channels 0 and 1<br>Enables the combine feature for channels 0 and 1. In input capture mode, the combined channels use the even channel input. In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare.<br>0b - Channels 0 and 1 are independent.<br>1b - Channels 0 and 1 are combined. |

## 51.4.2.12 Channel Trigger (TRIG)

### 51.4.2.12.1 Offset

| Register | Offset |
|---|---|
| TRIG | 6Ch |

### 51.4.2.12.2 Function

In input capture mode, configures the trigger input that is used by the channel to capture the counter value. In output compare or PWM mode, configures the trigger input used to modulate the channel output. When modulating the output, the output is forced to the channel initial value whenever the trigger is not asserted. Note that the even numbered channels share the first input trigger source and the odd numbered channels share the second input trigger source.

## 51.4.3.6 Counter (CNT)

### 51.4.3.6.1 Offset

| Register | Offset |
|---|---|
| CNT | 14h |

### 51.4.3.6.2 Function

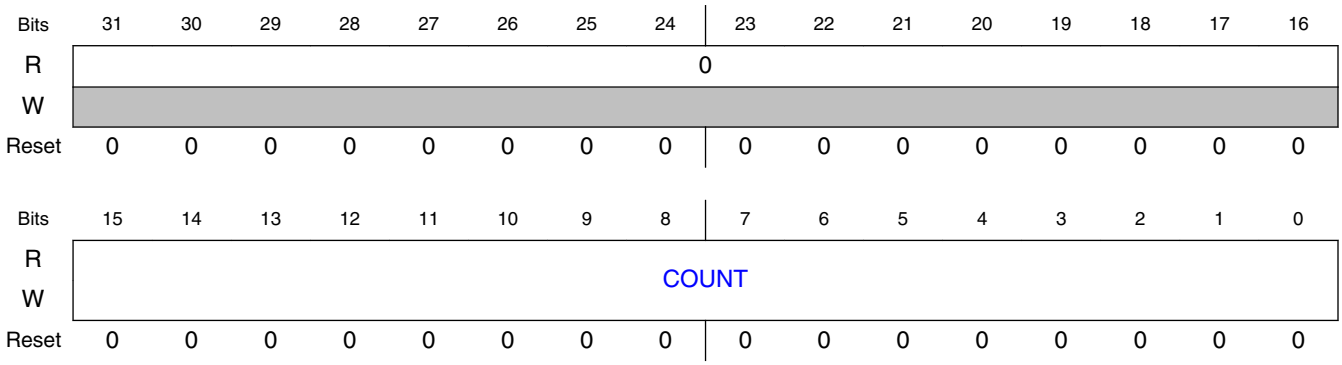
The CNT register contains the TPM counter value.

Reset clears the CNT register. Writing any value to COUNT will trigger a reload of the counter, this will force PWM outputs to their reload state..

When debug is active, the TPM counter does not increment unless configured otherwise.

Reading the CNT register adds two wait states to the register access due to synchronization delays.

#### 51.4.3.6.3 Diagram



#### 51.4.3.6.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>COUNT | Counter value |

### 51.4.3.7 Modulo (MOD)

#### 51.4.3.7.1 Offset

| Register | Offset |
|---|---|
| MOD | 18h |

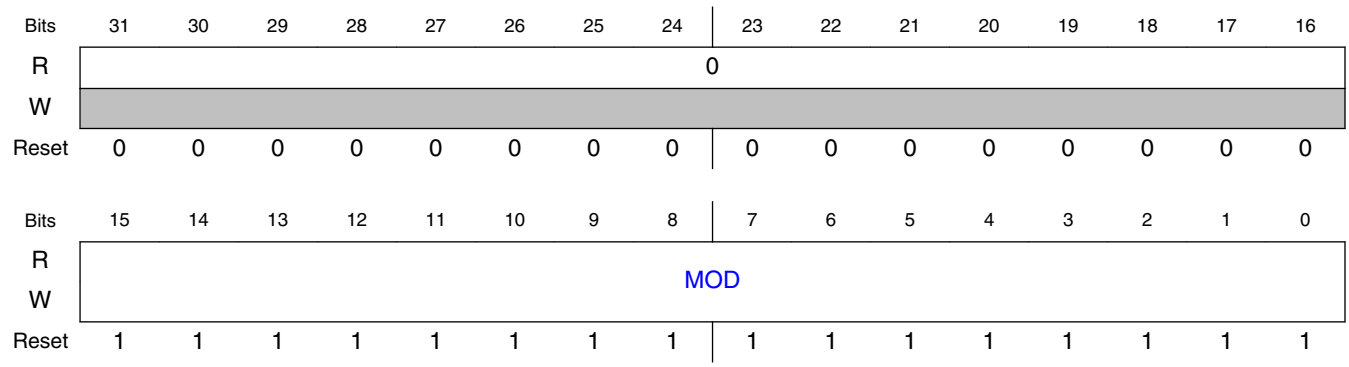
#### 51.4.3.7.2 Function

The Modulo register contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, the overflow flag (TOF) is set and the next value of TPM counter depends on the selected counting method (see Counter ).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to MOD Register Update . Additional writes to the MOD write buffer are ignored until the register has been updated.

It is recommended to initialize the TPM counter (write to CNT) before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

#### 51.4.3.7.3 Diagram



#### 51.4.3.7.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>MOD | Modulo value<br>This field must be written with single 16-bit or 32-bit access. |

### 51.4.3.8 Capture and Compare Status (STATUS)

#### 51.4.3.8.1 Offset

| Register | Offset |
|---|---|
| STATUS | 1Ch |

#### 51.4.3.8.2 Function

The STATUS register contains a copy of the status flag, CnSC[CHnF] for each TPM channel, as well as SC[TOF], for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by writing all ones to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. Writing a 1 to CHF clears it. Writing a 0 to CHF has no effect.

If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

## 51.4.3.10 Channel (n) Value (C0V - C5V)

### 51.4.3.10.1 Offset

For a = 0 to 5:

| Register | Offset |
|---|---|
| CaV | 24h + (a × 8h) |

### 51.4.3.10.2 Function

These registers contain the captured TPM counter value for the input modes or the match value for the output modes.

In input capture mode, any write to a CnV register is ignored.

In compare modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to CnV Register Update . Additional writes to the CnV write buffer are ignored until the register has been updated.

In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare.<br>0b - Channels 2 and 3 are independent.<br>1b - Channels 2 and 3 are combined. |
| 7-2<br>— | Reserved |
| 1<br>COMSWAP0 | Combine Channel 0 and 1 Swap<br>When set in combine mode, the even channel is used for the input capture and 1st compare, the odd channel is used for the 2nd compare.<br>0b - Even channel is used for input capture and 1st compare.<br>1b - Odd channel is used for input capture and 1st compare. |
| 0<br>COMBINE0 | Combine Channels 0 and 1<br>Enables the combine feature for channels 0 and 1. In input capture mode, the combined channels use the even channel input. In software compare modes, the even channel match asserts the output trigger and the odd channel match negates the output trigger. In PWM modes, the even channel match is used for the 1st compare and odd channel match for the 2nd compare.<br>0b - Channels 0 and 1 are independent.<br>1b - Channels 0 and 1 are combined. |

## 51.4.3.12 Channel Trigger (TRIG)

### 51.4.3.12.1 Offset

| Register | Offset |
|---|---|
| TRIG | 6Ch |

### 51.4.3.12.2 Function

In input capture mode, configures the trigger input that is used by the channel to capture the counter value. In output compare or PWM mode, configures the trigger input used to modulate the channel output. When modulating the output, the output is forced to the channel initial value whenever the trigger is not asserted. Note that the even numbered channels share the first input trigger source and the odd numbered channels share the second input trigger source.

### 51.4.3.12.3 Diagram

Deadtime insertion is disabled when CH0FVAL is zero, otherwise deadtime insertion for channel 0 is configured as (CH0FVAL * 4) clock cycles. |

## 51.4.3.15 Quadrature Decoder Control and Status (QDCTRL)

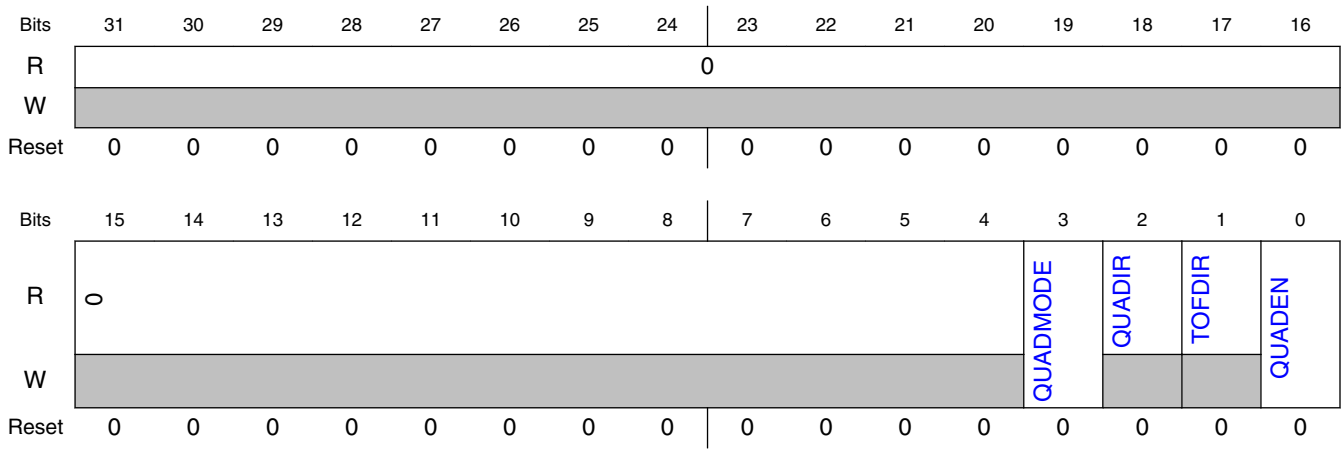
### 51.4.3.15.1 Offset

| Register | Offset |
|---|---|
| QDCTRL | 80h |

### 51.4.3.15.2 Function

This register has the control and status bits for the quadrature decoder mode.

## 51.4.3.15.3 Diagram



## 51.4.3.15.4 Fields

| Field | Function |
|---|---|
| 31-4<br>— | Reserved |
| 3<br>QUADMODE | Quadrature Decoder Mode<br>Selects the encoding mode used in the quadrature decoder mode.<br>0b - Phase encoding mode.<br>1b - Count and direction encoding mode. |
| 2<br>QUADIR | Counter Direction in Quadrature Decode Mode<br>Indicates the counting direction.<br>0b - Counter direction is decreasing (counter decrement).<br>1b - Counter direction is increasing (counter increment). |
| 1<br>TOFDIR | TOFDIR<br>Indicates if the TOF bit was set on the top or the bottom of counting.<br>0b - TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (zero) to its maximum value (MOD register).<br>1b - TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (zero). |
| 0<br>QUADEN | QUADEN<br>Enables the quadrature decoder mode. In this mode, the channel 0 and channel 1 inputs control the TPM counter direction and can only be used for software compare. The quadrature decoder mode has precedence over the other modes.<br>0b - Quadrature decoder mode is disabled.<br>1b - Quadrature decoder mode is enabled. |

## 51.4.3.16 Configuration (CONF)

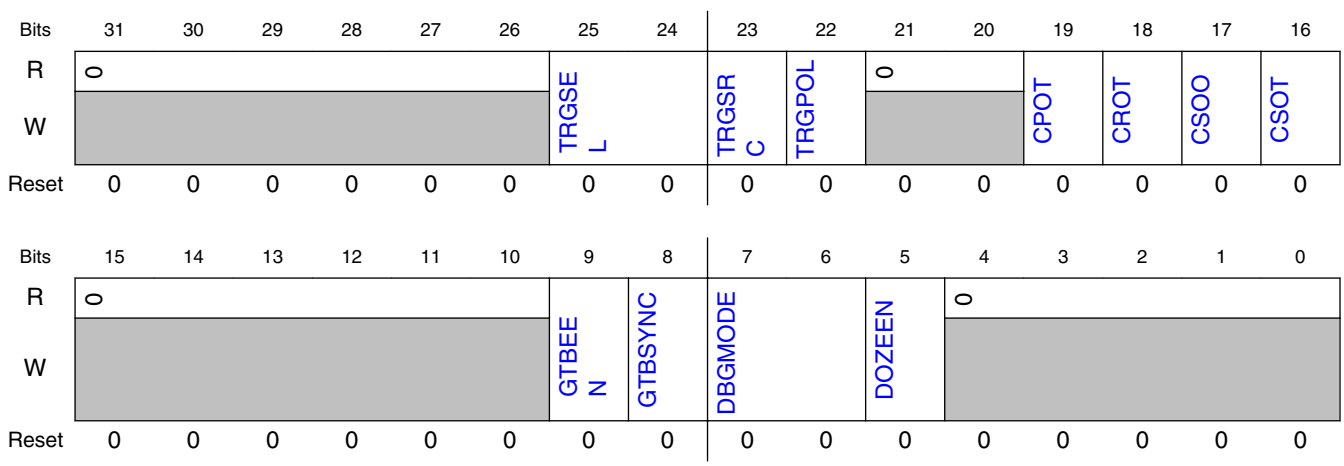
### 51.4.3.16.1 Offset

| Register | Offset |
|---|---|
| CONF | 84h |

### 51.4.3.16.2 Function

This register selects the behavior in debug and wait modes and the use of an external global time base.

### 51.4.3.16.3 Diagram



### 51.4.3.16.4 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-24<br>TRGSEL | Trigger Select<br>Selects the input trigger to use for starting, reloading and/or pausing the counter. The source of the trigger (external or internal to the TPM) is configured by the TRGSRC field. This field should only be changed when the TPM counter is disabled.<br>Refer to chip configuration section for available external trigger options.<br>The available internal trigger sources are listed below.<br>01b - Channel 0 pin input capture<br>10b - Channel 1 pin input capture |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 11b - Channel 0 or Channel 1 pin input capture |
| 23<br>TRGSRC | Trigger Source<br>Selects between internal (channel pin input capture) or external trigger sources.<br>When selecting an internal trigger, the channel selected should be configured for input capture. Only a rising edge input capture can be used to initially start the counter using the CSOT configuration; either rising edge or falling edge input capture can be used to reload the counter using the CROT configuration; and the state of the channel input pin is used to pause the counter using the CPOT configuration. The channel polarity register can be used to invert the polarity of the channel input pins.<br>This field should only be changed when the TPM counter is disabled.<br>0b - Trigger source selected by TRGSEL is external.<br>1b - Trigger source selected by TRGSEL is internal (channel pin input capture). |
| 22<br>TRGPOL | Trigger Polarity<br>Selects the polarity of the external trigger source. This field should only be changed when the TPM counter is disabled.<br>0b - Trigger is active high.<br>1b - Trigger is active low. |
| 21-20<br>— | Reserved |
| 19<br>CPOT | Counter Pause On Trigger<br>When enabled, the counter will pause incrementing while the trigger remains asserted (level sensitive). While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state.<br>The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled. |
| 18<br>CROT | Counter Reload On Trigger<br>When set, the TPM counter will reload with zero (and set PWM outputs to their reload state) when a rising edge is detected on the selected trigger input.<br>The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled.<br>0b - Counter is not reloaded due to a rising edge on the selected input trigger<br>1b - Counter is reloaded when a rising edge is detected on the selected input trigger |
| 17<br>CSOO | Counter Stop On Overflow<br>When set, the TPM counter will pause incrementing once the counter equals the MOD value and increments (this also sets the TOF). Reloading the counter with 0 due to writing to the counter register or due to a trigger input does not cause the counter to stop incrementing. Once the counter has stopped incrementing, the counter will not start incrementing unless it is disabled and then enabled again, or a rising edge on the selected trigger input is detected when CSOT is set. While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state.<br>This field should only be changed when the TPM counter is disabled.<br>0b - TPM counter continues incrementing or decrementing after overflow<br>1b - TPM counter stops incrementing or decrementing after overflow. |
| 16<br>CSOT | Counter Start on Trigger<br>When set, the TPM counter will pause incrementing when it is enabled until a rising edge on the selected trigger input is detected. If the TPM counter is paused due to an overflow, a rising edge on the selected trigger input will also cause the TPM counter to start incrementing again. While the counter is paused input capture events are ignored, and PWM outputs are forced to their default state. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | The trigger input is ignored if the TPM counter is paused during debug mode or doze mode. This field should only be changed when the TPM counter is disabled.<br>0b - TPM counter starts to increment immediately, once it is enabled.<br>1b - TPM counter only starts to increment when it a rising edge on the selected input trigger is detected, after it has been enabled or after it has stopped due to overflow. |
| 15-10<br>— | Reserved |
| 9<br>GTBEEN | Global time base enable<br>Configures the TPM to use an externally generated global time base counter. When an externally generated timebase is used, the internal TPM counter is not used by the channels but can be used to generate a periodic interruptor DMA request using the Modulo register and timer overflow flag.<br>0b - All channels use the internally generated TPM counter as their timebase<br>1b - All channels use an externally generated global timebase as their timebase |
| 8<br>GTBSYNC | Global Time Base Synchronization<br>When enabled, the TPM counter is synchronized to the global time base. It uses the global timebase enable, trigger, paused state and overflow to ensure the TPM counter starts incrementing at the same time as the global timebase, stops incrementing at the same time as the global timebase and is reset at the same time as the global timebase. This field should only be changed when the TPM counter is disabled.<br>0b - Global timebase synchronization disabled.<br>1b - Global timebase synchronization enabled. |
| 7-6<br>DBGMODE | Debug Mode<br>Configures the TPM behavior in debug mode. All other configurations are reserved.<br>00b - TPM counter is paused and does not increment during debug mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their default state.<br>11b - TPM counter continues in debug mode. |
| 5<br>DOZEEN | Doze Enable<br>Configures the TPM behavior in wait mode.<br>0b - Internal TPM counter continues in Doze mode.<br>1b - Internal TPM counter is paused and does not increment during Doze mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their default state. |

## 51.4.4.6 Counter (CNT)

### 51.4.4.6.1 Offset

| Register | Offset |
|---|---|
| CNT | 14h |

### 51.4.4.6.2 Function

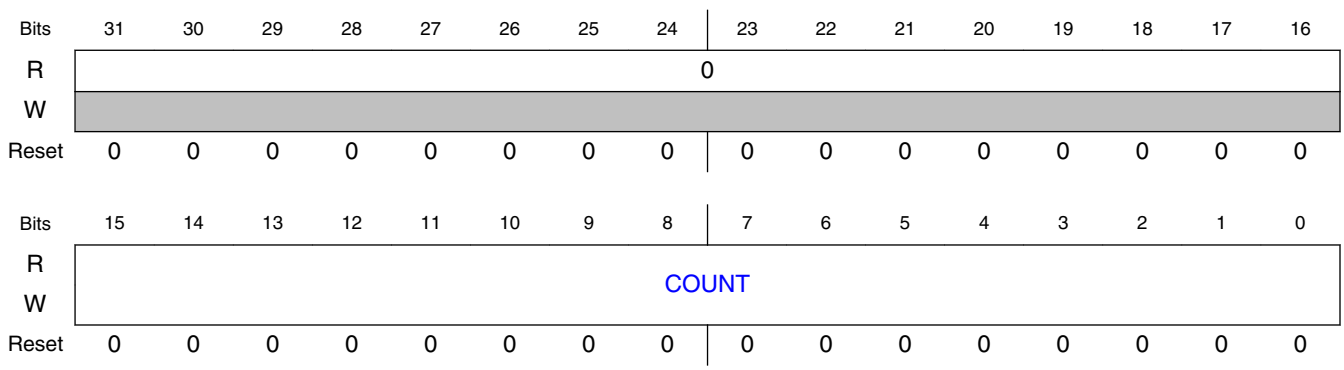
The CNT register contains the TPM counter value.

Reset clears the CNT register. Writing any value to COUNT will trigger a reload of the counter, this will force PWM outputs to their reload state..

When debug is active, the TPM counter does not increment unless configured otherwise.

Reading the CNT register adds two wait states to the register access due to synchronization delays.

### 51.4.4.6.3 Diagram



### 51.4.4.6.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>COUNT | Counter value |

## 51.4.4.7 Modulo (MOD)

### 51.4.4.7.1 Offset

| Register | Offset |
|---|---|
| MOD | 18h |

### 51.4.4.7.2 Function

The Modulo register contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, the overflow flag (TOF) is set and the next value of TPM counter depends on the selected counting method (see Counter ).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to MOD Register Update . Additional writes to the MOD write buffer are ignored until the register has been updated.

It is recommended to initialize the TPM counter (write to CNT) before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

### 51.4.4.7.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Field | Function |
|---|---|
| MOD | This field must be written with single 16-bit or 32-bit access. |

## 51.4.4.8 Capture and Compare Status (STATUS)

### 51.4.4.8.1 Offset

| Register | Offset |
|---|---|
| STATUS | 1Ch |

### 51.4.4.8.2 Function

The STATUS register contains a copy of the status flag, CnSC[CHnF] for each TPM channel, as well as SC[TOF], for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by writing all ones to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. Writing a 1 to CHF clears it. Writing a 0 to CHF has no effect.

If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set indicating another event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.

## 51.4.4.10 Channel (n) Value (C0V - C1V)

### 51.4.4.10.1 Offset

For a = 0 to 1:

| Register | Offset |
|---|---|
| CaV | 24h + (a × 8h) |

### 51.4.4.10.2 Function

These registers contain the captured TPM counter value for the input modes or the match value for the output modes.

In input capture mode, any write to a CnV register is ignored.

In compare modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to CnV Register Update . Additional writes to the CnV write buffer are ignored until the register has been updated.

## 51.5 Functional description

The following sections describe the TPM features.

### 51.5.1 Clock domains

The TPM module supports two clock domains.

The bus clock domain is used by the register interface and for synchronizing interrupts and DMA requests.

The TPM counter clock domain is used to clock the counter and prescaler along with the output compare and input capture logic. The TPM counter clock is considered asynchronous to the bus clock, can be a higher or lower frequency than the bus clock and can remain operational in Stop mode. Multiple TPM instances are all clocked by the same TPM counter clock in support of the external timebase feature.

#### 51.5.1.1 Counter Clock Mode

The CMOD[1:0] bits in the SC register either disable the TPM counter or select one of three possible clock sources for the TPM counter. After any reset, CMOD[1:0] = 0:0 so the TPM counter is disabled. The CMOD[1:0] can configure one of the following counter clock sources.

- Asynchronous counter clock
- External clock input pin
- External trigger source

The CMOD[1:0] bits may be read or written at any time. Disabling the TPM counter by writing zero to the CMOD[1:0] bits does not affect the TPM counter value or other registers, but must be acknowledged by the TPM counter clock domain before they read as zero.

The external clock input and external trigger source pass through a synchronizer clocked by the TPM counter clock to ensure that counter transitions are properly aligned to counter clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must be less than half of the counter clock frequency.

## 51.5.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter.

The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and TPM counter.

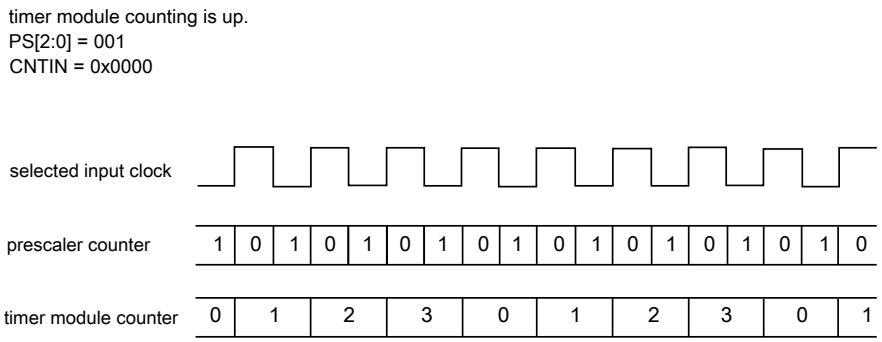

**Figure 51-2. Example of the Prescaler Counter**

## 51.5.3 Counter

The TPM has a 16-bit counter that is used by the channels either for input or output modes.

The counter updates from the selected clock divided by the prescaler.

The TPM counter has these modes of operation:

- up counting (see Up counting)
- up-down counting (see Up-down counting)

### 51.5.3.1 Up counting

Up counting is selected when SC[CPWMS] = 0.

The value of zero is loaded into the TPM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with zero.

The TPM period when using up counting is (MOD + 0x0001) × period of the TPM counter clock.

The TOF bit is set when the TPM counter changes from MOD to zero.

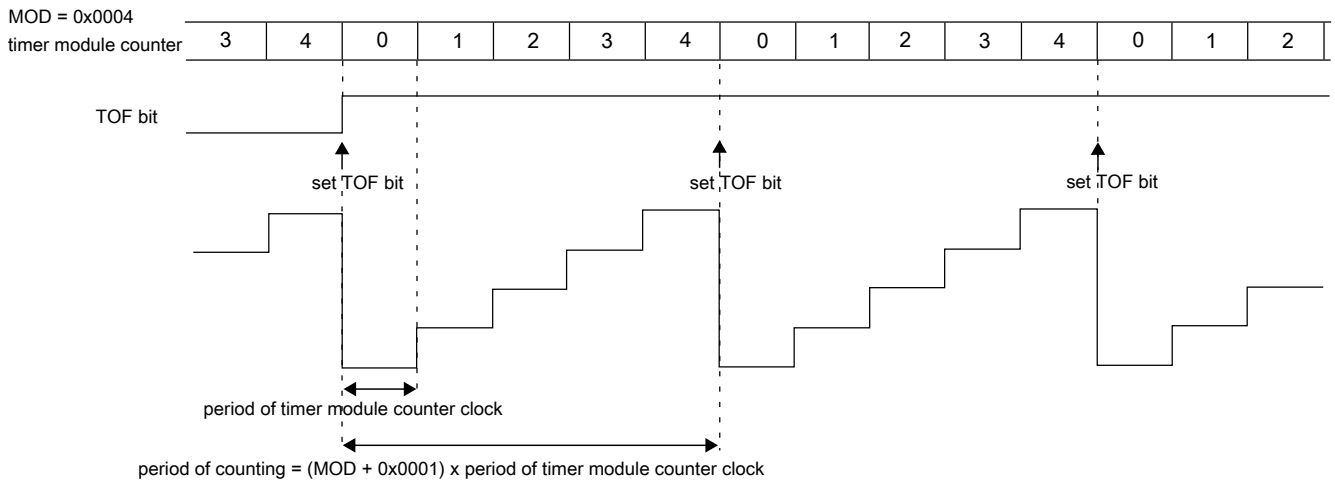

**Figure 51-3. Example of TPM Up Counting**

**Note**

- MOD = 0000 is a redundant condition. In this case, the TPM counter is always equal to MOD and the TOF bit is set in each rising edge of the TPM counter clock.

### 51.5.3.2 Up-down counting

Up-down counting is selected when SC[CPWMS] = 1. When configured for up-down counting, configuring CONF[MOD] to less than 2 is not supported.

The value of 0 is loaded into the TPM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to zero and the up-down counting restarts.

The TPM period when using up-down counting is 2 × MOD × period of the TPM counter clock.

The TOF bit is set when the TPM counter changes from MOD to (MOD – 1).

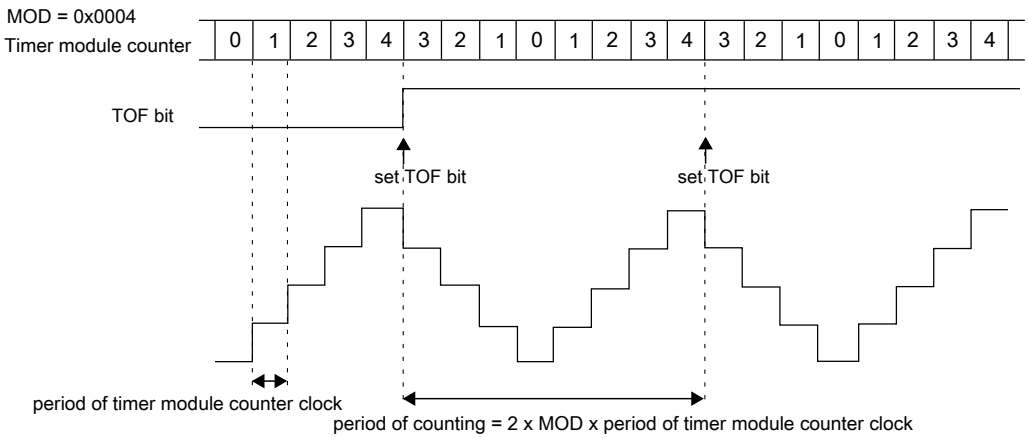

**Figure 51-4. Example of up-down counting**

### 51.5.3.3 Counter Reset

Any write to CNT resets the TPM counter and the channel outputs to their initial values (except for channels in output compare mode).

### 51.5.3.4 Global time base (GTB)

The global time base (GTB) is a TPM function that allows multiple TPM modules to share the same timebase. When the global time base is enabled (CONF[GTBEEN] = 1), the local TPM channels use the counter value, counter enable and overflow indication from the TPM generating the global time base. If the local TPM counter is not generating the global time base, then it can be used as an independent counter or pulse accumulator.

The local TPM counter can also be configured to synchronize to the global time base, by configuring (GTBSYNC = 1). When synchronized to the global time base, the local counter will use the counter enable and counter overflow indication from the TPM generating the global time base. This enables multiple TPM to be configured with the same phase, but with different periods (although the global time base must be configured with the longest period).

### 51.5.3.5 Counter trigger

The TPM counter can be configured to start, stop or reset in response to a hardware trigger input. The trigger input is synchronized to the asynchronous counter clock, so there is a 3 counter clock delay between the trigger assertion and the counter responding.

- When (CSOT = 1), the counter will not start incrementing until a rising edge is detected on the trigger input.
- When (CSOO= 1), the counter will stop incrementing whenever the TOF flag is set. The counter does not increment again unless it is disabled, or if CSOT = 1 and a rising edge is detected on the trigger input.
- When (CROT= 1), the counter will reset to zero as if an overflow occurred whenever a rising edge is detected on the trigger input. Any PWM channels will update to their reload state.
- When (CPOT = 1), the counter will pause incrementing whenever the trigger input is asserted. The counter will continue incrementing when the trigger input negates. PWM output channels are forced to their default state.

The polarity of the external input trigger can be configured by the TRGPOL register bit.

When an internal trigger source is selected, the trigger input is selected from one or more channel input capture events. The input capture filters are used with the internal trigger sources and the POLn bits can be used to invert the polarity of the input channels. Note that following restrictions apply with input capture channel sources.

- When (CSOT = 1), the counter will only start incrementing on a rising edge on the channel input, provided ELSnA = 1.
- When (CROT= 1), the counter will reset to zero on either edge of the channel input, as configured by ELSnB:ELSnA.
- When (CPOT = 1), the counter will pause incrementing whenever the channel input is asserted. PWM output channels are forced to their default state.

### 51.5.4 Input Capture Mode

The input capture mode is selected when (CPWMS = 0), (MSnB:MSnA = 0:0), and (ELSnB:ELSnA ≠ 0:0).

When a selected edge occurs on the channel input, the current value of the TPM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1 (see the following figure).

When a channel is configured for input capture, the TPM_CHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is counter clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register are ignored in input capture mode.

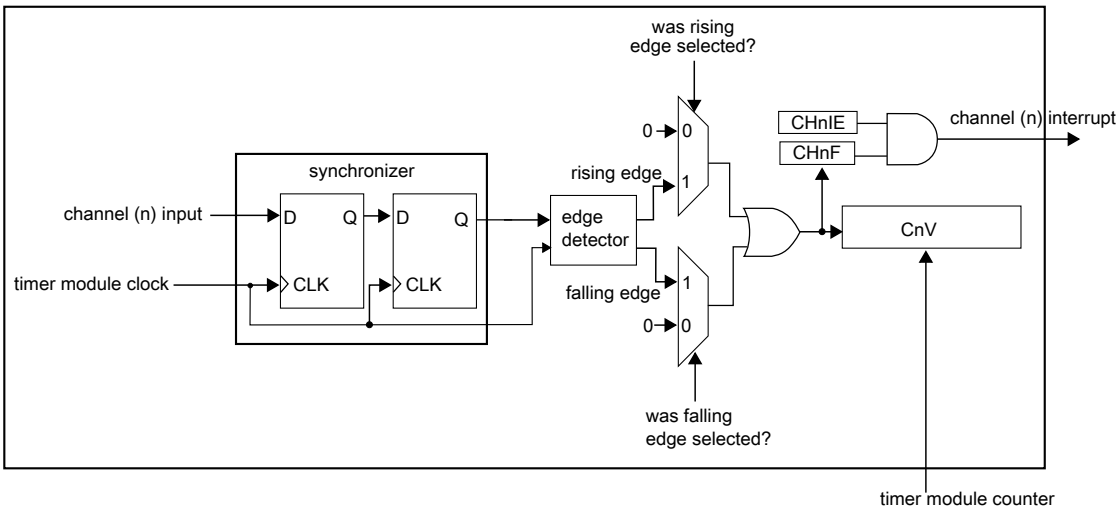

**Figure 51-5. Input capture mode**

The CHnF bit is set on the third rising edge of the counter clock after a valid edge occurs on the channel input.

## 51.5.5 Output Compare Mode

The output compare mode is selected when (CPWMS = 0), and (MSnB:MSnA = X:1).

In output compare mode, the TPM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared or toggled if MSnB is clear. If MSnB is set then the channel (n) output is pulsed high or low for as long as the counter matches the value in the CnV register.

When a channel is initially configured to output compare mode, the channel output updates with its negated value (logic 0 for set/toggle/pulse high and logic one for clear/ pulse low).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV).

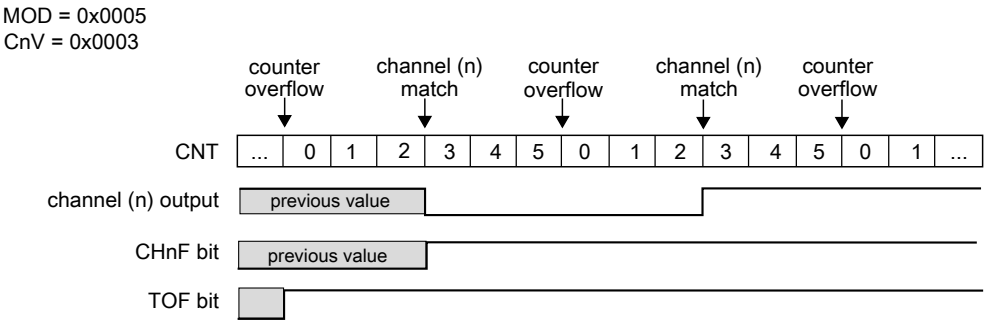

**Figure 51-6. Example of the output compare mode when the match toggles the channel output**

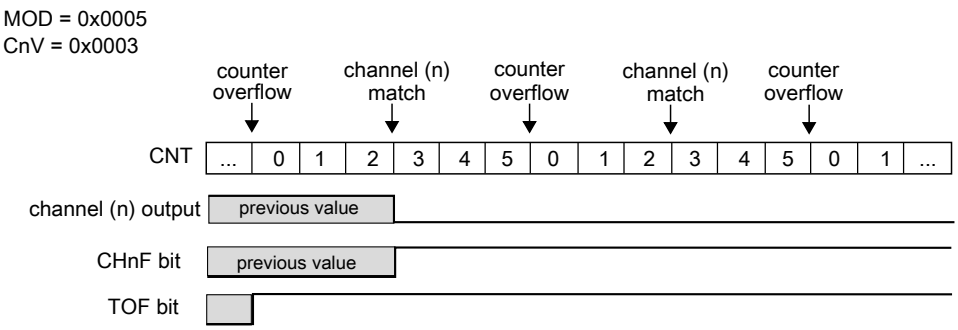

**Figure 51-7. Example of the output compare mode when the match clears the channel output**

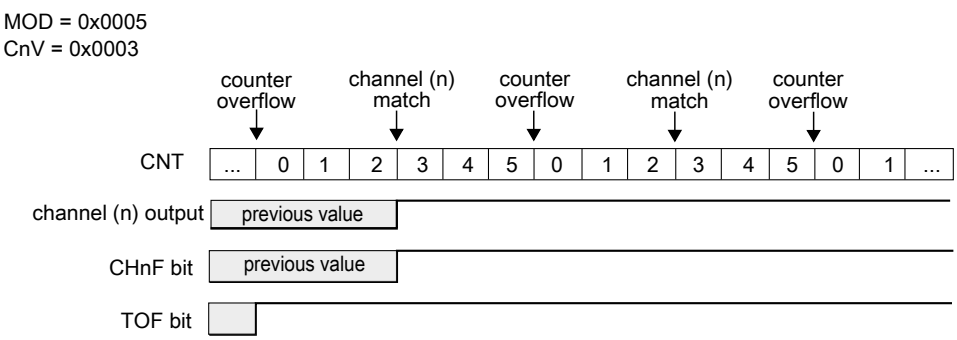

**Figure 51-8. Example of the output compare mode when the match sets the channel output**

It is possible to use the output compare mode with (ELSnB:ELSnA = 0:0). In this case, when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not modified and controlled by TPM.

## 51.5.6 Edge-Aligned PWM (EPWM) Mode

The edge-aligned mode is selected when (CPWMS = 0), and (MSnB:MSnA = 1:0).

The EPWM period is determined by (MOD + 0x0001) and the pulse width (duty cycle) is determined by CnV.

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an TPM.

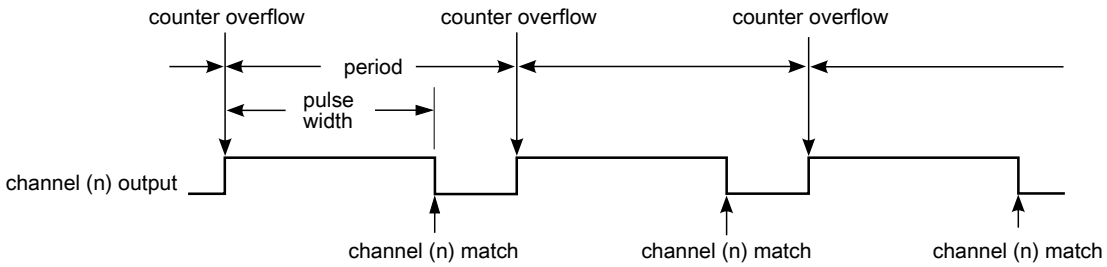

**Figure 51-9. EPWM period and pulse width with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow or reload (when the zero is loaded into the TPM counter), and it is forced low at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced high.

If (ELSnB:ELSnA = 0:0), then the channel (n) output is forced high at the counter overflow or reload (when the zero is loaded into the TPM counter), and it is forced low at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced low.

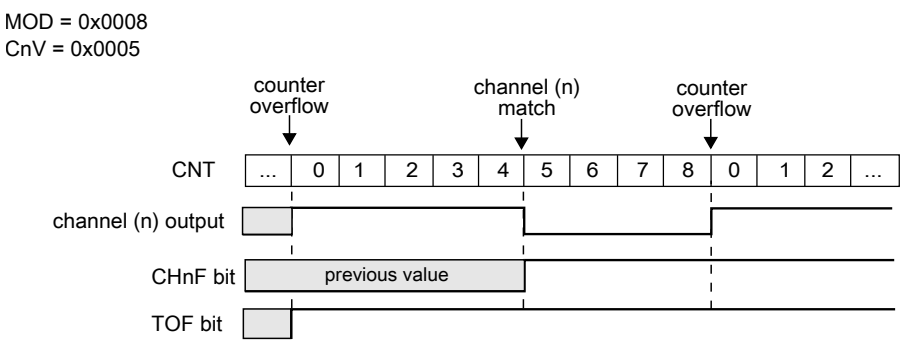

**Figure 51-10. EPWM signal with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the counter overflow or reload (when zero is loaded into the TPM counter), and it is forced high at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced low.

If (ELSnB:ELSnA = 1:1), then the channel (n) output is forced low at the counter overflow or reload (when zero is loaded into the TPM counter), and it is forced high at the channel (n) match (TPM counter = CnV). When first enabled or whenever the TPM counter is paused, the channel (n) output is forced high.

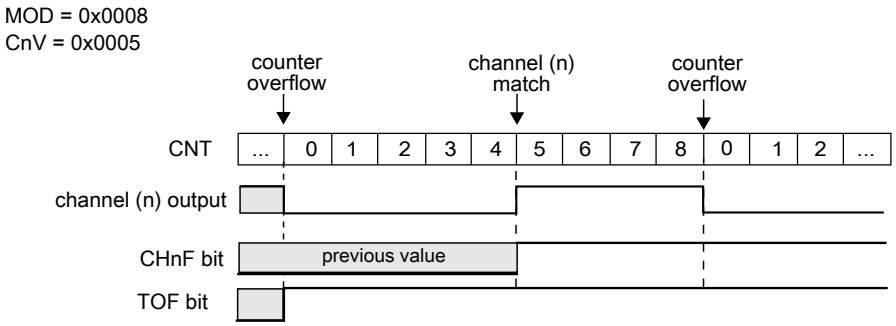

**Figure 51-11. EPWM signal with ELSnB:ELSnA = 0:1**

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal. If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set since there is never a channel (n) match. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

## 51.5.7 Center-Aligned PWM (CPWM) Mode

The center-aligned mode is selected when (CPWMS = 1) and (MSnB:MSnA = 1:0).

The CPWM pulse width (duty cycle) is determined by 2 × CnV and the period is determined by 2 × MOD (see the following figure). MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the TPM counter counts up until it reaches MOD and then counts down until it reaches zero.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = CnV) when the TPM counting is down (at the begin of the pulse width) and when the TPM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are when the TPM counter is zero.

The other channel modes are not designed to be used with the up-down counter (CPWMS = 1). Therefore, all TPM channels should be used in CPWM mode when (CPWMS = 1).

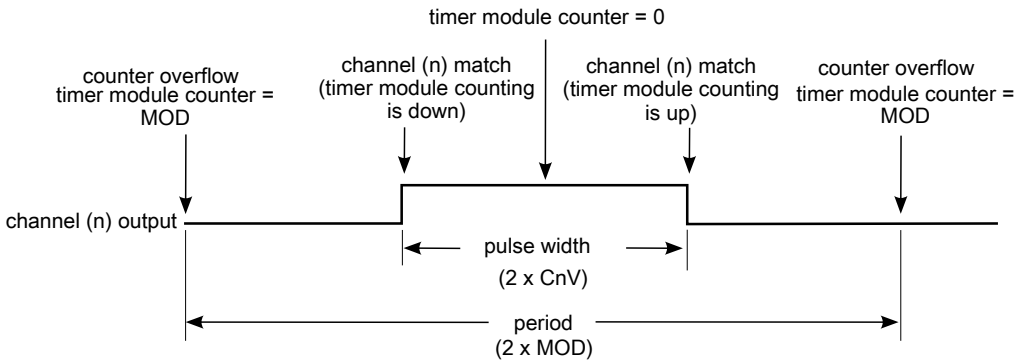

**Figure 51-12. CPWM period and pulse width with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (TPM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced high.

If (ELSnB:ELSnA = 0:0), then the channel (n) output is forced high at the channel (n) match (TPM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced low.

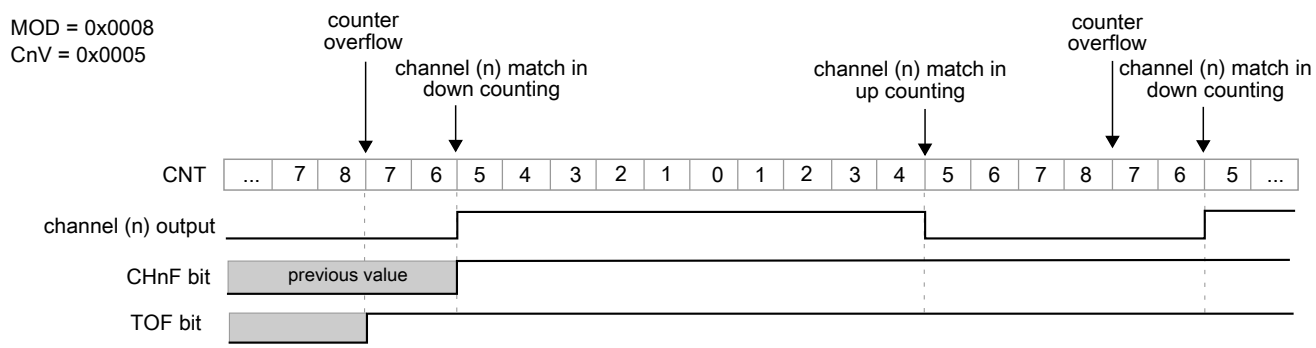

**Figure 51-13. CPWM signal with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the channel (n) match (TPM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced low.

If (ELSnB:ELSnA = 1:1), then the channel (n) output is forced low at the channel (n) match (TPM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. When first enabled, when the TPM counter is reloaded, or whenever the TPM counter is paused, the channel (n) output is forced high.

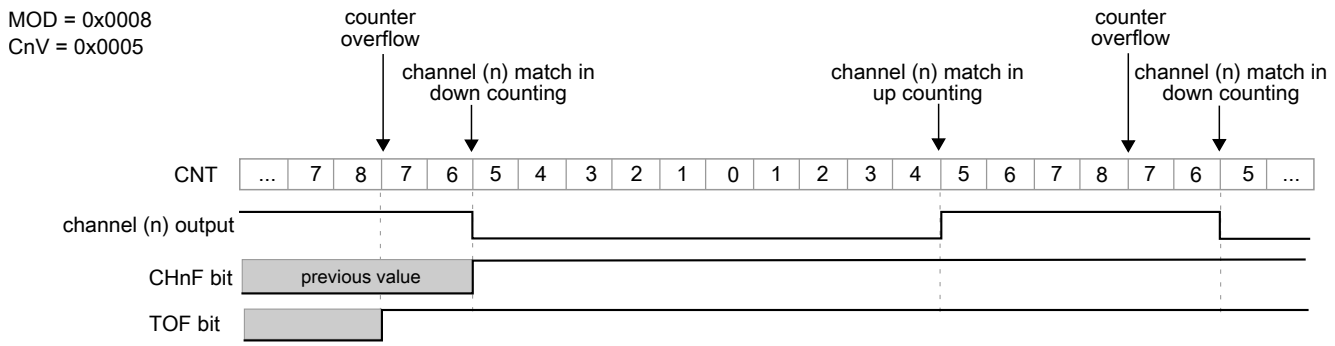

**Figure 51-14. CPWM signal with ELSnB:ELSnA = 0:1**

If (CnV = 0x0000) then the channel (n) output is a 0% duty cycle CPWM signal.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle CPWM signal, although the CHnF bit is set when the counter changes from incrementing to decrementing. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle CPWM signal.

## 51.5.8 Combine PWM mode

The Combine PWM mode is selected when:

- MSnB:MSnA = 10
- COMBINEn = 1
- QUADEN = 0, and
- CPWMS = 0

In Combine PWM mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by (MOD + 0x0001) and the PWM pulse width (duty cycle) is determined by (|C(n+1)V − C(n)V|).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (TPM counter = C(n)V). The CH(n+1)F bit is set and the channel (n +1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (TPM counter = C(n+1)V).

If channel (n) (ELSnB:ELSnA = 0:1), then the channel (n) output is forced low at the beginning of the period (TPM counter is zero) and at the channel (n+1) match (TPM counter = C(n+1)V). It is forced high at the channel (n) match (TPM counter = C(n)V).

If channel (n) (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the beginning of the period (TPM counter is zero) and at the channel (n+1) match (TPM counter = C(n+1)V). It is forced low at the channel (n) match (TPM counter = C(n)V).

When (COMSWAPn = 1), then the channel (n) output is forced low or high at the beginning of the period (TPM counter is zero) and at the channel (n) match (TPM counter = C(n)V). It is forced high or low at the channel (n+1) match (TPM counter = C(n+1)V).

The channel (n+1) output is generated the same as the channel (n) output, but the output polarity is controlled by the channel (n+1) ELSnB:ELSnA configuration.

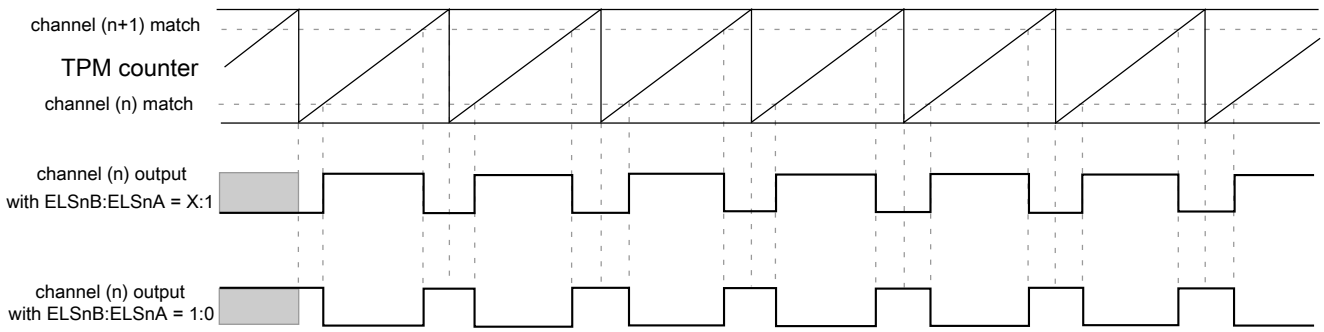

**Figure 51-15. Combine mode**

The following figures illustrate the PWM signals generation using Combine mode.

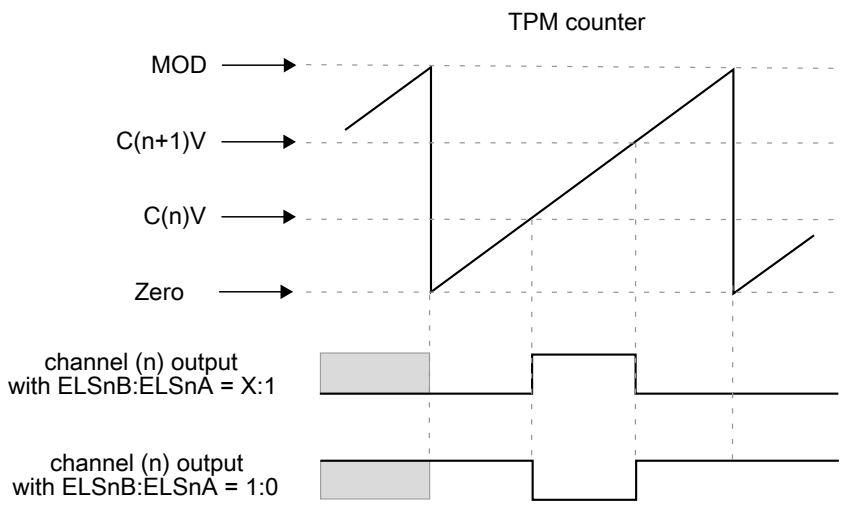

**Figure 51-16. Channel (n) output if (C(n)V < MOD) and (C(n+1)V < MOD) and (C(n)V < C(n+1)V)**

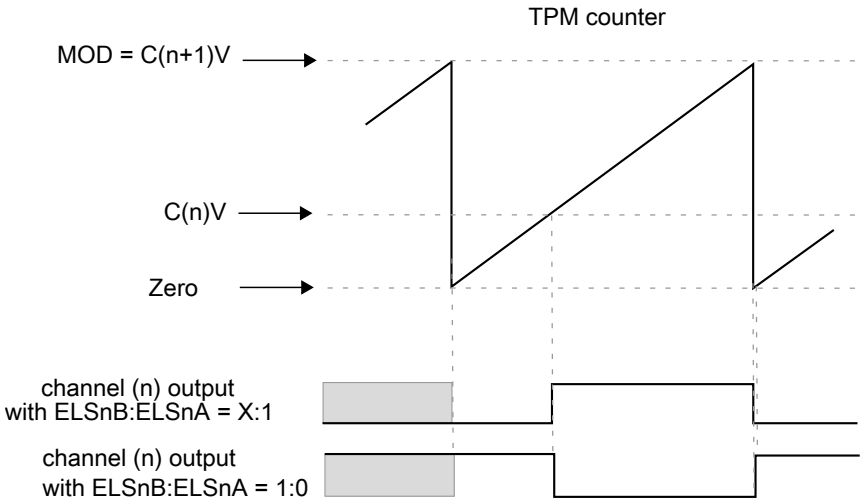

**Figure 51-17. Channel (n) output if (C(n)V < MOD) and (C(n+1)V = MOD)**

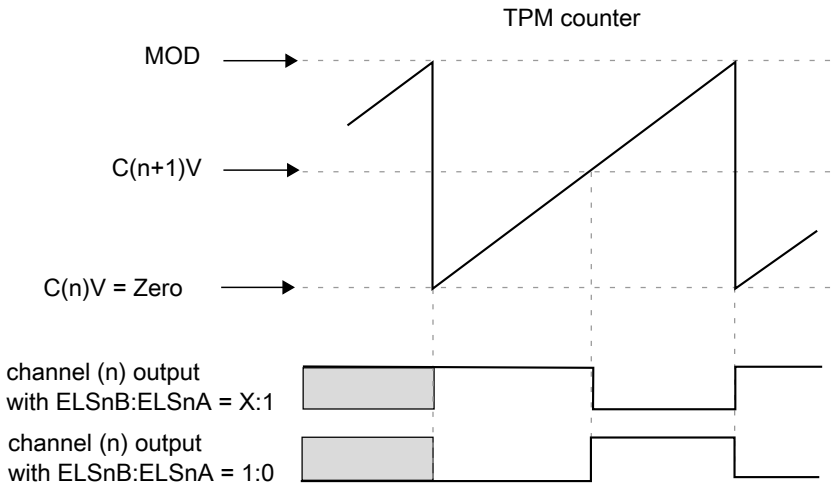

**Figure 51-18. Channel (n) output if (C(n)V = zero) and (C(n+1)V < MOD)**

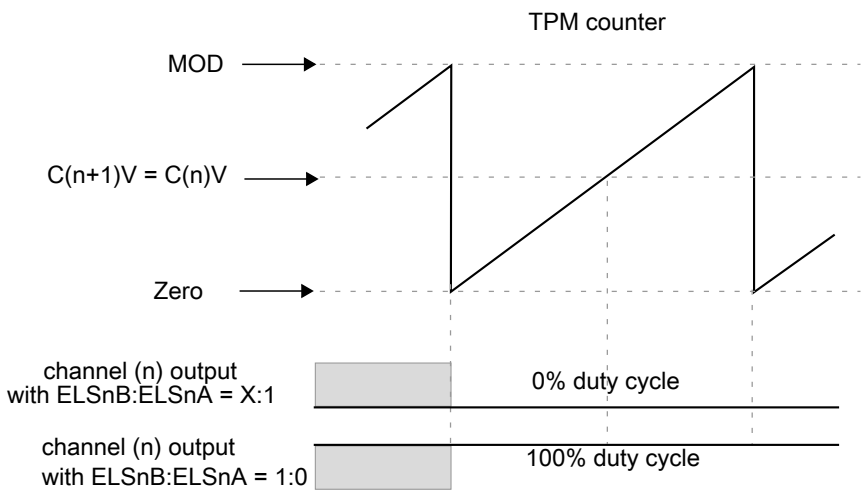

**Figure 51-19. Channel (n) output if (C(n)V < MOD) and (C(n+1)V < MOD) and (C(n)V = C(n +1)V)**

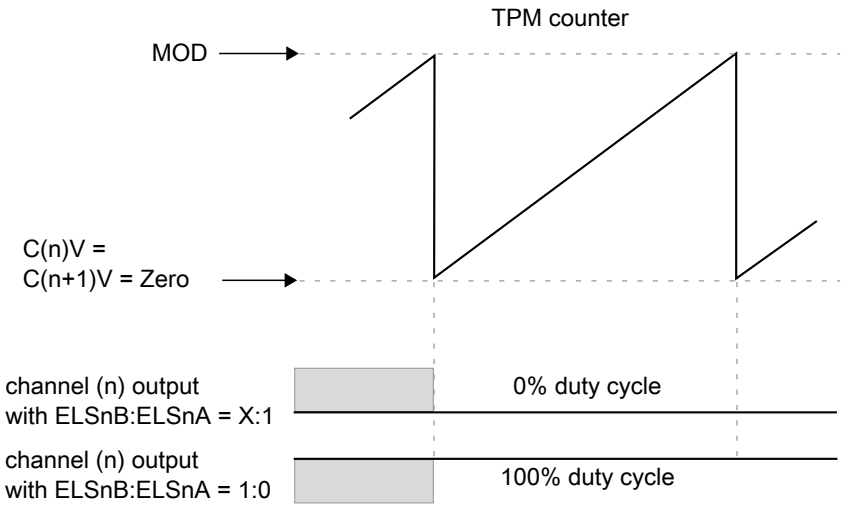

**Figure 51-20. Channel (n) output if (C(n)V = C(n+1)V = zero)**

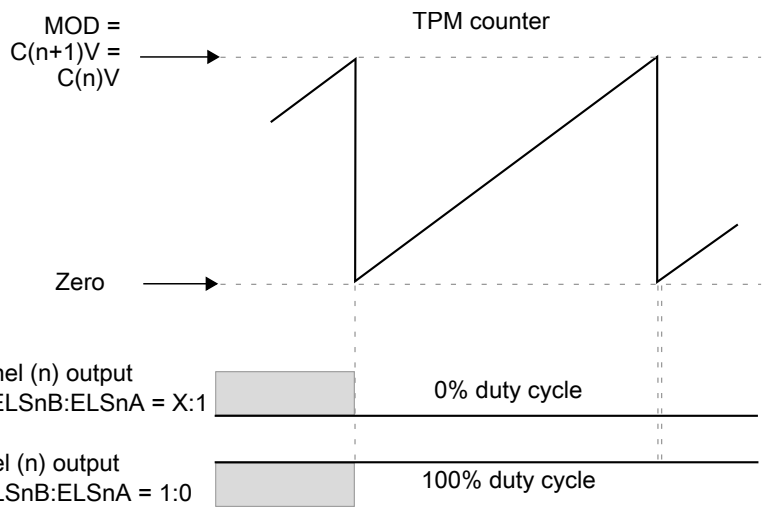

**Figure 51-21. Channel (n) output if (C(n)V = C(n+1)V = MOD)**

## 51.5.9 Combine Input Capture mode

The Combine Input Capture mode is selected if COMBINEn= 1 and MSnB:MSnA = 00 and ELSnB:ELSnA != 00. This mode allows to measure a pulse width of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode.

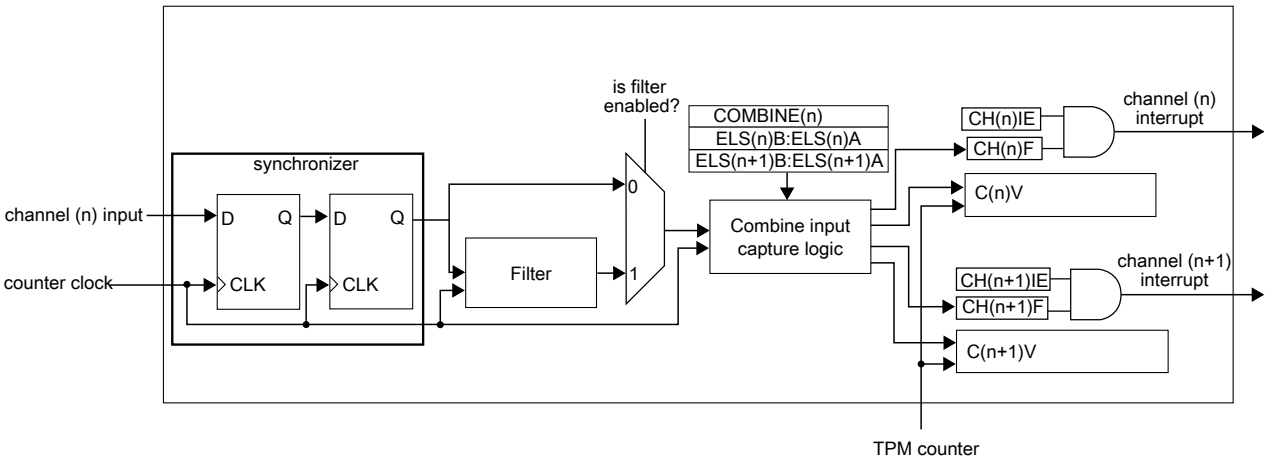

**Figure 51-22. Combine Input Capture mode block diagram**

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n +1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1).

In the Combine Input Capture mode, only channel (n) input is used and channel (n+1) input is ignored, when COMSWAPn=1 then only channel (n+1) input is used and channel (n) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input, then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of TPM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of TPM counter when the selected edge by channel (n+1) is detected at channel (n) input.

### Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.
- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Combine Input Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0.

## 51.5.10 Input Capture Filter

The input capture filter function is only in input capture mode, or in software compare mode when quadrature decoder mode is enabled.

First, the input signal is synchronized by the counter clock. Following synchronization, the input signal enters the filter block. See the following figure.

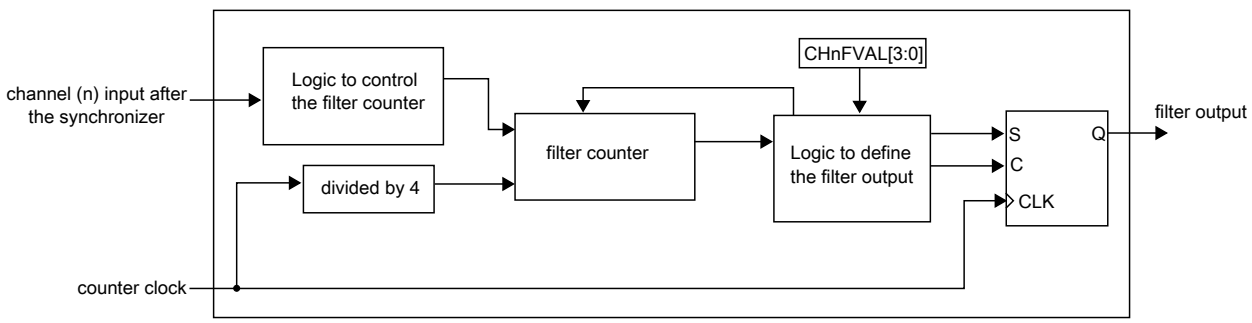

**Figure 51-23. Channel input filter**

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to (CHnFVAL[3:0] × 4), the state change of the input signal is validated.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by (CHnFVAL[3:0] × 4 counter clocks) is regarded as a glitch and is not passed through the filter. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when CHnFVAL[3:0] bits are zero. In this case, the input signal is delayed by 2 rising edges of the counter clock. If (CHnFVAL[3:0] ≠ 0000), then the input signal is delayed by the minimum pulse width (CHnFVAL[3:0] × 4 system clocks) plus a further 3 rising edges of the system clock: two rising edges to the synchronizer, plus one more to the edge detector. In other words, CHnF is set (3 + 4 × CHnFVAL[3:0]) counter clock periods after a valid edge occurs on the channel input.

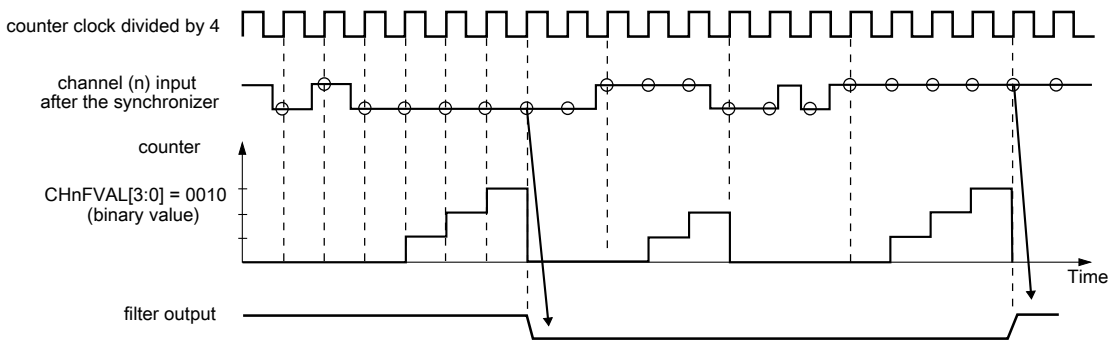

**Figure 51-24. Channel input filter example**

## 51.5.11 Deadtime insertion

The deadtime insertion is enabled in PWM combine modes for each pair of channels when CH(n)FVAL and CH(n+1)FVAL are non-zero. The deadtime delay that is used for each TPM channel is defined as (CH(n+1)FVAL[3:0] x 64) + (CH(n)FVAL[3:0] x 4).

The deadtime delay insertion ensures that no two complementary signals (even channel (n) and odd channel (n+1)) drive the active state at the same time.

If ELSnB:ELSnA = 0:1, ELS(n+1)B:ELS(n+1)A = 1:0, COMSWAPn = 0, and the deadtime is enabled, then when the channel (n) match (TPM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (TPM counter = C(n +1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If ELSnB:ELSnA = 1:0, ELS(n+1)B:ELS(n+1)A = 0:1, COMSWAPn = 1,and the deadtime is enabled, then when the channel (n+1) match (TPM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. Similarly, when the channel (n) match (TPM counter = CnV) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set.

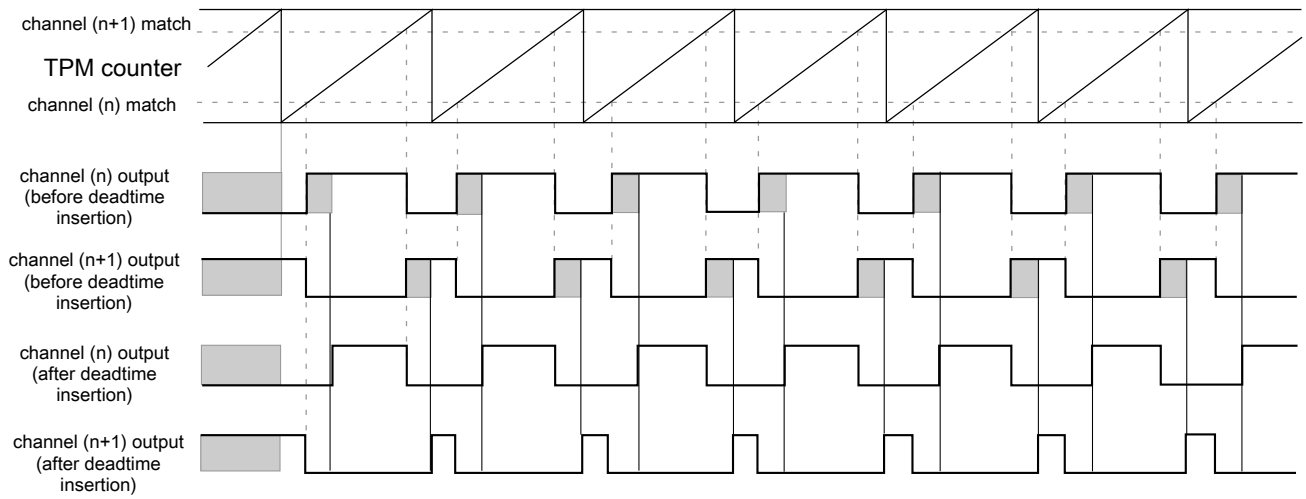

**Figure 51-25. Deadtime insertion with ELSnB:ELSnA = 0:1, ELS(n+1)B:ELS(n+1)A = 1:0, COMSWAPn = 0**

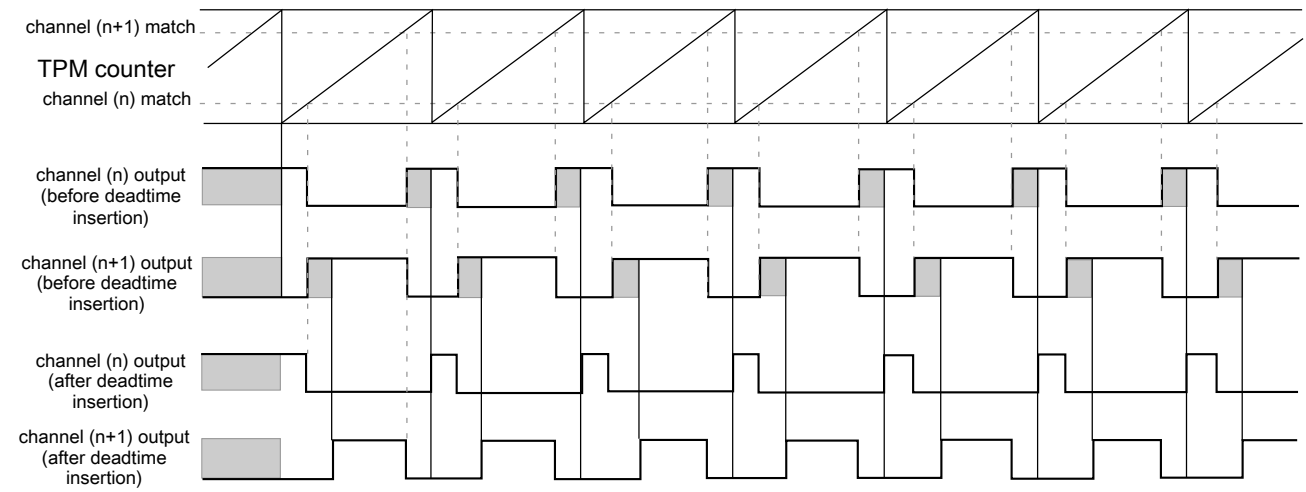

**Figure 51-26. Deadtime insertion with ELSnB:ELSnA = 1:0, ELS(n+1)B:ELS(n+1)A = 0:1, COMSWAPn = 1**

## 51.5.12 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (QUADEN = 1). The Quadrature Decoder mode uses the channel 0 (phase A) and channel 1 (phase B) input signals to control the TPM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

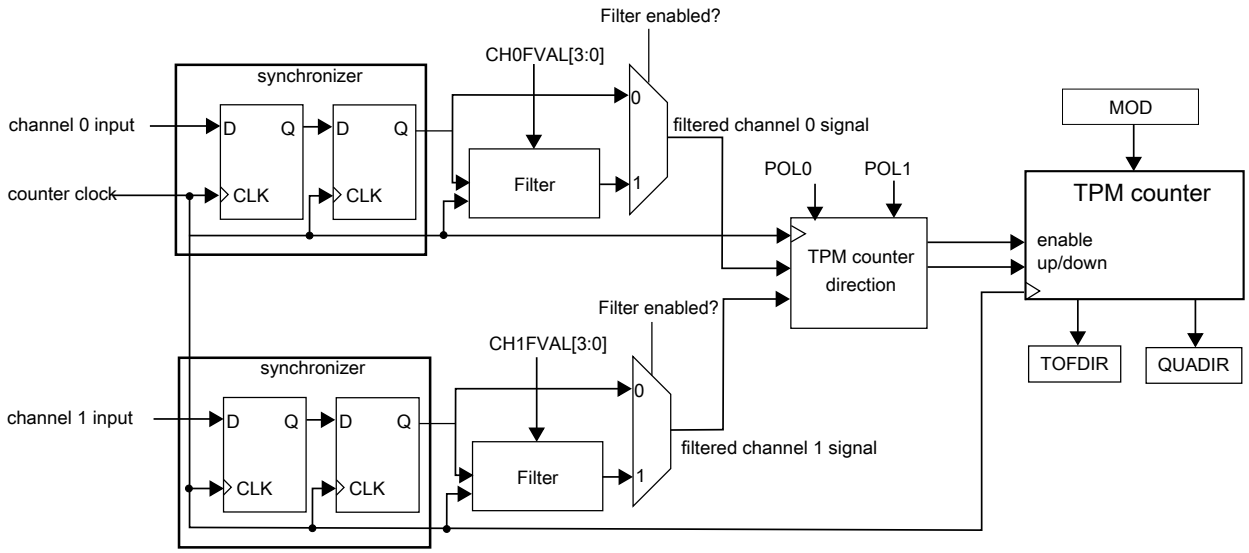

**Figure 51-27. Quadrature Decoder block diagram**

The input capture filter and channel polarity registers are used to configure the input filter and polarity for the channel 0 and channel 1 inputs in quadrature decode mode.

## Note

Notice that the TPM counter is clocked by the channel 0 and channel 1 input signals when quadrature decoder mode is selected. Therefore In quadrature decoder mode, channel 0 and channel 1 can only be used in software compare mode and other TPM channels can only be used in input capture or output compare modes.

The QUADMODE selects the encoding mode used in the Quadrature Decoder mode. If QUADMODE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the channel 1 input value indicates the counting direction, and the channel 0 input defines the counting rate. The TPM counter is updated when there is a rising edge at channel 0 input signal.

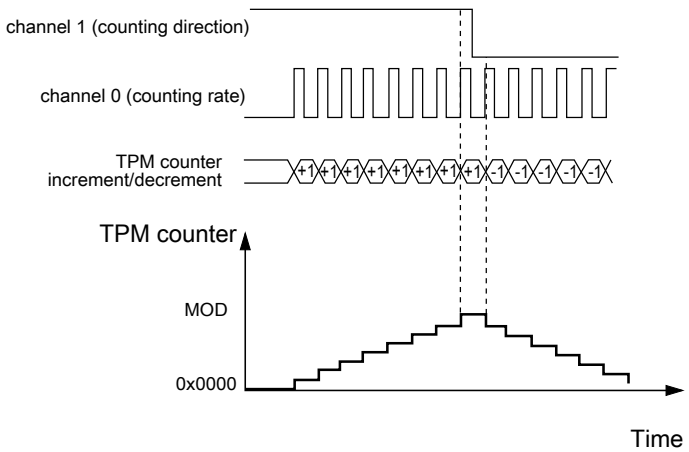

**Figure 51-28. Quadrature Decoder – Count and Direction Encoding mode**

If QUADMODE = 0, then the Phase Encoding mode is enabled; see the following figure. In this mode, the relationship between channel 0 and channel 1 signals indicates the counting direction, and channel 0 and channel 1 signals define the counting rate. The TPM counter is updated when there is an edge either at the channel 0 or channel 1 signals.

If CH0POL= 0 and CH1POL = 0, then the TPM counter increment happens when:

- there is a rising edge at channel 0 signal and channel 1 signal is at logic zero;
- there is a rising edge at channel 1 signal and channel 0 signal is at logic one;
- there is a falling edge at channel 1 signal and channel 0 signal is at logic zero;
- there is a falling edge at channel 0 signal and channel 1 signal is at logic one;

and the TPM counter decrement happens when:

- there is a falling edge at channel 0 signal and channel 1 signal is at logic zero;
- there is a falling edge at channel 1 signal and channel 0 signal is at logic one;
- there is a rising edge at channel 1 signal and channel 0 signal is at logic zero;
- there is a rising edge at channel 0 signal and channel 1 signal is at logic one.

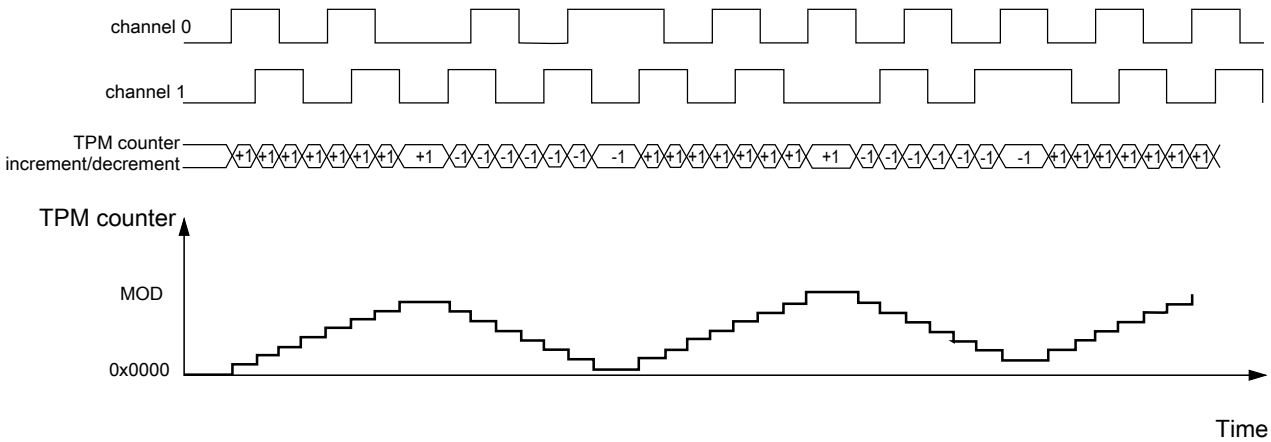

**Figure 51-29. Quadrature Decoder – Phase Encoding mode**

The following figure shows the TPM counter overflow in up counting. In this case, when the TPM counter changes from MOD to zero, TOF and TOFDIR bits are set. TOF bit indicates the TPM counter overflow occurred. TOFDIR indicates the counting was up when the TPM counter overflow occurred.

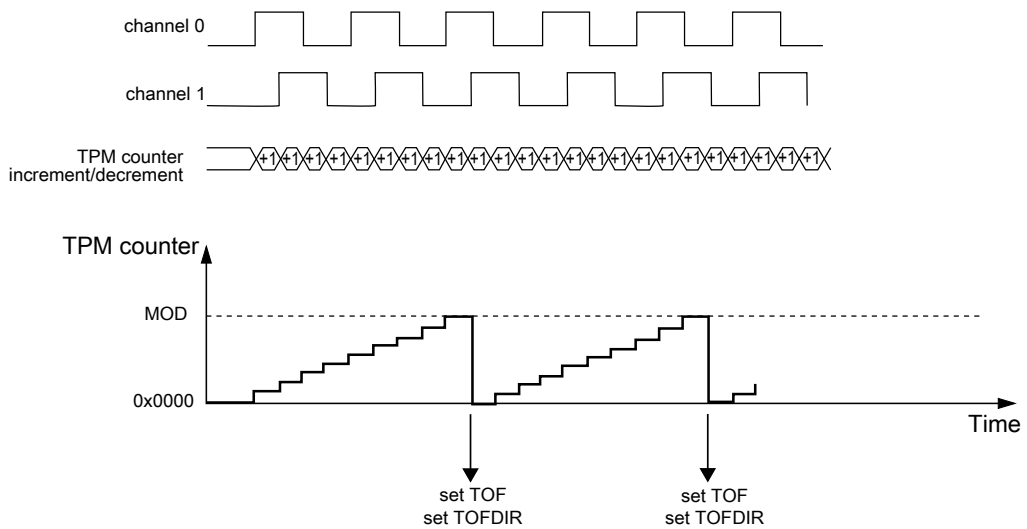

**Figure 51-30. TPM Counter overflow in up counting for Quadrature Decoder mode**

The following figure shows the TPM counter overflow in down counting. In this case, when the TPM counter changes from zero to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the TPM counter overflow occurred. TOFDIR indicates the counting was down when the TPM counter overflow occurred.

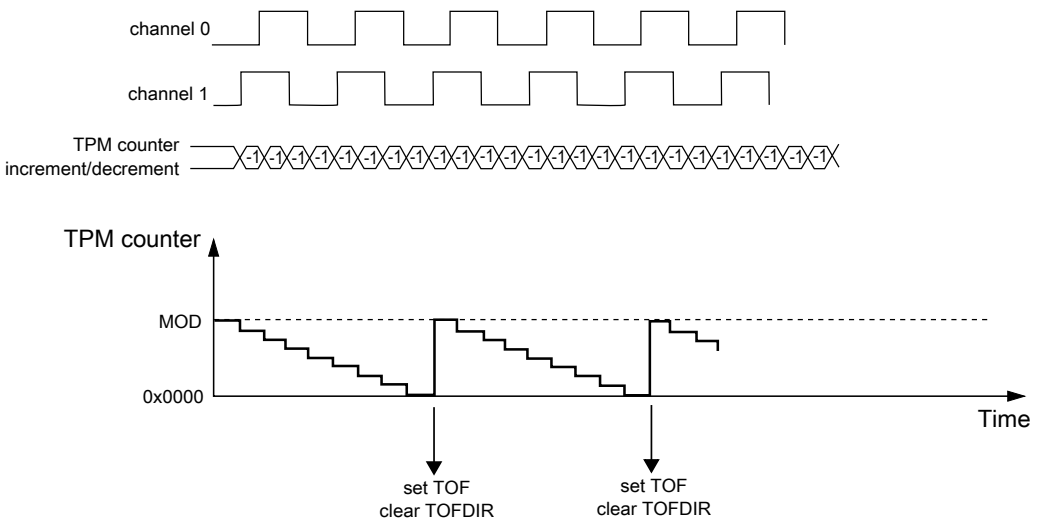

**Figure 51-31. TPM counter overflow in down counting for Quadrature Decoder mode**

## 51.5.13 Registers Updated from Write Buffers

### 51.5.13.1 MOD Register Update

If (CMOD[1:0] = 0:0) then MOD register is updated when MOD register is written.

If (CMOD[1:0] ≠ 0:0), then MOD register is updated according to the CPWMS bit, that is:

- If the selected mode is not CPWM then MOD register is updated after MOD register was written and the TPM counter changes from MOD to zero.
- If the selected mode is CPWM then MOD register is updated after MOD register was written and the TPM counter changes from MOD to (MOD – 1).

### 51.5.13.2 CnV Register Update

If (CMOD[1:0] = 0:0) then CnV register is updated when CnV register is written.

If (CMOD[1:0] ≠ 0:0), then CnV register is updated according to the selected mode, that is:

- If the selected mode is output compare then CnV register is updated on the next TPM counter increment (end of the prescaler counting) after CnV register was written.

- If the selected mode is EPWM then CnV register is updated after CnV register was written and the TPM counter changes from MOD to zero.
- If the selected mode is CPWM then CnV register is updated after CnV register was written and the TPM counter changes from MOD to (MOD – 1).

## 51.5.14 DMA

The channel and overflow flags generate a DMA transfer request according to DMA and CHnIE/TOIE bits.

See the following table for more information.

**Table 51-7. DMA Transfer Request**

| DMA | CHnIE/ TOIE | Channel/Overflow DMA Transfer Request | Channel/Overflow Interrupt |
|---|---|---|---|
| 0 | 0 | The channel/overflow DMA transfer request is not generated. | The channel/overflow interrupt is not generated. |
| 0 | 1 | The channel/overflow DMA transfer request is not generated. | The channel/overflow interrupt is generated if (CHnF/TOF = 1). |
| 1 | 0 | The channel/overflow DMA transfer request is generated if (CHnF/TOF = 1). | The channel/overflow interrupt is not generated. |
| 1 | 1 | The channel/overflow DMA transfer request is generated if (CHnF/TOF = 1). | The channel/overflow interrupt is generated if (CHnF/TOF = 1). |

If DMA = 1, the CHnF/TOF bit can be cleared either by DMA transfer done or writing a one to CHnF/TOF bit (see the following table).

**Table 51-8. Clear CHnF/TOF Bit**

| DMA | How CHnF/TOF Bit Can Be Cleared |
|---|---|
| 0 | CHnF/TOF bit is cleared by writing a 1 to CHnF/TOF bit. |
| 1 | CHnF/TOF bit is cleared either when the DMA transfer is done or by writing a 1 to CHnF/TOF bit. |

## 51.5.15 Output triggers

The TPM generates output triggers for the counter and each channel that can be used to trigger events in other peripherals.

The counter trigger asserts whenever the TOF is set and remains asserted until the next increment.

Each TPM channel generates both a pre-trigger output and a trigger output. The pre-trigger output asserts whenever the CHnF is set, the trigger output asserts on the first counter increment after the pre-trigger asserts, and then both the trigger and pre-trigger negate on the first counter increment after the trigger asserts.

When (COMBINEn = 1) in output compare modes, the pre-trigger output for both channel (n) and channel (n+1) will assert when CH(n)F is set and will negate when CH(n +1)F is set. The trigger continues to assert on the first counter increment after the pre-trigger asserts and negates at the same time as the pre-trigger negation.

## 51.5.16 Reset Overview

The TPM is reset whenever any chip reset occurs.

When the TPM exits from reset:

- the TPM counter and the prescaler counter are zero and are stopped (CMOD[1:0] = 0:0);
- the timer overflow interrupt is zero;
- the channels interrupts are zero;
- the channels are in input capture mode;
- the channels outputs are zero;
- the channels pins are not controlled by TPM (ELS(n)B:ELS(n)A = 0:0).

## 51.5.17 TPM Interrupts

This section describes TPM interrupts.

### 51.5.17.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

### 51.5.17.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

# Chapter 52
# Time Stamp Timer Module (TSTMR)

## 52.1 Chip-specific TSTMR information

This module can be enabled or disabled by FTFE_FOPT[TSTMR_EN].

## 52.2 Introduction

The Time Stamp Timer (TSTMR) is a 56-bit clock cycle counter, reset by system reset.

### 52.2.1 Features

- Free-running Time Stamp Timer

## 52.3 TSTMR Memory map and register definition

The TSTMR Memory Map/Register Definition can be found here.

Each set of TSTMR registers can be accessed from the Processor it is associated with. For example, if there is a TSTMRA set of registers, then those can be accessed from ProcessorA.

**NOTE**

TSTMR registers can be read with 32-bit accesses only.

### 52.3.1 TSTMRA register descriptions

This section contains the detailed register descriptions for the TSTMRA registers.

### 52.3.1.1 TSTMRA Memory map

TSTMRA base address: 4003_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Time Stamp Timer Register Low (LOW) | 32 | RO | 0000_0000h |
| 4h | Time Stamp Timer Register High (HIGH) | 32 | RO | 0000_0000h |

### 52.3.1.2 Time Stamp Timer Register Low (LOW)

#### 52.3.1.2.1 Offset

| Register | Offset |
|---|---|
| LOW | 0h |

#### 52.3.1.2.2 Function

The Time Stamp Timer is a 56-bit clock cycle counter, reset by system reset. It is readable by way of the TSTMR HIGH and LOW registers. Only 32-bit read accesses are allowed. Any other access will generate a transfer error.

Note the following:

- A complete read operation should include both TSTMR LOW and HIGH reads. If a HIGH read does not follow a LOW read, the resulting read value is unknown.
- The TSTMR LOW read should occur first, followed by the TSTMR HIGH read.

#### 52.3.1.2.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | VALUE | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 52.3.2.2.4 Fields

| Field | Function |
|---|---|
| 31-0<br>VALUE | Time Stamp Timer Low<br>Lower 32 bits of the 56-bit time stamp value. The software must read the LOW first, followed by a read to HIGH to retrieve the complete value. The all-zero reset value may not be readable because the value will increment before it can be read by the software. |

## 52.3.2.3 Time Stamp Timer Register High (HIGH)

### 52.3.2.3.1 Offset

| Register | Offset |
|---|---|
| HIGH | 4h |

### 52.3.2.3.2 Function

The Time Stamp Timer is a 56-bit counters clock cycle counter, reset by system reset. It is readable by way of the TSTMR HIGH and LOW registers. Only 32-bit read accesses are allowed. Any other access will generate a transfer error.

Note the following:

- A complete read operation should include both TSTMR LOW and HIGH reads. If a HIGH read does not follow a LOW read, the resulting read value is unknown.
- The TSTMR LOW read should occur first, followed by the TSTMR HIGH read.

### 52.3.2.3.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-0<br>VALUE | Time Stamp Timer High<br>Upper 24 bits of the 56-bit time stamp value. The software must read the LOW first, followed by a read to HIGH to retrieve the complete value. The all-zero reset value may not be readable because the value will increment before it can be read by the software. |

## 52.4 Functional description

The TSTMR module is a free running incrementing counter that starts running after system reset de-assertion and can be read at any time by the software for determining the software ticks. However, the software must follow the read sequence as mentioned in the TSTMR register descriptions for correctly reading the TSTMR value. The TSTMR is a 56-bit counter and hence requires two 32-bit reads to read the full value. The TSTMR runs off the 1 MHz clock and resets on every system reset. The counter only stops when the clock to the TSTMR is disabled.

See the chip-specific TSTMR information for implementation details of this module's instances.

# Chapter 53
# Low-Power Timer (LPTMR)

## 53.1 Chip-specific LPTMR information

### 53.1.1 LPTMRx prescaler/glitch filter clocking options

The prescaler and glitch filter of the LPTMR module can be clocked from one of four sources determined by the LPTMRx_PSR[PCS] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

**NOTE**

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes.

The LPTMR allows the maximum clock frequency of 24 MHz.

| LPTMRx_PSR[PCS] | Prescaler/glitch filter clock number | Chip clock |
|---|---|---|
| 00 | 0 | SIRC DIV3 |
| 01 | 1 | LPO — 1 kHz clock |
| 10 | 2 | RTC — 32 kHz clock |
| 11 | 3 | RFOSC |

See Clock Distribution for more details on these clocks.

### 53.1.2 LPTMRx pulse counter input options

The LPTMRx_CSR[TPS] bitfield configures the input source used in pulse counter mode. The following table shows the chip-specific input assignments for this bitfield for LPTMR0 and LPTMR1.

| LPTMR0/1_CSR[TPS] | Pulse counter input number | Chip input |
|---|---|---|
| 00 | 0 | LPCMP0 output |
| 01 | 1 | LPTMR0/1_ALT1 pin |
| 10 | 2 | LPTMR0/1_ALT2 pin |
| 11 | 3 | LPTMR0/1_ALT3 pin |

The following table shows the chip-specific input assignments for this bitfield for LPTMR2.

| LPTMR2_CSR[TPS] | Pulse counter input number | Chip input |
|---|---|---|
| 00 | 0 | LPCMP1 output |
| 01 | 1 | LPTMR2_ALT1 pin |
| 10 | 2 | LPTMR2_ALT2 pin |
| 11 | 3 | LPTMR2_ALT3 pin |

## 53.2 Introduction

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

### 53.2.1 Features

The features of the LPTMR module include:

- 32-bit time counter or pulse counter with compare
  - Optional interrupt can generate asynchronous wakeup from any low-power mode
  - Hardware trigger output
  - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
  - Rising-edge or falling-edge

### 53.2.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

**Table 53-1. Modes of operation**

| Modes | Description |
|---|---|
| Run | The LPTMR operates normally. |
| Wait | The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request. |
| Stop | The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request. |
| Low-Leakage | The LPTMR continues to operate normally and can be configured to exit the low-power mode by generating an interrupt request. |
| Debug | The LPTMR operates normally in Pulse Counter mode, but the counter does not increment in Time Counter mode. |

## 53.3 LPTMR signal descriptions

**Table 53-2. LPTMR signal descriptions**

| Signal | I/O | Description |
|---|---|---|
| LPTMR_ALT*n* | I | Pulse Counter Input pin |

### 53.3.1 Detailed signal descriptions

**Table 53-3. LPTMR interface—detailed signal descriptions**

| Signal | I/O | Description | |
|---|---|---|---|
| LPTMR_ALT*n* | I | Pulse Counter Input<br>The LPTMR can select one of the input pins to be used in Pulse Counter mode. | |
| | | State meaning | Assertion—If configured for pulse counter mode with active-high input, then assertion causes the CNR to increment.<br>Deassertion—If configured for pulse counter mode with active-low input, then deassertion causes the CNR to increment. |
| | | Timing | Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock. |

## 53.4 Memory map and register definition

**NOTE**

The LPTMR registers are reset only on a POR or LVD event.
See LPTMR power and reset for more details.

### 53.4.1 LPTMR0 register descriptions

#### 53.4.1.1 LPTMR0 Memory map

LPTMR0 base address: 4003_2000h

| Field | Function |
|---|---|
| 31-0<br>COUNTER | Counter Value<br>The CNR returns the current value of the LPTMR counter at the time this register was last written. |

## 53.5 Functional description

### 53.5.1 LPTMR power and reset

The LPTMR remains powered in all power modes, including low-leakage modes. If the LPTMR is not required to remain operating during a low-power mode, then it must be disabled before entering the mode.

The LPTMR is reset only on global Power On Reset (POR) or Low Voltage Detect (LVD). When configuring the LPTMR registers, the CSR must be initially written with the timer disabled, before configuring the PSR and CMR. Then, CSR[TIE] must be set as the last step in the initialization. This ensures the LPTMR is configured correctly and the LPTMR counter is reset to zero following a warm reset.

### 53.5.2 LPTMR clocking

The LPTMR prescaler/glitch filter can be clocked by one of the four clocks. The clock source must be enabled before the LPTMR is enabled.

**NOTE**

The clock source selected by PSR[PCS] may need to be configured to remain enabled in low-power modes, otherwise the LPTMR will not operate during low-power modes.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

**NOTE**

The clock source or pulse input source selected for the LPTMR should not exceed the frequency $f_{LPTMR}$ defined in the device datasheet.

## 53.5.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

**NOTE**

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

### 53.5.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR will increment every $2^2$ to $2^{16}$ prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR will take an additional one or two prescaler clock cycles due to synchronization logic.

### 53.5.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment will take an additional one or two prescaler clock cycles due to synchronization logic.

### 53.5.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

| If | Then |
|---|---|
| The selected input source remains deasserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising edges | The glitch filter output will also deassert. |
| The selected input source remains asserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising-edges | The glitch filter output will also assert. |

**NOTE**

The input is only sampled on the rising clock edge.

The CNR will increment each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every $2^2$ to $2^{16}$ prescaler clock edges. When first enabled, the glitch filter will wait an additional one or two prescaler clock edges due to synchronization logic.

#### 53.5.3.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

### 53.5.4 LPTMR compare

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

### 53.5.5 LPTMR counter

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

When the core is halted in Debug mode:

- If configured for Pulse Counter mode, the CNR continues incrementing.
- If configured for Time Counter mode, the CNR stops incrementing.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This will synchronize and register the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

### 53.5.6 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

| When | Then |
|---|---|
| The CMR is set to 0 with CSR[TFC] clear | The LPTMR hardware trigger will assert on the first compare and does not deassert. |
| The CMR is set to a nonzero value, or, if CSR[TFC] is set | The LPTMR hardware trigger will assert on each compare and deassert on the following increment of the CNR. |

### 53.5.7 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

# Chapter 54
# Real Time Clock (RTC)

## 54.1 Chip-specific RTC information

### 54.1.1 RTC_CLKOUT signal

When the RTC is enabled and the port control module selects the RTC_CLKOUT function, the RTC_CLKOUT signal outputs a 1 Hz or 32 kHz output derived from RTC oscillator as shown below.

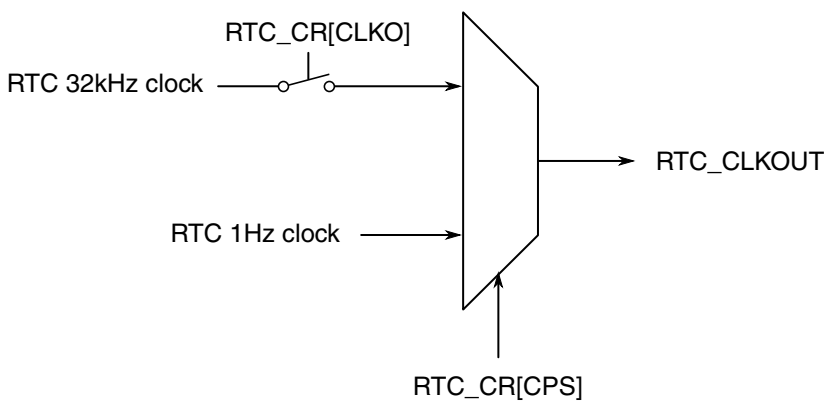

**Figure 54-1. RTC_CLKOUT generation**

**NOTE**

It is possible on variants of this device with RTC_WAKEUP pin to output the RTC clock signal to the RTC_WAKEUP pin. Please refer to the RTC Control Register for details.

### 54.1.2 Number of tamper inputs

This device contains up to 4 tamper input pins. See the device pinouts to see which tamper pins are available in a given package.

## 54.2 Introduction

### 54.2.1 Features

The RTC module features include:

- Independent power supply, POR, and 32.768 kHz crystal oscillator
- 32-bit seconds counter with roll-over protection and 32-bit alarm
- 16-bit prescaler with compensation that can correct errors between 0.12 ppm and 3906 ppm
- Option to increment prescaler using a 1 kHz LPO (prescaler increments by 32 every clock edge)
- Register write protection
  - Lock register requires VBAT POR or software reset to enable write access
  - Access control registers require system reset to enable read and/or write access
- Configurable 1, 2, 4, 8, 16, 32, 64 or 128 Hz square wave output with optional interrupt
- 64-bit monotonic counter with roll-over protection
- Up to 4 tamper input pins with optional interrupt and seconds timestamp when interrupt asserts

### 54.2.2 Modes of operation

The RTC remains functional in all low power modes and can generate an interrupt to exit any low power mode. It operates in one of two modes of operation: chip power-up and chip power-down.

During chip power-down, RTC is powered from the backup power supply (VBAT) and is electrically isolated from the rest of the chip but continues to increment the time counter (if enabled) and retain the state of the RTC registers. The RTC registers are not accessible.

During chip power-up, RTC remains powered from the backup power supply (VBAT). All RTC registers are accessible by software and all functions are operational. If enabled, the 32.768 kHz clock can be supplied to the rest of the chip.

## 54.2.3 RTC signal descriptions

**Table 54-1. RTC signal descriptions**

| Signal | Description | I/O |
|---|---|---|
| EXTAL32 | 32.768 kHz oscillator input | I |
| XTAL32 | 32.768 kHz oscillator output | O |
| RTC_CLKOUT | Prescaler square-wave output or RTC 32.768 kHz clock | O |
| RTC_WAKEUP_b | Active low wakeup for external device | O |
| RTC_TAMPER[3:0] | Tamper pin input | I |

### 54.2.3.1 RTC clock output

The RTC_CLKOUT signal can output either a square wave prescaler output (configurable to 1, 2, 4, 8, 16, 32, 64 or 128 Hz) or the RTC 32.768 kHz clock.

### 54.2.3.2 RTC wakeup pin

The RTC wakeup pin is an open drain, active low, output that allows the RTC to wakeup the chip via an external component. The wakeup pin asserts when the wakeup pin enable is set and either the RTC interrupt is asserted or the wakeup pin is turned on via a register bit. The wakeup pin does not assert from the RTC seconds interrupt.

**NOTE**

The wakeup pin is optional and may not be implemented on all devices.

### 54.2.3.3 RTC Tamper pins

The RTC tamper pins are input pins that can be used to generate an interrupt or invalidate the time counter. The first tamper pin to assert an interrupt will also capture a timestamp of the seconds register.

## 54.3 Register definition

All registers must be accessed using 32-bit writes and all register accesses incur three wait states.

Write accesses to any register and read accesses to tamper and monotonic registers by non-supervisor mode software, when the supervisor access bit in the control register is clear, will terminate with a bus error.

Read accesses to other registers by non-supervisor mode software complete as normal.

Writing to a register protected by the write access register or lock register does not generate a bus error, but the write will not complete.

Reading a register protected by the read access register does not generate a bus error, but the register will read zero.

### 54.3.1.3.3 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>TPR | Time Prescaler Register<br>When the time counter is enabled, the TPR is read only and increments every 32.768 kHz clock cycle. The time counter will read as zero when SR[TOF] or SR[TIF] are set. When the time counter is disabled, the TPR can be read or written. The TSR[TSR] increments when bit 14 of the TPR transitions from a logic one to a logic zero. |

## 54.3.1.4 RTC Time Alarm Register (TAR)

### 54.3.1.4.1 Offset

| Register | Offset |
|---|---|
| TAR | 8h |

### 54.3.1.4.2 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | CIR | | | | | | | | TCR | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 54.3.1.5.3 Fields

| Field | Function |
|---|---|
| 31-24<br>CIC | Compensation Interval Counter<br>Current value of the compensation interval counter. If the compensation interval counter equals zero then it is loaded with the contents of the CIR. If the CIC does not equal zero then it is decremented once a second. Reading this register at the same time as the seconds counter is incrementing can result in an incorrect value being read. |
| 23-16<br>TCV | Time Compensation Value<br>Current value used by the compensation logic for the present second interval. Updated once a second if the CIC equals 0 with the contents of the TCR field. If the CIC does not equal zero then it is loaded with zero (compensation is not enabled for that second increment). Reading this register at the same time as the seconds counter is incrementing can result in an incorrect value being read. |
| 15-8<br>CIR | Compensation Interval Register<br>Configures the compensation interval in seconds from 1 to 256 to control how frequently the TCR should adjust the number of 32.768 kHz cycles in each second. The value written should be one less than the number of seconds. For example, write zero to configure for a compensation interval of one second. This register is double buffered and writes do not take affect until the end of the current compensation interval. |
| 7-0<br>TCR | Time Compensation Register<br>Configures the number of 32.768 kHz clock cycles in each second, equal to 32,768 - TCR (where TCR is a twos complement sign extended value). This register is double buffered and writes do not take affect until the end of the current compensation interval. Some example values are show below.<br>00000000b - Time Prescaler Register overflows every 32768 clock cycles.<br>00000001b - Time Prescaler Register overflows every 32767 clock cycles.<br>01111110b - Time Prescaler Register overflows every 32642 clock cycles.<br>01111111b - Time Prescaler Register overflows every 32641 clock cycles.<br>10000000b - Time Prescaler Register overflows every 32896 clock cycles.<br>10000001b - Time Prescaler Register overflows every 32895 clock cycles.<br>11111111b - Time Prescaler Register overflows every 32769 clock cycles. |

## 54.3.1.6 RTC Control Register (CR)

### 54.3.1.6.1 Offset

| Register | Offset |

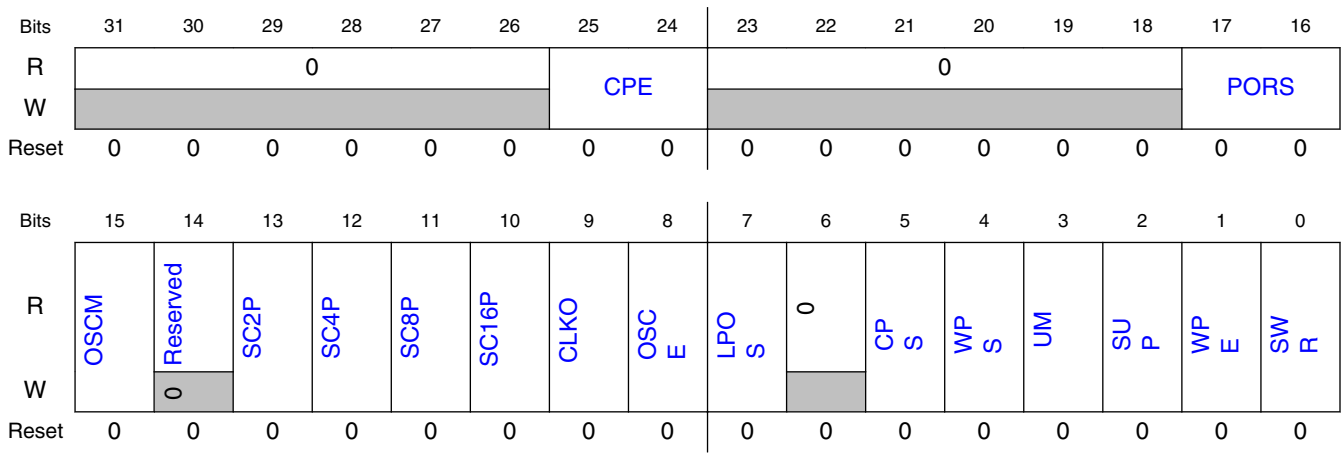
| CR | 10h |

### 54.3.1.6.2 Diagram



### 54.3.1.6.3 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-24<br>CPE | Clock Pin Enable<br>00b - The RTC_CLKOUT function is disabled.<br>01b - Enable RTC_CLKOUT pin on pin 1.<br>10b - Enable RTC_CLKOUT pin on pin 2.<br>11b - Enable RTC_CLKOUT pin on pin 3. |
| 23-18<br>— | Reserved |
| 17-16<br>PORS | POR Select<br>Configures pulsing of the POR brownout, this reduces average power consumption. POR brownout is always enabled on a loss of clock event, if the time invalid flag is set or if the 32.768kHz crystal oscillator is disabled.<br>00b - POR brownout enabled for 120us every 128ms.<br>01b - POR brownout enabled for 120us every 64ms.<br>10b - POR brownout enabled for 120us every 32ms.<br>11b - POR brownout always enabled. |
| 15<br>OSCM | Oscillator Mode Select<br>0b - Configures the 32.768kHz crystal oscillator for robust operation supporting a wide range of crystals. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - Configures the 32.768kHz crystal oscillator for low power operation supporting a more limited range of crystals. |
| 14<br>— | Reserved<br>It must always be written to 0. |
| 13<br>SC2P | Oscillator 2pF Load Configure<br>0b - Disable the load.<br>1b - Enable the additional load. |
| 12<br>SC4P | Oscillator 4pF Load Configure<br>0b - Disable the load.<br>1b - Enable the additional load. |
| 11<br>SC8P | Oscillator 8pF Load Configure<br>0b - Disable the load.<br>1b - Enable the additional load. |
| 10<br>SC16P | Oscillator 16pF Load Configure<br>0b - Disable the load.<br>1b - Enable the additional load. |
| 9<br>CLKO | Clock Output<br>0b - The 32 kHz clock is output to other peripherals.<br>1b - The 32 kHz clock is not output to other peripherals. |
| 8<br>OSCE | Oscillator Enable<br>0b - 32.768 kHz oscillator is disabled.<br>1b - 32.768 kHz oscillator is enabled. After setting this bit, wait the oscillator startup time before enabling the time counter to allow the 32.768 kHz clock time to stabilize. |
| 7<br>LPOS | LPO Select<br>When set, the RTC prescaler increments using the LPO 1 kHz clock and not the RTC 32.768 kHz clock. The LPO increments the prescaler from bit TPR[5] (TPR[4:0] are ignored), supporting close to 1 second increment of the seconds register. Although compensation is supported when clocked from the LPO, TCR[4:0] of the compensation register are also ignored and only TCR[7:5] set the compensation value (can overflow after 1020 to 1027 cycles).<br>0b - RTC prescaler increments using 32.768 kHz clock.<br>1b - RTC prescaler increments using 1 kHz LPO, bits [4:0] of the prescaler are ignored. |
| 6<br>— | Reserved |
| 5<br>CPS | Clock Pin Select<br>0b - The prescaler output clock (as configured by TSIC) is output on RTC_CLKOUT.<br>1b - The RTC 32.768 kHz clock is output on RTC_CLKOUT, provided it is output to other peripherals. |
| 4<br>WPS | Wakeup Pin Select<br>The RTC_WAKEUP pin is optional and not available on all devices.<br>0b - RTC_WAKEUP pin asserts (active low, open drain) if the RTC interrupt asserts or the wakeup pin is turned on.<br>1b - RTC_WAKEUP pin outputs the RTC 32kHz clock, provided the wakeup pin is turned on and the 32kHz clock is output to other peripherals. |
| 3<br>UM | Update Mode<br>Allows SR[TCE] to be written even when the Status Register is locked. When set, the SR[TCE] can be written if the SR[TIF] or SR[TOF] are set or if the SR[TCE] is clear. Whenever both SR[TCE] and CR[UM] are set, then SR[TCE] should only be written once either SR[TIF] or SR[TOF] are set. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | Allows the monotonic enable register to be written when it is locked. When set, the monotonic enable register can always be written if the SR[TIF] or SR[MOF] are set or if the montonic counter enable is clear.<br>Allows the tamper detect register to be written when it is locked. When set, the tamper detect register can always be written if the SR[TIF] is clear.<br>0b - Registers cannot be written when locked.<br>1b - Registers can be written when locked under limited conditions. |
| 2<br>SUP | Supervisor Access<br>Configures non-supervisor mode write access to all RTC registers and non-supervisor mode read access to RTC tamper/monotonic registers<br>0b - Non-supervisor mode write accesses are not supported and generate a bus error.<br>1b - Non-supervisor mode write accesses are supported. |
| 1<br>WPE | Wakeup Pin Enable<br>The RTC_WAKEUP pin is optional and not available on all devices.<br>0b - RTC_WAKEUP pin is disabled.<br>1b - RTC_WAKEUP pin is enabled and asserts if the RTC interrupt asserts or if the wakeup pin is forced on. |
| 0<br>SWR | Software Reset<br>0b - No effect.<br>1b - Resets all RTC registers except for the SWR bit and the RTC_WAR and RTC_RAR registers . The SWR bit is cleared by VBAT POR and by software explicitly clearing it. |

# 54.4 Functional description

## 54.4.1 Power, clocking, and reset

The RTC is an always powered block that remains active in all low power modes and is powered by the battery power supply (VBAT). The battery power supply ensures that the RTC registers retain their state during chip power-down and that the RTC time counter remains operational.

The time counter within the RTC is clocked by default from a 32.768 kHz clock and can supply this clock to other peripherals. The 32.768 kHz clock can be sourced from an external crystal using the oscillator that is part of the RTC module. Alternatively, the time counter can be clocked by a LPO 1 kHz clock and the prescaler will increment by 32 for each LPO clock.

The RTC includes its own analog POR block, which generates a VBAT power-on-reset signal whenever the RTC module is powered up and initializes all RTC registers to their default state. A software reset bit can also initialize all RTC registers. The RTC also monitors the chip power supply and electrically isolates itself when the rest of the chip is powered down.

**NOTE**

An attempt to access an RTC register, except the access control registers, results in a bus error when:

- VBAT is powered down,
- the RTC is electrically isolated, or
- VBAT POR is asserted.

#### 54.4.1.1 Oscillator control

The 32.768 kHz crystal oscillator is disabled at VBAT POR and must be enabled by software. After enabling the cystal oscillator, wait the oscillator startup time before setting SR[TCE] or using the oscillator clock external to the RTC.

The crystal oscillator includes tunable capacitors that can be configured by software. Do not change the capacitance unless the oscillator is disabled.

#### 54.4.1.2 Software reset

Writing 1 to CR[SWR] forces the equivalent of a VBAT POR to the rest of the RTC module. CR[SWR] is not affected by the software reset and must be cleared by software. The access control registers are not affected by either VBAT POR or the software reset; they are reset by the chip reset.

#### 54.4.1.3 Supervisor access

When the supervisor access control bit is clear, only supervisor mode software can write to the RTC registers or read the RTC tamper and monotonic registers, non-supervisor mode software will generate a bus error. Both supervisor and non-supervisor mode software can always read the other RTC registers.

### 54.4.2 Time counter

The time counter consists of a 32-bit seconds counter that increments once every second and a 16-bit prescaler register that increments once every 32.768 kHz clock cycle. There is also the option to clock the prescaler using a 1 kHz LPO that increments the prescaler by 32 on every clock cycle.

Reading the time counter (either seconds or prescaler) while it is incrementing may return invalid data due to synchronization of the read data bus. If it is necessary for software to read the prescaler or seconds counter when they could be incrementing, it is recommended that two read accesses are performed and that software verifies that the same data was returned for both reads.

The time seconds register and time prescaler register can be written only when SR[TCE] is clear. Always write to the prescaler register before writing to the seconds register, because the seconds register increments on the falling edge of bit 14 of the prescaler register.

The time prescaler register increments provided SR[TCE] is set, SR[TIF] is clear, SR[TOF] is clear, and the 32.768 kHz (or 1 kHz) clock source is present. After enabling the oscillator, wait the oscillator startup time before setting SR[TCE] to allow time for the oscillator clock output to stabilize.

If the time seconds register overflows then the SR[TOF] will set and the time prescaler register will stop incrementing. Clear SR[TOF] by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TOF] is set.

SR[TIF] is set on VBAT POR, software reset, and when an enabled tamper source is detected. It is cleared by clearing the enabled tamper detect flag and then initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TIF] is set.

### 54.4.3 Compensation

The compensation logic provides an accurate and wide compensation range and can correct errors as high as 3906 ppm and as low as 0.12 ppm. The compensation factor must be calculated externally to the RTC and supplied by software to the compensation register. The RTC itself does not calculate the amount of compensation that is required, although the 1 Hz clock is output to an external pin in support of external calibration logic.

Crystal compensation can be supported by using firmware and crystal characteristics to determine the compensation amount. Temperature compensation can be supported by firmware that periodically measures the external temperature via ADC and updates the compensation register based on a look-up table that specifies the change in crystal frequency over temperature.

The compensation logic alters the number of 32.768 kHz clock cycles it takes for the prescaler register to overflow and increment the time seconds counter. The time compensation value is used to adjust the number of clock cycles between -127 and +128. Cycles are added or subtracted from the prescaler register when the prescaler register equals 0x3FFF and then increments. The compensation interval is used to adjust the frequency at which the time compensation value is used, that is, from once a second to once every 256 seconds.

Updates to the time compensation register will not take effect until the next time the time seconds register increments and provided the previous compensation interval has expired. When the compensation interval is set to other than once a second then the compensation is applied in the first second interval and the remaining second intervals receive no compensation.

Compensation is disabled by configuring the time compensation register to zero.

When the prescaler is configured to increment using the 1 kHz LPO, the effective compensation value is divided by 32 and can only adjust the number of clock cycles between -4 and +3.

### 54.4.4 Time alarm

The Time Alarm register (TAR), SR[TAF], and IER[TAIE] allow the RTC to generate an interrupt at a predefined time. The 32-bit TAR is compared with the 32-bit Time Seconds register (TSR) each time it increments. SR[TAF] will set when TAR equals TSR and TSR increments.

SR[TAF] is cleared by writing TAR. This will usually be the next alarm value, although writing a value that is less than TSR, such as 0, will prevent SR[TAF] from setting again. SR[TAF] cannot otherwise be disabled, although the interrupt it generates is enabled or disabled by IER[TAIE].

### 54.4.5 Update mode

The Update Mode field in the Control register (CR[UM]) configures software write access to the Time Counter Enable (SR[TCE]) field. When CR[UM] is clear, SR[TCE] can be written only when LR[SRL] is set. When CR[UM] is set, SR[TCE] can also be written when SR[TCE] is clear or when SR[TIF] or SR[TOF] are set. This allows the time seconds and prescaler registers to be initialized whenever time is invalidated, while preventing the time seconds and prescaler registers from being changed on the fly. When LR[SRL] is set, CR[UM] has no effect on SR[TCE].

CR[UM] also configures software write access to the Monotonic Counter Enable (MER[MCE]) bit. When CR[UM] is clear, MER[MCE] can be written only when LR[MEL] is set. When CR[UM] is set, MER[MCE] can also be written when MER[MCE] is clear or when SR[TIF] or SR[MOF] are set. This allows the monotonic counter register to be initialized whenever the monotonic counter is invalid, while preventing the monotonic counter from being changed on the fly. When LR[MEL] is set, CR[UM] has no effect on MCR[MCE].

### 54.4.6 Monotonic counter

The 64-bit Monotonic Counter is a counter that cannot be exhausted or return to any previous value, once it has been initialized. If the monotonic overflow flag is set, the monotonic counter returns zero and does not increment.

Depending on the value of the monotonic counter enable bit, writing to the monotonic counter either initializes the register with the value written, or increments the register by one (and the value written is ignored).

When the monotonic counter is enabled, the monotonic counter high increments on either a write to the monotonic counter high register or if the monotonic counter low register overflows (due to a write to the monotonic counter low register). The monotonic overflow flag sets when the monotonic counter high register overflows and is cleared by writing the monotonic counter high register when the monotonic counter is disabled.

The monotonic counter is held in reset whenever the time invalid flag is set. Always clear the time invalid flag before initializing the monotonic counter.

### 54.4.7 Tamper detect

Each external tamper pin and internal tamper source can be configured to generate a tamper interrupt. The contents of the seconds register are latched in the tamper time seconds register when the tamper interrupt asserts. Read the tamper time seconds register before clearing the flag in the tamper detect register.

Writing the tamper time seconds register at any time will set the time invalid flag. Since this is a software initiated tamper, there is no status flag to indicate this tamper source. To disable the software initiated tamper, lock the tamper time seconds register to prevent write accesses to that register.

### 54.4.8 Register lock

The Lock register (LR) can be used to block write accesses to certain registers until the next VBAT POR or software reset. Locking the Control register (CR) will disable the software reset. Locking LR will block future updates to LR.

Write accesses to a locked register are ignored and do not generate a bus error.

### 54.4.9 Access control

The read access and write access registers are implemented in the chip power domain and reset on the chip reset. They are not affected by the VBAT POR or the software reset. They are used to block read or write accesses to each register until the next chip system reset. When accesses are blocked, the bus access is not seen in the VBAT power supply and does not generate a bus error.

### 54.4.10 Interrupt

The RTC interrupt is asserted whenever a status flag and the corresponding interrupt enable bit are both set. It is always asserted on VBAT POR, and software reset, and when the VBAT power supply is powered down. The RTC interrupt is enabled at the chip level by enabling the chip-specific RTC clock gate control bit. The RTC interrupt can be used to wakeup the chip from any low-power mode. If the RTC wakeup pin is enabled and the chip is powered down, the RTC interrupt will cause the wakeup pin to assert.

The RTC interrupt is also asserted when a configured tamper flag asserts and the corresponding tamper interrupt enable bit is set. Both internal tamper events and external tamper pins can cause the tamper interrupt to assert. The contents of the seconds register are recorded in the tamper time seconds register when the tamper interrupt asserts.

The RTC seconds interrupt is an edge-sensitive interrupt with a dedicated interrupt vector that is generated once a second and requires no software overhead (there is no corresponding status flag to clear). It is enabled in the RTC by the time seconds interrupt enable bit and enabled at the chip level by setting the chip-specific RTC clock gate control bit. The frequency of the seconds interrupt defaults to 1 Hz, but can instead be configured to trigger every 2, 4, 8, 16, 32, 64 or 128 Hz. The RTC seconds interrupt does not cause the RTC wakeup pin to assert.

# Chapter 55
# Low Power Inter-Integrated Circuit (LPI2C)

## 55.1 Chip-specific LPI2C information

### 55.1.1 LPI2C instantiations

The following list describes the LPI2C instantiations on this device:

- Instantiations: 4
- Configuration: Master and Slave
- Receive FIFO size: 4 entries
- Transmit FIFO size: 4 entries

## 55.2 Introduction

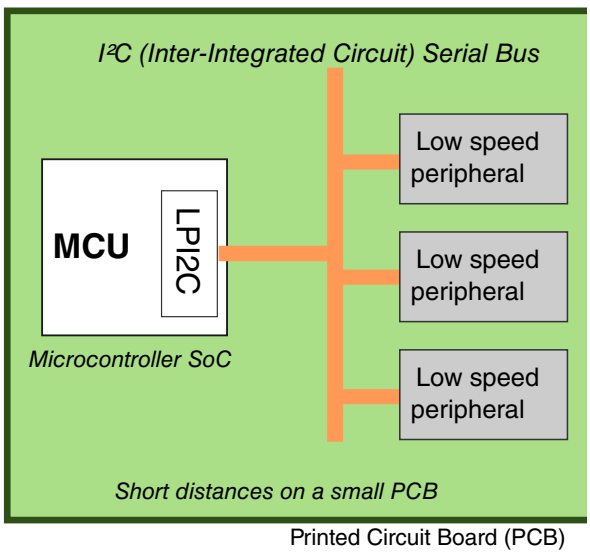

**Figure 55-1. I²C bus connects MCU to low speed peripherals on PCB**

The LPI2C is a low power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I2C bus as a master and/or as a slave.

- The LPI2C implements logic support for standard-mode, fast-mode, fast-mode plus and ultra-fast modes of operation.
- The LPI2C is designed to use little CPU overhead, with DMA offloading of FIFO register accesses.
- The LPI2C can continue operating in stop modes if an appropriate clock is available.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 2. The SMBus is a single-ended simple two-wire bus, which is typically used for low bandwidth communications.

**NOTE**

The I²C (Inter-Integrated Circuit) serial bus is multi-master, multi-slave, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

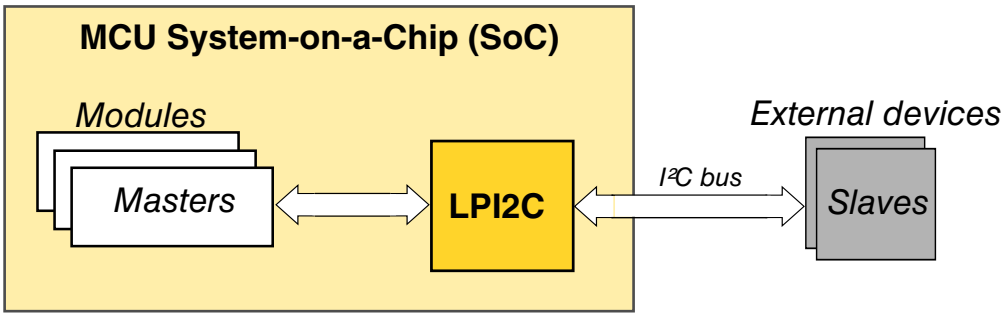

**Figure 55-2. LPI2C connects masters in MCU to external slaves on PCB**

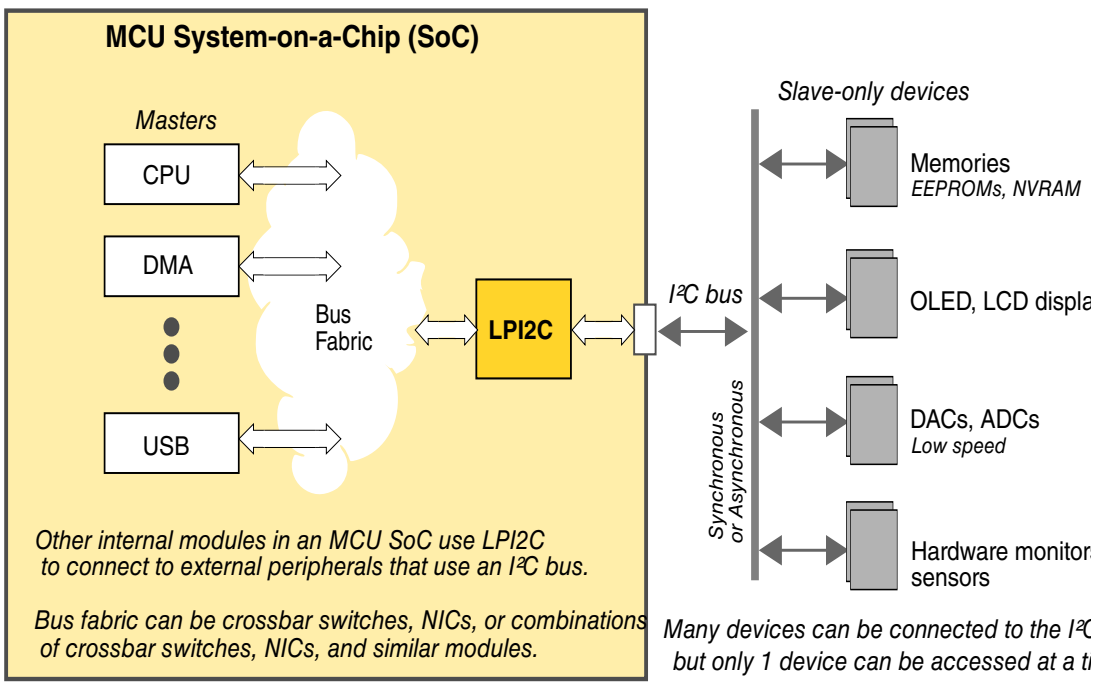

**Figure 55-3. Typical LPI2C connection scheme**

## 55.2.1 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes are supported
- High speed mode (HS) in slave mode
- High speed mode (HS) in master mode, if SCL pin implements current source pull-up (device-specific)

- Multi-master support, including synchronization and arbitration. Multi-master means any number of master nodes can be present. Additionally, master and slave roles may be changed between messages (after a STOP is sent).
- Clock stretching: Sometimes multiple I2C nodes may be driving the lines at the same time. If any I2C node is driving a line low, then that line will be low. I2C nodes that are starting to transmit a logical one (by letting the line float high) can detect that the line is low, and thereby know that another I2C node is active at the same time.
  - When node detection is used on the SCL line, it is called *clock stretching*, and clock stretching is used as a I2C flow control mechanism for multiple laves.
  - When node detection is used on the SDA line, it is called *arbitration*, and arbitration ensures that there is only one I2C node transmitter at a time.
- General call, 7-bit and 10-bit addressing
- Software reset, START byte and Device ID (also require software support)

The LPI2C master supports:

- Command/transmit FIFO of 4words.
- Receive FIFO of 4words.
- Command FIFO will wait for idle I2C bus before initiating transfer
- Command FIFO can initiate (repeated) START and STOP conditions and one or more master-receiver transfers
- STOP condition can be generated from command FIFO, or generated automatically when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Flexible receive data match can generate interrupt on data match and/or discard unwanted data
- Flag and optional interrupt to signal Repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors
- Supports configurable bus idle timeout and pin-stuck-low timeout

The LPI2C slave supports:

- Separate I2C slave registers to minimize software overhead because of master/slave switching
- Support for 7-bit or 10-bit addressing, address range, SMBus alert and general call address
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit
- Configurable clock stretching, to avoid transmit FIFO underrun and receive FIFO overrun errors
- Flag and optional interrupt at end of packet, STOP condition, or bit error detection

## 55.2.2 Block Diagram

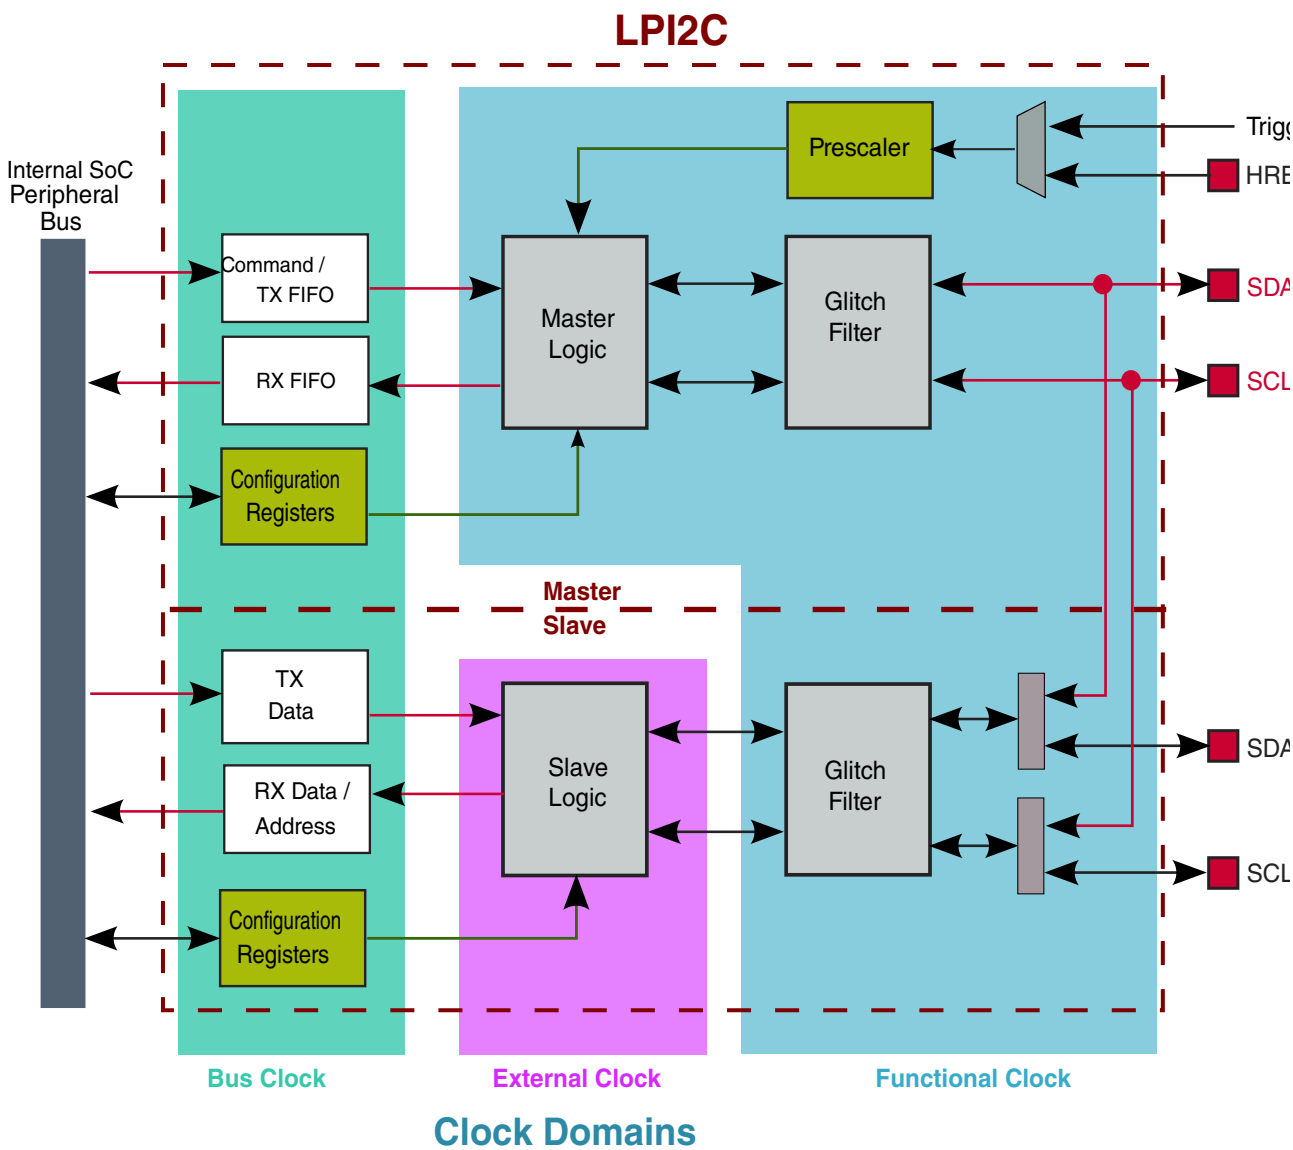

**Figure 55-4. LPI2C block diagram**

## 55.2.3 Modes of operation

**Table 55-1. Chip modes supported by the LPI2C module**

| Chip mode | LPI2C Operation |
|---|---|
| Run | Normal operations |

*Table continues on the next page...*

**Table 55-1. Chip modes supported by the LPI2C module (continued)**

| Chip mode | LPI2C Operation |
|---|---|
| Stop/Wait | Can continue operating in stop/wait modes if the Doze Enable bit (MCR[DOZEN]) is clear and the LPI2C is using an external or internal clock source that remains operating during stop/wait modes. |
| Low Power Stop (also called Low Leakage Stop or LLS) | Before entering low power stop mode, the LPI2C will wait for the current transfer to finish any pending operation, while temporarily ignoring The Doze Enable (MCR[DOZEN]) bit. |
| Debug | Can continue operating in debug mode if the Debug Enable bit (MCR[DBGE]) is set. |

## 55.2.4 Signal Descriptions

**Table 55-2. Signals**

| Signal | Name | 2-Wire Scheme | 4-Wire Scheme | I/O |
|---|---|---|---|---|
| SCL | LPI2C clock line | SCL | In 4-wire mode, this is the SCL input pin. | I/O |
| SDA | LPI2C data line | SDA | In 4-wire mode, this is the SDA input pin. | I/O |
| HREQ | Host request | If host request is asserted and the I2C bus is idle, then it will initiate an LPI2C master transfer. | | I |
| SCLS | Secondary I2C clock line | Not used | In 4-wire mode, this is the SCLS output pin. If LPI2C master/slave are configured to use separate pins, then this the LPI2C slave SCL pin. | I/O |
| SDAS | Secondary I2C data line | Not used | In 4-wire mode, this is the SDAS output pin. If LPI2C master/slave are configured to use separate pins, then this the LPI2C slave SDA pin. | I/O |

## 55.2.5 Wiring options

LPI2C can be used to implement 2-wire or 4-wire $I^2C$ serial busses.

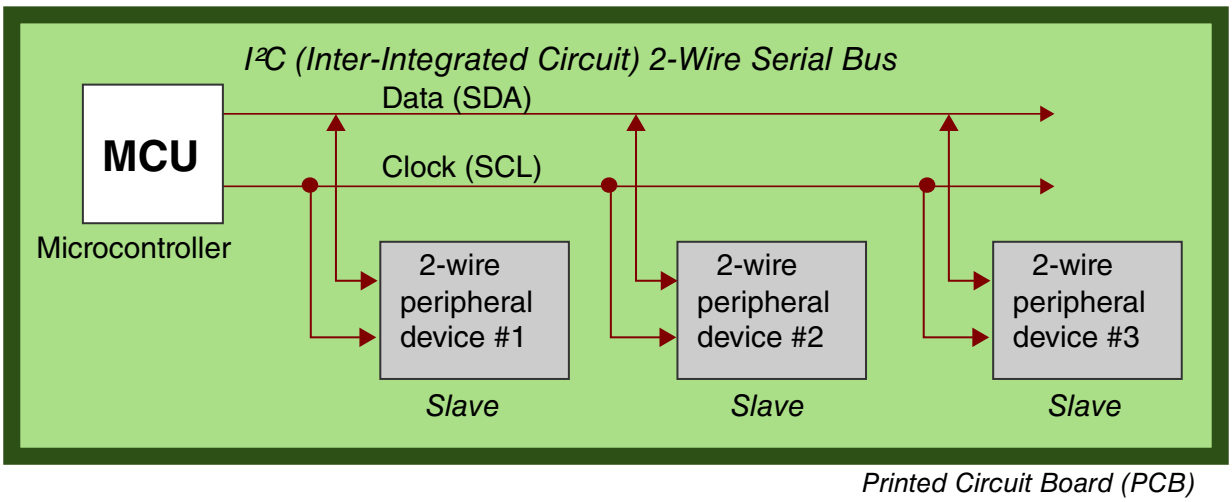

**Figure 55-5. 2-Wire scheme**

Some applications can provide a lot of load and noise on the $I^2C$ bus; to ensure robust $I^2C$ operations, a 4-wire interface with the MCU can be used, splitting the 2 lines into inputs and outputs. Using a few transistors, resistors and diodes, designers can make their own inexpensive line drivers.

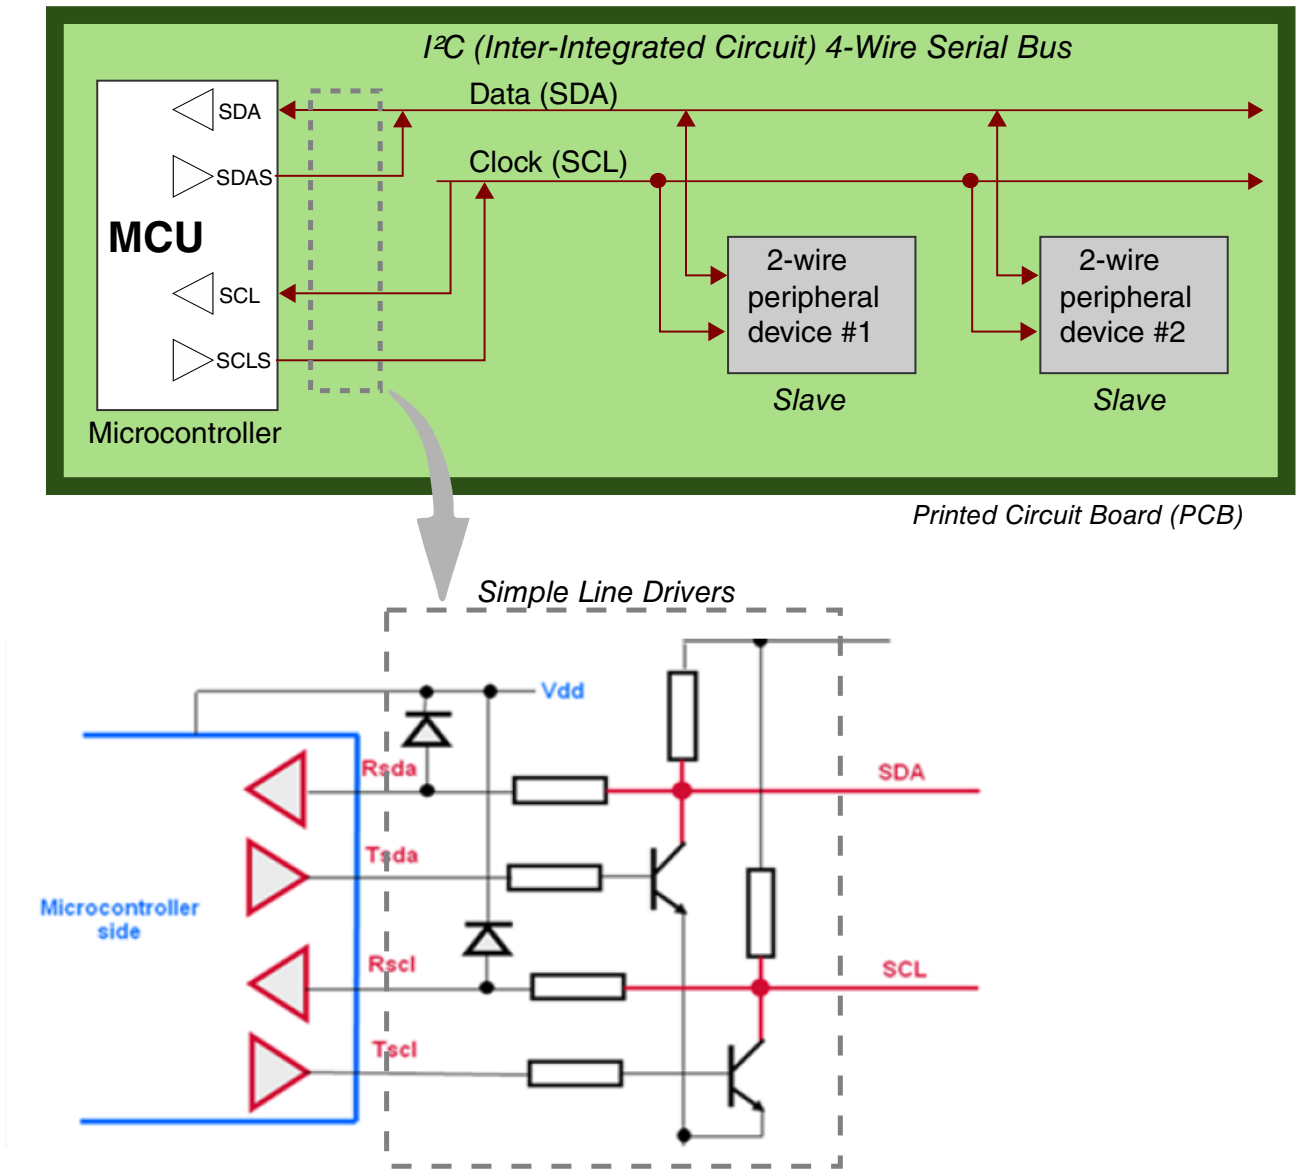

**Figure 55-6. 4-Wire scheme**

## 55.3 Memory Map and Registers

### 55.3.1 LPI2C0 register descriptions

| 7-6<br>— | Reserved |
| 5-0<br>CLKLO | Clock Low Period<br>Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles. |

## 55.3.1.14 Master Clock Configuration Register 1 (MCCR1)

### 55.3.1.14.1 Offset

| Register | Offset |
|---|---|
| MCCR1 | 50h |

### 55.3.1.14.2 Function

The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by MCCR0), before switching to high speed mode (with timing configured by MCCR1).

## 55.3.1.17 Master Transmit Data Register (MTDR)

### 55.3.1.17.1 Offset

| Register | Offset |
|---|---|
| MTDR | 60h |

### 55.3.1.17.2 Function

- An 8-bit write to the CMD field will store the data in the Command FIFO, but does not increment the FIFO write pointer.

- An 8-bit write to the DATA field will zero extend the CMD field, unless the CMD field has been written separately since the last FIFO write; it (the 8-bit write) also increments the FIFO write pointer.
- A 16-bit or 32-bit will write both the CMD and DATA fields and increment the FIFO.

The R/W bit is therefore always stored in RADDR[0] |

## 55.3.1.27 Slave Transmit ACK Register (STAR)

### 55.3.1.27.1 Offset

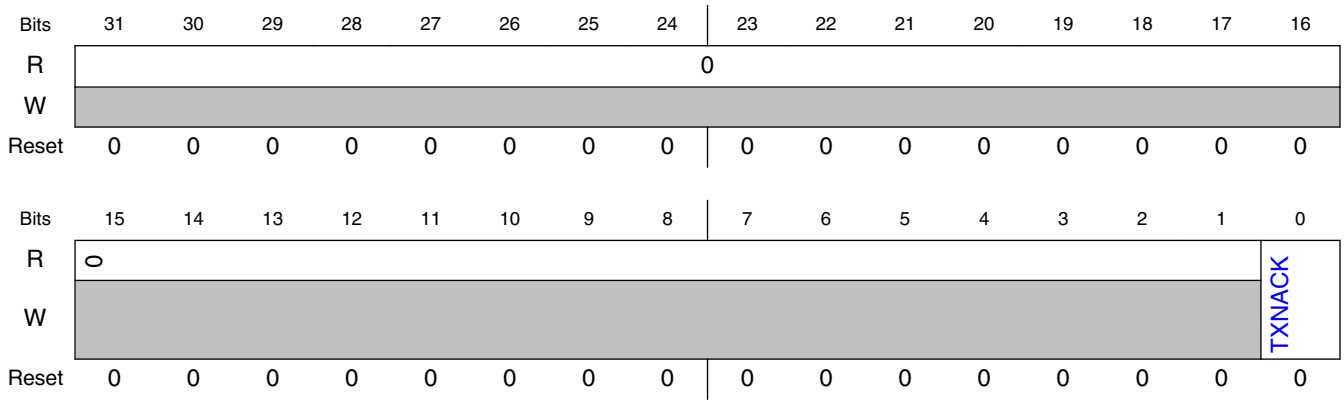
| Register | Offset |
|---|---|
| STAR | 154h |

### 55.3.1.27.2 Function

The Slave Transmit ACK Register can only be written when the ACK SCL Stall bit is set in Slave Configuration Register 1 (SCFGR1[ACKSTALL].

- The ACKSTALL bit will enable clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).

### 55.3.1.27.3 Diagram



### 55.3.1.27.4 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>TXNACK | Transmit NACK<br>After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK.<br>• When ACKSTALL is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that will stall the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK).<br>• To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle.<br><br>0b - Write a Transmit ACK for each received word<br>1b - Write a Transmit NACK for each received word |

## 55.3.1.28 Slave Transmit Data Register (STDR)

### 55.3.1.28.1 Offset

| Register | Offset |
|---|---|
| STDR | 160h |

### 55.3.1.28.2 Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The TXDSTALL bit will enable clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (TXDSTALL=1)**, then the transmit data transfer is stalled until the Slave Transmit register (STDR) is updated. Clock stretching is extended by at least 1 bus clock cycle after the Slave Transmit Data Register (STDR) is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).
- **If clock stretching is disabled (TXDSTALL=0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (i.e., if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) will be set.

The R/W bit is therefore always stored in RADDR[0] |

## 55.3.2.27 Slave Transmit ACK Register (STAR)

### 55.3.2.27.1 Offset

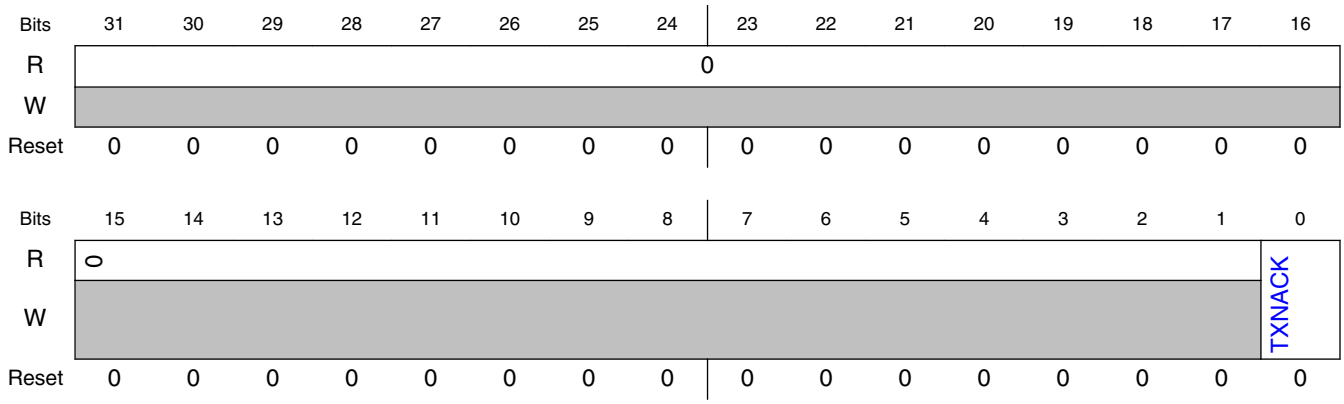
| Register | Offset |
|---|---|
| STAR | 154h |

### 55.3.2.27.2 Function

The Slave Transmit ACK Register can only be written when the ACK SCL Stall bit is set in Slave Configuration Register 1 (SCFGR1[ACKSTALL].

- The ACKSTALL bit will enable clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).

### 55.3.2.27.3 Diagram



### 55.3.2.27.4 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>TXNACK | Transmit NACK<br>After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK.<br>• When ACKSTALL is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that will stall the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK).<br>• To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle.<br><br>0b - Write a Transmit ACK for each received word<br>1b - Write a Transmit NACK for each received word |

## 55.3.2.28 Slave Transmit Data Register (STDR)

### 55.3.2.28.1 Offset

| Register | Offset |
|---|---|
| STDR | 160h |

#### 55.3.2.28.2 Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The TXDSTALL bit will enable clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (TXDSTALL=1)**, then the transmit data transfer is stalled until the Slave Transmit register (STDR) is updated. Clock stretching is extended by at least 1 bus clock cycle after the Slave Transmit Data Register (STDR) is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).
- **If clock stretching is disabled (TXDSTALL=0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (i.e., if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) will be set.

The MCCR0 cannot be changed when the I2C master is enabled and is used for standard, fast, fast-mode plus and ultra-fast transfers.

Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles. |
| 7-6<br>— | Reserved |
| 5-0<br>CLKLO | Clock Low Period<br>Minimum number of cycles (minus one) that the SCL clock is driven low by the master. The Clock Low Period value is also used for the minimum bus free time between a STOP and a START condition; this is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) / 2^PRESCALE cycles. |

## 55.3.3.14 Master Clock Configuration Register 1 (MCCR1)

### 55.3.3.14.1 Offset

| Register | Offset |
|---|---|
| MCCR1 | 50h |

### 55.3.3.14.2 Function

The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by MCCR0), before switching to high speed mode (with timing configured by MCCR1).

## 55.3.3.17 Master Transmit Data Register (MTDR)

### 55.3.3.17.1 Offset

| Register | Offset |
|---|---|
| MTDR | 60h |

### 55.3.3.17.2 Function

- An 8-bit write to the CMD field will store the data in the Command FIFO, but does not increment the FIFO write pointer.

- An 8-bit write to the DATA field will zero extend the CMD field, unless the CMD field has been written separately since the last FIFO write; it (the 8-bit write) also increments the FIFO write pointer.
- A 16-bit or 32-bit will write both the CMD and DATA fields and increment the FIFO.

### 55.3.3.17.3 Diagram

The R/W bit is therefore always stored in RADDR[0] |

## 55.3.3.27 Slave Transmit ACK Register (STAR)

### 55.3.3.27.1 Offset

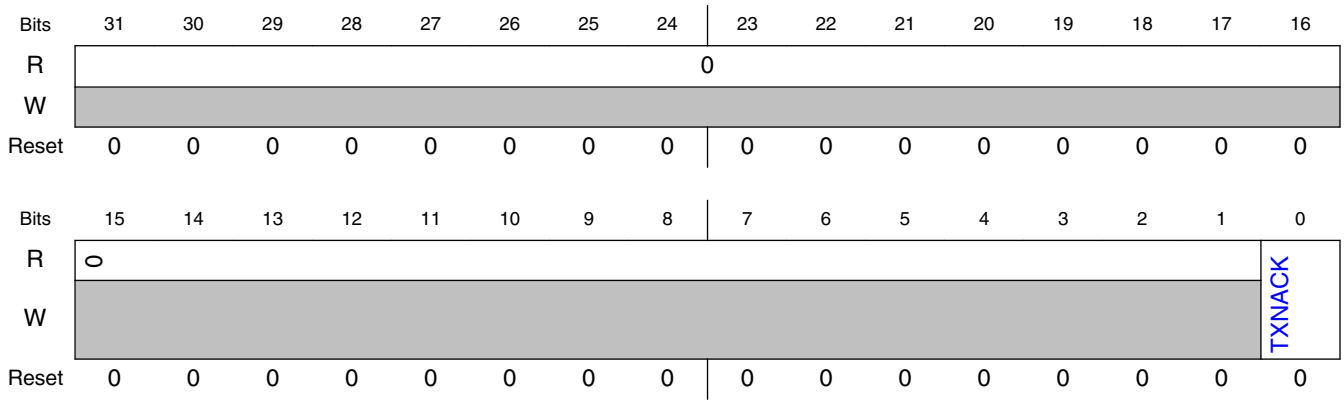
| Register | Offset |
|---|---|
| STAR | 154h |

### 55.3.3.27.2 Function

The Slave Transmit ACK Register can only be written when the ACK SCL Stall bit is set in Slave Configuration Register 1 (SCFGR1[ACKSTALL].

- The ACKSTALL bit will enable clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).

### 55.3.3.27.3 Diagram



### 55.3.3.27.4 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>TXNACK | Transmit NACK<br>After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK.<br>• When ACKSTALL is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that will stall the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK).<br>• To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle.<br><br>0b - Write a Transmit ACK for each received word<br>1b - Write a Transmit NACK for each received word |

## 55.3.3.28 Slave Transmit Data Register (STDR)

### 55.3.3.28.1 Offset

| Register | Offset |
|---|---|
| STDR | 160h |

### 55.3.3.28.2 Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The TXDSTALL bit will enable clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (TXDSTALL=1)**, then the transmit data transfer is stalled until the Slave Transmit register (STDR) is updated. Clock stretching is extended by at least 1 bus clock cycle after the Slave Transmit Data Register (STDR) is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).
- **If clock stretching is disabled (TXDSTALL=0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (i.e., if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) will be set.

The R/W bit is therefore always stored in RADDR[0] |

## 55.3.4.27 Slave Transmit ACK Register (STAR)

### 55.3.4.27.1 Offset

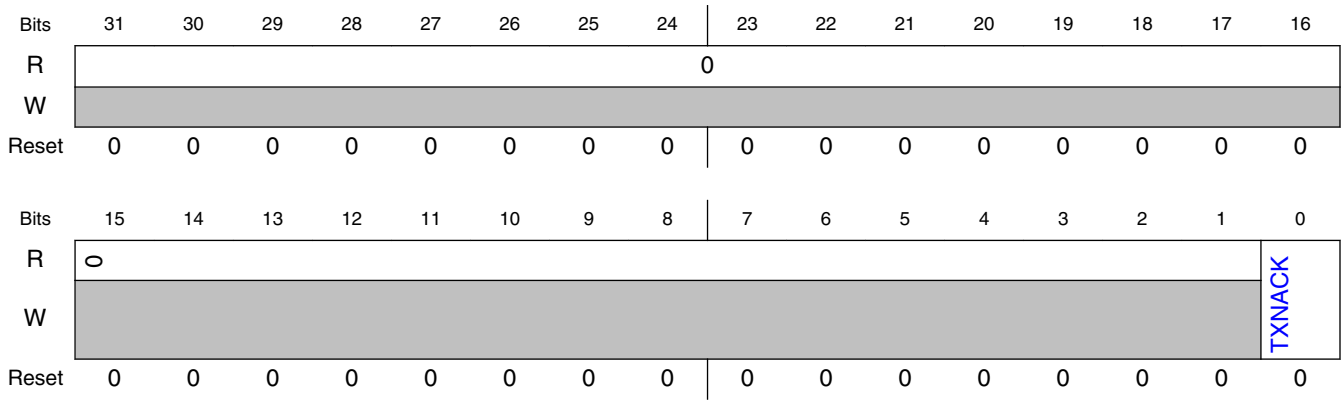
| Register | Offset |
|---|---|
| STAR | 154h |

### 55.3.4.27.2 Function

The Slave Transmit ACK Register can only be written when the ACK SCL Stall bit is set in Slave Configuration Register 1 (SCFGR1[ACKSTALL].

- The ACKSTALL bit will enable clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).

### 55.3.4.27.3 Diagram



### 55.3.4.27.4 Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>TXNACK | Transmit NACK<br>After receiving each word, software can transmit either an ACK (logic 0) or a NACK (logic 1); Transmit NACK selects which to use: ACK or NACK.<br>• When ACKSTALL is set, a Transmit NACK must be written once for each matching address byte and each received word. ACKSTALL must be set, because that will stall the data transfer until software reads the received word (and decides whether to respond with an ACK or NACK).<br>• To configure the default ACK/NACK, Transmit NACK can also be written when LPI2C Slave is disabled or idle.<br><br>0b - Write a Transmit ACK for each received word<br>1b - Write a Transmit NACK for each received word |

## 55.3.4.28 Slave Transmit Data Register (STDR)

### 55.3.4.28.1 Offset

| Register | Offset |
|---|---|
| STDR | 160h |

### 55.3.4.28.2 Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The TXDSTALL bit will enable clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled (TXDSTALL=1)**, then the transmit data transfer is stalled until the Slave Transmit register (STDR) is updated. Clock stretching is extended by at least 1 bus clock cycle after the Slave Transmit Data Register (STDR) is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).
- **If clock stretching is disabled (TXDSTALL=0)**, then the transmit data should be written before the start of the slave-transmit transfer; otherwise (i.e., if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) will be set.

## 55.4 Functional description

## 55.4.1 Clocking and Resets

**Table 55-7. Clocks**

| | |
|---|---|
| LPI2C Functional clock | The LPI2C functional clock is asynchronous to the bus clock and can remain enabled in low power modes to support I2C bus transfers by the LPI2C master. The functional clock is also used by the LPI2C slave to support digital filter and data hold time configurations. The LPI2C master divides the functional clock by a prescaler and the resulting frequency must be at least 8 times faster than the I2C bus bandwidth. |
| External clock | The LPI2C slave logic is clocked directly from the external pins SCL and SDA (or SCLS and SDAS if master and slave are implemented on separate pins). This allows the LPI2C slave to remain operational, even when the LPI2C functional clock is disabled.<br>**NOTE:** The LPI2C slave digital filter must be disabled if the LPI2C functional clock is disabled, and this can affect compliance with some of the timing parameters of the I2C specification, such as the data hold time. |
| Bus clock | The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C master and slave registers. |

**Table 55-8. Resets**

| | |
|---|---|
| Chip reset | The logic and registers for the LPI2C master and slave are reset to their default state on a chip reset. |
| Software reset | • The LPI2C master implements a software reset bit in its Control Register. The MCR[RST] will reset all master logic and registers to their default state, except for the MCR itself.<br>• The LPI2C slave implements a software reset bit in its Control Register. The SCR[RST] will reset all slave logic and registers to their default state, except for the SCR itself. |
| FIFO reset | • The LPI2C master implements write-only control bits that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty.<br>• The LPI2C slave implements write-only control bits that reset the transmit data register (SCR[RTF] and receive data register (SCR[RRF]). After a data register is reset, that data register is empty. |

## 55.4.2 Master Mode

The LPI2C master logic operates independently from the slave logic to perform all master mode transfers on the I2C bus.

### 55.4.2.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate the various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- START or Repeated START condition with address byte and expecting ACK or NACK.
- Transmit data (this is the default for zero extended byte writes to the transmit FIFO).

- Receive 1-256 bytes of data (can also be configured to discard receive data and not store in receive FIFO).
- STOP condition (can also be configured to send STOP condition when transmit FIFO is empty).

Multiple transmit and receive commands can be inserted between the START condition and STOP conditon; transmit and receive commands must not be interleaved (to comply with the I2C specification). The receive data command and the receive data and discard commands can be interleaved, to ensure that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C master will automatically transmit a NACK on the last byte of a receive data command unless the next command in the FIFO is also a receive data command. A NACK is also automatically transmitted if the transmit FIFO is empty when a receive data command completes.

The LPI2C master supports 10-bit addressing through a (repeated) START condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the master-transmit data.

A START or Repeated START condition that is expecting a NACK (for example,HS-mode master code) must be followed by a STOP or (repeated) START condition.

### 55.4.2.2 Master operations

Whenever the LPI2C is enabled, it monitors the I2C bus to detect when the I2C bus is idle (MSR[BBF]). The I2C bus is no longer considered idle if either SCL or SDA are low, and the I2C bus becomes idle if a STOP condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the I2C bus is idle, the transmit FIFO is not empty, and the host request is either asserted or disabled, then the LPI2C master will initiate a transfer on the I2C bus. This involves the following steps:

- Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
- Transmit a START condition and address byte using the timing configuration in the Master Clock Configuration Register 0 (MCCR0); if a high speed mode transfer is configured, then the timing configuration from Master Clock Configuration Register 1 (MCCR1) is used instead.
- Perform master-transmit or master-receive transfers, as configured by the transmit FIFO.

- Transmit NACK on the last byte of a master-receive transfer, unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
- Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or MCFGR1[AUTOSTOP]. A repeated START can change which timing configuration register is used.

When the LPI2C master is disabled (either due to MCR[MEN] being clear or automatically due to mode entry), the LPI2C will continue to empty the transmit FIFO until a STOP condition is transmitted. However, the LPI2C will no longer stall the I2C bus waiting for the transmit or receive FIFO, and after the transmit FIFO is empty, the LPI2C will generate a STOP condition automatically.

The LPI2C master can stall the I2C bus under certain conditions; this will result in SCL pulled low continuously on the first bit of a byte, until the condition is removed:

- LPI2C master is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is clear.
- LPI2C master is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full.

#### 55.4.2.3 Receive FIFO and Data Matching

The receive FIFO is used to store receive data during master-receiver transfers. Receive data can also be configured to discard receive data instead of storing in the receive FIFO; this is configured by the command word in the transmit FIFO.

Receive data supports a receive data match function that can match received data against one of two bytes or against a masked data byte. The data match function can also be configured to compare only the first one or two received data words since the last (repeated) START condition. Receive data that is already discarded due to the command word cannot cause the data match to set, and will delay the match on the first received data word until after the discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the MCFGR0[RDMO] control bit. When clearing the MCFGR0[RDMO] control bit following a data match, clear MCFGR0[RDMO] before clearing MSR[DMF], to allow all subsequent data to be received.

### 55.4.2.4 Timing Parameters

The following timing parameters can be configured by the LPI2C master. Parameters are configured separately for high speed mode (MCCR1) and other modes (MCCR0). This allows the high speed mode master code to be sent using the regular timing parameters, and then switch to the high speed mode timing (following a repeated START) until the next STOP condition.

The LPI2C master timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

**Table 55-9. Timing Parameters**

| I2C Specification Timing Parameter | I2C Specification Timing Symbol | LPI2C Timing Parameter (LPI2C functional clock cycles) |
|---|---|---|
| hold time (repeated) START condition | tHD:STA | (SETHOLD +1) x (2 ^ PRESCALE) |
| LOW period of the SCL clock | tLOW | (CLKLO + 1) x (2 ^ PRESCALE) |
| HIGH period of the SCL clock | tHIGH | (CLKHI + 1 + SCL_LATENCY) x (2 ^ PRESCALE) |
| setup time for a repeated START condition or STOP condition | tSU:STA, tSU:STO | (SETHOLD + 1 + SCL_LATENCY) x (2 ^ PRESCALE) |
| data hold time | tHD:DAT | (DATAVD + 1) x (2 ^ PRESCALE) |
| data setup time | tSU:DAT | (SDA_LATENCY + 1) x (2 ^ PRESCALE) |
| bus free time between a STOP and START condition | tBUF | (CLKLO + 1 + SDA_LATENCY) x (2 ^ PRESCALE) |
| data valid time, data valid acknowledge time | tVD:DAT, tVD:ACK | (DATAVD + 1) x (2 ^ PRESCALE) |

The latency parameters are defined in the following table, these parameters assume the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I2C bus loading and external pull-up resistor sizing. A larger risetime will increase the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

**Table 55-10. Synchronization Latency**

| Timing Parameter | Timing Definition |
|---|---|
| SCL_LATENCY | ROUNDDOWN ( (2 + FILTSCL + SCL_RISETIME) / (2 ^ PRESCALE) ) |
| SDA_LATENCY | ROUNDDOWN ( (2 + FILTSDA + SDA_RISETIME) / (2 ^ PRESCALE) ) |

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus, or to avoid unexpected START or STOP conditions detected by the LPI2C master. The timing restrictions can be summarized as **SDA cannot change when SCL is high outside of a transmitted (repeated) START or STOP condition**.

**Table 55-11. LPI2C Timing Parameter Restrictions**

| Timing Parameter | Minimum | Maximum | Comment |
|---|---|---|---|
| CLKLO | 0x03 | - | Also: CLKLO x (2 ^ PRESCALE) > SCL_LATENCY |
| CLKHI | 0x01 | - | Configure CLKHI to meet the duty cycle requirements in the I2C specification |
| SETHOLD | 0x02 | - | |
| DATAVD | 0x01 | CLKLO - SDA_LATENCY - 1 | Configure DATAVD to meet the data hold requirement in the I2C specification |
| FILTSCL | 0x00 | [CLKLO × (2 ^ PRESCALE)] - 3 | FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE) |
| FILTSDA | FILTSCL | [CLKLO × (2 ^ PRESCALE)] - 3 | Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew |
| BUSIDLE | (CLKLO+SETHOLD+2) × 2 | - | Must also be greater than (CLKHI+1) |

The timing parameters must be configured to meet the requirements of the I2C specification; this will depend on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, Fast and HS-mode), the PRESCALE factor must remain constant between the modes. Some example timing configurations are provided below.

**Table 55-12. LPI2C Example Timing Configurations**

| I2C Mode | Clock Frequency | Baud Rate | PRESCALE | FILTSCL / FILTSDA | SETHOLD | CLKLO | CLKHI | DATAVD |
|---|---|---|---|---|---|---|---|---|
| Fast | 8 MHz | 400 kbps | 0x0 | 0x0/0x0 | 0x04 | 0x0B | 0x05 | 0x02 |
| Fast+ | 8 MHz | 1 Mbps | 0x0 | 0x0/0x0 | 0x02 | 0x03 | 0x01 | 0x01 |
| Fast | 48 MHz | 400 kbps | 0x0 | 0x1/0x1 | 0x1D | 0x3E | 0x35 | 0x0F |
| Fast | 48 MHz | 400 kbps | 0x2 | 0x1/0x1 | 0x07 | 0x11 | 0x0B | 0x03 |
| Fast+ | 48 MHz | 1 Mbps | 0x2 | 0x1/0x1 | 0x03 | 0x06 | 0x04 | 0x04 |
| HS-mode | 48 MHz | 3.2 Mbps | 0x0 | 0x0/0x0 | 0x07 | 0x08 | 0x03 | 0x01 |
| Fast | 60 MHz | 400 kbps | 0x1 | 0x2/0x2 | 0x11 | 0x28 | 0x1F | 0x08 |
| Fast+ | 60 MHz | 1 Mbps | 0x1 | 0x2/0x2 | 0x07 | 0x0F | 0x0B | 0x01 |
| HS-mode | 60 MHz | 3.33 Mbps | 0x1 | 0x0/0x0 | 0x04 | 0x04 | 0x02 | 0x01 |

### 55.4.2.5 Error Conditions

The LPI2C master will monitor for errors while it is active, the following conditions will generate an error flag and block a new START condition from being sent, until the flag is cleared by software:

- A START or STOP condition is detected and is not generated by the LPI2C master (sets MSR[ALF]).
- Transmitting data on SDA and different values are being received (sets MSR[ALF]).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- Transmit FIFO is requesting to transmit or receive data without a START condition (sets MSR[FEF]).
- SCL (or SDA if MCFGR1[TIMECFG] is set) is low for (MCFGR2[TIMELOW] * 256) prescaler cycles without a pin transition (sets MSR[PLTF]).

Software must respond to the MSR[PTLF] flag to terminate the existing command either cleanly (by clearing MCR[MEN]), or abruptly (by setting MCR[SWRST]).

The MCFGR2[BUSIDLE] field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The I2C bus is normally considered idle when the LPI2C master is first enabled, but when BUSIDLE is configured greater than zero then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is first considered idle.

### 55.4.2.6 Pin Configuration

- **Open-drain support:** The LPI2C master defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High Speed mode support:** Support for high speed mode also depends on the specific device, and requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-Fast mode support:** The LPI2C master also supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the IGNACK bit to be set.
- **Push-pull 2-wire support:** A push-pull 2-wire configuration is also available to the LPI2C master that may support a partial high speed mode, if the LPI2C is the only

master and all I2C pins on the bus are at the same voltage. This will configure the SCL pin as push-pull for every clock except the 9th clock pulse, to allow high speed mode compatible slaves to perform clock stretching. In this mode, the SDA pin is tristated for master-receive data bits and master-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.

- **Push-pull 4-wire support:** The push-pull 4-wire configuration separates the SCL input data and output data into separate pins, and separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this 4-wire configuration, the LPI2C master logic and LPI2C slave logic are not able to connect to separate I2C buses.

## 55.4.3 Slave Mode

To perform all slave mode transfers on the I2C bus, the LPI2C slave logic operates independently from the LPI2C master logic.

### 55.4.3.1 Address Matching

The LPI2C slave can be configured:

- to match one of two addresses, using either 7-bit or 10-bit addressing modes for each address
- to match a range of addresses in either 7-bit or 10-bit addressing modes
- to match the General Call Address, and generate appropriate flags
- to match the SMBus Alert Address, and generate appropriate flags
- to detect the high speed mode master code, and to disable the digital filters and output valid delay time until the next STOP condition is detected

After a valid address is matched, the LPI2C slave will automatically perform slave-transmit or slave-receive transfers until:

- a NACK is detected (unless IGNACK is set)
- a bit error is detected (the LPI2C slave is driving SDA, but a different value is sampled)
- a (repeated) START or STOP condition is detected

### 55.4.3.2 Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a slave-transmit and slave-receive transfer, respectively.
- The slave address *that was received* can be configured to be read from either the Receive Data register (for example, when using DMA to transfer data), or from the Address Status register.
- The Transmit Data register can be configured to only request data after a slave-transmit transfer is detected, or to request new data whenever the Transmit Data register is empty.
- The Transmit Data register should only be written when the Transmit Data flag is set.
- The Receive Data register should only be read when the Received Data flag is set (or the Address Valid flag is set and RXCFG=1).
- The Address Status register should only be read when the Address Valid flag is set.

### 55.4.3.3 Clock Stretching

The LPI2C slave supports many configurable options for when clock stretching is performed. The following conditions can be configured to perform clock stretching:

- During the 9th clock pulse of the address byte and the Address Valid flag is set.
- During the 9th clock pulse of a slave-transmit transfer and the Transmit Data flag is set.
- During the 9th clock pulse of a slave-receive transfer and the Receive Data flag is set.
- During the 8th clock pulse of an address byte or a slave-receive transfer and the Transmit ACK flag is set. In high speed mode, this is disabled.
- Clock stretching can also be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high speed mode, this is disabled.

Unless extended by the CLKHOLD configuration, clock stretching will extend for one peripheral bus clock cycle after SDA updates when clock stretching is enabled.

### 55.4.3.4 Timing Parameters

The LPI2C slave can configure the following timing parameters. These parameters are disabled when SCR[FILTEN] is clear, when SCR[FILTDZ] is set in Doze mode, and when LPI2C slave detects high speed mode. When disabled, the LPI2C slave is clocked directly from the I2C bus, and may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

The LPI2C slave imposes the following restrictions on the timing parameters.

- FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
- DATAVD must be configured less than the minimum SCL low period.

#### 55.4.3.5 Error Conditions

The LPI2C slave can detect the following error conditions:

- Bit error flag will set when the LPI2C slave is driving SDA, but samples a different value than what is expected.
- FIFO error flag will set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun occurring, enable clock stretching.
- FIFO error flag will also set due to an address overrun when RXCFG is set, otherwise an address overrun is not flagged. To eliminate the possibility of overrun occurring, enable clock stretching.

The LPI2C slave does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, then the LPI2C master logic should be used and so software can reset the LPI2C slave when this condition is detected.

### 55.4.4 Interrupts and DMA Requests

Depending on the specific device, interrupts and DMA requests can be combined in some ways:

- The LPI2C master and slave interrupts may be combined
- The LPI2C master and slave transmit DMA requests may be combined
- The LPI2C master and slave receive DMA requests may be combined

#### 55.4.4.1 Master mode

The next table lists the master mode sources that can generate LPI2C master interrupts and LPI2C master transmit/receive DMA requests.

**Table 55-13. Master Interrupts and DMA Requests**

| Master Status Register (MSR) | | Description | Can generate | | |
|---|---|---|---|---|---|
| Flag | Name | | Interrupt? | DMA Request? | Low Power Wakeup? |
| TDF | Transmit Data Flag | Data can be written to Transmit FIFO, as configured by the Transmit FIFO Watermark MFCR[TXWATER] | Y | TX | Y |
| RDF | Receive Data Flag | Data can be read from the Receive FIFO, as configured by the Receive FIFO Watermark MFCR[RXWATER] | Y | RX | Y |
| EPF | End Packet Flag | Master has transmitted a Repeated START or STOP condition | Y | N | Y |
| SDF | STOP Detect Flag | Master has transmitted a STOP condition | Y | N | Y |
| NDF | NACK Detect Flag | • During an address byte, the master expected an ACK but detected a NACK<br>• During an address byte, the master expected a NACK but detected an ACK<br>• During a master-transmitter data byte, the master detected a NACK | Y | N | Y |
| ALF | Arbitration Lost Flag | • The master lost arbitration due to a START/STOP condition detected at the wrong time<br>• Or the master was transmitting data but received different data than the data that was transmitted | Y | N | Y |
| FEF | FIFO Error Flag | The master is expecting a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition | Y | N | Y |
| PLTF | Pin Low Timeout Flag | Pin low timeout is enabled and SCL (or SDA if configured) is low for longer than the configured timeout | Y | N | Y |
| DMF | Data Match Flag | The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry | Y | N | Y |
| MBF | Master Busy Flag | LPI2C master is busy transmitting/receiving data | N | N | N |
| BBF | Bus Busy Flag | LPI2C master is enabled and activity is detected on I2C bus, but a STOP condition has not been detected and a bus idle timeout (if enabled) has not occurred. | N | N | N |

### 55.4.4.2 Slave mode

The next table lists the slave mode sources that can generate LPI2C slave interrupts and the LPI2C slave transmit/receive DMA requests.

## Table 55-14. Slave Interrupts and DMA Requests

| Slave Status Register (SSR) | | Description | Can generate | | |
|---|---|---|---|---|---|
| Flag | Name | | Interrupt? | DMA Request? | Low Power Wakeup? |
| TDF | Transmit Data Flag | Data can be written to the Slave Transmit Data Register (STDR) | Y | TX | Y |
| RDF | Receive Data Flag | Data can be read from the Slave Receive Data Register (SRDR) | Y | RX | Y |
| AVF | Address Valid Flag | Address can be read from the Slave Address Status Register (SASR) | Y | RX | Y |
| TAF | Transmit ACK Flag | ACK/NACK can be written to the Slave Transmit ACK Register (STAR) | Y | N | Y |
| RSF | Repeated Start Flag | Slave has detected an address match followed by a Repeated START condition | Y | N | Y |
| SDF | STOP Detect Flag | Slave has detected an address match followed by a STOP condition | Y | N | Y |
| BEF | Bit Error Flag | Slave was transmitting data, but received different data than what was transmitted | Y | N | Y |
| FEF | FIFO Error Flag | • Transmit data underrun<br>• Receive data overrun<br>• Address status overrun (when Receive Data Configuration SCFGR1[RXCFG] = 1, )<br><br>FEF flag can only set when clock stretching is disabled. | Y | N | Y |
| AM0F | Address Match 0 Flag | Slave detected an address match with SAMR[ADDR0] field | Y | N | N |
| AM1F | Address Match 1 Flag | Slave detected an address match with SAMR[ADDR1] field or using an address range | Y | N | N |
| GCF | General Call Flag | Slave detected an address match with the General Call address | Y | N | N |
| SARF | SMBus Alert Response Flag | Slave detected an address match with the SMBus Alert address | Y | N | N |
| SBF | Slave Busy Flag | LPI2C slave is busy receiving an address byte or is transmitting/receiving data | N | N | N |
| BBF | Bus Busy Flag | LPI2C slave is enabled and a START condition is detected on I2C bus, but a STOP condition has not been detected | N | N | N |

### 55.4.5 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

**Table 55-15. LPI2C Triggers**

| Trigger | Description |
|---|---|
| Master Output Trigger | The LPI2C master generates an output trigger that can be connected to other peripherals on the device. The master output trigger asserts on both a Repeated START or STOP condition, and the master output trigger remains asserted for one cycle of the LPI2C functional clock divided by the prescaler. |
| Slave Output Trigger | The LPI2C slave generates an output trigger that can be connected to other peripherals on the device. The slave output trigger asserts on both a Repeated START or STOP condition that occurs after a slave address match, and the slave output trigger remains asserted until the next slave SCL pin negation. |
| Input Trigger | To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized and to be detected, the input trigger must assert for at least 2 cycles of the LPI2C functional clock divided by the PRESCALE configuration. When the LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored. |

# Chapter 56
# Low Power Universal Asynchronous Receiver/ Transmitter (LPUART)

## 56.1 Chip-specific LPUART information

### 56.1.1 LPUART overview

The LPUART module supports basic UART with DMA interface function and x4 to x32 oversampling of baud-rate.

The module can remain functional in Stop and VLPS mode provided the clock it is using remains enabled.

This module supports LIN slave operation.

### 56.1.2 LPUART Instantiation

This device contains 4 LPUART modules. This section describes how each module is configured on this device.

**Table 56-1. LPUART instantiations**

| Feature | Receive Buffer Size |
|---|---|
| LPUARTs instantiated | 4 |
| LPUART0 FIFO (RX & TX) | 8 Byte |
| LPUART1 FIFO (RX & TX) | 8 Byte |
| LPUART2 FIFO (RX & TX) | 8 Byte |
| LPUART3 FIFO (RX & TX) | 8 Byte |

## 56.2 Introduction

### 56.2.1 Features

Features of the LPUART module include:

- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates (13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Transmit and receive baud rate can operate asynchronous to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency
  - Supports operation in Stop modes
- Interrupt, DMA or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Three receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit break character generation / 11-bit break character detection
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64 or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals

- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- Independent FIFO structure for transmit and receive
  - Separate configurable watermark for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

## 56.2.2 Modes of operation

### 56.2.2.1 Stop mode

The LPUART will remain functional during Stop mode, provided the CTRL[DOZEEN] bit is clear and the asynchronous transmit and receive clock remain enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from Stop mode.

If the LPUART is disabled in Stop mode, then it can generate a wakeup via the STAT[RXEDGIF] flag if the receiver detects an active edge.

### 56.2.2.2 Wait mode

The LPUART can be configured to Stop in Wait modes, when the CTRL[DOZEEN] bit is set. The transmitter and receiver will finish transmitting/receiving the current word.

### 56.2.2.3 Debug mode

The LPUART remains functional in debug mode.

## 56.2.3 Signal Descriptions

| Signal | Description | I/O |
|---|---|---|
| TXD | Transmit data. This pin is normally an output, but is an input (tristated) in single wire mode whenever the transmitter is disabled or transmit direction is configured for receive data. | I/O |
| RXD | Receive data. | I |
| CTS_B | Clear to send. | I |
| RTS_B | Request to send. | O |

## 56.2.4 Block diagram

The following figure shows the transmitter portion of the LPUART.

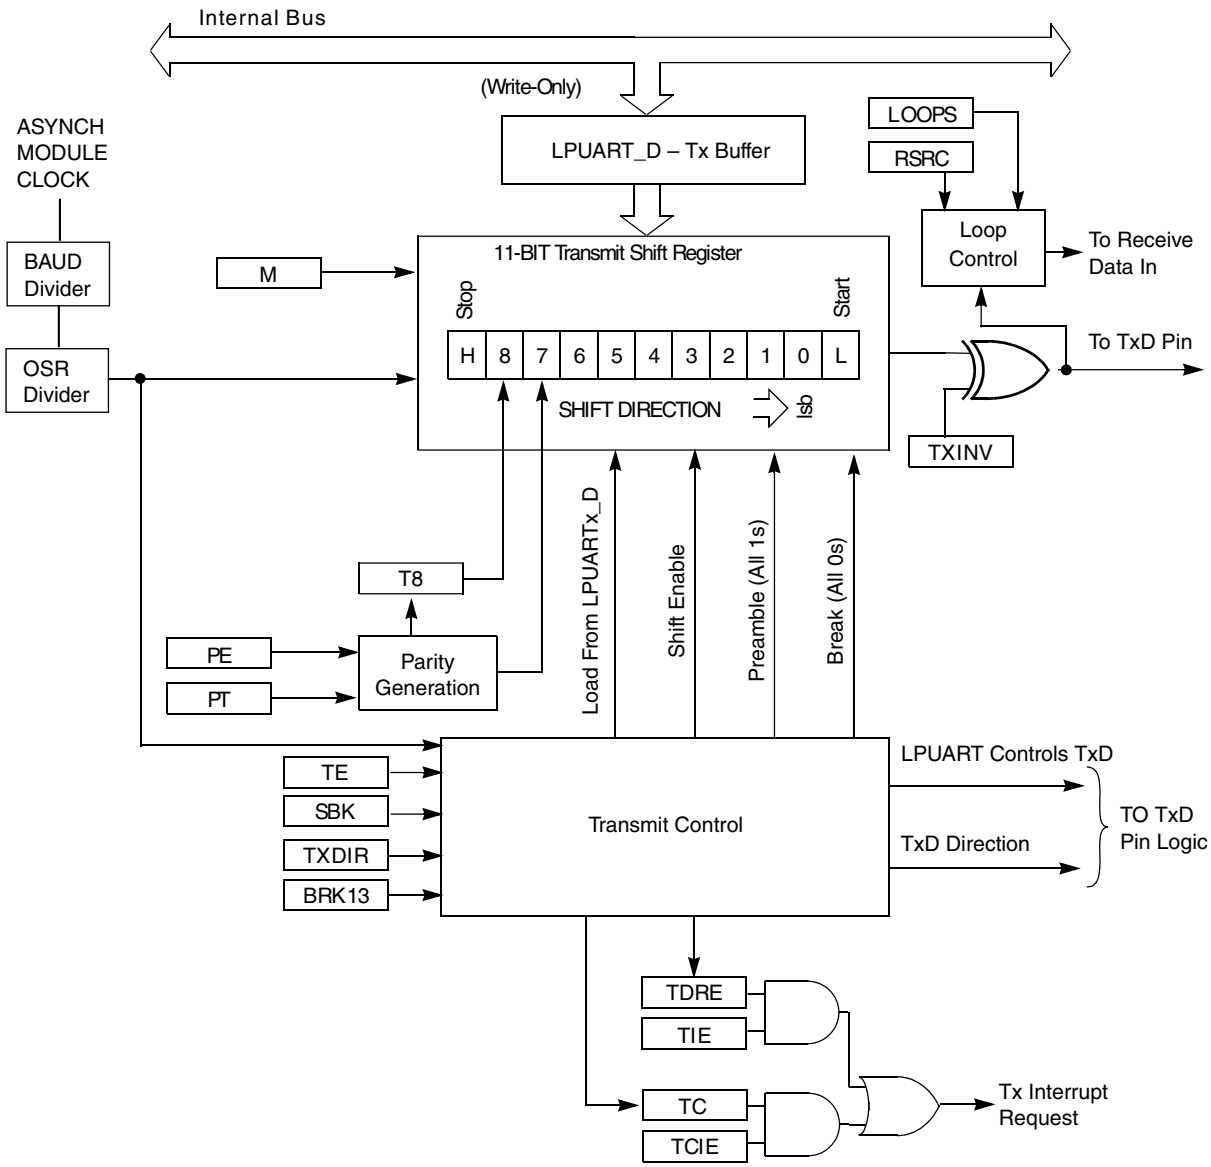

**Figure 56-1. LPUART transmitter block diagram**

The following figure shows the receiver portion of the LPUART.

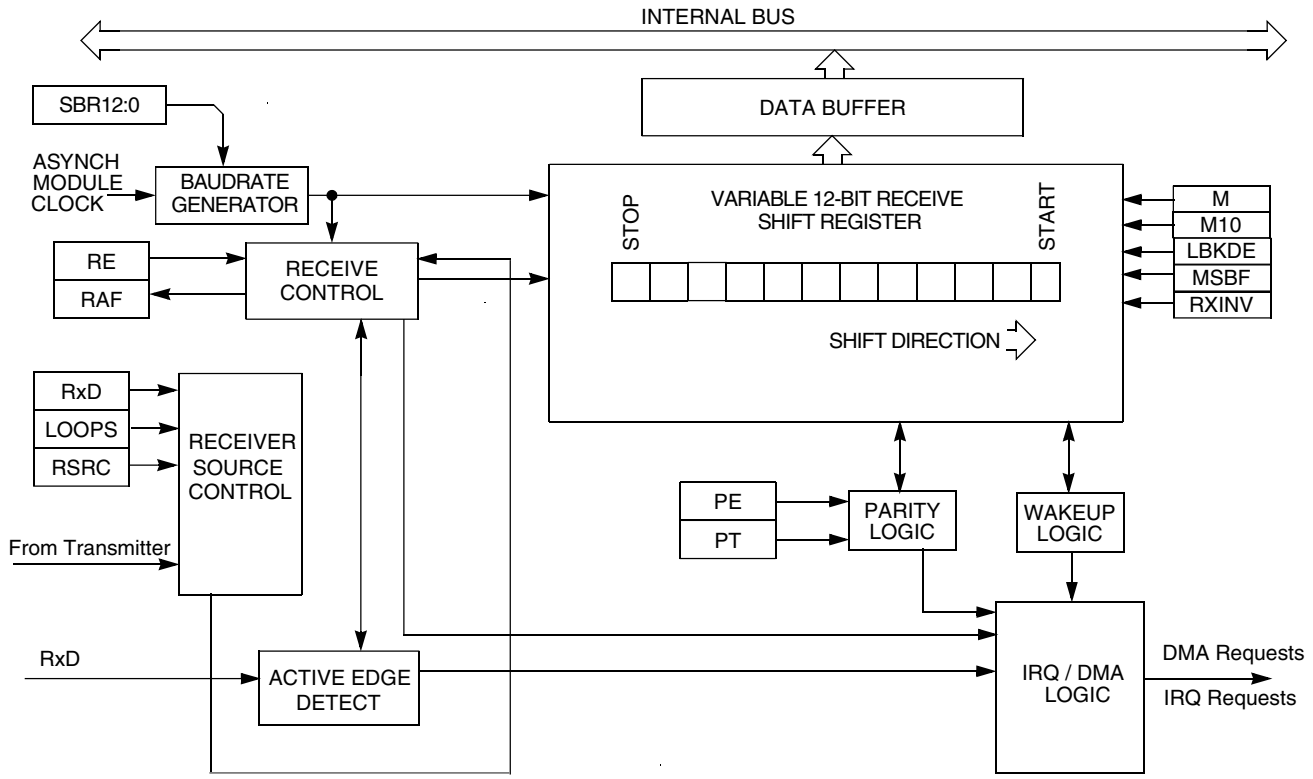

**Figure 56-2. LPUART receiver block diagram**

## 56.3 Register definition

The LPUART includes registers to control baud rate, select options, report status, and store transmit/receive data. Access to an address outside the valid memory map will generate a bus error.

### 56.3.1 LPUART0 register descriptions

#### 56.3.1.1 LPUART0 Memory map

LPUART0 base address: 4004_2000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID Register (VERID) | 32 | RO | 0401_0003h |

*Table continues on the next page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 4h | Parameter Register (PARAM) | 32 | RO | 0000_0303h |
| 8h | LPUART Global Register (GLOBAL) | 32 | RW | 0000_0000h |
| Ch | LPUART Pin Configuration Register (PINCFG) | 32 | RW | 0000_0000h |
| 10h | LPUART Baud Rate Register (BAUD) | 32 | RW | 0F00_0004h |
| 14h | LPUART Status Register (STAT) | 32 | RW | 00C0_0000h |
| 18h | LPUART Control Register (CTRL) | 32 | RW | 0000_0000h |

| 23<br>TDMAE | Transmitter DMA Enable<br>TDMAE configures the transmit data register empty flag, LPUART_STAT[TDRE], to generate a DMA request.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 22<br>— | Reserved |
| 21<br>RDMAE | Receiver Full DMA Enable<br>RDMAE configures the receiver data register full flag, LPUART_STAT[RDRF], to generate a DMA request.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 20<br>RIDMAE | Receiver Idle DMA Enable<br>RIDMAE configures the receiver idle flag, LPUART_STAT[IDLE], to generate a DMA request. When this bit is set, reading LPUART_DATA when either DATA[RXEMPT] or DATA[IDLINE] bit is set, will generate an End Of Packet response until the completion of the existing DMA transfer. During an End of Packet response, reading the LPUART_DATA register will return 0x0000_33FF and does not pull data from the FIFO.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 19-18<br>MATCFG | Match Configuration<br>Configures the match addressing mode used. This field should only be changed when the transmitter and receiver are both disabled.<br>00b - Address Match Wakeup<br>01b - Idle Match Wakeup<br>10b - Match On and Match Off<br>11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input |
| 17 | Both Edge Sampling |

*Table continues on the next page...*

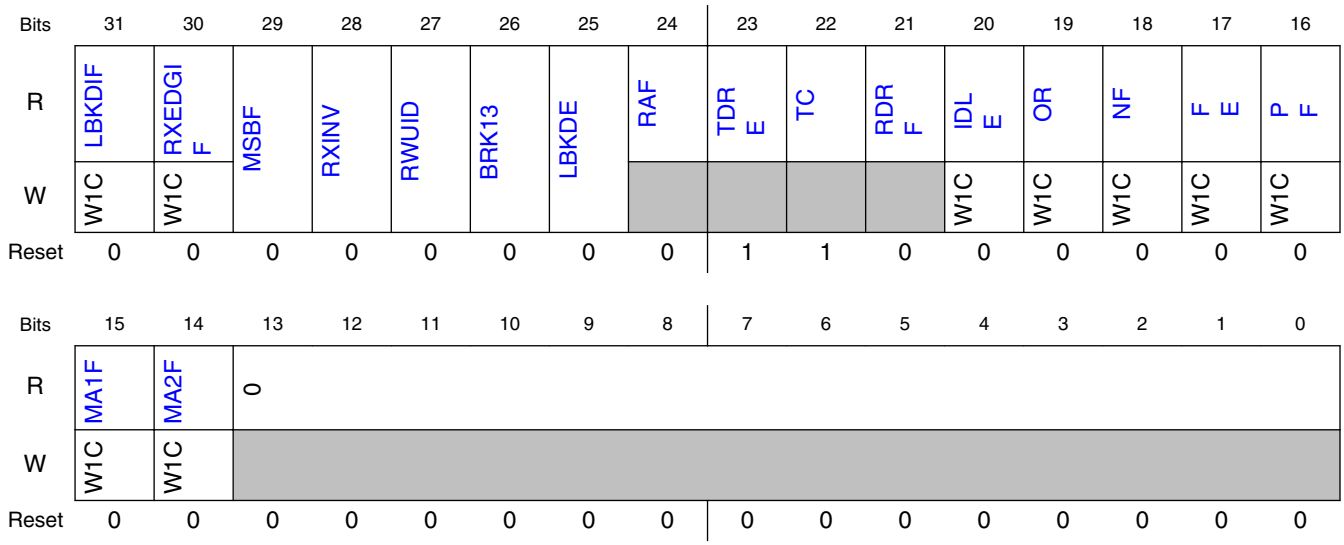
| Field | Function |
|---|---|
| BOTHEDGE | Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should only be changed when the receiver is disabled.<br>0b - Receiver samples input data using the rising edge of the baud rate clock.<br>1b - Receiver samples input data using the rising and falling edge of the baud rate clock. |
| 16<br>RESYNCDIS | Resynchronization Disable<br>When set, disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should only be changed when the receiver is disabled.<br>0b - Resynchronization during received data word is supported<br>1b - Resynchronization during received data word is disabled |
| 15<br>LBKDIE | LIN Break Detect Interrupt Enable<br>LBKDIE enables the LIN break detect flag, LBKDIF, to generate interrupt requests.<br>0b - Hardware interrupts from LPUART_STAT[LBKDIF] disabled (use polling).<br>1b - Hardware interrupt requested when LPUART_STAT[LBKDIF] flag is 1. |
| 14<br>RXEDGIE | RX Input Active Edge Interrupt Enable<br>Enables the receive input active edge, RXEDGIF, to generate interrupt requests. Changing CTRL[LOOP] or CTRL[RSRC] when RXEDGIE is set can cause the RXEDGIF to set.<br>0b - Hardware interrupts from LPUART_STAT[RXEDGIF] disabled.<br>1b - Hardware interrupt requested when LPUART_STAT[RXEDGIF] flag is 1. |
| 13<br>SBNS | Stop Bit Number Select<br>SBNS determines whether data characters are one or two stop bits. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - One stop bit.<br>1b - Two stop bits. |
| 12-0<br>SBR | Baud Rate Modulo Divisor.<br>The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) × SBR)". The 13-bit baud rate setting [SBR12:SBR0] must only be updated when the transmitter and receiver are both disabled (LPUART_CTRL[RE] and LPUART_CTRL[TE] are both 0). |

## 56.3.1.7 LPUART Status Register (STAT)

### 56.3.1.7.1 Offset

| Register | Offset |
|---|---|
| STAT | 14h |

### 56.3.1.7.2 Diagram



### 56.3.1.7.3 Fields

| Field | Function |
|---|---|
| 31<br>LBKDIF | LIN Break Detect Interrupt Flag<br>LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it.<br>0b - No LIN break character has been detected.<br>1b - LIN break character has been detected. |
| 30<br>RXEDGIF | RXD Pin Active Edge Interrupt Flag<br>RXEDGIF is set whenever the receiver is enabled and an active edge, falling if RXINV = 0, rising if RXINV=1, on the RXD pin occurs. RXEDGIF is cleared by writing a 1 to it.<br>0b - No active edge on the receive pin has occurred.<br>1b - An active edge on the receive pin has occurred. |
| 29<br>MSBF | MSB First<br>Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit or the location of the start or stop bits. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0.<br>1b - MSB (bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. Further, the first bit received after the start bit is identified as bit9, bit8, bit7 or bit6 depending on the setting of CTRL[M] and CTRL[PE]. |
| 28<br>RXINV | Receive Data Inversion<br>Setting this bit reverses the polarity of the received data input. This bit should only be changed when the receiver is disabled.<br>**NOTE:** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle.<br>0b - Receive data not inverted.<br>1b - Receive data inverted. |
| 27 | Receive Wake Up Idle Detect |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RWUID | For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should only be changed when the receiver is disabled.<br>0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match.<br>1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match. |
| 26<br>BRK13 | Break Character Generation Length<br>BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit. This bit should only be changed when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.<br>0b - Break character is transmitted with length of 9 to 13 bit times.<br>1b - Break character is transmitted with length of 12 to 15 bit times. |
| 25<br>LBKDE | LIN Break Detection Enable<br>LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive data buffer.<br>0b - LIN break detect is disabled, normal break character can be detected.<br>1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1). |
| 24<br>RAF | Receiver Active Flag<br>RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line.<br>0b - LPUART receiver idle waiting for a start bit.<br>1b - LPUART receiver active (RXD input not idle). |
| 23<br>TDRE | Transmit Data Register Empty Flag<br>When the transmit FIFO is enabled, TDRE will set when the number of datawords in the transmit FIFO (LPUART_DATA) is equal to or less than the number indicated by LPUART_WATER[TXWATER]). To clear TDRE, write to the LPUART data register (LPUART_DATA) until the number of words in the transmit FIFO is greater than the number indicated by LPUART_WATER[TXWATER]. When the transmit FIFO is disabled,TDRE will set when the transmit data register (LPUART_DATA) is empty. To clear TDRE, write to the LPUART data register (LPUART_DATA).<br>TDRE is not affected by a character that is in the process of being transmitted, it is updated at the start of each transmitted character.<br>0b - Transmit data buffer full.<br>1b - Transmit data buffer empty. |
| 22<br>TC | Transmission Complete Flag<br>TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to LPUART_DATA to transmit new data, queuing a preamble by clearing and then setting LPUART_CTRL[TE], queuing a break character by writing 1 to LPUART_CTRL[SBK].<br>0b - Transmitter active (sending data, a preamble, or a break).<br>1b - Transmitter idle (transmission activity complete). |
| 21<br>RDRF | Receive Data Register Full Flag<br>When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by LPUART_WATER[RXWATER]. To clear RDRF, read LPUART_DATA until the number of datawords in the receive data buffer is equal to or less than the number indicated by LPUART_WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (LPUART_DATA) is full. To clear RDRF, read the LPUART_DATA register. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character will continue to be received until an overrun condition occurs once the entire character is received.<br>0b - Receive data buffer empty.<br>1b - Receive data buffer full. |
| 20<br>IDLE | Idle Line Flag<br>IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When ILT is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When ILT is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.<br>To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot become set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period.<br>0b - No idle line detected.<br>1b - Idle line was detected. |
| 19<br>OR | Receiver Overrun Flag<br>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received.<br>While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag.<br>0b - No overrun.<br>1b - Receive overrun (new LPUART data lost). |
| 18<br>NF | Noise Flag<br>The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from LPUART_DATA was received with noise detected within the character. To clear NF, write logic one to the NF.<br>0b - No noise detected.<br>1b - Noise detected in the received character in LPUART_DATA. |
| 17<br>FE | Framing Error Flag<br>FE is set whenever the next character to be read from LPUART_DATA was received with logic 0 detected where a stop bit was expected. To clear FE, write logic one to the FE.<br>0b - No framing error detected. This does not guarantee the framing is correct.<br>1b - Framing error. |
| 16<br>PF | Parity Error Flag<br>PF is set whenever the next character to be read from LPUART_DATA was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic one to the PF.<br>0b - No parity error.<br>1b - Parity error. |
| 15<br>MA1F | Match 1 Flag |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | MA1F is set whenever the next character to be read from LPUART_DATA matches MA1. To clear MA1F, write a logic one to the MA1F.<br>0b - Received data is not equal to MA1<br>1b - Received data is equal to MA1 |
| 14<br>MA2F | Match 2 Flag<br>MA2F is set whenever the next character to be read from LPUART_DATA matches MA2. To clear MA2F, write a logic one to the MA2F.<br>0b - Received data is not equal to MA2<br>1b - Received data is equal to MA2 |
| 13-0<br>— | Reserved |

### 56.3.1.8.4 Fields

| Field | Function |
|---|---|
| 31<br>R8T9 | Receive Bit 8 / Transmit Bit 9<br>R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading LPUART_DATA.<br>T9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing LPUART_DATA. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.<br>**NOTE:** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written. |
| 30<br>R9T8 | Receive Bit 9 / Transmit Bit 8<br>R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading LPUART_DATA<br>T8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing LPUART_DATA. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.<br>**NOTE:** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written. |
| 29<br>TXDIR | TXD Pin Direction in Single-Wire Mode<br>When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter will finish receiving the current character (if any) before the receiver starts receiving data from the TXD pin.<br>0b - TXD pin is an input in single-wire mode.<br>1b - TXD pin is an output in single-wire mode. |
| 28<br>TXINV | Transmit Data Inversion<br>Setting this bit reverses the polarity of the transmitted data output.<br>**NOTE:** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle.<br>0b - Transmit data not inverted.<br>1b - Transmit data inverted. |
| 27<br>ORIE | Overrun Interrupt Enable<br>This bit enables the overrun flag (OR) to generate hardware interrupt requests.<br>0b - OR interrupts disabled; use polling.<br>1b - Hardware interrupt requested when OR is set. |
| 26<br>NEIE | Noise Error Interrupt Enable<br>This bit enables the noise flag (NF) to generate hardware interrupt requests.<br>0b - NF interrupts disabled; use polling.<br>1b - Hardware interrupt requested when NF is set. |
| 25<br>FEIE | Framing Error Interrupt Enable<br>This bit enables the framing error flag (FE) to generate hardware interrupt requests.<br>0b - FE interrupts disabled; use polling.<br>1b - Hardware interrupt requested when FE is set. |
| 24<br>PEIE | Parity Error Interrupt Enable<br>This bit enables the parity error flag (PF) to generate hardware interrupt requests.<br>0b - PF interrupts disabled; use polling).<br>1b - Hardware interrupt requested when PF is set. |
| 23 | Transmit Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TIE | Enables STAT[TDRE] to generate interrupt requests.<br>0b - Hardware interrupts from TDRE disabled; use polling.<br>1b - Hardware interrupt requested when TDRE flag is 1. |
| 22<br>TCIE | Transmission Complete Interrupt Enable for<br>TCIE enables the transmission complete flag, TC, to generate interrupt requests.<br>0b - Hardware interrupts from TC disabled; use polling.<br>1b - Hardware interrupt requested when TC flag is 1. |
| 21<br>RIE | Receiver Interrupt Enable<br>Enables STAT[RDRF] to generate interrupt requests.<br>0b - Hardware interrupts from RDRF disabled; use polling.<br>1b - Hardware interrupt requested when RDRF flag is 1. |
| 20<br>ILIE | Idle Line Interrupt Enable<br>ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests.<br>0b - Hardware interrupts from IDLE disabled; use polling.<br>1b - Hardware interrupt requested when IDLE flag is 1. |
| 19<br>TE | Transmitter Enable<br>Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit will read as 1 until the transmitter has completed the current character and the TXD pin is tristated.<br>A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set.<br>0b - Transmitter disabled.<br>1b - Transmitter enabled. |
| 18<br>RE | Receiver Enable<br>Enables the LPUART receiver. When RE is written to 0, this register bit will read as 1 until the receiver finishes receiving the current character (if any).<br>0b - Receiver disabled.<br>1b - Receiver enabled. |
| 17<br>RWU | Receiver Wakeup Control<br>This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear.<br>**NOTE:** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted.<br>0b - Normal receiver operation.<br>1b - LPUART receiver in standby waiting for wakeup condition. |
| 16<br>SBK | Send Break<br>Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if LPUART_STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK.<br>A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.<br>0b - Normal transmitter operation.<br>1b - Queue break character(s) to be sent. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 15<br>MA1IE | Match 1 Interrupt Enable<br>0b - MA1F interrupt disabled<br>1b - MA1F interrupt enabled |
| 14<br>MA2IE | Match 2 Interrupt Enable<br>0b - MA2F interrupt disabled<br>1b - MA2F interrupt enabled |
| 13-12<br>— | Reserved |
| 11<br>M7 | 7-Bit Mode Select<br>This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - Receiver and transmitter use 8-bit to 10-bit data characters.<br>1b - Receiver and transmitter use 7-bit data characters. |
| 10-8<br>IDLECFG | Idle Configuration<br>Configures the number of idle characters that must be received before the IDLE flag is set.<br>000b - 1 idle character<br>001b - 2 idle characters<br>010b - 4 idle characters<br>011b - 8 idle characters<br>100b - 16 idle characters<br>101b - 32 idle characters<br>110b - 64 idle characters<br>111b - 128 idle characters |
| 7<br>LOOPS | Loop Mode Select<br>When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.<br>0b - Normal operation - RXD and TXD use separate pins.<br>1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit). |
| 6<br>DOZEEN | Doze Enable<br>0b - LPUART is enabled in Doze mode.<br>1b - LPUART is disabled in Doze mode. |
| 5<br>RSRC | Receiver Source Select<br>This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.<br>0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin.<br>1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input. |
| 4<br>M | 9-Bit or 8-Bit Mode Select<br>0b - Receiver and transmitter use 8-bit data characters.<br>1b - Receiver and transmitter use 9-bit data characters. |
| 3<br>WAKE | Receiver Wakeup Method Select<br>Determines which condition wakes the LPUART when RWU=1:<br>• Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character, or<br>• An idle condition on the receive pin input signal.<br><br>0b - Configures RWU for idle-line wakeup.<br>1b - Configures RWU with address-mark wakeup. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 2<br>ILT | Idle Line Type Select<br>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.<br>**NOTE:** In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count.<br>0b - Idle character bit count starts after start bit.<br>1b - Idle character bit count starts after stop bit. |
| 1<br>PE | Parity Enable<br>Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit.<br>0b - No hardware parity generation or checking.<br>1b - Parity enabled. |
| 0<br>PT | Parity Type<br>Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even.<br>0b - Even parity.<br>1b - Odd parity. |

## 56.3.1.9 LPUART Data Register (DATA)

### 56.3.1.9.1 Offset

| Register | Offset |
|---|---|
| DATA | 1Ch |

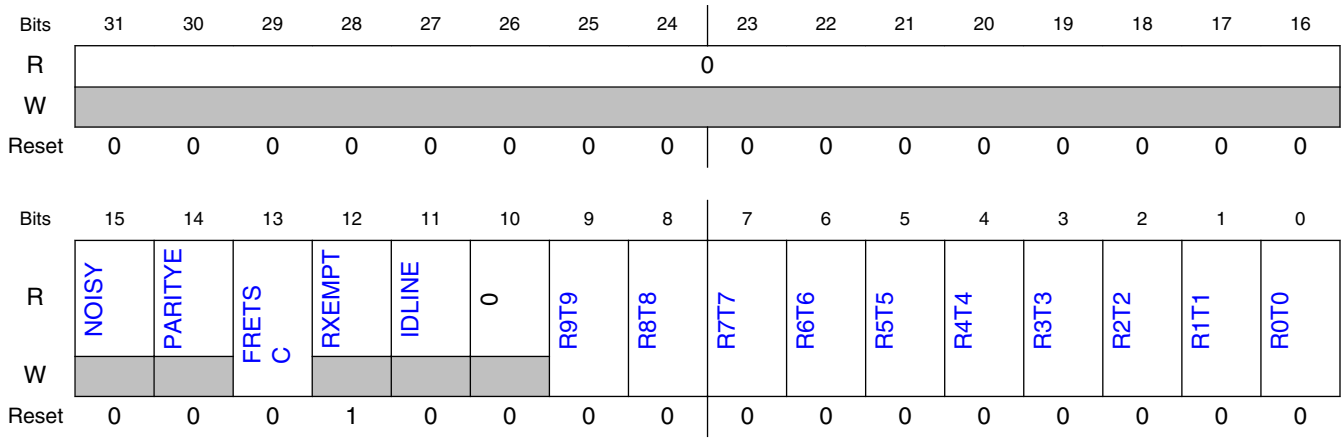
### 56.3.1.9.2 Function

**NOTE**

This register is two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags.

### 56.3.1.9.3 Diagram



### 56.3.1.9.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15<br>NOISY | NOISY<br>The current received dataword contained in DATA[R9:R0] was received with noise.<br>0b - The dataword was received without noise.<br>1b - The data was received with noise. |
| 14<br>PARITYE | PARITYE<br>The current received dataword contained in DATA[R9:R0] was received with a parity error.<br>0b - The dataword was received without a parity error.<br>1b - The dataword was received with a parity error. |
| 13<br>FRETSC | Frame Error / Transmit Special Character<br>For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, he contents of DATA[T8:T0] should be zero.<br>0b - The dataword was received without a frame error on read, or transmit a normal character on write.<br>1b - The dataword was received with a frame error, or transmit an idle or break character on transmit. |
| 12<br>RXEMPT | Receive Buffer Empty<br>Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register.<br>0b - Receive buffer contains valid data.<br>1b - Receive buffer is empty, data returned on read is not valid. |
| 11<br>IDLINE | Idle Line<br>Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled.<br>0b - Receiver was not idle before receiving this character.<br>1b - Receiver was idle before receiving this character. |

*Table continues on the next page...*

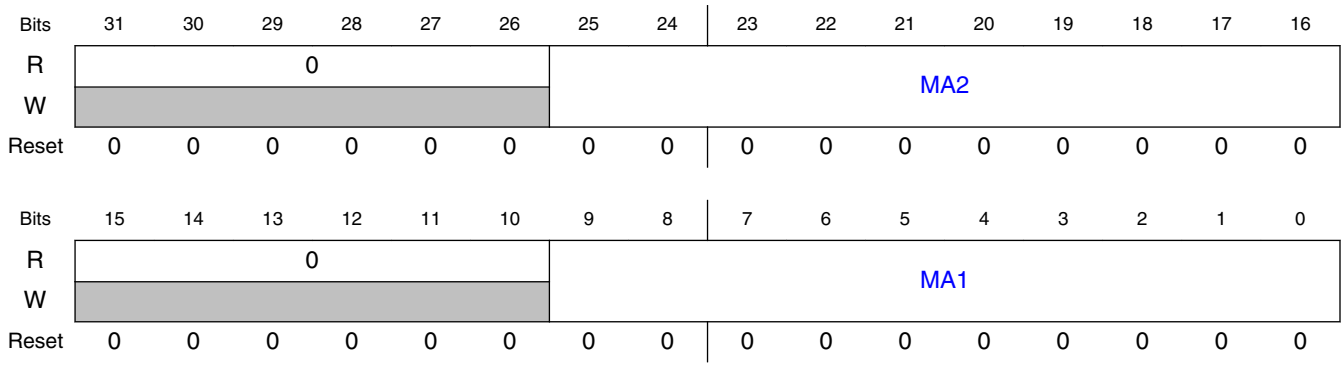
| 0<br>R0T0 | R0T0<br>Read receive data buffer 0 or write transmit data buffer 0. |

## 56.3.1.10 LPUART Match Address Register (MATCH)

### 56.3.1.10.1 Offset

| Register | Offset |
|---|---|
| MATCH | 20h |

### 56.3.1.10.2 Diagram



### 56.3.1.10.3 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-16<br>MA2 | Match Address 2<br>The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. Software should only write a MA register when the associated BAUD[MAEN] bit is clear. |
| 15-10<br>— | Reserved |
| 9-0<br>MA1 | Match Address 1<br>The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. Software should only write a MA register when the associated BAUD[MAEN] bit is clear. |

## 56.3.1.11 LPUART Modem IrDA Register (MODIR)

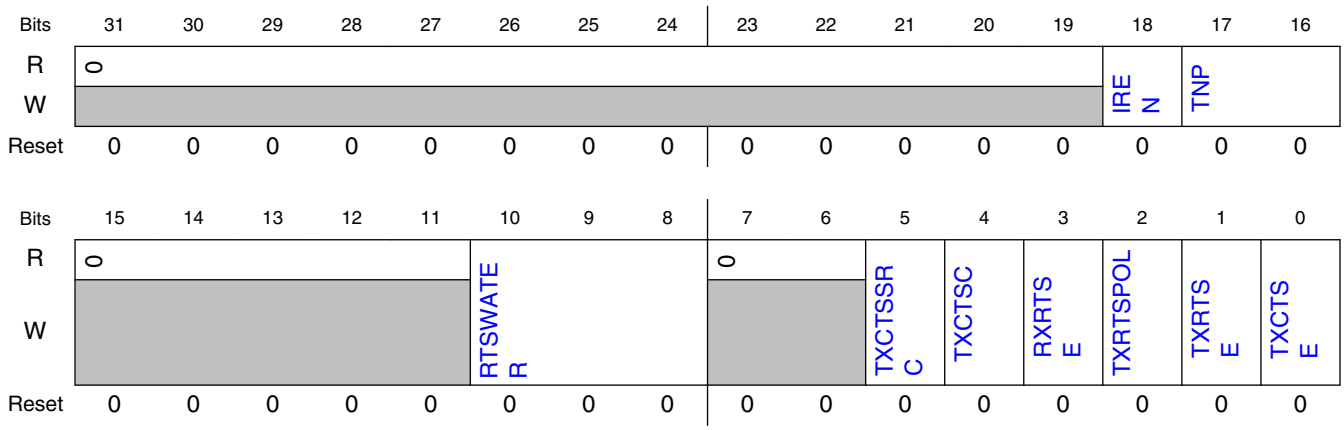
### 56.3.1.11.1 Offset

| Register | Offset |
|---|---|
| MODIR | 24h |

### 56.3.1.11.2 Function

The MODEM register controls options for setting the modem configuration.

### 56.3.1.11.3 Diagram



### 56.3.1.11.4 Fields

| Field | Function |
|---|---|
| 31-19<br>— | Reserved |
| 18<br>IREN | Infrared enable<br>Enables/disables the infrared modulation/demodulation. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - IR disabled.<br>1b - IR enabled. |
| 17-16<br>TNP | Transmitter narrow pulse<br>Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should only be changed when the transmitter and receiver are both disabled.<br>The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width.<br>00b - 1/OSR.<br>01b - 2/OSR.<br>10b - 3/OSR.<br>11b - 4/OSR. |
| 15-11<br>— | Reserved |
| 10-8<br>RTSWATER | Receive RTS Configuration<br>Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This field should only be changed when the receiver is disabled. |
| 7-6<br>— | Reserved |
| 5<br>TXCTSSRC | Transmit CTS Source<br>Configures the source of the CTS input.<br>0b - CTS input is the CTS_B pin.<br>1b - CTS input is the inverted Receiver Match result. |
| 4<br>TXCTSC | Transmit CTS Configuration<br>Configures if the CTS state is checked at the start of each character or only when the transmitter is idle.<br>0b - CTS input is sampled at the start of each character.<br>1b - CTS input is sampled when the transmitter is idle. |
| 3<br>RXRTSE | Receiver request-to-send enable<br>Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should only be changed when the receiver is disabled.<br>**NOTE:** Do not set both RXRTSE and TXRTSE.<br>0b - The receiver has no effect on RTS.<br>1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full. |
| 2<br>TXRTSPOL | Transmitter request-to-send polarity<br>Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. This bit should only be changed when the transmitter is disabled.<br>0b - Transmitter RTS is active low.<br>1b - Transmitter RTS is active high. |
| 1<br>TXRTSE | Transmitter request-to-send enable<br>Controls RTS before and after a transmission. This bit should only be changed when the transmitter is disabled.<br>0b - The transmitter has no effect on RTS.<br>1b - When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. |
| 0<br>TXCTSE | Transmitter clear-to-send enable<br>TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.<br>0b - CTS has no effect on the transmitter.<br>1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission. |

## 56.3.1.12 LPUART FIFO Register (FIFO)

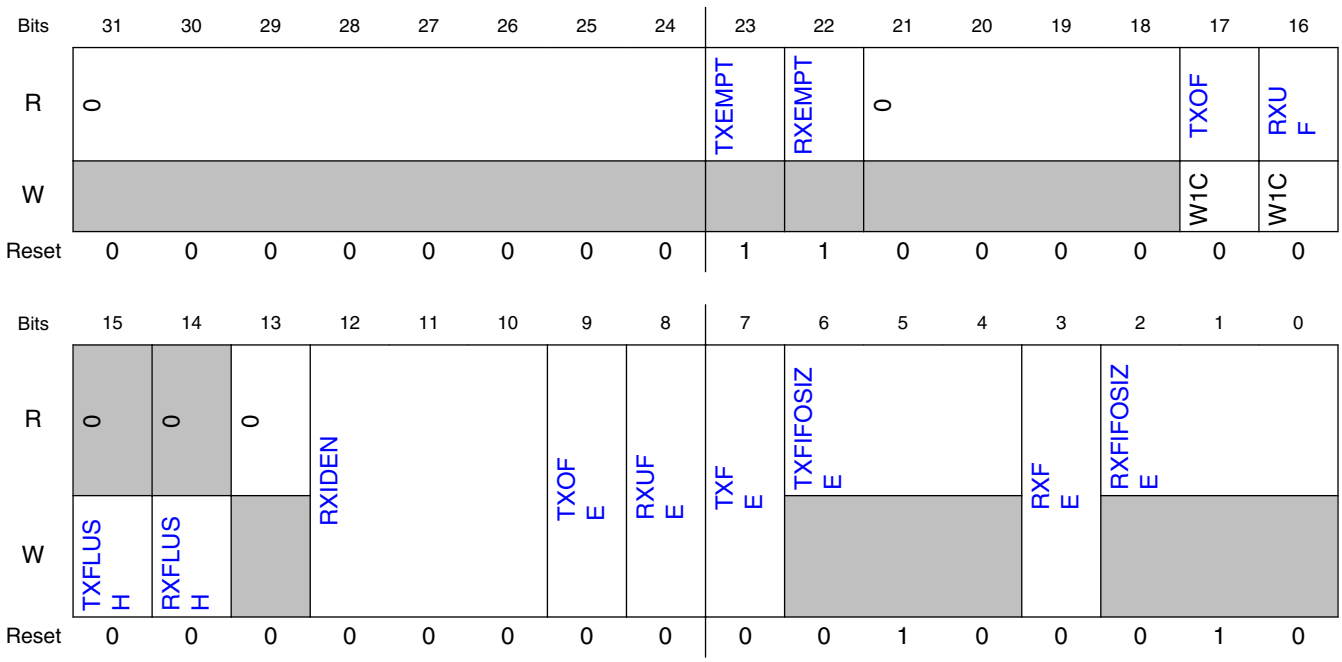
### 56.3.1.12.1 Offset

| Register | Offset |
|---|---|
| FIFO | 28h |

### 56.3.1.12.2 Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the data buffer/FIFO is empty.

### 56.3.1.12.3 Diagram



### 56.3.1.12.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23<br>TXEMPT | Transmit Buffer/FIFO Empty<br>Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register.<br>0b - Transmit buffer is not empty. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - Transmit buffer is empty. |
| 22<br>RXEMPT | Receive Buffer/FIFO Empty<br>Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register.<br>0b - Receive buffer is not empty.<br>1b - Receive buffer is empty. |
| 21-18<br>— | Reserved |
| 17<br>TXOF | Transmitter Buffer Overflow Flag<br>Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of TXOFE. However, an interrupt will be issued to the host only if TXOFE is set. This flag is cleared by writing a 1.<br>0b - No transmit buffer overflow has occurred since the last time the flag was cleared.<br>1b - At least one transmit buffer overflow has occurred since the last time the flag was cleared. |
| 16<br>RXUF | Receiver Buffer Underflow Flag<br>Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of RXUFE. However, an interrupt will be issued to the host only if RXUFE is set. This flag is cleared by writing a 1.<br>0b - No receive buffer underflow has occurred since the last time the flag was cleared.<br>1b - At least one receive buffer underflow has occurred since the last time the flag was cleared. |
| 15<br>TXFLUSH | Transmit FIFO/Buffer Flush<br>Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register.<br>0b - No flush operation occurs.<br>1b - All data in the transmit FIFO/Buffer is cleared out. |
| 14<br>RXFLUSH | Receive FIFO/Buffer Flush<br>Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register.<br>0b - No flush operation occurs.<br>1b - All data in the receive FIFO/buffer is cleared out. |
| 13<br>— | Reserved |
| 12-10<br>RXIDEN | Receiver Idle Empty Enable<br>When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty.<br>000b - Disable RDRF assertion due to partially filled FIFO when receiver is idle.<br>001b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character.<br>010b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters.<br>011b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters.<br>100b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters.<br>101b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters.<br>110b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters.<br>111b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters. |
| 9<br>TXOFE | Transmit FIFO Overflow Interrupt Enable<br>When this field is set, the TXOF flag generates an interrupt to the host.<br>0b - TXOF flag does not generate an interrupt to the host.<br>1b - TXOF flag generates an interrupt to the host. |
| 8 | Receive FIFO Underflow Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RXUFE | When this field is set, the RXUF flag generates an interrupt to the host.<br>0b - RXUF flag does not generate an interrupt to the host.<br>1b - RXUF flag generates an interrupt to the host. |
| 7<br>TXFE | Transmit FIFO Enable<br>When this field is set, the built in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field.<br>0b - Transmit FIFO is not enabled. Buffer is depth 1. (Legacy support).<br>1b - Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE. |
| 6-4<br>TXFIFOSIZE | Transmit FIFO. Buffer Depth<br>The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only.<br>000b - Transmit FIFO/Buffer depth = 1 dataword.<br>001b - Transmit FIFO/Buffer depth = 4 datawords.<br>010b - Transmit FIFO/Buffer depth = 8 datawords.<br>011b - Transmit FIFO/Buffer depth = 16 datawords.<br>100b - Transmit FIFO/Buffer depth = 32 datawords.<br>101b - Transmit FIFO/Buffer depth = 64 datawords.<br>110b - Transmit FIFO/Buffer depth = 128 datawords.<br>111b - Transmit FIFO/Buffer depth = 256 datawords |
| 3<br>RXFE | Receive FIFO Enable<br>When this field is set, the built in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field.<br>0b - Receive FIFO is not enabled. Buffer is depth 1. (Legacy support)<br>1b - Receive FIFO is enabled. Buffer is depth indicted by RXFIFOSIZE. |
| 2-0<br>RXFIFOSIZE | Receive FIFO. Buffer Depth<br>The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only.<br>000b - Receive FIFO/Buffer depth = 1 dataword.<br>001b - Receive FIFO/Buffer depth = 4 datawords.<br>010b - Receive FIFO/Buffer depth = 8 datawords.<br>011b - Receive FIFO/Buffer depth = 16 datawords.<br>100b - Receive FIFO/Buffer depth = 32 datawords.<br>101b - Receive FIFO/Buffer depth = 64 datawords.<br>110b - Receive FIFO/Buffer depth = 128 datawords.<br>111b - Receive FIFO/Buffer depth = 256 datawords. |

## 56.3.1.13 LPUART Watermark Register (WATER)

### 56.3.1.13.1 Offset

| Register | Offset |
|---|---|
| WATER | 2Ch |

### 56.3.1.13.2 Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

### 56.3.1.13.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 31<br>MAEN1 | Match Address Mode Enable 1<br>0b - Normal operation.<br>1b - Enables automatic address matching or data matching mode for MATCH[MA1]. |
| 30<br>MAEN2 | Match Address Mode Enable 2<br>0b - Normal operation.<br>1b - Enables automatic address matching or data matching mode for MATCH[MA2]. |
| 29<br>M10 | 10-bit Mode select<br>The M10 bit causes a tenth bit to be part of the serial transmission. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - Receiver and transmitter use 7-bit to 9-bit data characters.<br>1b - Receiver and transmitter use 10-bit data characters. |
| 28-24<br>OSR | Oversampling Ratio<br>This field configures the oversampling ratio for the receiver. This field should only be changed when the transmitter and receiver are both disabled.<br>00000b - Writing 0 to this field will result in an oversampling ratio of 16<br>00001b - Reserved<br>00010b - Reserved<br>00011b - Oversampling ratio of 4, requires BOTHEDGE to be set.<br>00100b - Oversampling ratio of 5, requires BOTHEDGE to be set.<br>00101b - Oversampling ratio of 6, requires BOTHEDGE to be set.<br>00110b - Oversampling ratio of 7, requires BOTHEDGE to be set.<br>00111b - Oversampling ratio of 8.<br>01000b - Oversampling ratio of 9.<br>01001b - Oversampling ratio of 10.<br>01010b - Oversampling ratio of 11.<br>01011b - Oversampling ratio of 12.<br>01100b - Oversampling ratio of 13.<br>01101b - Oversampling ratio of 14.<br>01110b - Oversampling ratio of 15.<br>01111b - Oversampling ratio of 16.<br>10000b - Oversampling ratio of 17. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 10001b - Oversampling ratio of 18.<br>10010b - Oversampling ratio of 19.<br>10011b - Oversampling ratio of 20.<br>10100b - Oversampling ratio of 21.<br>10101b - Oversampling ratio of 22.<br>10110b - Oversampling ratio of 23.<br>10111b - Oversampling ratio of 24.<br>11000b - Oversampling ratio of 25.<br>11001b - Oversampling ratio of 26.<br>11010b - Oversampling ratio of 27.<br>11011b - Oversampling ratio of 28.<br>11100b - Oversampling ratio of 29.<br>11101b - Oversampling ratio of 30.<br>11110b - Oversampling ratio of 31.<br>11111b - Oversampling ratio of 32. |
| 23<br>TDMAE | Transmitter DMA Enable<br>TDMAE configures the transmit data register empty flag, LPUART_STAT[TDRE], to generate a DMA request.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 22<br>— | Reserved |
| 21<br>RDMAE | Receiver Full DMA Enable<br>RDMAE configures the receiver data register full flag, LPUART_STAT[RDRF], to generate a DMA request.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 20<br>RIDMAE | Receiver Idle DMA Enable<br>RIDMAE configures the receiver idle flag, LPUART_STAT[IDLE], to generate a DMA request. When this bit is set, reading LPUART_DATA when either DATA[RXEMPT] or DATA[IDLINE] bit is set, will generate an End Of Packet response until the completion of the existing DMA transfer. During an End of Packet response, reading the LPUART_DATA register will return 0x0000_33FF and does not pull data from the FIFO.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 19-18<br>MATCFG | Match Configuration<br>Configures the match addressing mode used. This field should only be changed when the transmitter and receiver are both disabled.<br>00b - Address Match Wakeup<br>01b - Idle Match Wakeup<br>10b - Match On and Match Off<br>11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input |
| 17<br>BOTHEDGE | Both Edge Sampling<br>Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should only be changed when the receiver is disabled.<br>0b - Receiver samples input data using the rising edge of the baud rate clock.<br>1b - Receiver samples input data using the rising and falling edge of the baud rate clock. |
| 16<br>RESYNCDIS | Resynchronization Disable |

*Table continues on the next page...*

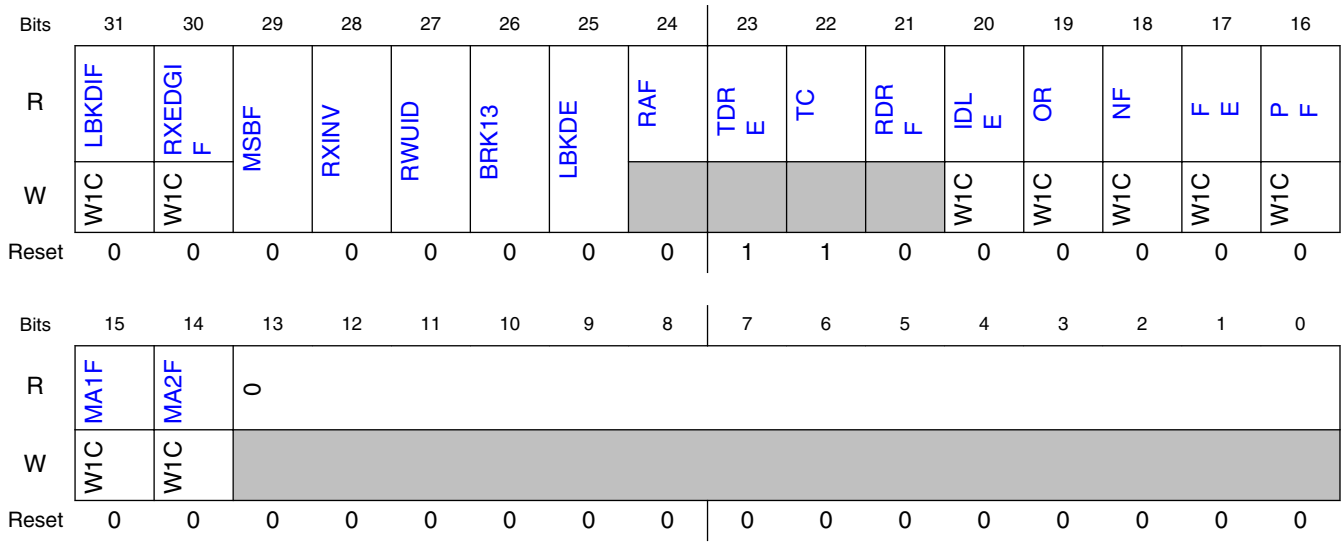
| Field | Function |
|---|---|
| | When set, disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should only be changed when the receiver is disabled.<br>0b - Resynchronization during received data word is supported<br>1b - Resynchronization during received data word is disabled |
| 15<br>LBKDIE | LIN Break Detect Interrupt Enable<br>LBKDIE enables the LIN break detect flag, LBKDIF, to generate interrupt requests.<br>0b - Hardware interrupts from LPUART_STAT[LBKDIF] disabled (use polling).<br>1b - Hardware interrupt requested when LPUART_STAT[LBKDIF] flag is 1. |
| 14<br>RXEDGIE | RX Input Active Edge Interrupt Enable<br>Enables the receive input active edge, RXEDGIF, to generate interrupt requests. Changing CTRL[LOOP] or CTRL[RSRC] when RXEDGIE is set can cause the RXEDGIF to set.<br>0b - Hardware interrupts from LPUART_STAT[RXEDGIF] disabled.<br>1b - Hardware interrupt requested when LPUART_STAT[RXEDGIF] flag is 1. |
| 13<br>SBNS | Stop Bit Number Select<br>SBNS determines whether data characters are one or two stop bits. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - One stop bit.<br>1b - Two stop bits. |
| 12-0<br>SBR | Baud Rate Modulo Divisor.<br>The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) × SBR)". The 13-bit baud rate setting [SBR12:SBR0] must only be updated when the transmitter and receiver are both disabled (LPUART_CTRL[RE] and LPUART_CTRL[TE] are both 0). |

## 56.3.2.7 LPUART Status Register (STAT)

### 56.3.2.7.1 Offset

| Register | Offset |
|---|---|
| STAT | 14h |

## 56.3.2.7.2 Diagram



## 56.3.2.7.3 Fields

| Field | Function |
|---|---|
| 31<br>LBKDIF | LIN Break Detect Interrupt Flag<br>LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it.<br>0b - No LIN break character has been detected.<br>1b - LIN break character has been detected. |
| 30<br>RXEDGIF | RXD Pin Active Edge Interrupt Flag<br>RXEDGIF is set whenever the receiver is enabled and an active edge, falling if RXINV = 0, rising if RXINV=1, on the RXD pin occurs. RXEDGIF is cleared by writing a 1 to it.<br>0b - No active edge on the receive pin has occurred.<br>1b - An active edge on the receive pin has occurred. |
| 29<br>MSBF | MSB First<br>Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit or the location of the start or stop bits. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0.<br>1b - MSB (bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. Further, the first bit received after the start bit is identified as bit9, bit8, bit7 or bit6 depending on the setting of CTRL[M] and CTRL[PE]. |
| 28<br>RXINV | Receive Data Inversion<br>Setting this bit reverses the polarity of the received data input. This bit should only be changed when the receiver is disabled.<br>**NOTE:** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle.<br>0b - Receive data not inverted.<br>1b - Receive data inverted. |
| 27 | Receive Wake Up Idle Detect |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RWUID | For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should only be changed when the receiver is disabled.<br>0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match.<br>1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match. |
| 26<br>BRK13 | Break Character Generation Length<br>BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit. This bit should only be changed when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.<br>0b - Break character is transmitted with length of 9 to 13 bit times.<br>1b - Break character is transmitted with length of 12 to 15 bit times. |
| 25<br>LBKDE | LIN Break Detection Enable<br>LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive data buffer.<br>0b - LIN break detect is disabled, normal break character can be detected.<br>1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1). |
| 24<br>RAF | Receiver Active Flag<br>RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line.<br>0b - LPUART receiver idle waiting for a start bit.<br>1b - LPUART receiver active (RXD input not idle). |
| 23<br>TDRE | Transmit Data Register Empty Flag<br>When the transmit FIFO is enabled, TDRE will set when the number of datawords in the transmit FIFO (LPUART_DATA) is equal to or less than the number indicated by LPUART_WATER[TXWATER]). To clear TDRE, write to the LPUART data register (LPUART_DATA) until the number of words in the transmit FIFO is greater than the number indicated by LPUART_WATER[TXWATER]. When the transmit FIFO is disabled,TDRE will set when the transmit data register (LPUART_DATA) is empty. To clear TDRE, write to the LPUART data register (LPUART_DATA).<br>TDRE is not affected by a character that is in the process of being transmitted, it is updated at the start of each transmitted character.<br>0b - Transmit data buffer full.<br>1b - Transmit data buffer empty. |
| 22<br>TC | Transmission Complete Flag<br>TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to LPUART_DATA to transmit new data, queuing a preamble by clearing and then setting LPUART_CTRL[TE], queuing a break character by writing 1 to LPUART_CTRL[SBK].<br>0b - Transmitter active (sending data, a preamble, or a break).<br>1b - Transmitter idle (transmission activity complete). |
| 21<br>RDRF | Receive Data Register Full Flag<br>When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by LPUART_WATER[RXWATER]. To clear RDRF, read LPUART_DATA until the number of datawords in the receive data buffer is equal to or less than the number indicated by LPUART_WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (LPUART_DATA) is full. To clear RDRF, read the LPUART_DATA register. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character will continue to be received until an overrun condition occurs once the entire character is received.<br>0b - Receive data buffer empty.<br>1b - Receive data buffer full. |
| 20<br>IDLE | Idle Line Flag<br>IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When ILT is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When ILT is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.<br>To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot become set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period.<br>0b - No idle line detected.<br>1b - Idle line was detected. |
| 19<br>OR | Receiver Overrun Flag<br>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received.<br>While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag.<br>0b - No overrun.<br>1b - Receive overrun (new LPUART data lost). |
| 18<br>NF | Noise Flag<br>The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from LPUART_DATA was received with noise detected within the character. To clear NF, write logic one to the NF.<br>0b - No noise detected.<br>1b - Noise detected in the received character in LPUART_DATA. |
| 17<br>FE | Framing Error Flag<br>FE is set whenever the next character to be read from LPUART_DATA was received with logic 0 detected where a stop bit was expected. To clear FE, write logic one to the FE.<br>0b - No framing error detected. This does not guarantee the framing is correct.<br>1b - Framing error. |
| 16<br>PF | Parity Error Flag<br>PF is set whenever the next character to be read from LPUART_DATA was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic one to the PF.<br>0b - No parity error.<br>1b - Parity error. |
| 15<br>MA1F | Match 1 Flag |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | MA1F is set whenever the next character to be read from LPUART_DATA matches MA1. To clear MA1F, write a logic one to the MA1F.<br>0b - Received data is not equal to MA1<br>1b - Received data is equal to MA1 |
| 14<br>MA2F | Match 2 Flag<br>MA2F is set whenever the next character to be read from LPUART_DATA matches MA2. To clear MA2F, write a logic one to the MA2F.<br>0b - Received data is not equal to MA2<br>1b - Received data is equal to MA2 |
| 13-0<br>— | Reserved |

## 56.3.2.8 LPUART Control Register (CTRL)

### 56.3.2.8.1 Offset

| Register | Offset |
|---|---|
| CTRL | 18h |

### 56.3.2.8.2 Function

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

### 56.3.2.8.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 56.3.2.8.4 Fields

| Field | Function |
|---|---|
| 31<br>R8T9 | Receive Bit 8 / Transmit Bit 9<br>R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading LPUART_DATA.<br>T9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing LPUART_DATA. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.<br>**NOTE:** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written. |
| 30<br>R9T8 | Receive Bit 9 / Transmit Bit 8<br>R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading LPUART_DATA<br>T8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing LPUART_DATA. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.<br>**NOTE:** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written. |
| 29<br>TXDIR | TXD Pin Direction in Single-Wire Mode<br>When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter will finish receiving the current character (if any) before the receiver starts receiving data from the TXD pin.<br>0b - TXD pin is an input in single-wire mode.<br>1b - TXD pin is an output in single-wire mode. |
| 28<br>TXINV | Transmit Data Inversion<br>Setting this bit reverses the polarity of the transmitted data output.<br>**NOTE:** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle.<br>0b - Transmit data not inverted.<br>1b - Transmit data inverted. |
| 27<br>ORIE | Overrun Interrupt Enable<br>This bit enables the overrun flag (OR) to generate hardware interrupt requests.<br>0b - OR interrupts disabled; use polling.<br>1b - Hardware interrupt requested when OR is set. |
| 26<br>NEIE | Noise Error Interrupt Enable<br>This bit enables the noise flag (NF) to generate hardware interrupt requests.<br>0b - NF interrupts disabled; use polling.<br>1b - Hardware interrupt requested when NF is set. |
| 25<br>FEIE | Framing Error Interrupt Enable<br>This bit enables the framing error flag (FE) to generate hardware interrupt requests.<br>0b - FE interrupts disabled; use polling.<br>1b - Hardware interrupt requested when FE is set. |
| 24<br>PEIE | Parity Error Interrupt Enable<br>This bit enables the parity error flag (PF) to generate hardware interrupt requests.<br>0b - PF interrupts disabled; use polling).<br>1b - Hardware interrupt requested when PF is set. |
| 23 | Transmit Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TIE | Enables STAT[TDRE] to generate interrupt requests.<br>0b - Hardware interrupts from TDRE disabled; use polling.<br>1b - Hardware interrupt requested when TDRE flag is 1. |
| 22<br>TCIE | Transmission Complete Interrupt Enable for<br>TCIE enables the transmission complete flag, TC, to generate interrupt requests.<br>0b - Hardware interrupts from TC disabled; use polling.<br>1b - Hardware interrupt requested when TC flag is 1. |
| 21<br>RIE | Receiver Interrupt Enable<br>Enables STAT[RDRF] to generate interrupt requests.<br>0b - Hardware interrupts from RDRF disabled; use polling.<br>1b - Hardware interrupt requested when RDRF flag is 1. |
| 20<br>ILIE | Idle Line Interrupt Enable<br>ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests.<br>0b - Hardware interrupts from IDLE disabled; use polling.<br>1b - Hardware interrupt requested when IDLE flag is 1. |
| 19<br>TE | Transmitter Enable<br>Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit will read as 1 until the transmitter has completed the current character and the TXD pin is tristated.<br>A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set.<br>0b - Transmitter disabled.<br>1b - Transmitter enabled. |
| 18<br>RE | Receiver Enable<br>Enables the LPUART receiver. When RE is written to 0, this register bit will read as 1 until the receiver finishes receiving the current character (if any).<br>0b - Receiver disabled.<br>1b - Receiver enabled. |
| 17<br>RWU | Receiver Wakeup Control<br>This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear.<br>**NOTE:** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted.<br>0b - Normal receiver operation.<br>1b - LPUART receiver in standby waiting for wakeup condition. |
| 16<br>SBK | Send Break<br>Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if LPUART_STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK.<br>A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.<br>0b - Normal transmitter operation.<br>1b - Queue break character(s) to be sent. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 15<br>MA1IE | Match 1 Interrupt Enable<br>0b - MA1F interrupt disabled<br>1b - MA1F interrupt enabled |
| 14<br>MA2IE | Match 2 Interrupt Enable<br>0b - MA2F interrupt disabled<br>1b - MA2F interrupt enabled |
| 13-12<br>— | Reserved |
| 11<br>M7 | 7-Bit Mode Select<br>This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - Receiver and transmitter use 8-bit to 10-bit data characters.<br>1b - Receiver and transmitter use 7-bit data characters. |
| 10-8<br>IDLECFG | Idle Configuration<br>Configures the number of idle characters that must be received before the IDLE flag is set.<br>000b - 1 idle character<br>001b - 2 idle characters<br>010b - 4 idle characters<br>011b - 8 idle characters<br>100b - 16 idle characters<br>101b - 32 idle characters<br>110b - 64 idle characters<br>111b - 128 idle characters |
| 7<br>LOOPS | Loop Mode Select<br>When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.<br>0b - Normal operation - RXD and TXD use separate pins.<br>1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit). |
| 6<br>DOZEEN | Doze Enable<br>0b - LPUART is enabled in Doze mode.<br>1b - LPUART is disabled in Doze mode. |
| 5<br>RSRC | Receiver Source Select<br>This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.<br>0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin.<br>1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input. |
| 4<br>M | 9-Bit or 8-Bit Mode Select<br>0b - Receiver and transmitter use 8-bit data characters.<br>1b - Receiver and transmitter use 9-bit data characters. |
| 3<br>WAKE | Receiver Wakeup Method Select<br>Determines which condition wakes the LPUART when RWU=1:<br>• Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character, or<br>• An idle condition on the receive pin input signal.<br><br>0b - Configures RWU for idle-line wakeup.<br>1b - Configures RWU with address-mark wakeup. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 2<br>ILT | Idle Line Type Select<br>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.<br>**NOTE:** In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count.<br>0b - Idle character bit count starts after start bit.<br>1b - Idle character bit count starts after stop bit. |
| 1<br>PE | Parity Enable<br>Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit.<br>0b - No hardware parity generation or checking.<br>1b - Parity enabled. |
| 0<br>PT | Parity Type<br>Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even.<br>0b - Even parity.<br>1b - Odd parity. |

## 56.3.2.9 LPUART Data Register (DATA)

### 56.3.2.9.1 Offset

| Register | Offset |
|---|---|
| DATA | 1Ch |

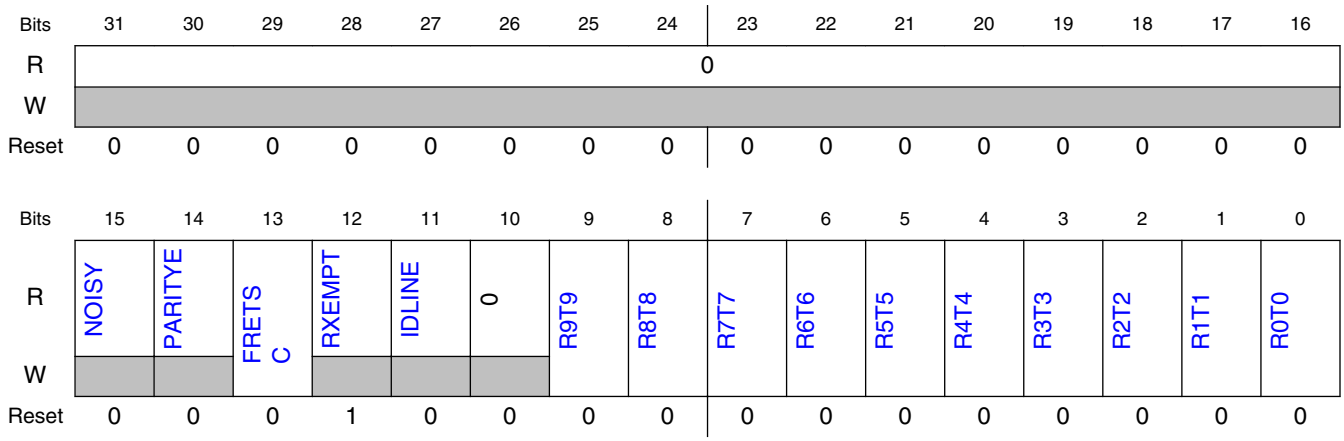
### 56.3.2.9.2 Function

**NOTE**

This register is two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags.

### 56.3.2.9.3 Diagram



### 56.3.2.9.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15<br>NOISY | NOISY<br>The current received dataword contained in DATA[R9:R0] was received with noise.<br>0b - The dataword was received without noise.<br>1b - The data was received with noise. |
| 14<br>PARITYE | PARITYE<br>The current received dataword contained in DATA[R9:R0] was received with a parity error.<br>0b - The dataword was received without a parity error.<br>1b - The dataword was received with a parity error. |
| 13<br>FRETSC | Frame Error / Transmit Special Character<br>For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, he contents of DATA[T8:T0] should be zero.<br>0b - The dataword was received without a frame error on read, or transmit a normal character on write.<br>1b - The dataword was received with a frame error, or transmit an idle or break character on transmit. |
| 12<br>RXEMPT | Receive Buffer Empty<br>Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register.<br>0b - Receive buffer contains valid data.<br>1b - Receive buffer is empty, data returned on read is not valid. |
| 11<br>IDLINE | Idle Line<br>Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled.<br>0b - Receiver was not idle before receiving this character.<br>1b - Receiver was idle before receiving this character. |

### 56.3.2.10.3 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-16<br>MA2 | Match Address 2<br>The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. Software should only write a MA register when the associated BAUD[MAEN] bit is clear. |
| 15-10<br>— | Reserved |
| 9-0<br>MA1 | Match Address 1<br>The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. Software should only write a MA register when the associated BAUD[MAEN] bit is clear. |

## 56.3.2.11 LPUART Modem IrDA Register (MODIR)

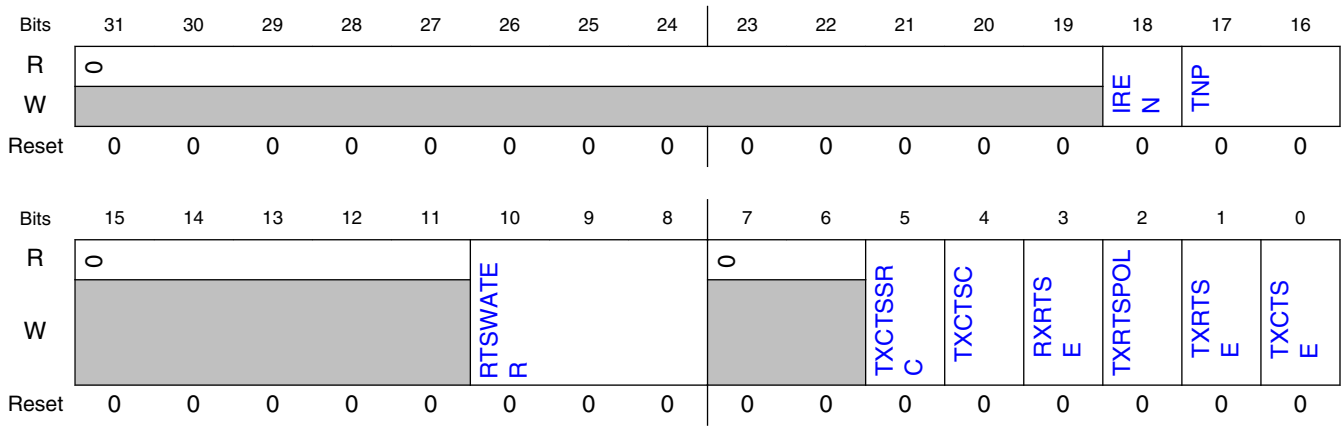
### 56.3.2.11.1 Offset

| Register | Offset |
|---|---|
| MODIR | 24h |

### 56.3.2.11.2 Function

The MODEM register controls options for setting the modem configuration.

### 56.3.2.11.3 Diagram



### 56.3.2.11.4 Fields

| Field | Function |
|---|---|
| 31-19<br>— | Reserved |
| 18<br>IREN | Infrared enable<br>Enables/disables the infrared modulation/demodulation. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - IR disabled.<br>1b - IR enabled. |
| 17-16<br>TNP | Transmitter narrow pulse<br>Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should only be changed when the transmitter and receiver are both disabled.<br>The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width.<br>00b - 1/OSR.<br>01b - 2/OSR.<br>10b - 3/OSR.<br>11b - 4/OSR. |
| 15-11<br>— | Reserved |
| 10-8<br>RTSWATER | Receive RTS Configuration<br>Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This field should only be changed when the receiver is disabled. |
| 7-6<br>— | Reserved |
| 5<br>TXCTSSRC | Transmit CTS Source<br>Configures the source of the CTS input.<br>0b - CTS input is the CTS_B pin.<br>1b - CTS input is the inverted Receiver Match result. |
| 4<br>TXCTSC | Transmit CTS Configuration<br>Configures if the CTS state is checked at the start of each character or only when the transmitter is idle.<br>0b - CTS input is sampled at the start of each character.<br>1b - CTS input is sampled when the transmitter is idle. |
| 3<br>RXRTSE | Receiver request-to-send enable<br>Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should only be changed when the receiver is disabled.<br>**NOTE:** Do not set both RXRTSE and TXRTSE.<br>0b - The receiver has no effect on RTS.<br>1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full. |
| 2<br>TXRTSPOL | Transmitter request-to-send polarity<br>Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. This bit should only be changed when the transmitter is disabled.<br>0b - Transmitter RTS is active low.<br>1b - Transmitter RTS is active high. |
| 1<br>TXRTSE | Transmitter request-to-send enable<br>Controls RTS before and after a transmission. This bit should only be changed when the transmitter is disabled.<br>0b - The transmitter has no effect on RTS.<br>1b - When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. |
| 0<br>TXCTSE | Transmitter clear-to-send enable<br>TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.<br>0b - CTS has no effect on the transmitter.<br>1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission. |

## 56.3.2.12 LPUART FIFO Register (FIFO)

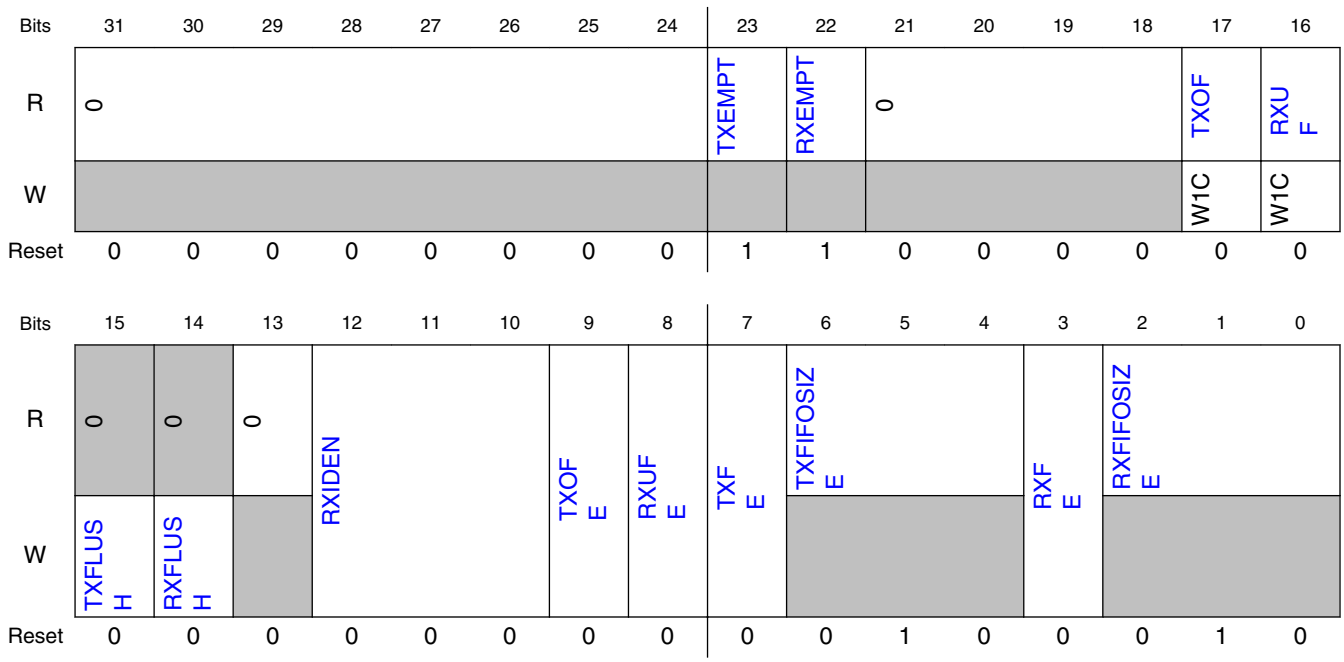
### 56.3.2.12.1 Offset

| Register | Offset |
|---|---|
| FIFO | 28h |

### 56.3.2.12.2 Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the data buffer/FIFO is empty.

### 56.3.2.12.3 Diagram



### 56.3.2.12.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23<br>TXEMPT | Transmit Buffer/FIFO Empty<br>Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register.<br>0b - Transmit buffer is not empty. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - Transmit buffer is empty. |
| 22<br>RXEMPT | Receive Buffer/FIFO Empty<br>Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register.<br>0b - Receive buffer is not empty.<br>1b - Receive buffer is empty. |
| 21-18<br>— | Reserved |
| 17<br>TXOF | Transmitter Buffer Overflow Flag<br>Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of TXOFE. However, an interrupt will be issued to the host only if TXOFE is set. This flag is cleared by writing a 1.<br>0b - No transmit buffer overflow has occurred since the last time the flag was cleared.<br>1b - At least one transmit buffer overflow has occurred since the last time the flag was cleared. |
| 16<br>RXUF | Receiver Buffer Underflow Flag<br>Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of RXUFE. However, an interrupt will be issued to the host only if RXUFE is set. This flag is cleared by writing a 1.<br>0b - No receive buffer underflow has occurred since the last time the flag was cleared.<br>1b - At least one receive buffer underflow has occurred since the last time the flag was cleared. |
| 15<br>TXFLUSH | Transmit FIFO/Buffer Flush<br>Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register.<br>0b - No flush operation occurs.<br>1b - All data in the transmit FIFO/Buffer is cleared out. |
| 14<br>RXFLUSH | Receive FIFO/Buffer Flush<br>Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register.<br>0b - No flush operation occurs.<br>1b - All data in the receive FIFO/buffer is cleared out. |
| 13<br>— | Reserved |
| 12-10<br>RXIDEN | Receiver Idle Empty Enable<br>When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty.<br>000b - Disable RDRF assertion due to partially filled FIFO when receiver is idle.<br>001b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character.<br>010b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters.<br>011b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters.<br>100b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters.<br>101b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters.<br>110b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters.<br>111b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters. |
| 9<br>TXOFE | Transmit FIFO Overflow Interrupt Enable<br>When this field is set, the TXOF flag generates an interrupt to the host.<br>0b - TXOF flag does not generate an interrupt to the host.<br>1b - TXOF flag generates an interrupt to the host. |
| 8 | Receive FIFO Underflow Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RXUFE | When this field is set, the RXUF flag generates an interrupt to the host.<br>0b - RXUF flag does not generate an interrupt to the host.<br>1b - RXUF flag generates an interrupt to the host. |
| 7<br>TXFE | Transmit FIFO Enable<br>When this field is set, the built in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field.<br>0b - Transmit FIFO is not enabled. Buffer is depth 1. (Legacy support).<br>1b - Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE. |
| 6-4<br>TXFIFOSIZE | Transmit FIFO. Buffer Depth<br>The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only.<br>000b - Transmit FIFO/Buffer depth = 1 dataword.<br>001b - Transmit FIFO/Buffer depth = 4 datawords.<br>010b - Transmit FIFO/Buffer depth = 8 datawords.<br>011b - Transmit FIFO/Buffer depth = 16 datawords.<br>100b - Transmit FIFO/Buffer depth = 32 datawords.<br>101b - Transmit FIFO/Buffer depth = 64 datawords.<br>110b - Transmit FIFO/Buffer depth = 128 datawords.<br>111b - Transmit FIFO/Buffer depth = 256 datawords |
| 3<br>RXFE | Receive FIFO Enable<br>When this field is set, the built in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field.<br>0b - Receive FIFO is not enabled. Buffer is depth 1. (Legacy support)<br>1b - Receive FIFO is enabled. Buffer is depth indicted by RXFIFOSIZE. |
| 2-0<br>RXFIFOSIZE | Receive FIFO. Buffer Depth<br>The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only.<br>000b - Receive FIFO/Buffer depth = 1 dataword.<br>001b - Receive FIFO/Buffer depth = 4 datawords.<br>010b - Receive FIFO/Buffer depth = 8 datawords.<br>011b - Receive FIFO/Buffer depth = 16 datawords.<br>100b - Receive FIFO/Buffer depth = 32 datawords.<br>101b - Receive FIFO/Buffer depth = 64 datawords.<br>110b - Receive FIFO/Buffer depth = 128 datawords.<br>111b - Receive FIFO/Buffer depth = 256 datawords. |

## 56.3.2.13 LPUART Watermark Register (WATER)

### 56.3.2.13.1 Offset

| Register | Offset |
|---|---|
| WATER | 2Ch |

### 56.3.2.13.2 Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

### 56.3.2.13.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 31<br>MAEN1 | Match Address Mode Enable 1<br>0b - Normal operation.<br>1b - Enables automatic address matching or data matching mode for MATCH[MA1]. |
| 30<br>MAEN2 | Match Address Mode Enable 2<br>0b - Normal operation.<br>1b - Enables automatic address matching or data matching mode for MATCH[MA2]. |
| 29<br>M10 | 10-bit Mode select<br>The M10 bit causes a tenth bit to be part of the serial transmission. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - Receiver and transmitter use 7-bit to 9-bit data characters.<br>1b - Receiver and transmitter use 10-bit data characters. |
| 28-24<br>OSR | Oversampling Ratio<br>This field configures the oversampling ratio for the receiver. This field should only be changed when the transmitter and receiver are both disabled.<br>00000b - Writing 0 to this field will result in an oversampling ratio of 16<br>00001b - Reserved<br>00010b - Reserved<br>00011b - Oversampling ratio of 4, requires BOTHEDGE to be set.<br>00100b - Oversampling ratio of 5, requires BOTHEDGE to be set.<br>00101b - Oversampling ratio of 6, requires BOTHEDGE to be set.<br>00110b - Oversampling ratio of 7, requires BOTHEDGE to be set.<br>00111b - Oversampling ratio of 8.<br>01000b - Oversampling ratio of 9.<br>01001b - Oversampling ratio of 10.<br>01010b - Oversampling ratio of 11.<br>01011b - Oversampling ratio of 12.<br>01100b - Oversampling ratio of 13.<br>01101b - Oversampling ratio of 14.<br>01110b - Oversampling ratio of 15.<br>01111b - Oversampling ratio of 16.<br>10000b - Oversampling ratio of 17. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 10001b - Oversampling ratio of 18.<br>10010b - Oversampling ratio of 19.<br>10011b - Oversampling ratio of 20.<br>10100b - Oversampling ratio of 21.<br>10101b - Oversampling ratio of 22.<br>10110b - Oversampling ratio of 23.<br>10111b - Oversampling ratio of 24.<br>11000b - Oversampling ratio of 25.<br>11001b - Oversampling ratio of 26.<br>11010b - Oversampling ratio of 27.<br>11011b - Oversampling ratio of 28.<br>11100b - Oversampling ratio of 29.<br>11101b - Oversampling ratio of 30.<br>11110b - Oversampling ratio of 31.<br>11111b - Oversampling ratio of 32. |
| 23<br>TDMAE | Transmitter DMA Enable<br>TDMAE configures the transmit data register empty flag, LPUART_STAT[TDRE], to generate a DMA request.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 22<br>— | Reserved |
| 21<br>RDMAE | Receiver Full DMA Enable<br>RDMAE configures the receiver data register full flag, LPUART_STAT[RDRF], to generate a DMA request.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 20<br>RIDMAE | Receiver Idle DMA Enable<br>RIDMAE configures the receiver idle flag, LPUART_STAT[IDLE], to generate a DMA request. When this bit is set, reading LPUART_DATA when either DATA[RXEMPT] or DATA[IDLINE] bit is set, will generate an End Of Packet response until the completion of the existing DMA transfer. During an End of Packet response, reading the LPUART_DATA register will return 0x0000_33FF and does not pull data from the FIFO.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 19-18<br>MATCFG | Match Configuration<br>Configures the match addressing mode used. This field should only be changed when the transmitter and receiver are both disabled.<br>00b - Address Match Wakeup<br>01b - Idle Match Wakeup<br>10b - Match On and Match Off<br>11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input |
| 17<br>BOTHEDGE | Both Edge Sampling<br>Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should only be changed when the receiver is disabled.<br>0b - Receiver samples input data using the rising edge of the baud rate clock.<br>1b - Receiver samples input data using the rising and falling edge of the baud rate clock. |
| 16<br>RESYNCDIS | Resynchronization Disable |

*Table continues on the next page...*

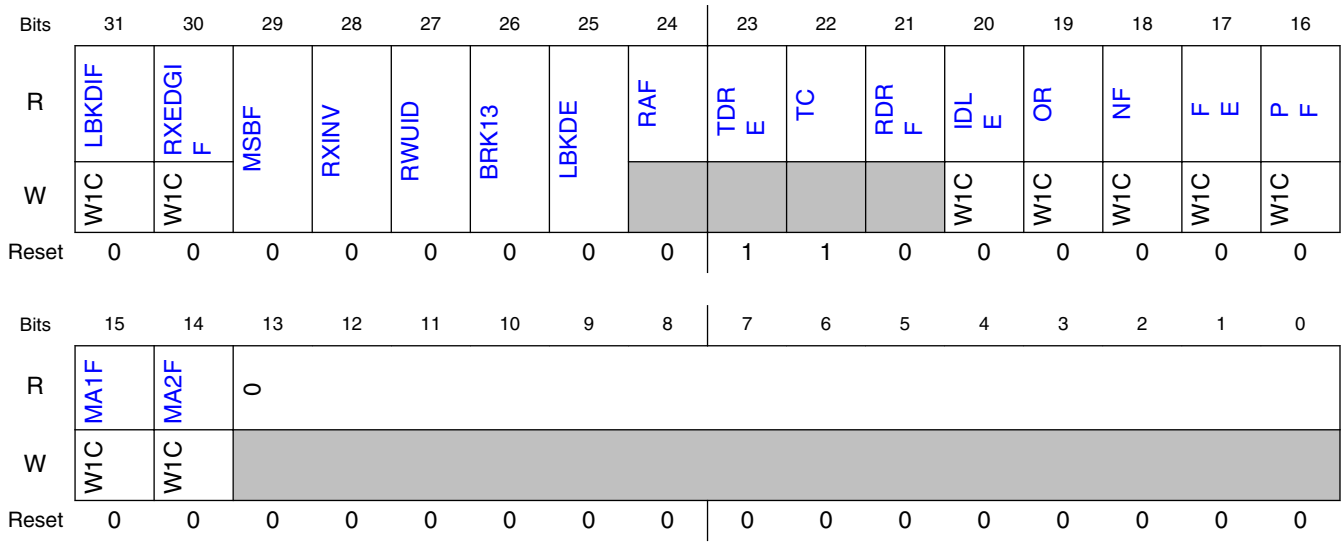
| Field | Function |
|---|---|
| | When set, disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should only be changed when the receiver is disabled.<br>0b - Resynchronization during received data word is supported<br>1b - Resynchronization during received data word is disabled |
| 15<br>LBKDIE | LIN Break Detect Interrupt Enable<br>LBKDIE enables the LIN break detect flag, LBKDIF, to generate interrupt requests.<br>0b - Hardware interrupts from LPUART_STAT[LBKDIF] disabled (use polling).<br>1b - Hardware interrupt requested when LPUART_STAT[LBKDIF] flag is 1. |
| 14<br>RXEDGIE | RX Input Active Edge Interrupt Enable<br>Enables the receive input active edge, RXEDGIF, to generate interrupt requests. Changing CTRL[LOOP] or CTRL[RSRC] when RXEDGIE is set can cause the RXEDGIF to set.<br>0b - Hardware interrupts from LPUART_STAT[RXEDGIF] disabled.<br>1b - Hardware interrupt requested when LPUART_STAT[RXEDGIF] flag is 1. |
| 13<br>SBNS | Stop Bit Number Select<br>SBNS determines whether data characters are one or two stop bits. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - One stop bit.<br>1b - Two stop bits. |
| 12-0<br>SBR | Baud Rate Modulo Divisor.<br>The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) × SBR)". The 13-bit baud rate setting [SBR12:SBR0] must only be updated when the transmitter and receiver are both disabled (LPUART_CTRL[RE] and LPUART_CTRL[TE] are both 0). |

## 56.3.3.7 LPUART Status Register (STAT)

### 56.3.3.7.1 Offset

| Register | Offset |
|---|---|
| STAT | 14h |

### 56.3.3.7.2 Diagram



### 56.3.3.7.3 Fields

| Field | Function |
|---|---|
| 31<br>LBKDIF | LIN Break Detect Interrupt Flag<br>LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it.<br>0b - No LIN break character has been detected.<br>1b - LIN break character has been detected. |
| 30<br>RXEDGIF | RXD Pin Active Edge Interrupt Flag<br>RXEDGIF is set whenever the receiver is enabled and an active edge, falling if RXINV = 0, rising if RXINV=1, on the RXD pin occurs. RXEDGIF is cleared by writing a 1 to it.<br>0b - No active edge on the receive pin has occurred.<br>1b - An active edge on the receive pin has occurred. |
| 29<br>MSBF | MSB First<br>Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit or the location of the start or stop bits. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0.<br>1b - MSB (bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. Further, the first bit received after the start bit is identified as bit9, bit8, bit7 or bit6 depending on the setting of CTRL[M] and CTRL[PE]. |
| 28<br>RXINV | Receive Data Inversion<br>Setting this bit reverses the polarity of the received data input. This bit should only be changed when the receiver is disabled.<br>**NOTE:** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle.<br>0b - Receive data not inverted.<br>1b - Receive data inverted. |
| 27 | Receive Wake Up Idle Detect |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RWUID | For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should only be changed when the receiver is disabled.<br>0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match.<br>1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match. |
| 26<br>BRK13 | Break Character Generation Length<br>BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit. This bit should only be changed when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.<br>0b - Break character is transmitted with length of 9 to 13 bit times.<br>1b - Break character is transmitted with length of 12 to 15 bit times. |
| 25<br>LBKDE | LIN Break Detection Enable<br>LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive data buffer.<br>0b - LIN break detect is disabled, normal break character can be detected.<br>1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1). |
| 24<br>RAF | Receiver Active Flag<br>RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line.<br>0b - LPUART receiver idle waiting for a start bit.<br>1b - LPUART receiver active (RXD input not idle). |
| 23<br>TDRE | Transmit Data Register Empty Flag<br>When the transmit FIFO is enabled, TDRE will set when the number of datawords in the transmit FIFO (LPUART_DATA) is equal to or less than the number indicated by LPUART_WATER[TXWATER]). To clear TDRE, write to the LPUART data register (LPUART_DATA) until the number of words in the transmit FIFO is greater than the number indicated by LPUART_WATER[TXWATER]. When the transmit FIFO is disabled,TDRE will set when the transmit data register (LPUART_DATA) is empty. To clear TDRE, write to the LPUART data register (LPUART_DATA).<br>TDRE is not affected by a character that is in the process of being transmitted, it is updated at the start of each transmitted character.<br>0b - Transmit data buffer full.<br>1b - Transmit data buffer empty. |
| 22<br>TC | Transmission Complete Flag<br>TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to LPUART_DATA to transmit new data, queuing a preamble by clearing and then setting LPUART_CTRL[TE], queuing a break character by writing 1 to LPUART_CTRL[SBK].<br>0b - Transmitter active (sending data, a preamble, or a break).<br>1b - Transmitter idle (transmission activity complete). |
| 21<br>RDRF | Receive Data Register Full Flag<br>When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by LPUART_WATER[RXWATER]. To clear RDRF, read LPUART_DATA until the number of datawords in the receive data buffer is equal to or less than the number indicated by LPUART_WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (LPUART_DATA) is full. To clear RDRF, read the LPUART_DATA register. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character will continue to be received until an overrun condition occurs once the entire character is received.<br>0b - Receive data buffer empty.<br>1b - Receive data buffer full. |
| 20<br>IDLE | Idle Line Flag<br>IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When ILT is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When ILT is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.<br>To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot become set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period.<br>0b - No idle line detected.<br>1b - Idle line was detected. |
| 19<br>OR | Receiver Overrun Flag<br>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received.<br>While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag.<br>0b - No overrun.<br>1b - Receive overrun (new LPUART data lost). |
| 18<br>NF | Noise Flag<br>The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from LPUART_DATA was received with noise detected within the character. To clear NF, write logic one to the NF.<br>0b - No noise detected.<br>1b - Noise detected in the received character in LPUART_DATA. |
| 17<br>FE | Framing Error Flag<br>FE is set whenever the next character to be read from LPUART_DATA was received with logic 0 detected where a stop bit was expected. To clear FE, write logic one to the FE.<br>0b - No framing error detected. This does not guarantee the framing is correct.<br>1b - Framing error. |
| 16<br>PF | Parity Error Flag<br>PF is set whenever the next character to be read from LPUART_DATA was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic one to the PF.<br>0b - No parity error.<br>1b - Parity error. |
| 15<br>MA1F | Match 1 Flag |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | MA1F is set whenever the next character to be read from LPUART_DATA matches MA1. To clear MA1F, write a logic one to the MA1F.<br>0b - Received data is not equal to MA1<br>1b - Received data is equal to MA1 |
| 14<br>MA2F | Match 2 Flag<br>MA2F is set whenever the next character to be read from LPUART_DATA matches MA2. To clear MA2F, write a logic one to the MA2F.<br>0b - Received data is not equal to MA2<br>1b - Received data is equal to MA2 |
| 13-0<br>— | Reserved |

## 56.3.3.8 LPUART Control Register (CTRL)

### 56.3.3.8.1 Offset

| Register | Offset |
|---|---|
| CTRL | 18h |

### 56.3.3.8.2 Function

This read/write register controls various optional features of the LPUART system. This register should only be altered when the transmitter and receiver are both disabled.

### 56.3.3.8.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 56.3.3.8.4 Fields

| Field | Function |
|---|---|
| 31<br>R8T9 | Receive Bit 8 / Transmit Bit 9<br>R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading LPUART_DATA.<br>T9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing LPUART_DATA. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.<br>**NOTE:** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written. |
| 30<br>R9T8 | Receive Bit 9 / Transmit Bit 8<br>R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading LPUART_DATA<br>T8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing LPUART_DATA. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.<br>**NOTE:** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written. |
| 29<br>TXDIR | TXD Pin Direction in Single-Wire Mode<br>When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter will finish receiving the current character (if any) before the receiver starts receiving data from the TXD pin.<br>0b - TXD pin is an input in single-wire mode.<br>1b - TXD pin is an output in single-wire mode. |
| 28<br>TXINV | Transmit Data Inversion<br>Setting this bit reverses the polarity of the transmitted data output.<br>**NOTE:** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle.<br>0b - Transmit data not inverted.<br>1b - Transmit data inverted. |
| 27<br>ORIE | Overrun Interrupt Enable<br>This bit enables the overrun flag (OR) to generate hardware interrupt requests.<br>0b - OR interrupts disabled; use polling.<br>1b - Hardware interrupt requested when OR is set. |
| 26<br>NEIE | Noise Error Interrupt Enable<br>This bit enables the noise flag (NF) to generate hardware interrupt requests.<br>0b - NF interrupts disabled; use polling.<br>1b - Hardware interrupt requested when NF is set. |
| 25<br>FEIE | Framing Error Interrupt Enable<br>This bit enables the framing error flag (FE) to generate hardware interrupt requests.<br>0b - FE interrupts disabled; use polling.<br>1b - Hardware interrupt requested when FE is set. |
| 24<br>PEIE | Parity Error Interrupt Enable<br>This bit enables the parity error flag (PF) to generate hardware interrupt requests.<br>0b - PF interrupts disabled; use polling).<br>1b - Hardware interrupt requested when PF is set. |
| 23 | Transmit Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TIE | Enables STAT[TDRE] to generate interrupt requests.<br>0b - Hardware interrupts from TDRE disabled; use polling.<br>1b - Hardware interrupt requested when TDRE flag is 1. |
| 22<br>TCIE | Transmission Complete Interrupt Enable for<br>TCIE enables the transmission complete flag, TC, to generate interrupt requests.<br>0b - Hardware interrupts from TC disabled; use polling.<br>1b - Hardware interrupt requested when TC flag is 1. |
| 21<br>RIE | Receiver Interrupt Enable<br>Enables STAT[RDRF] to generate interrupt requests.<br>0b - Hardware interrupts from RDRF disabled; use polling.<br>1b - Hardware interrupt requested when RDRF flag is 1. |
| 20<br>ILIE | Idle Line Interrupt Enable<br>ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests.<br>0b - Hardware interrupts from IDLE disabled; use polling.<br>1b - Hardware interrupt requested when IDLE flag is 1. |
| 19<br>TE | Transmitter Enable<br>Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit will read as 1 until the transmitter has completed the current character and the TXD pin is tristated.<br>A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set.<br>0b - Transmitter disabled.<br>1b - Transmitter enabled. |
| 18<br>RE | Receiver Enable<br>Enables the LPUART receiver. When RE is written to 0, this register bit will read as 1 until the receiver finishes receiving the current character (if any).<br>0b - Receiver disabled.<br>1b - Receiver enabled. |
| 17<br>RWU | Receiver Wakeup Control<br>This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear.<br>**NOTE:** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted.<br>0b - Normal receiver operation.<br>1b - LPUART receiver in standby waiting for wakeup condition. |
| 16<br>SBK | Send Break<br>Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if LPUART_STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK.<br>A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.<br>0b - Normal transmitter operation.<br>1b - Queue break character(s) to be sent. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 15<br>MA1IE | Match 1 Interrupt Enable<br>0b - MA1F interrupt disabled<br>1b - MA1F interrupt enabled |
| 14<br>MA2IE | Match 2 Interrupt Enable<br>0b - MA2F interrupt disabled<br>1b - MA2F interrupt enabled |
| 13-12<br>— | Reserved |
| 11<br>M7 | 7-Bit Mode Select<br>This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - Receiver and transmitter use 8-bit to 10-bit data characters.<br>1b - Receiver and transmitter use 7-bit data characters. |
| 10-8<br>IDLECFG | Idle Configuration<br>Configures the number of idle characters that must be received before the IDLE flag is set.<br>000b - 1 idle character<br>001b - 2 idle characters<br>010b - 4 idle characters<br>011b - 8 idle characters<br>100b - 16 idle characters<br>101b - 32 idle characters<br>110b - 64 idle characters<br>111b - 128 idle characters |
| 7<br>LOOPS | Loop Mode Select<br>When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.<br>0b - Normal operation - RXD and TXD use separate pins.<br>1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit). |
| 6<br>DOZEEN | Doze Enable<br>0b - LPUART is enabled in Doze mode.<br>1b - LPUART is disabled in Doze mode. |
| 5<br>RSRC | Receiver Source Select<br>This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.<br>0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin.<br>1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input. |
| 4<br>M | 9-Bit or 8-Bit Mode Select<br>0b - Receiver and transmitter use 8-bit data characters.<br>1b - Receiver and transmitter use 9-bit data characters. |
| 3<br>WAKE | Receiver Wakeup Method Select<br>Determines which condition wakes the LPUART when RWU=1:<br>• Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character, or<br>• An idle condition on the receive pin input signal.<br><br>0b - Configures RWU for idle-line wakeup.<br>1b - Configures RWU with address-mark wakeup. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 2<br>ILT | Idle Line Type Select<br>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.<br>**NOTE:** In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count.<br>0b - Idle character bit count starts after start bit.<br>1b - Idle character bit count starts after stop bit. |
| 1<br>PE | Parity Enable<br>Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit.<br>0b - No hardware parity generation or checking.<br>1b - Parity enabled. |
| 0<br>PT | Parity Type<br>Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even.<br>0b - Even parity.<br>1b - Odd parity. |

## 56.3.3.9 LPUART Data Register (DATA)

### 56.3.3.9.1 Offset

| Register | Offset |
|---|---|
| DATA | 1Ch |

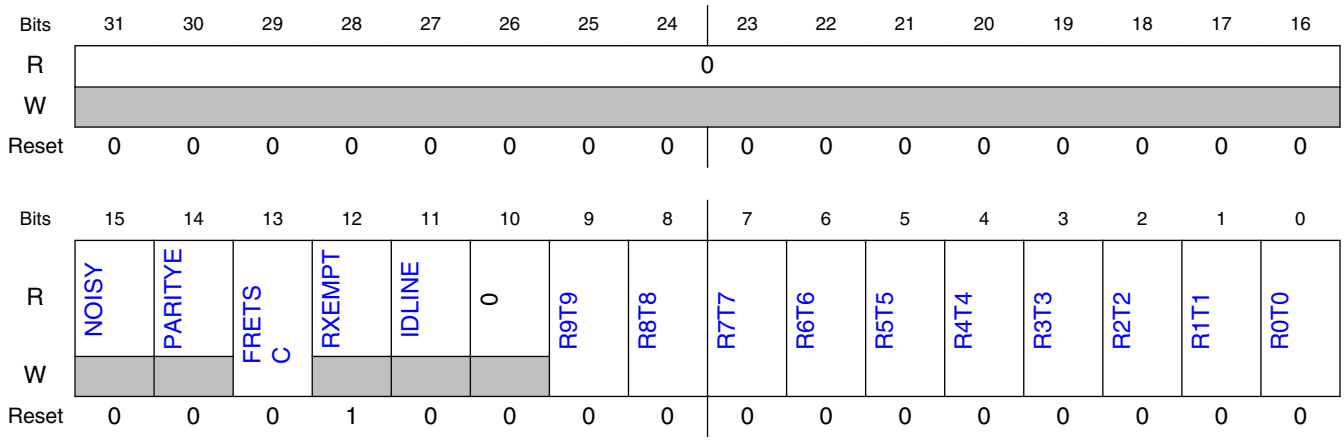
### 56.3.3.9.2 Function

**NOTE**

This register is two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags.

### 56.3.3.9.3 Diagram



### 56.3.3.9.4 Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15<br>NOISY | NOISY<br>The current received dataword contained in DATA[R9:R0] was received with noise.<br>0b - The dataword was received without noise.<br>1b - The data was received with noise. |
| 14<br>PARITYE | PARITYE<br>The current received dataword contained in DATA[R9:R0] was received with a parity error.<br>0b - The dataword was received without a parity error.<br>1b - The dataword was received with a parity error. |
| 13<br>FRETSC | Frame Error / Transmit Special Character<br>For reads, indicates the current received dataword contained in DATA[R9:R0] was received with a frame error. For writes, indicates a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 is used to indicate a break character when 0 and a idle character when 1, he contents of DATA[T8:T0] should be zero.<br>0b - The dataword was received without a frame error on read, or transmit a normal character on write.<br>1b - The dataword was received with a frame error, or transmit an idle or break character on transmit. |
| 12<br>RXEMPT | Receive Buffer Empty<br>Asserts when there is no data in the receive buffer. This field does not take into account data that is in the receive shift register.<br>0b - Receive buffer contains valid data.<br>1b - Receive buffer is empty, data returned on read is not valid. |
| 11<br>IDLINE | Idle Line<br>Indicates the receiver line was idle before receiving the character in DATA[9:0]. Unlike the IDLE flag, this bit can set for the first character received when the receiver is first enabled.<br>0b - Receiver was not idle before receiving this character.<br>1b - Receiver was idle before receiving this character. |

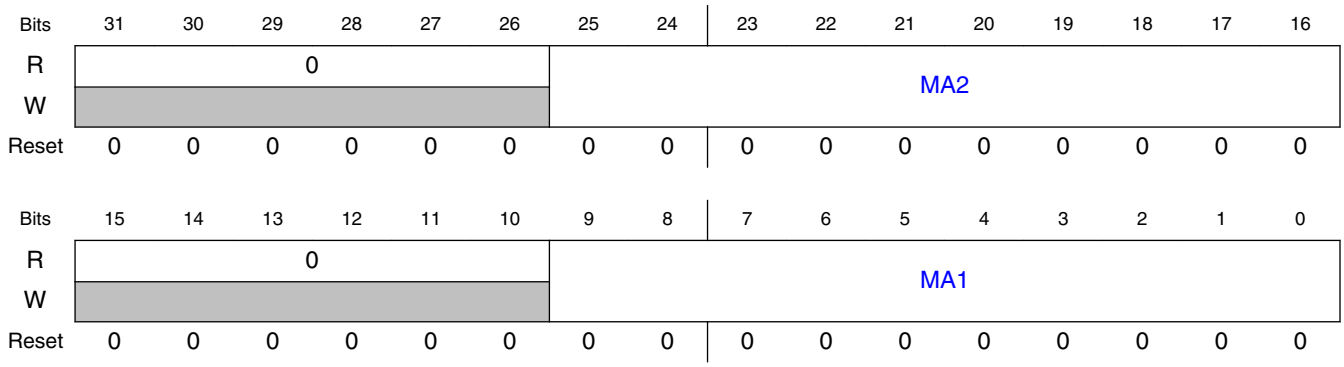
| 0<br>R0T0 | R0T0<br>Read receive data buffer 0 or write transmit data buffer 0. |

## 56.3.3.10 LPUART Match Address Register (MATCH)

### 56.3.3.10.1 Offset

| Register | Offset |
|---|---|
| MATCH | 20h |

### 56.3.3.10.2 Diagram



### 56.3.3.10.3 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-16<br>MA2 | Match Address 2<br>The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. Software should only write a MA register when the associated BAUD[MAEN] bit is clear. |
| 15-10<br>— | Reserved |
| 9-0<br>MA1 | Match Address 1<br>The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated BAUD[MAEN] bit is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. Software should only write a MA register when the associated BAUD[MAEN] bit is clear. |

## 56.3.3.11 LPUART Modem IrDA Register (MODIR)

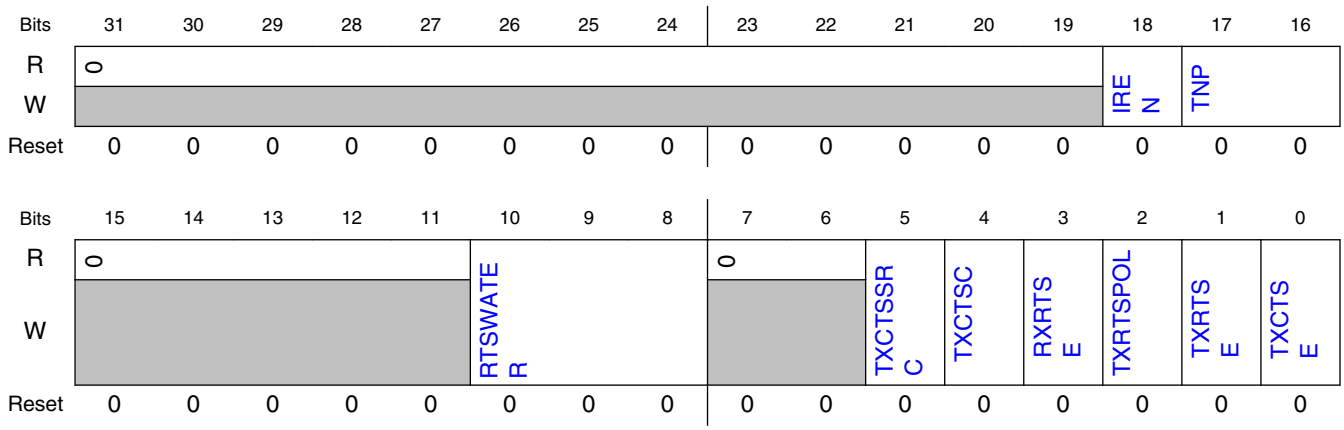
### 56.3.3.11.1 Offset

| Register | Offset |
|---|---|
| MODIR | 24h |

### 56.3.3.11.2 Function

The MODEM register controls options for setting the modem configuration.

## 56.3.3.11.3 Diagram



## 56.3.3.11.4 Fields

| Field | Function |
|---|---|
| 31-19<br>— | Reserved |
| 18<br>IREN | Infrared enable<br>Enables/disables the infrared modulation/demodulation. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - IR disabled.<br>1b - IR enabled. |
| 17-16<br>TNP | Transmitter narrow pulse<br>Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should only be changed when the transmitter and receiver are both disabled.<br>The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width.<br>00b - 1/OSR.<br>01b - 2/OSR.<br>10b - 3/OSR.<br>11b - 4/OSR. |
| 15-11<br>— | Reserved |
| 10-8<br>RTSWATER | Receive RTS Configuration<br>Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This field should only be changed when the receiver is disabled. |
| 7-6<br>— | Reserved |
| 5<br>TXCTSSRC | Transmit CTS Source<br>Configures the source of the CTS input.<br>0b - CTS input is the CTS_B pin.<br>1b - CTS input is the inverted Receiver Match result. |
| 4<br>TXCTSC | Transmit CTS Configuration<br>Configures if the CTS state is checked at the start of each character or only when the transmitter is idle.<br>0b - CTS input is sampled at the start of each character.<br>1b - CTS input is sampled when the transmitter is idle. |
| 3<br>RXRTSE | Receiver request-to-send enable<br>Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should only be changed when the receiver is disabled.<br>**NOTE:** Do not set both RXRTSE and TXRTSE.<br>0b - The receiver has no effect on RTS.<br>1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full. |
| 2<br>TXRTSPOL | Transmitter request-to-send polarity<br>Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. This bit should only be changed when the transmitter is disabled.<br>0b - Transmitter RTS is active low.<br>1b - Transmitter RTS is active high. |
| 1<br>TXRTSE | Transmitter request-to-send enable<br>Controls RTS before and after a transmission. This bit should only be changed when the transmitter is disabled.<br>0b - The transmitter has no effect on RTS.<br>1b - When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. |
| 0<br>TXCTSE | Transmitter clear-to-send enable<br>TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.<br>0b - CTS has no effect on the transmitter.<br>1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission. |

## 56.3.3.12 LPUART FIFO Register (FIFO)

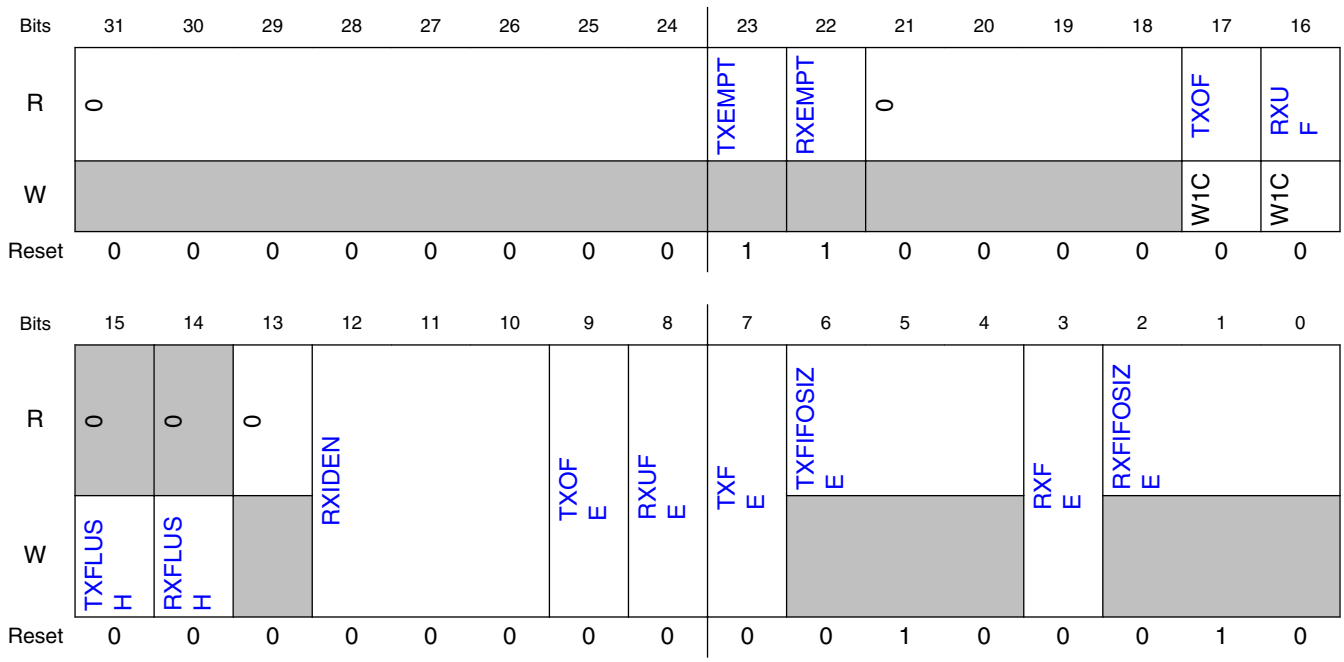
### 56.3.3.12.1 Offset

| Register | Offset |
|---|---|
| FIFO | 28h |

### 56.3.3.12.2 Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the data buffer/FIFO is empty.

### 56.3.3.12.3 Diagram



### 56.3.3.12.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23<br>TXEMPT | Transmit Buffer/FIFO Empty<br>Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register.<br>0b - Transmit buffer is not empty. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - Transmit buffer is empty. |
| 22<br>RXEMPT | Receive Buffer/FIFO Empty<br>Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register.<br>0b - Receive buffer is not empty.<br>1b - Receive buffer is empty. |
| 21-18<br>— | Reserved |
| 17<br>TXOF | Transmitter Buffer Overflow Flag<br>Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of TXOFE. However, an interrupt will be issued to the host only if TXOFE is set. This flag is cleared by writing a 1.<br>0b - No transmit buffer overflow has occurred since the last time the flag was cleared.<br>1b - At least one transmit buffer overflow has occurred since the last time the flag was cleared. |
| 16<br>RXUF | Receiver Buffer Underflow Flag<br>Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of RXUFE. However, an interrupt will be issued to the host only if RXUFE is set. This flag is cleared by writing a 1.<br>0b - No receive buffer underflow has occurred since the last time the flag was cleared.<br>1b - At least one receive buffer underflow has occurred since the last time the flag was cleared. |
| 15<br>TXFLUSH | Transmit FIFO/Buffer Flush<br>Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register.<br>0b - No flush operation occurs.<br>1b - All data in the transmit FIFO/Buffer is cleared out. |
| 14<br>RXFLUSH | Receive FIFO/Buffer Flush<br>Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register.<br>0b - No flush operation occurs.<br>1b - All data in the receive FIFO/buffer is cleared out. |
| 13<br>— | Reserved |
| 12-10<br>RXIDEN | Receiver Idle Empty Enable<br>When set, enables the assertion of RDRF when the receiver is idle for a number of idle characters and the FIFO is not empty.<br>000b - Disable RDRF assertion due to partially filled FIFO when receiver is idle.<br>001b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 1 character.<br>010b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 2 characters.<br>011b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 4 characters.<br>100b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 8 characters.<br>101b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 16 characters.<br>110b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 32 characters.<br>111b - Enable RDRF assertion due to partially filled FIFO when receiver is idle for 64 characters. |
| 9<br>TXOFE | Transmit FIFO Overflow Interrupt Enable<br>When this field is set, the TXOF flag generates an interrupt to the host.<br>0b - TXOF flag does not generate an interrupt to the host.<br>1b - TXOF flag generates an interrupt to the host. |
| 8 | Receive FIFO Underflow Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RXUFE | When this field is set, the RXUF flag generates an interrupt to the host.<br>0b - RXUF flag does not generate an interrupt to the host.<br>1b - RXUF flag generates an interrupt to the host. |
| 7<br>TXFE | Transmit FIFO Enable<br>When this field is set, the built in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field.<br>0b - Transmit FIFO is not enabled. Buffer is depth 1. (Legacy support).<br>1b - Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE. |
| 6-4<br>TXFIFOSIZE | Transmit FIFO. Buffer Depth<br>The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only.<br>000b - Transmit FIFO/Buffer depth = 1 dataword.<br>001b - Transmit FIFO/Buffer depth = 4 datawords.<br>010b - Transmit FIFO/Buffer depth = 8 datawords.<br>011b - Transmit FIFO/Buffer depth = 16 datawords.<br>100b - Transmit FIFO/Buffer depth = 32 datawords.<br>101b - Transmit FIFO/Buffer depth = 64 datawords.<br>110b - Transmit FIFO/Buffer depth = 128 datawords.<br>111b - Transmit FIFO/Buffer depth = 256 datawords |
| 3<br>RXFE | Receive FIFO Enable<br>When this field is set, the built in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both CTRL[TE] and CTRL[RE] must be cleared prior to changing this field.<br>0b - Receive FIFO is not enabled. Buffer is depth 1. (Legacy support)<br>1b - Receive FIFO is enabled. Buffer is depth indicted by RXFIFOSIZE. |
| 2-0<br>RXFIFOSIZE | Receive FIFO. Buffer Depth<br>The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only.<br>000b - Receive FIFO/Buffer depth = 1 dataword.<br>001b - Receive FIFO/Buffer depth = 4 datawords.<br>010b - Receive FIFO/Buffer depth = 8 datawords.<br>011b - Receive FIFO/Buffer depth = 16 datawords.<br>100b - Receive FIFO/Buffer depth = 32 datawords.<br>101b - Receive FIFO/Buffer depth = 64 datawords.<br>110b - Receive FIFO/Buffer depth = 128 datawords.<br>111b - Receive FIFO/Buffer depth = 256 datawords. |

## 56.3.3.13 LPUART Watermark Register (WATER)

### 56.3.3.13.1 Offset

| Register | Offset |
|---|---|
| WATER | 2Ch |

### 56.3.3.13.2 Function

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when CTRL[TE] is not set.

### 56.3.3.13.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 30<br>MAEN2 | Match Address Mode Enable 2<br>0b - Normal operation.<br>1b - Enables automatic address matching or data matching mode for MATCH[MA2]. |
| 29<br>M10 | 10-bit Mode select<br>The M10 bit causes a tenth bit to be part of the serial transmission. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - Receiver and transmitter use 7-bit to 9-bit data characters.<br>1b - Receiver and transmitter use 10-bit data characters. |
| 28-24<br>OSR | Oversampling Ratio<br>This field configures the oversampling ratio for the receiver. This field should only be changed when the transmitter and receiver are both disabled.<br>00000b - Writing 0 to this field will result in an oversampling ratio of 16<br>00001b - Reserved<br>00010b - Reserved<br>00011b - Oversampling ratio of 4, requires BOTHEDGE to be set.<br>00100b - Oversampling ratio of 5, requires BOTHEDGE to be set.<br>00101b - Oversampling ratio of 6, requires BOTHEDGE to be set.<br>00110b - Oversampling ratio of 7, requires BOTHEDGE to be set.<br>00111b - Oversampling ratio of 8.<br>01000b - Oversampling ratio of 9.<br>01001b - Oversampling ratio of 10.<br>01010b - Oversampling ratio of 11.<br>01011b - Oversampling ratio of 12.<br>01100b - Oversampling ratio of 13.<br>01101b - Oversampling ratio of 14.<br>01110b - Oversampling ratio of 15.<br>01111b - Oversampling ratio of 16.<br>10000b - Oversampling ratio of 17. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 10001b - Oversampling ratio of 18.<br>10010b - Oversampling ratio of 19.<br>10011b - Oversampling ratio of 20.<br>10100b - Oversampling ratio of 21.<br>10101b - Oversampling ratio of 22.<br>10110b - Oversampling ratio of 23.<br>10111b - Oversampling ratio of 24.<br>11000b - Oversampling ratio of 25.<br>11001b - Oversampling ratio of 26.<br>11010b - Oversampling ratio of 27.<br>11011b - Oversampling ratio of 28.<br>11100b - Oversampling ratio of 29.<br>11101b - Oversampling ratio of 30.<br>11110b - Oversampling ratio of 31.<br>11111b - Oversampling ratio of 32. |
| 23<br>TDMAE | Transmitter DMA Enable<br>TDMAE configures the transmit data register empty flag, LPUART_STAT[TDRE], to generate a DMA request.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 22<br>— | Reserved |
| 21<br>RDMAE | Receiver Full DMA Enable<br>RDMAE configures the receiver data register full flag, LPUART_STAT[RDRF], to generate a DMA request.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 20<br>RIDMAE | Receiver Idle DMA Enable<br>RIDMAE configures the receiver idle flag, LPUART_STAT[IDLE], to generate a DMA request. When this bit is set, reading LPUART_DATA when either DATA[RXEMPT] or DATA[IDLINE] bit is set, will generate an End Of Packet response until the completion of the existing DMA transfer. During an End of Packet response, reading the LPUART_DATA register will return 0x0000_33FF and does not pull data from the FIFO.<br>0b - DMA request disabled.<br>1b - DMA request enabled. |
| 19-18<br>MATCFG | Match Configuration<br>Configures the match addressing mode used. This field should only be changed when the transmitter and receiver are both disabled.<br>00b - Address Match Wakeup<br>01b - Idle Match Wakeup<br>10b - Match On and Match Off<br>11b - Enables RWU on Data Match and Match On/Off for transmitter CTS input |
| 17<br>BOTHEDGE | Both Edge Sampling<br>Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given oversampling ratio. This bit must be set for oversampling ratios between x4 and x7 and is optional for higher oversampling ratios. This bit should only be changed when the receiver is disabled.<br>0b - Receiver samples input data using the rising edge of the baud rate clock.<br>1b - Receiver samples input data using the rising and falling edge of the baud rate clock. |
| 16<br>RESYNCDIS | Resynchronization Disable |

*Table continues on the next page...*

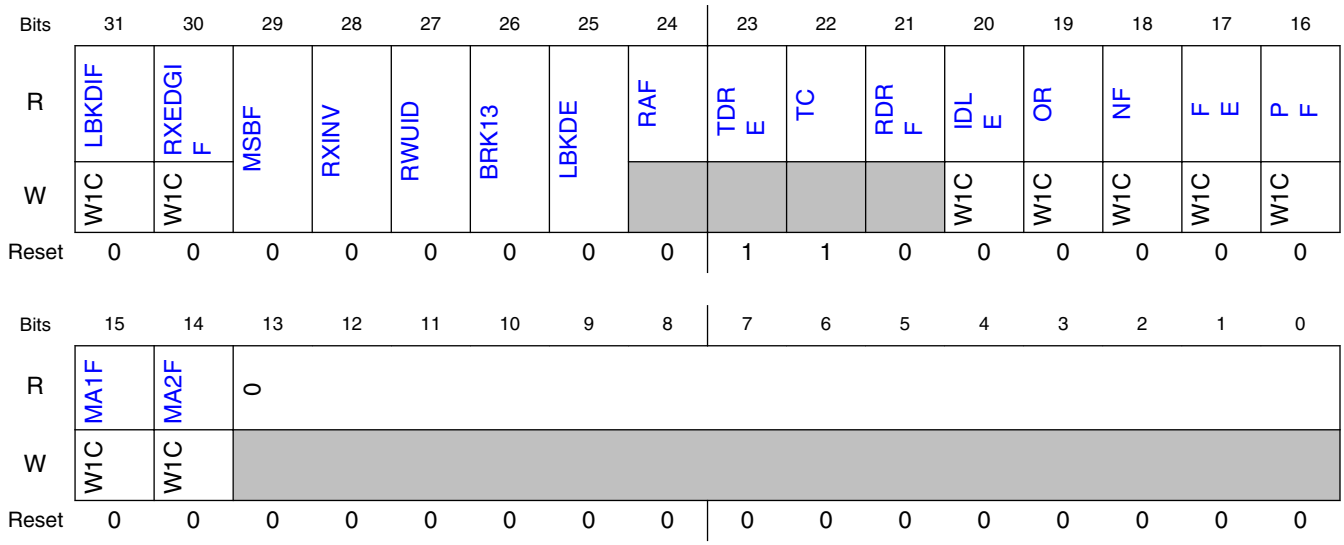
| Field | Function |
|---|---|
| | When set, disables the resynchronization of the received data word when a data one followed by data zero transition is detected. This bit should only be changed when the receiver is disabled.<br>0b - Resynchronization during received data word is supported<br>1b - Resynchronization during received data word is disabled |
| 15<br>LBKDIE | LIN Break Detect Interrupt Enable<br>LBKDIE enables the LIN break detect flag, LBKDIF, to generate interrupt requests.<br>0b - Hardware interrupts from LPUART_STAT[LBKDIF] disabled (use polling).<br>1b - Hardware interrupt requested when LPUART_STAT[LBKDIF] flag is 1. |
| 14<br>RXEDGIE | RX Input Active Edge Interrupt Enable<br>Enables the receive input active edge, RXEDGIF, to generate interrupt requests. Changing CTRL[LOOP] or CTRL[RSRC] when RXEDGIE is set can cause the RXEDGIF to set.<br>0b - Hardware interrupts from LPUART_STAT[RXEDGIF] disabled.<br>1b - Hardware interrupt requested when LPUART_STAT[RXEDGIF] flag is 1. |
| 13<br>SBNS | Stop Bit Number Select<br>SBNS determines whether data characters are one or two stop bits. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - One stop bit.<br>1b - Two stop bits. |
| 12-0<br>SBR | Baud Rate Modulo Divisor.<br>The 13 bits in SBR[12:0] set the modulo divide rate for the baud rate generator. When SBR is 1 - 8191, the baud rate equals "baud clock / ((OSR+1) × SBR)". The 13-bit baud rate setting [SBR12:SBR0] must only be updated when the transmitter and receiver are both disabled (LPUART_CTRL[RE] and LPUART_CTRL[TE] are both 0). |

## 56.3.4.7 LPUART Status Register (STAT)

### 56.3.4.7.1 Offset

| Register | Offset |
|---|---|
| STAT | 14h |

## 56.3.4.7.2 Diagram



## 56.3.4.7.3 Fields

| Field | Function |
|---|---|
| 31<br>LBKDIF | LIN Break Detect Interrupt Flag<br>LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it.<br>0b - No LIN break character has been detected.<br>1b - LIN break character has been detected. |
| 30<br>RXEDGIF | RXD Pin Active Edge Interrupt Flag<br>RXEDGIF is set whenever the receiver is enabled and an active edge, falling if RXINV = 0, rising if RXINV=1, on the RXD pin occurs. RXEDGIF is cleared by writing a 1 to it.<br>0b - No active edge on the receive pin has occurred.<br>1b - An active edge on the receive pin has occurred. |
| 29<br>MSBF | MSB First<br>Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit or the location of the start or stop bits. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0.<br>1b - MSB (bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. Further, the first bit received after the start bit is identified as bit9, bit8, bit7 or bit6 depending on the setting of CTRL[M] and CTRL[PE]. |
| 28<br>RXINV | Receive Data Inversion<br>Setting this bit reverses the polarity of the received data input. This bit should only be changed when the receiver is disabled.<br>**NOTE:** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle.<br>0b - Receive data not inverted.<br>1b - Receive data inverted. |
| 27 | Receive Wake Up Idle Detect |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RWUID | For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should only be changed when the receiver is disabled.<br>0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match.<br>1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match. |
| 26<br>BRK13 | Break Character Generation Length<br>BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit. This bit should only be changed when the transmitter is disabled. A break character can be sent by setting CTRL[SBK] or by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.<br>0b - Break character is transmitted with length of 9 to 13 bit times.<br>1b - Break character is transmitted with length of 12 to 15 bit times. |
| 25<br>LBKDE | LIN Break Detection Enable<br>LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive data buffer.<br>0b - LIN break detect is disabled, normal break character can be detected.<br>1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1). |
| 24<br>RAF | Receiver Active Flag<br>RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line.<br>0b - LPUART receiver idle waiting for a start bit.<br>1b - LPUART receiver active (RXD input not idle). |
| 23<br>TDRE | Transmit Data Register Empty Flag<br>When the transmit FIFO is enabled, TDRE will set when the number of datawords in the transmit FIFO (LPUART_DATA) is equal to or less than the number indicated by LPUART_WATER[TXWATER]). To clear TDRE, write to the LPUART data register (LPUART_DATA) until the number of words in the transmit FIFO is greater than the number indicated by LPUART_WATER[TXWATER]. When the transmit FIFO is disabled,TDRE will set when the transmit data register (LPUART_DATA) is empty. To clear TDRE, write to the LPUART data register (LPUART_DATA).<br>TDRE is not affected by a character that is in the process of being transmitted, it is updated at the start of each transmitted character.<br>0b - Transmit data buffer full.<br>1b - Transmit data buffer empty. |
| 22<br>TC | Transmission Complete Flag<br>TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to LPUART_DATA to transmit new data, queuing a preamble by clearing and then setting LPUART_CTRL[TE], queuing a break character by writing 1 to LPUART_CTRL[SBK].<br>0b - Transmitter active (sending data, a preamble, or a break).<br>1b - Transmitter idle (transmission activity complete). |
| 21<br>RDRF | Receive Data Register Full Flag<br>When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by LPUART_WATER[RXWATER]. To clear RDRF, read LPUART_DATA until the number of datawords in the receive data buffer is equal to or less than the number indicated by LPUART_WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (LPUART_DATA) is full. To clear RDRF, read the LPUART_DATA register. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character will continue to be received until an overrun condition occurs once the entire character is received.<br>0b - Receive data buffer empty.<br>1b - Receive data buffer full. |
| 20<br>IDLE | Idle Line Flag<br>IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When ILT is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When ILT is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.<br>To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot become set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag . IDLE is set only once even if the receive line remains idle for an extended period.<br>0b - No idle line detected.<br>1b - Idle line was detected. |
| 19<br>OR | Receiver Overrun Flag<br>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received.<br>While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag.<br>0b - No overrun.<br>1b - Receive overrun (new LPUART data lost). |
| 18<br>NF | Noise Flag<br>The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from LPUART_DATA was received with noise detected within the character. To clear NF, write logic one to the NF.<br>0b - No noise detected.<br>1b - Noise detected in the received character in LPUART_DATA. |
| 17<br>FE | Framing Error Flag<br>FE is set whenever the next character to be read from LPUART_DATA was received with logic 0 detected where a stop bit was expected. To clear FE, write logic one to the FE.<br>0b - No framing error detected. This does not guarantee the framing is correct.<br>1b - Framing error. |
| 16<br>PF | Parity Error Flag<br>PF is set whenever the next character to be read from LPUART_DATA was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic one to the PF.<br>0b - No parity error.<br>1b - Parity error. |
| 15<br>MA1F | Match 1 Flag |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | MA1F is set whenever the next character to be read from LPUART_DATA matches MA1. To clear MA1F, write a logic one to the MA1F.<br>0b - Received data is not equal to MA1<br>1b - Received data is equal to MA1 |
| 14<br>MA2F | Match 2 Flag<br>MA2F is set whenever the next character to be read from LPUART_DATA matches MA2. To clear MA2F, write a logic one to the MA2F.<br>0b - Received data is not equal to MA2<br>1b - Received data is equal to MA2 |
| 13-0<br>— | Reserved |

## 56.3.4.8.4 Fields

| Field | Function |
|---|---|
| 31<br>R8T9 | Receive Bit 8 / Transmit Bit 9<br>R8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading LPUART_DATA.<br>T9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When writing 10-bit data, write T9 before writing LPUART_DATA. If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.<br>**NOTE:** R8 is a read-only bit and T9 is a write-only bit, the value read is different from the value written. |
| 30<br>R9T8 | Receive Bit 9 / Transmit Bit 8<br>R9 is the tenth data bit received when the LPUART is configured for 10-bit data formats. When reading 10-bit data, read R9 before reading LPUART_DATA<br>T8 is the ninth data bit received when the LPUART is configured for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing LPUART_DATA. If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, they it need not be written each time LPUART_DATA is written.<br>**NOTE:** R9 is a read-only bit and T8 is a write-only bit, the value read is different from the value written. |
| 29<br>TXDIR | TXD Pin Direction in Single-Wire Mode<br>When the LPUART is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TXD pin. When clearing TXDIR, the transmitter will finish receiving the current character (if any) before the receiver starts receiving data from the TXD pin.<br>0b - TXD pin is an input in single-wire mode.<br>1b - TXD pin is an output in single-wire mode. |
| 28<br>TXINV | Transmit Data Inversion<br>Setting this bit reverses the polarity of the transmitted data output.<br>**NOTE:** Setting TXINV inverts the TXD output for all cases: data bits, start and stop bits, break, and idle.<br>0b - Transmit data not inverted.<br>1b - Transmit data inverted. |
| 27<br>ORIE | Overrun Interrupt Enable<br>This bit enables the overrun flag (OR) to generate hardware interrupt requests.<br>0b - OR interrupts disabled; use polling.<br>1b - Hardware interrupt requested when OR is set. |
| 26<br>NEIE | Noise Error Interrupt Enable<br>This bit enables the noise flag (NF) to generate hardware interrupt requests.<br>0b - NF interrupts disabled; use polling.<br>1b - Hardware interrupt requested when NF is set. |
| 25<br>FEIE | Framing Error Interrupt Enable<br>This bit enables the framing error flag (FE) to generate hardware interrupt requests.<br>0b - FE interrupts disabled; use polling.<br>1b - Hardware interrupt requested when FE is set. |
| 24<br>PEIE | Parity Error Interrupt Enable<br>This bit enables the parity error flag (PF) to generate hardware interrupt requests.<br>0b - PF interrupts disabled; use polling).<br>1b - Hardware interrupt requested when PF is set. |
| 23 | Transmit Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TIE | Enables STAT[TDRE] to generate interrupt requests.<br>0b - Hardware interrupts from TDRE disabled; use polling.<br>1b - Hardware interrupt requested when TDRE flag is 1. |
| 22<br>TCIE | Transmission Complete Interrupt Enable for<br>TCIE enables the transmission complete flag, TC, to generate interrupt requests.<br>0b - Hardware interrupts from TC disabled; use polling.<br>1b - Hardware interrupt requested when TC flag is 1. |
| 21<br>RIE | Receiver Interrupt Enable<br>Enables STAT[RDRF] to generate interrupt requests.<br>0b - Hardware interrupts from RDRF disabled; use polling.<br>1b - Hardware interrupt requested when RDRF flag is 1. |
| 20<br>ILIE | Idle Line Interrupt Enable<br>ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests.<br>0b - Hardware interrupts from IDLE disabled; use polling.<br>1b - Hardware interrupt requested when IDLE flag is 1. |
| 19<br>TE | Transmitter Enable<br>Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit will read as 1 until the transmitter has completed the current character and the TXD pin is tristated.<br>A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set.<br>0b - Transmitter disabled.<br>1b - Transmitter enabled. |
| 18<br>RE | Receiver Enable<br>Enables the LPUART receiver. When RE is written to 0, this register bit will read as 1 until the receiver finishes receiving the current character (if any).<br>0b - Receiver disabled.<br>1b - Receiver enabled. |
| 17<br>RWU | Receiver Wakeup Control<br>This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear.<br>**NOTE:** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted.<br>0b - Normal receiver operation.<br>1b - LPUART receiver in standby waiting for wakeup condition. |
| 16<br>SBK | Send Break<br>Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if LPUART_STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK.<br>A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.<br>0b - Normal transmitter operation.<br>1b - Queue break character(s) to be sent. |

| Field | Function |
|---|---|
| 15<br>MA1IE | Match 1 Interrupt Enable<br>0b - MA1F interrupt disabled<br>1b - MA1F interrupt enabled |
| 14<br>MA2IE | Match 2 Interrupt Enable<br>0b - MA2F interrupt disabled<br>1b - MA2F interrupt enabled |
| 13-12<br>— | Reserved |
| 11<br>M7 | 7-Bit Mode Select<br>This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - Receiver and transmitter use 8-bit to 10-bit data characters.<br>1b - Receiver and transmitter use 7-bit data characters. |
| 10-8<br>IDLECFG | Idle Configuration<br>Configures the number of idle characters that must be received before the IDLE flag is set.<br>000b - 1 idle character<br>001b - 2 idle characters<br>010b - 4 idle characters<br>011b - 8 idle characters<br>100b - 16 idle characters<br>101b - 32 idle characters<br>110b - 64 idle characters<br>111b - 128 idle characters |
| 7<br>LOOPS | Loop Mode Select<br>When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.<br>0b - Normal operation - RXD and TXD use separate pins.<br>1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit). |
| 6<br>DOZEEN | Doze Enable<br>0b - LPUART is enabled in Doze mode.<br>1b - LPUART is disabled in Doze mode. |
| 5<br>RSRC | Receiver Source Select<br>This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.<br>0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin.<br>1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input. |
| 4<br>M | 9-Bit or 8-Bit Mode Select<br>0b - Receiver and transmitter use 8-bit data characters.<br>1b - Receiver and transmitter use 9-bit data characters. |
| 3<br>WAKE | Receiver Wakeup Method Select<br>Determines which condition wakes the LPUART when RWU=1:<br>• Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character, or<br>• An idle condition on the receive pin input signal.<br><br>0b - Configures RWU for idle-line wakeup.<br>1b - Configures RWU with address-mark wakeup. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 2<br>ILT | Idle Line Type Select<br>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.<br>**NOTE:** In case the LPUART is programmed with ILT = 1, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count.<br>0b - Idle character bit count starts after start bit.<br>1b - Idle character bit count starts after stop bit. |
| 1<br>PE | Parity Enable<br>Enables hardware parity generation and checking. When parity is enabled, the bit immediately before the stop bit is treated as the parity bit.<br>0b - No hardware parity generation or checking.<br>1b - Parity enabled. |
| 0<br>PT | Parity Type<br>Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even.<br>0b - Even parity.<br>1b - Odd parity. |

## 56.3.4.9 LPUART Data Register (DATA)

### 56.3.4.9.1 Offset

| Register | Offset |
|---|---|
| DATA | 1Ch |

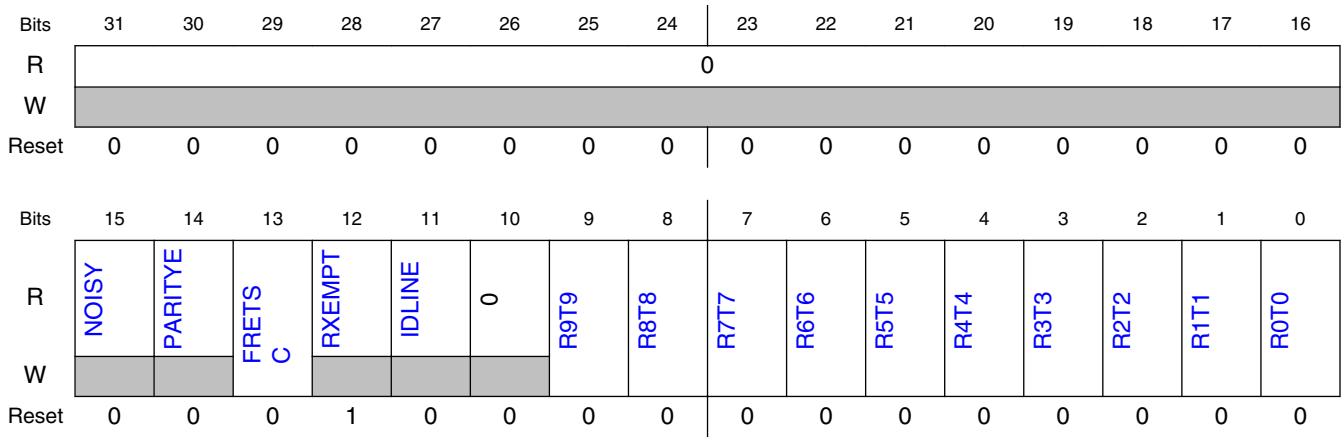
### 56.3.4.9.2 Function

**NOTE**

This register is two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer.

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status flags.

### 56.3.4.9.3 Diagram



### 56.3.4.9.4 Fields

| Field | Function |
|---|---|

Software should only write a MA register when the associated BAUD[MAEN] bit is clear. |

## 56.3.4.11 LPUART Modem IrDA Register (MODIR)

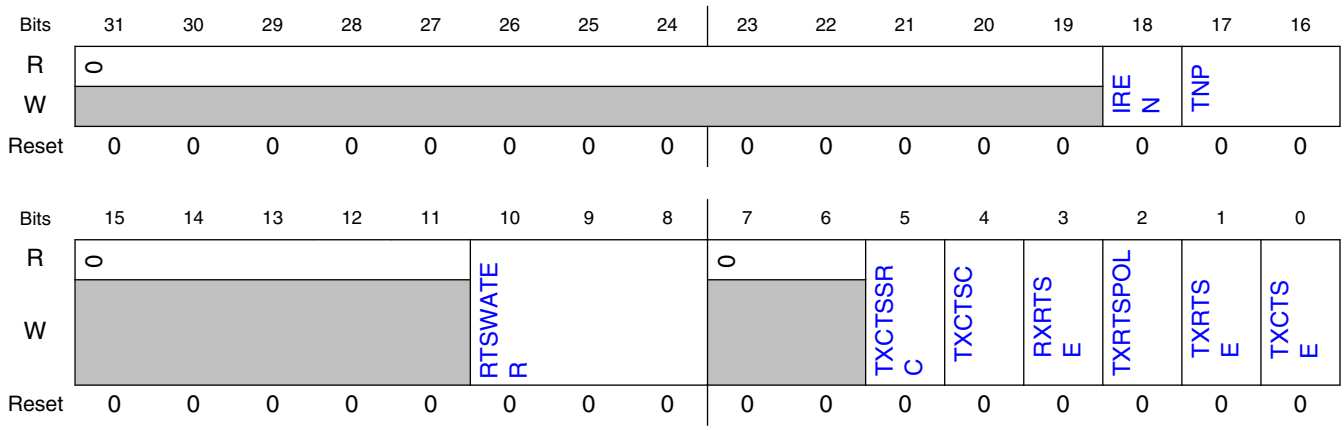
### 56.3.4.11.1 Offset

| Register | Offset |
|---|---|
| MODIR | 24h |

### 56.3.4.11.2 Function

The MODEM register controls options for setting the modem configuration.

## 56.3.4.11.3 Diagram



## 56.3.4.11.4 Fields

| Field | Function |
|---|---|
| 31-19<br>— | Reserved |
| 18<br>IREN | Infrared enable<br>Enables/disables the infrared modulation/demodulation. This bit should only be changed when the transmitter and receiver are both disabled.<br>0b - IR disabled.<br>1b - IR enabled. |
| 17-16<br>TNP | Transmitter narrow pulse<br>Configures whether the LPUART transmits a 1/OSR, 2/OSR, 3/OSR or 4/OSR narrow pulse when IR is enabled. This bit should only be changed when the transmitter and receiver are both disabled.<br>The IR pulse width should be configured to less than half of the oversampling ratio. Common pulse widths are 3/16, 1/16, 1/32 or 1/4 of the bit length. These can be configured by selecting the appropriate oversample ratio and pulse width.<br>00b - 1/OSR.<br>01b - 2/OSR.<br>10b - 3/OSR.<br>11b - 4/OSR. |
| 15-11<br>— | Reserved |
| 10-8<br>RTSWATER | Receive RTS Configuration<br>Configures the assertion and negation of the RX RTS_B output. The RX RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to RTSWATER. If RTSWATER is configured to zero, RTS_B negates when the receive FIFO is full. For the purpose of RX RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both RX RTS_B and address/data matching is enabled, then RTS_B could assert at the end of a character if there is not a match. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | This field should only be changed when the receiver is disabled. |
| 7-6<br>— | Reserved |
| 5<br>TXCTSSRC | Transmit CTS Source<br>Configures the source of the CTS input.<br>0b - CTS input is the CTS_B pin.<br>1b - CTS input is the inverted Receiver Match result. |
| 4<br>TXCTSC | Transmit CTS Configuration<br>Configures if the CTS state is checked at the start of each character or only when the transmitter is idle.<br>0b - CTS input is sampled at the start of each character.<br>1b - CTS input is sampled when the transmitter is idle. |
| 3<br>RXRTSE | Receiver request-to-send enable<br>Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. This bit should only be changed when the receiver is disabled.<br>**NOTE:** Do not set both RXRTSE and TXRTSE.<br>0b - The receiver has no effect on RTS.<br>1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full. |
| 2<br>TXRTSPOL | Transmitter request-to-send polarity<br>Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. This bit should only be changed when the transmitter is disabled.<br>0b - Transmitter RTS is active low.<br>1b - Transmitter RTS is active high. |
| 1<br>TXRTSE | Transmitter request-to-send enable<br>Controls RTS before and after a transmission. This bit should only be changed when the transmitter is disabled.<br>0b - The transmitter has no effect on RTS.<br>1b - When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. |
| 0<br>TXCTSE | Transmitter clear-to-send enable<br>TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.<br>0b - CTS has no effect on the transmitter.<br>1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission. |

## 56.3.4.12 LPUART FIFO Register (FIFO)

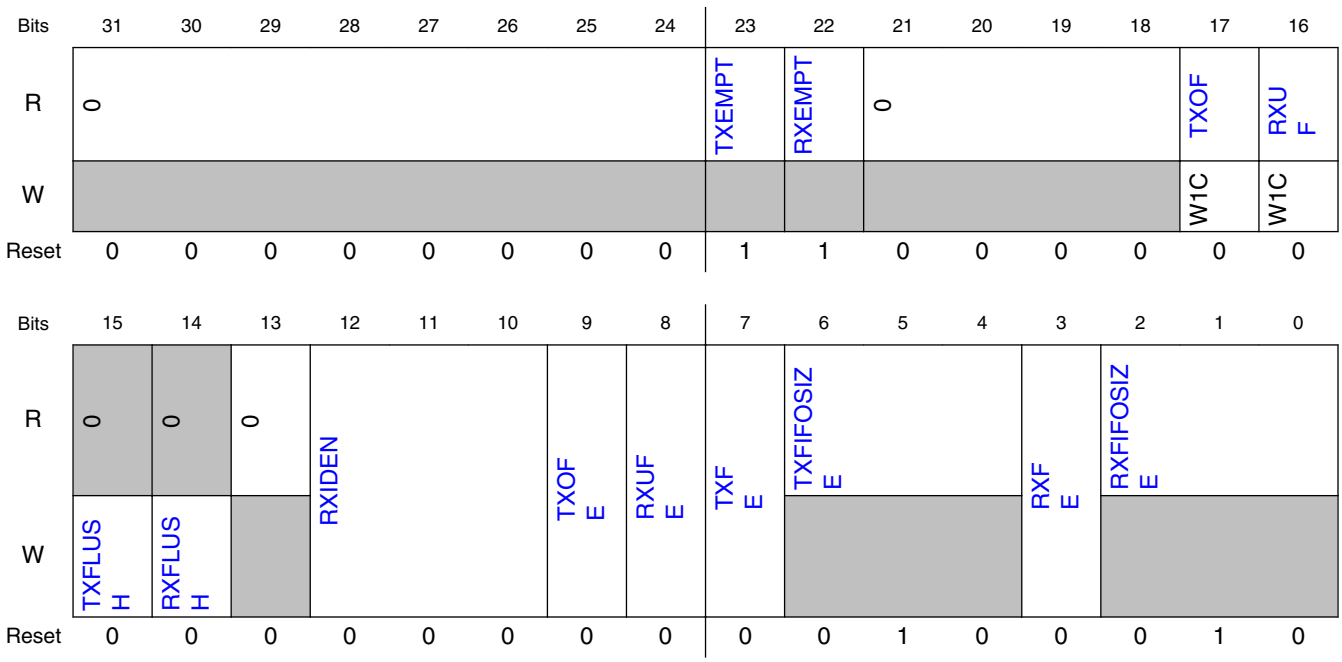
### 56.3.4.12.1 Offset

| Register | Offset |
|---|---|
| FIFO | 28h |

### 56.3.4.12.2 Function

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when CTRL[RE] and CTRL[TE] are cleared/not set and when the data buffer/FIFO is empty.

### 56.3.4.12.3 Diagram



### 56.3.4.12.4 Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23<br>TXEMPT | Transmit Buffer/FIFO Empty<br>Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register.<br>0b - Transmit buffer is not empty. |

For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE]. |

## 56.4 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

### 56.4.1 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while the transmitter is driven by a bit clock which is generated from baud rate clock divided by the over sampling ratio. Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

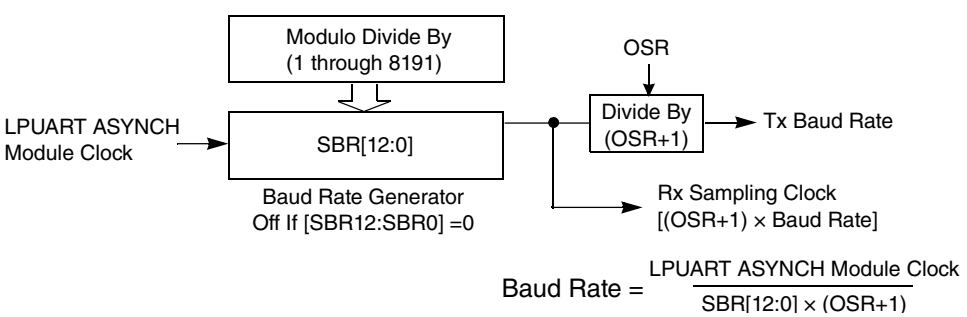

**Figure 56-3. LPUART baud rate generation**

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

The baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled, each transmitted character will align to the next edge of the transmit bit clock.

## 56.4.2 Transmitter functional description

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high, CTRL[TXINV] is cleared following reset. The transmitter output is inverted by setting CTRL[TXINV]. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit data buffer. Programs store data into the transmit data buffer by writing to the DATA register.

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13 bits long depending on the setting in the CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the transmit data register is transferred to the shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit data buffer at the DATA register.

If no new character is waiting in the transmit data buffer after a stop bit is shifted out the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter will not start transmitting another character.

### 56.4.2.1 Send break and queued idle

The CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting STAT[BRK13]. Normally, a program would wait for STAT[TDRE] to become set

to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. When the LPUART is the receiving device, a break character is received as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

A break character can also be transmitted by writing to the DATA register with bit 13 set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program would wait for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, then write 0 and then write 1 to the CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the TXD pin.

An idle character can also be transmitted by writing to the DATA register with bit 13 set and the data bits also set. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit a idle character.

The length of the break character is affected by the STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SNBS] bits as shown below.

**Table 56-2. Break character length**

| BRK13 | M | M10 | M7 | SBNS | Break character length |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | 10 bit times |
| 0 | 0 | 0 | 0 | 1 | 11 bit times |
| 0 | 0 | 0 | 1 | 0 | 9 bit times |
| 0 | 0 | 0 | 1 | 1 | 10 bit times |
| 0 | 1 | 0 | X | 0 | 11 bit times |
| 0 | 1 | 0 | X | 1 | 12 bit times |
| 0 | X | 1 | X | 0 | 12 bit times |
| 0 | X | 1 | X | 1 | 13 bit times |
| 1 | 0 | 0 | 0 | 0 | 13 bit times |
| 1 | 0 | 0 | 0 | 1 | 13 bit times |
| 1 | 0 | 0 | 1 | 0 | 12 bit times |
| 1 | 0 | 0 | 1 | 1 | 12 bit times |
| 1 | 1 | 0 | X | 0 | 14 bit times |
| 1 | 1 | 0 | X | 1 | 14 bit times |

*Table continues on the next page...*

**Table 56-2. Break character length (continued)**

| BRK13 | M | M10 | M7 | SBNS | Break character length |
|---|---|---|---|---|---|
| 1 | X | 1 | X | 0 | 15 bit times |
| 1 | X | 1 | X | 1 | 15 bit times |

### 56.4.2.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the clear-to-send operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter data buffer, the character in the shift register is sent and TXD remains in the mark state until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee a new transmission is started when the transmitter is idle with data to send.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can also be enabled even if the same LPUART receiver's RTS_B signal is disabled.

### 56.4.2.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, RTS_B asserts one bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmitter data buffer has any characters. RTS_B deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B will remain asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

### 56.4.2.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the LPUART is driving. The RTS_B signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

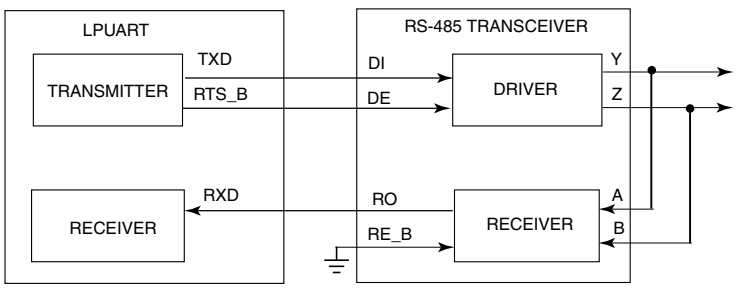

**Figure 56-4. Transceiver driver enable using RTS_B**

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the RXD pin for other uses.

## 56.4.3 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting STAT[RXINV]. The receiver is enabled by setting the CTRL[RE] bit. Character frames consist of a start bit of logic 0, seven to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit or 10-bit data mode, refer to Data Modes. For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (STAT[RDRF]) status flag is set. If [RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost. Because the LPUART receiver is double-buffered, the program has one full character time after [RDRF] is set before the data in the receive data buffer must be read to avoid a receiver overrun.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. Refer to Interrupts and status flags for details about flag clearing.

### 56.4.3.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (STAT[NF]) is set when the received character is transferred to the receive data buffer.

When the LPUART receiver is configured to sample on both edges of the baud rate clock, the number of segments in each received bit is effectively doubled (from 1 to OSR×2). The start and data bits are then sampled at OSR, OSR+1 and OSR+2. Sampling on both edges of the clock must be enabled for oversampling rates of 4× to 7× and is optional for higher oversampling rates.

The falling edge detection logic continuously looks for falling edges. If an edge is detected, the sample clock is resynchronized to bit times (unless resynchronization has been disabled). This improves the reliability of the receiver in the presence of noise or mismatched baud rates. It does not improve worst case analysis because some characters do not have any extra falling edges anywhere in the character frame.

In the case of a framing error, provided the received character was not a break character, the sampling logic that searches for a falling edge is filled with three logic 1 samples so that a new start bit can be detected almost immediately.

### 56.4.3.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (CTRL[RWU]). When CTRL[RWU] and STAT[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, STAT[IDLE], are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, or at the beginning of the next message, all receivers automatically force CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver will ignore all characters that do not meet the address match requirements.

**Table 56-3. Receiver Wakeup Options**

| RWU | MA1 \| MA2 | MATCFG | WAKE:RWUID | Receiver Wakeup |
|---|---|---|---|---|
| 0 | 0 | X | X | Normal operation |
| 1 | 0 | 00 | 00 | Receiver wakeup on idle line, IDLE flag not set |
| 1 | 0 | 00 | 01 | Receiver wakeup on idle line, IDLE flag set |
| 1 | 0 | 00 | 10 | Receiver wakeup on address mark |
| 1 | 1 | 11 | X0 | Receiver wakeup on data match |
| 0 | 1 | 00 | X0 | Address mark address match, IDLE flag not set for discarded characters |
| 0 | 1 | 00 | X1 | Address mark address match, IDLE flag set for discarded characters |
| 0 | 1 | 01 | X0 | Idle line address match |
| 0 | 1 | 10 | X0 | Address match on and address match off, IDLE flag not set for discarded characters |
| 0 | 1 | 10 | X1 | Address match on and address match off, IDLE flag set for discarded characters |

#### 56.4.3.2.1 Idle-line wakeup

When wake is cleared, the receiver is configured for idle-line wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The CTRL[M], CTRL[M7] and BAUD[M10] control bit selects 7-bit to 10-bit data mode and the BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is one and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not set the STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the STAT[RDRF] flag and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition sets the STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The idle-line type (CTRL[ILT]) control bit selects one of two ways to detect an idle line. When CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle. When CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

#### 56.4.3.2.2 Address-mark wakeup

When CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame clears the CTRL[RWU] bit and sets the STAT[RDRF] flag. In this case, the character with the address-mark bit is received even though the receiver was sleeping during most of this character time.

#### 56.4.3.2.3 Data match wakeup

When CTRL[RWU] is set and BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.

#### 56.4.3.2.4 Address Match operation

Address match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 00. In this function, a character received by the RXD pin with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs then no transfer is made to the receive data buffer, and all following characters with logic zero in the most significant bit (or second most significant bit when parity is enabled) are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register field and data is transferred to the receive data buffer only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either of the MATCH[MA1] or MATCH[MA2] fields.

#### 56.4.3.2.5 Idle Match operation

Idle match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 01. In this function, the first character received by the RXD pin after an idle line condition is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive data buffer until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive data buffer, and all following frames until the next idle condition are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Idle match operation functions in the same way for both MATCH[MA1] or MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, the first character after an idle line is compared with both MATCH[MA1] or MATCH[MA2] fields and data is transferred only on a match with either of the fields.

#### 56.4.3.2.6 Match On Match Off operation

Match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are set and BAUD[MATCFG] is equal to 10. In this function, a character received by the RXD pin that matches MATCH[MA1] is received and transferred to the receive buffer, and STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive data buffer, until a character is received that matches MATCH[MA2] field. The character that matches MATCH[MA2] and all following characters are discarded; this continues until another character that matches MATCH[MA1] is received. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

**NOTE**

Match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be asserted.

### 56.4.3.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS_B.

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS_B if the number of characters in the receiver data register is full or a start bit is detected that will cause the receiver data register to be full.
- The receiver asserts RTS_B when the number of characters in the receiver data register is not full and has not detected a start bit that will cause the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.

- Even if RTS_B is deasserted, the receiver continues to receive characters until the receiver data buffer is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS_B remains deasserted.

#### 56.4.3.4 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received.

##### 56.4.3.4.1 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

##### 56.4.3.4.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

##### 56.4.3.4.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

##### 56.4.3.4.4 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

## 56.4.4 Additional LPUART functions

The following sections describe additional LPUART functions.

### 56.4.4.1 Data Modes

The LPUART transmitter and receiver can be configured to operate in 7-bit data mode by setting CTRL[M7], 9-bit data mode by setting the CTRL[M] or 10-bit data mode by setting BAUD[M10]. In 9-bit mode, there is a ninth data bit and in 10-bit mode, there is a tenth data bit. For the transmit data buffer, these bits are stored in CTRL[T8] and CTRL[T9]. For the receiver, these bits are held in CTRL[R8] and CTRL[R9]. They are also accessible via 16-bit or 32-bit accesses to the DATA register.

For coherent 8-bit writes to the transmit data buffer, write to CTRL[T8] and CTRL[T9] before writing to DATA[7:0]. For 16-bit and 32-bit writes to the DATA register, all 10 transmit bits are written to the transmit data buffer at the same time.

If the bit values to be transmitted as the ninth and tenth bit of a new character are the same as for the previous character, it is not necessary to write to CTRL[T8] and CTRL[T9] again. When data is transferred from the transmit data buffer to the transmit shifter, the value in CTRL[T8] and CTRL[T9] is copied at the same time data is transferred from DATA[7:0] to the shifter.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

### 56.4.4.2 Idle length

An idle character is a character where the start bit, all data bits and stop bits are in the mark position. The CTRL[ILT] bit can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.

The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit will cause any discarded characters to be treated as if they were idle characters.

#### 56.4.4.3 Loop mode

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RXD pin is not used by the LPUART.

#### 56.4.4.4 Single-wire operation

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In single-wire mode, the CTRL[TXDIR] bit controls the direction of serial data on the TXD pin. When CTRL[TXDIR] is cleared, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so an external device can send serial data to the receiver. When CTRL[TXDIR] is set, the TXD pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

### 56.4.5 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This module covers data rates only between 2.4 kbits/s and 115.2 kbits/s.

The LPUART has an infrared transmit encoder and receive decoder. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the LPUART. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

#### 56.4.5.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1/OSR, 2/OSR, 3/OSR, or 4/OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is set.

#### 56.4.5.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is cleared, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

### 56.4.6 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit data register empty STAT[TDRE]) indicates when there is room in the transmit data buffer to write another transmit character to the DATA register. If the transmit interrupt enable CTRL[TIE]) bit is set, a hardware interrupt is requested when STAT[TDRE] is set. Transmit complete (STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at

the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (CTRL[TCIE]) bit is set, a hardware interrupt is requested when STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the STAT[TDRE] and STAT[TC] status flags if the corresponding CTRL[TIE] or CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. The STAT[RDRF] flag is cleared by reading the DATA register.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RXD line remains idle for an extended period of time. IDLE is cleared by writing 1 to the STAT[IDLE] flag. After STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set STAT[RDRF].

If the associated error was detected in the received character that caused STAT[RDRF] to be set, the error flags - noise flag (STAT[NF]), framing error (STAT[FE]), and parity error flag (STAT[PF]) - are set at the same time as STAT[RDRF]. These flags are not set in overrun cases.

If STAT[RDRF] was already set when a new character is ready to be transferred from the receive shifter to the receive data buffer, the overrun (STAT[OR]) flag is set instead of the data along with any associated NF, FE, or PF condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the STAT[MA1F] and/or STAT[MA2F] flags are set at the same time that STAT[RDRF] is set.

At any time, an active edge on the RXD serial data input pin causes the STAT[RXEDGIF] flag to set. The STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

## 56.4.7 Peripheral Triggers

The connection of the LPUART peripheral triggers with other peripherals are device specific.

### 56.4.7.1 Output Triggers

The LPUART generates three output triggers that can be connected to other peripherals on the device.

- The transmit word trigger asserts at the end of each transmitted word, it negates after one bit period.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts at when the idle flag would set, for one oversampling clock period.

### 56.4.7.2 Input Trigger

The LPUART supports one peripheral input trigger, that can be configured in one of the following ways.

- The input trigger can be connected in place of the CTS_B pin input. The input trigger must assert for longer than one bit clock period when the transmitter is idle with data to send to guarantee a new transmission.
- The input trigger can modulate the transmit data output (trigger is logically ANDed with the TXD output). The input trigger is expected to be generated from a PWM source with a period that is less than the bit clock frequency.
- The input trigger can be connected in place of the RXD pin input. The input trigger is expected to be generated from a receive data source, such as analog comparator or external pin.

# Chapter 57
# Low Power Serial Peripheral Interface (LPSPI)

## 57.1 Chip-specific LPSPI information

### 57.1.1 LPSPI instantiations

The following list describes the LPSPI instantions on this device:

- Instantiations: 4, LPSPI0-2 belong to CM4F domain, LPSPI3 belongs to CM0+ domain
- Receive FIFO size: 4 entries
- Transmit FIFO size: 4 entries

## 57.2 Introduction

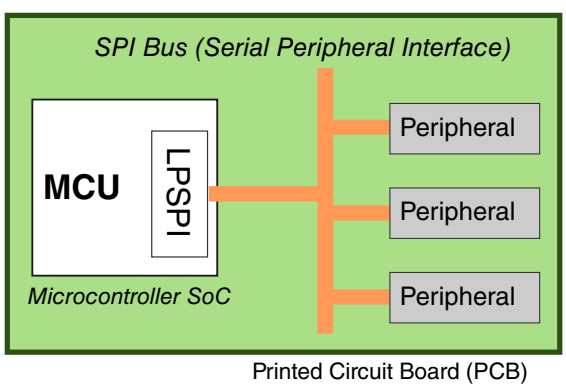

**Figure 57-1. SPI bus connects MCU to peripherals on PCB**

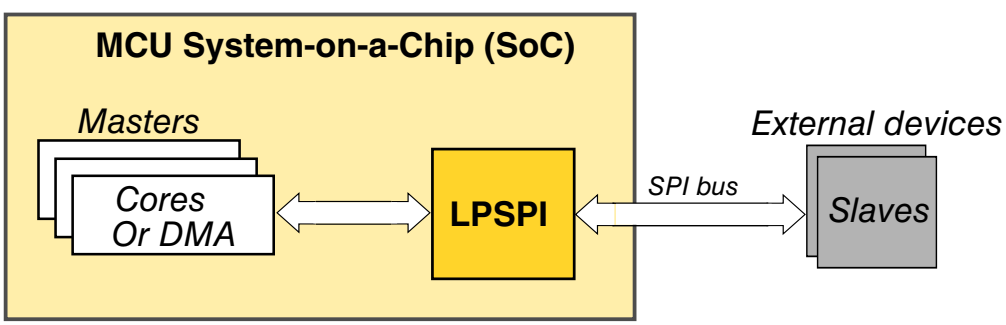
The LPSPI is a low power Serial Peripheral Interface (SPI) module that supports an efficient interface to an SPI bus, either as a master and/or as a slave.

- The LPSPI is designed to use little CPU overhead, with DMA offloading of FIFO register accesses.
- The LPSPI can continue operating in stop modes, if an appropriate clock is available.

**NOTE**

The Serial Peripheral Interface bus (SPI) is a synchronous serial communication interface used in embedded systems, typically to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing to Secure Digital cards and LCD displays.

- SPI devices communicate in full duplex mode using a master-slave scheme with a single master. This enables communication in both directions to happen simultaneously.
- Multiple slave devices are selected using individual slave select (SS) lines.
- The master device originates the frame for reading and writing.



*Cores or DMA in an MCU SoC use LPSPI to communicate with external devices over a serial bus.*

**Figure 57-2. LPSPI connects masters in MCU to external slaves on PCB**

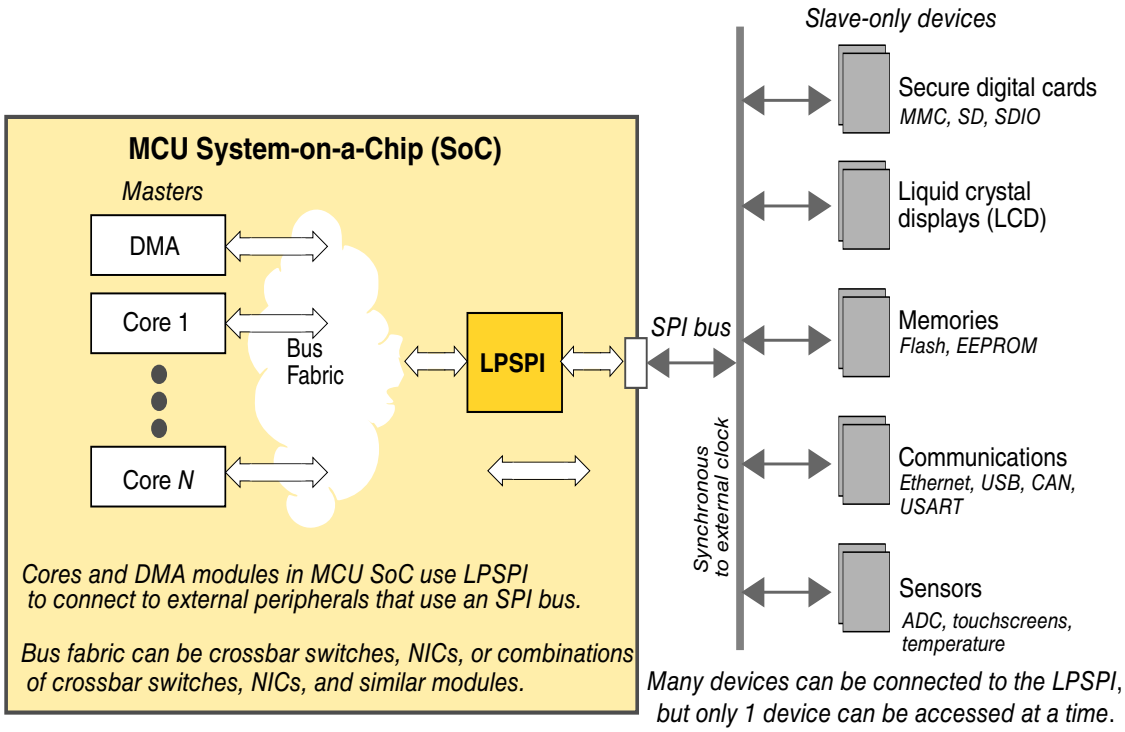


**Figure 57-3. Typical LPSPI connection scheme**

- SPI accesses are always synchronous to the external clock.
- Each SPI can only assert one chip select at a time, but technically there can be multiple SPI slaves sharing the same chip select (in the form of a larger shift register). This requires:
  - the SDO of the master to connect to the SDI of the first slave,
  - the SDO of first slave to connect to the SDI of the next slave,
  - and the SDO of last slave to connect to the SDI of the LPSPI master.

  Note that some SPI modules use MISO/MOSI for the input/output data.
- The LPSPI supports DMA accesses and generates a DMA request.

## 57.2.1 Features

The LPSPI supports:

- Word size = 32 bits
- Configurable clock polarity and clock phase
- Master operation supporting up to 4 peripheral chip select
- Slave operation
- Command/transmit FIFO of 4 words
- Receive FIFO of 4 words

- Flexible timing parameters in master mode, including SCK frequency and delays between PCS and SCK edges
- Support for full duplex transfers supporting 1-bit transmit and receive on each clock edge
- Support for half duplex transfers supporting 1-bit transmit or receive on each clock edge
- Support for half duplex transfers supporting 2-bit or 4-bit transmit or receive on each clock edge (master only)
- Host request input can be used to control the start time of an SPI bus transfer (master only)
- Receive data match logic supporting wakeup on data match

## 57.2.2 Block Diagram

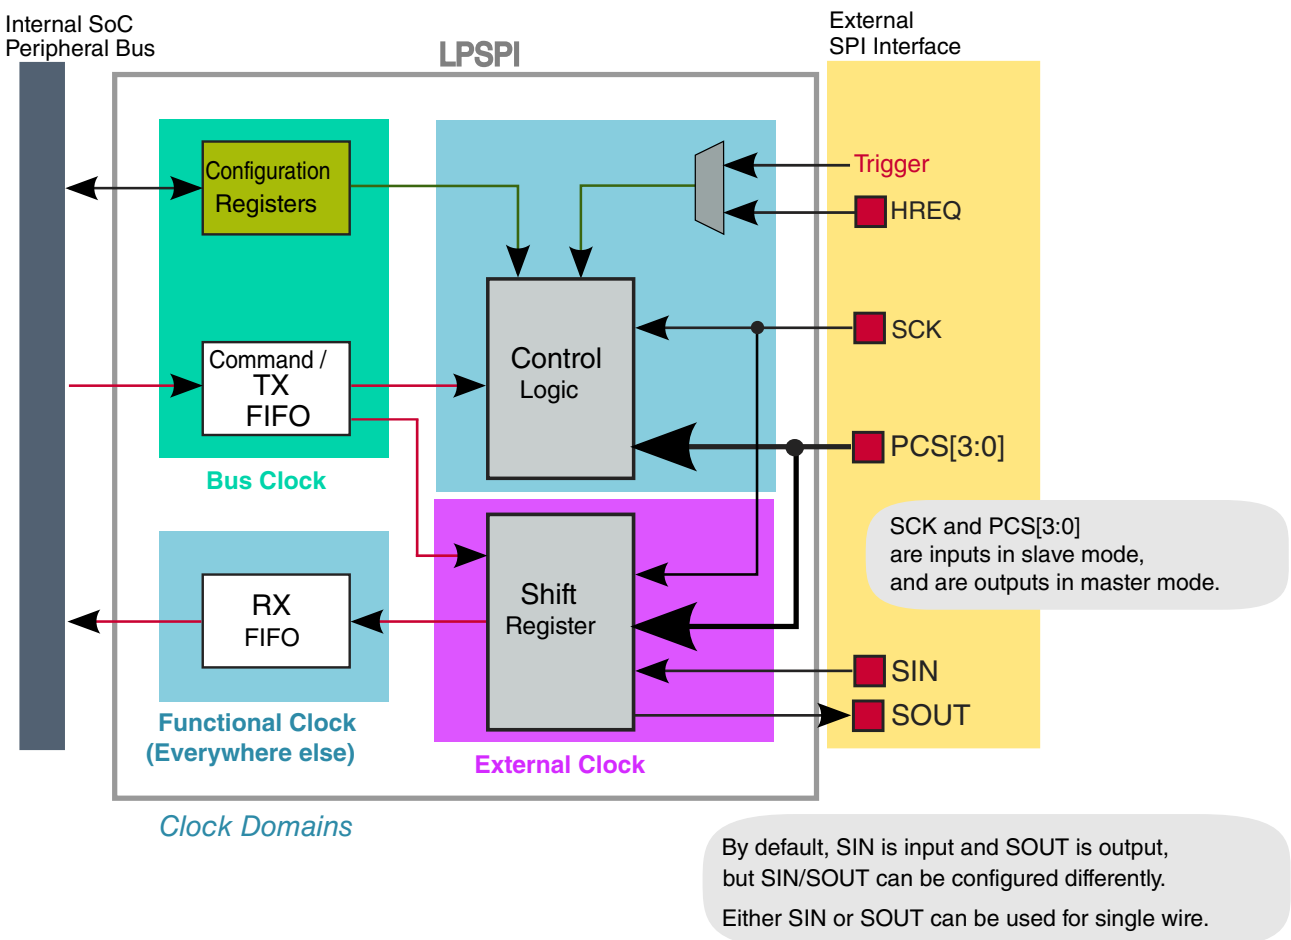

**Figure 57-4. Block Diagram**

## 57.2.3 Modes of operation

**Table 57-1. Chip modes supported by the LPSPI module**

| Chip mode | LPSPI Operation |
|---|---|
| Run | Normal operation |
| Stop/Wait | Can continue operating in stop mode if the Doze Enable bit (CR[DOZEN]) is clear and the LPSPI is using an external or internal clock source that remains operating during stop/wait modes. |
| Low Power Stop (also called Low Leakage Stop or LLS) | Before entering low power stop mode, the LPSPI will wait for the current transfer to finish any pending operation, temporarily ignoring the Doze Enable (CR[DOZEN]) bit. |
| Debug (the core is in Debug/Halted mode) | Can continue operating in debug mode, if the Debug Enable bit (CR[DBGEN]) is set. |

## 57.2.4 Signal Descriptions

**Table 57-2. Signals**

| Signal | Name | Description | I/O |
|---|---|---|---|
| SCK | Serial clock | • Input in slave mode<br>• Output in master mode | I/O |
| PCS[0] | Peripheral Chip Select | • Input in slave mode<br>• Output in master mode | I/O |
| PCS[1] / HREQ | Peripheral Chip Select<br>or<br>Host Request | Host Request pin is selected when HREN=1 and HRSEL=0<br>• Input in either slave mode or when used as Host Request<br>• Output in master mode | I/O |
| PCS[2] / DATA[2] | Peripheral Chip Select<br>or<br>data pin 2 during quad-data transfers | • Input in slave mode<br>• Output in master mode<br>• Input in quad-data receive transfers<br>• Output in quad-data transmit transfers | I/O |
| PCS[3] / DATA[3] | Peripheral Chip Select<br>or<br>data pin 3 during quad-data transfers | • Input in slave mode<br>• Output in master mode<br>• Input in quad-data receive transfers<br>• Output in quad-data transmit transfers | I/O |
| SOUT / DATA[0] | Serial Data Output | Can be configured as serial data input signal<br>• Used as data pin 0 in quad-data transfers<br>• Used as data pin 0 in dual-data transfers | I/O |
| SIN / DATA[1] | Serial Data Input | Can be configured as serial data output signal<br>• Used as data pin 1 in quad-data transfers<br>• Used as data pin 1 in dual-data transfers | I/O |

## 57.2.5 Wiring options

LPSPI can be used to implement typical (dedicated slave select lines) or daisy-chain (shared slave select lines) SPI busses.

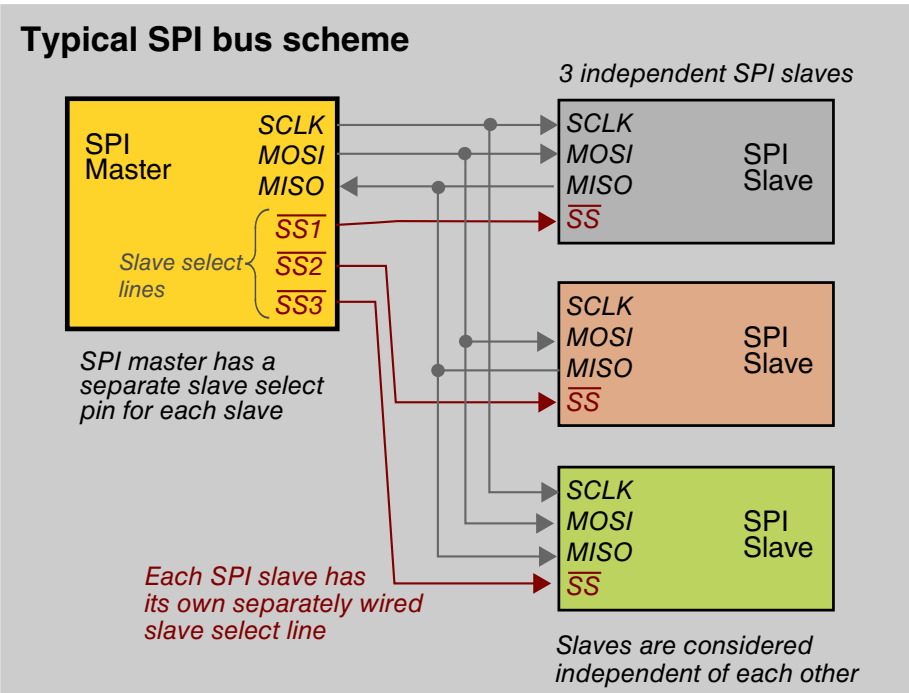

**Figure 57-5. Dedicated slave select lines scheme**

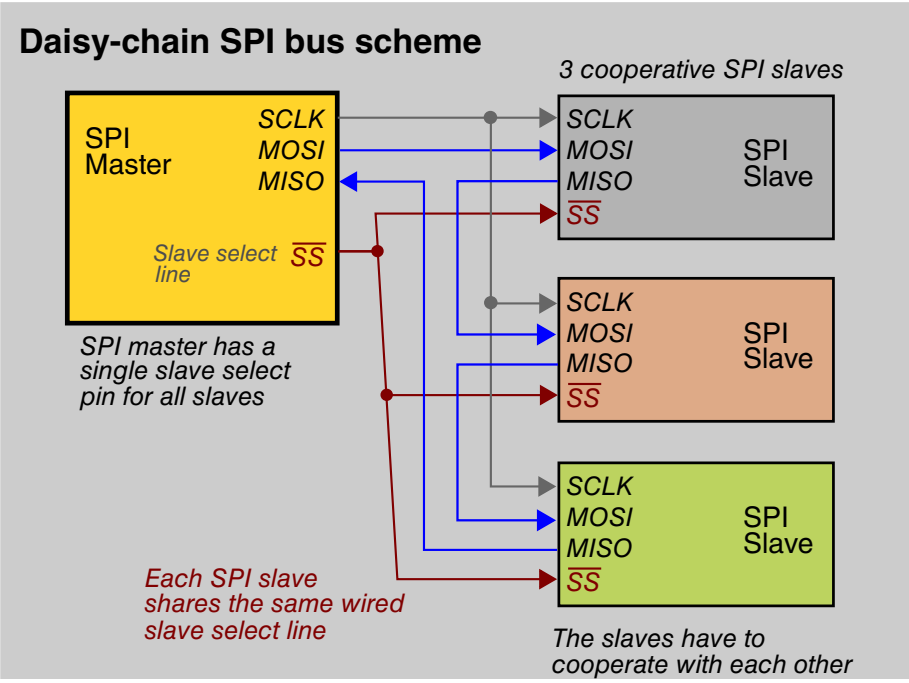

**Figure 57-6. Shared slave select lines (daisy-chain) scheme**

**Table 57-3. Wiring Scheme Differences**

| Item | Dedicated slave select lines | Shared slave select lines (daisy-chain) |
|---|---|---|
| slave select lines (pins on the master device) | • 1 slave select line (pin) for each slave; the scheme is limited by how many lines (pins) that the master device can support | • 1 slave select line (pin) for multiple slaves |
| data flow from master device to slave devices | • Master sends data directly to the slave that the data is for; the slaves for whom the data is not intended, simply ignore the data; this implies that those slaves could be asleep (if desired) | • Master sends data and multiple slaves have to forward the data through the daisy chain; this implies that all slaves must be on and awake when the master sends data to any slave |

# 57.3 Memory Map and Registers

## 57.3.1 LPSPI0 register descriptions

### 57.3.1.1 LPSPI0 Memory map

LPSPI0 base address: 4003_F000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID Register (VERID) | 32 | RO | 0101_0004h |

## 57.3.1.15 Transmit Command Register (TCR)

### 57.3.1.15.1 Offset

| Register | Offset |
|---|---|
| TCR | 60h |

### 57.3.1.15.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that the data are written. Command Register writes will be tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. Changing the command word will cause all subsequent SPI bus transfers to be performed using the new command word.

- **In master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware will clear TXMSK when the LPSPI_PCS negates.
- **In master mode,** if the command word is changed before an existing frame has completed, then the existing frame will terminate and the command word will then update. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In slave mode,** the command word should be changed only when the LPSPI is idle and there is no SPI bus transfer.

**Avoid register reading problems:** Reading the Transmit Command Register will return the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- to either read the Transmit Command Register when the transmit FIFO is empty,
- or to read the Transmit Command Register more than once and then compare the returned values.

The Peripheral Chip Select field is only updated between frames.<br>00b - Transfer using LPSPI_PCS[0]<br>01b - Transfer using LPSPI_PCS[1]<br>10b - Transfer using LPSPI_PCS[2]<br>11b - Transfer using LPSPI_PCS[3] |
| 23 | LSB First |

*Table continues on the next page...*

| Field | Function |
|---|---|
| LSBF | 0b - Data is transferred MSB first<br>1b - Data is transferred LSB first |
| 22<br>BYSW | Byte Swap<br>Byte swap will swap the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers).<br>0b - Byte swap is disabled<br>1b - Byte swap is enabled |
| 21<br>CONT | Continuous Transfer<br>• In master mode, continuous transfer will keep the PCS asserted at the end of the frame size, until a command word is received that starts a new frame.<br>• In slave mode, when continuous transfer is enabled, the LPSPI will only transmit the first FRAMESZ bits; after which the LPSPI will transmit received data (assuming a 32-bit shift register).<br><br>0b - Continuous transfer is disabled<br>1b - Continuous transfer is enabled |
| 20<br>CONTC | Continuing Command<br>In master mode, the Continuing Command bit allows the command word to be changed within a continuous transfer.<br>• The initial command word must enable continuous transfer (CONT=1),<br>• the continuing command must set this bit (CONTC=1),<br>• and the continuing command word must be loaded on a frame size boundary.<br><br>For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary.<br><br>0b - Command word for start of new transfer<br>1b - Command word for continuing transfer |
| 19<br>RXMSK | Receive Data Mask<br>When set, receive data is masked (receive data is not stored in receive FIFO).<br>0b - Normal transfer<br>1b - Receive data is masked |
| 18<br>TXMSK | Transmit Data Mask<br>When set, transmit data is masked (no data is loaded from transmit FIFO and output pin is tristated). In master mode, the Transmit Data Mask bit will initiate a new transfer which cannot be aborted by another command word; the Transmit Data Mask bit will be cleared by hardware at the end of the transfer.<br>0b - Normal transfer<br>1b - Mask transmit data |
| 17-16<br>WIDTH | Transfer Width<br>For 2-bit or 4-bit transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be set.<br>00b - 1 bit transfer<br>01b - 2 bit transfer<br>10b - 4 bit transfer<br>11b - Reserved |
| 15-12<br>— | Reserved. Software should only write zero to this field. |
| 11-0<br>FRAMESZ | Frame Size<br>Configures the frame size in number of bits equal to (FRAMESZ + 1).<br>• The minimum frame size is 8 bits<br>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. |

| Field | Function |
|---|---|
| | • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.<br>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32 bits, and the 3rd word is 8 bits. |

## 57.3.1.16 Transmit Data Register (TDR)

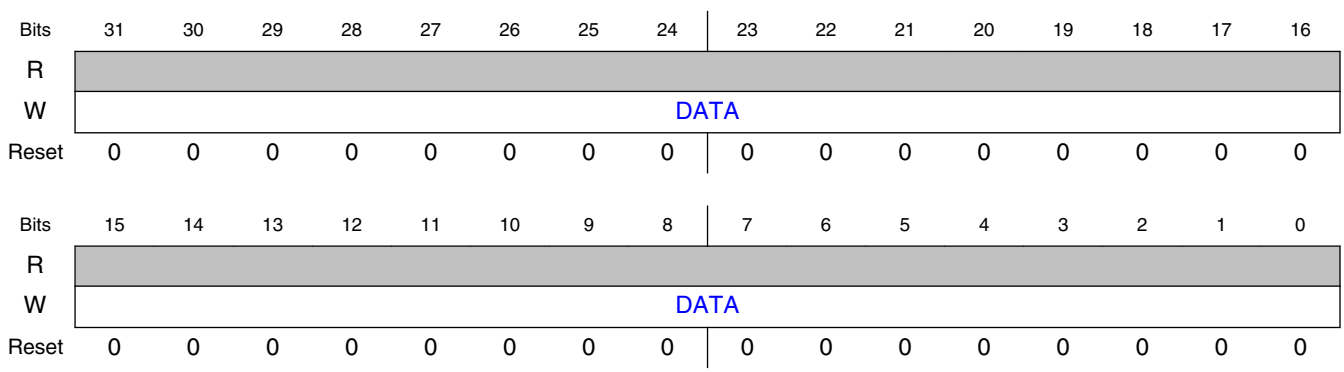
### 57.3.1.16.1 Offset

| Register | Offset |
|---|---|
| TDR | 64h |

### 57.3.1.16.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that it (the data) was written.

### 57.3.1.16.3 Diagram



### 57.3.1.16.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DATA | Transmit Data<br>Both 8-bit and 16-bit writes of transmit data will zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes. |

## 57.3.2.15 Transmit Command Register (TCR)

### 57.3.2.15.1 Offset

| Register | Offset |
|---|---|
| TCR | 60h |

### 57.3.2.15.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that the data are written. Command Register writes will be tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. Changing the command word will cause all subsequent SPI bus transfers to be performed using the new command word.

- **In master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware will clear TXMSK when the LPSPI_PCS negates.
- **In master mode,** if the command word is changed before an existing frame has completed, then the existing frame will terminate and the command word will then update. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In slave mode,** the command word should be changed only when the LPSPI is idle and there is no SPI bus transfer.

**Avoid register reading problems:** Reading the Transmit Command Register will return the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- to either read the Transmit Command Register when the transmit FIFO is empty,
- or to read the Transmit Command Register more than once and then compare the returned values.

| 22<br>BYSW | Byte Swap<br>Byte swap will swap the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers).<br>0b - Byte swap is disabled<br>1b - Byte swap is enabled |
| 21<br>CONT | Continuous Transfer<br>• In master mode, continuous transfer will keep the PCS asserted at the end of the frame size, until a command word is received that starts a new frame.<br>• In slave mode, when continuous transfer is enabled, the LPSPI will only transmit the first FRAMESZ bits; after which the LPSPI will transmit received data (assuming a 32-bit shift register).<br><br>0b - Continuous transfer is disabled<br>1b - Continuous transfer is enabled |
| 20<br>CONTC | Continuing Command<br>In master mode, the Continuing Command bit allows the command word to be changed within a continuous transfer.<br>• The initial command word must enable continuous transfer (CONT=1),<br>• the continuing command must set this bit (CONTC=1),<br>• and the continuing command word must be loaded on a frame size boundary.<br><br>For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary.<br><br>0b - Command word for start of new transfer<br>1b - Command word for continuing transfer |
| 19<br>RXMSK | Receive Data Mask<br>When set, receive data is masked (receive data is not stored in receive FIFO).<br>0b - Normal transfer<br>1b - Receive data is masked |
| 18<br>TXMSK | Transmit Data Mask<br>When set, transmit data is masked (no data is loaded from transmit FIFO and output pin is tristated). In master mode, the Transmit Data Mask bit will initiate a new transfer which cannot be aborted by another command word; the Transmit Data Mask bit will be cleared by hardware at the end of the transfer.<br>0b - Normal transfer<br>1b - Mask transmit data |
| 17-16<br>WIDTH | Transfer Width<br>For 2-bit or 4-bit transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be set.<br>00b - 1 bit transfer<br>01b - 2 bit transfer<br>10b - 4 bit transfer<br>11b - Reserved |
| 15-12<br>— | Reserved. Software should only write zero to this field. |
| 11-0<br>FRAMESZ | Frame Size<br>Configures the frame size in number of bits equal to (FRAMESZ + 1).<br>• The minimum frame size is 8 bits<br>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. |

| Field | Function |
|---|---|
| | • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.<br>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32 bits, and the 3rd word is 8 bits. |

## 57.3.2.16 Transmit Data Register (TDR)

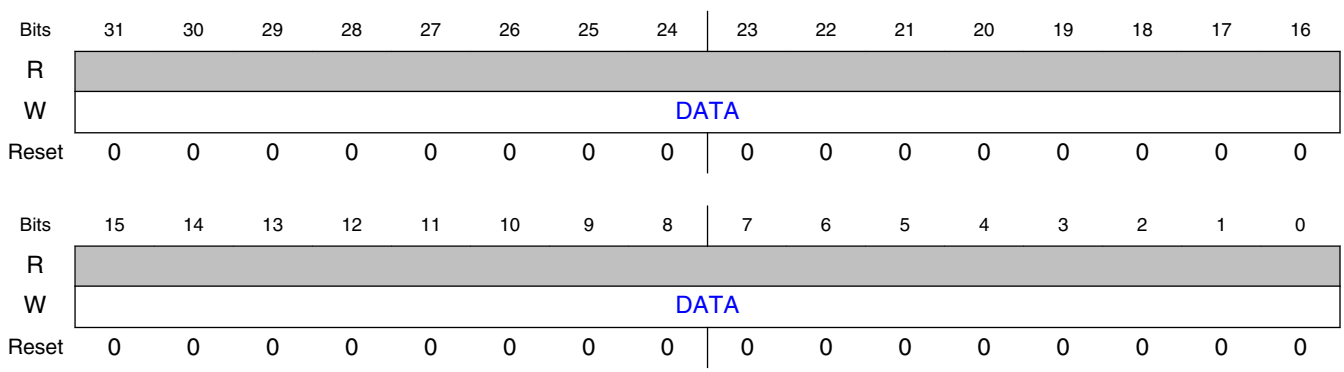
### 57.3.2.16.1 Offset

| Register | Offset |
|---|---|
| TDR | 64h |

### 57.3.2.16.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that it (the data) was written.

### 57.3.2.16.3 Diagram



### 57.3.2.16.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DATA | Transmit Data<br>Both 8-bit and 16-bit writes of transmit data will zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes. |

## 57.3.3.15 Transmit Command Register (TCR)

### 57.3.3.15.1 Offset

| Register | Offset |
|---|---|
| TCR | 60h |

### 57.3.3.15.2 Function

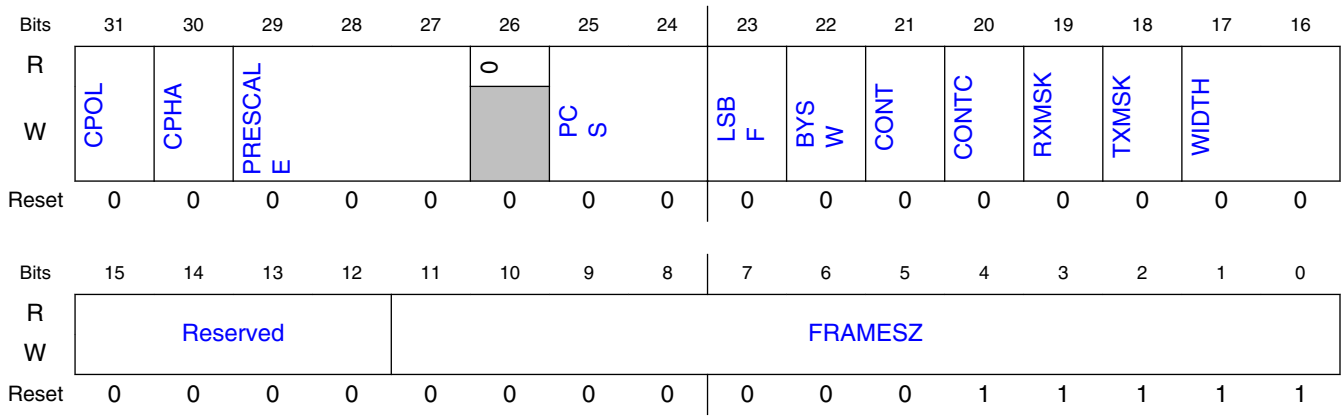
Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that the data are written. Command Register writes will be tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. Changing the command word will cause all subsequent SPI bus transfers to be performed using the new command word.

- **In master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware will clear TXMSK when the LPSPI_PCS negates.
- **In master mode,** if the command word is changed before an existing frame has completed, then the existing frame will terminate and the command word will then update. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In slave mode,** the command word should be changed only when the LPSPI is idle and there is no SPI bus transfer.

**Avoid register reading problems:** Reading the Transmit Command Register will return the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- to either read the Transmit Command Register when the transmit FIFO is empty,
- or to read the Transmit Command Register more than once and then compare the returned values.

## 57.3.3.15.3 Diagram



## 57.3.3.15.4 Fields

| Field | Function |
|---|---|
| 31<br>CPOL | Clock Polarity<br>The Clock Polarity field is only updated between frames.<br>0b - The inactive state value of SCK is low<br>1b - The inactive state value of SCK is high |
| 30<br>CPHA | Clock Phase<br>The Clock Phase field is only updated between frames.<br>0b - Data is captured on the leading edge of SCK and changed on the following edge of SCK<br>1b - Data is changed on the leading edge of SCK and captured on the following edge of SCK |
| 29-27<br>PRESCALE | Prescaler Value<br>For all SPI bus transfers, the Prescaler value applied to the clock configuration register. The Prescaler Value field is only updated between frames.<br>000b - Divide by 1<br>001b - Divide by 2<br>010b - Divide by 4<br>011b - Divide by 8<br>100b - Divide by 16<br>101b - Divide by 32<br>110b - Divide by 64<br>111b - Divide by 128 |
| 26<br>— | Reserved |
| 25-24<br>PCS | Peripheral Chip Select<br>Configures the peripheral chip select used for the transfer. The Peripheral Chip Select field is only updated between frames.<br>00b - Transfer using LPSPI_PCS[0]<br>01b - Transfer using LPSPI_PCS[1]<br>10b - Transfer using LPSPI_PCS[2]<br>11b - Transfer using LPSPI_PCS[3] |
| 23 | LSB First |

*Table continues on the next page...*

| Field | Function |
|---|---|
| LSBF | 0b - Data is transferred MSB first<br>1b - Data is transferred LSB first |
| 22<br>BYSW | Byte Swap<br>Byte swap will swap the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers).<br>0b - Byte swap is disabled<br>1b - Byte swap is enabled |
| 21<br>CONT | Continuous Transfer<br>• In master mode, continuous transfer will keep the PCS asserted at the end of the frame size, until a command word is received that starts a new frame.<br>• In slave mode, when continuous transfer is enabled, the LPSPI will only transmit the first FRAMESZ bits; after which the LPSPI will transmit received data (assuming a 32-bit shift register).<br><br>0b - Continuous transfer is disabled<br>1b - Continuous transfer is enabled |
| 20<br>CONTC | Continuing Command<br>In master mode, the Continuing Command bit allows the command word to be changed within a continuous transfer.<br>• The initial command word must enable continuous transfer (CONT=1),<br>• the continuing command must set this bit (CONTC=1),<br>• and the continuing command word must be loaded on a frame size boundary.<br><br>For example, if the continuous transfer has a frame size of 64-bits, then a continuing command word must be loaded on a 64-bit boundary.<br>0b - Command word for start of new transfer<br>1b - Command word for continuing transfer |
| 19<br>RXMSK | Receive Data Mask<br>When set, receive data is masked (receive data is not stored in receive FIFO).<br>0b - Normal transfer<br>1b - Receive data is masked |
| 18<br>TXMSK | Transmit Data Mask<br>When set, transmit data is masked (no data is loaded from transmit FIFO and output pin is tristated). In master mode, the Transmit Data Mask bit will initiate a new transfer which cannot be aborted by another command word; the Transmit Data Mask bit will be cleared by hardware at the end of the transfer.<br>0b - Normal transfer<br>1b - Mask transmit data |
| 17-16<br>WIDTH | Transfer Width<br>For 2-bit or 4-bit transfers, either Receive Data Mask (RXMSK) or Transmit Data Mask (TXMSK) must be set.<br>00b - 1 bit transfer<br>01b - 2 bit transfer<br>10b - 4 bit transfer<br>11b - Reserved |
| 15-12<br>— | Reserved. Software should only write zero to this field. |
| 11-0<br>FRAMESZ | Frame Size<br>Configures the frame size in number of bits equal to (FRAMESZ + 1).<br>• The minimum frame size is 8 bits<br>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported. |

| Field | Function |
|---|---|
| | • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.<br>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32 bits, and the 3rd word is 8 bits. |

## 57.3.3.16 Transmit Data Register (TDR)

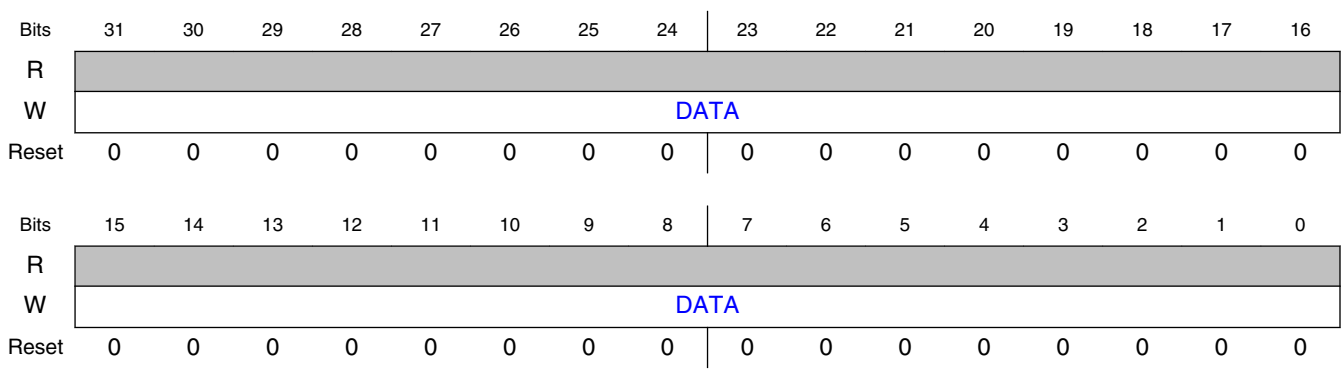
### 57.3.3.16.1 Offset

| Register | Offset |
|---|---|
| TDR | 64h |

### 57.3.3.16.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that it (the data) was written.

### 57.3.3.16.3 Diagram



### 57.3.3.16.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DATA | Transmit Data<br>Both 8-bit and 16-bit writes of transmit data will zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits), means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes. |
