| Register | Offset |
|---|---|
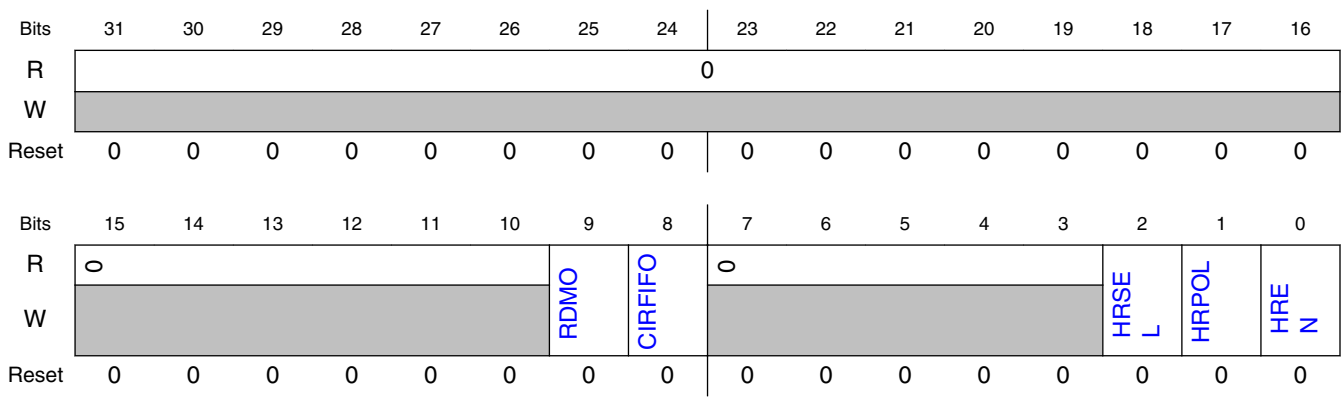
| CFGR0 | 20h |

#### 57.3.4.8.2 Diagram



#### 57.3.4.8.3 Fields

| Field | Function |
|---|---|
| 31-10<br>— | Reserved |
| 9 | Receive Data Match Only |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RDMO | When Receive Data Match Only is enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to set is discarded.<br>• Receive Data Match Only bit should be set when the LPSPI is idle and the Data Match Flag is clear<br>• After the Data Match Flag (DMF) is set, the Receive Data Match Only bit configuration is ignored<br>• When disabling RDMO and to ensure that no receive data is lost, before clearing the Data Match Flag, first clear Receive Data Match Only (RDMO)<br><br>0b - Received data is stored in the receive FIFO as in normal operations<br>1b - Received data is discarded unless the Data Match Flag (DMF) is set |
| 8<br>CIRFIFO | Circular FIFO Enable<br>When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO will be emptied as it normally is, but after the LPSPI is idle and the transmit FIFO is empty, then the read pointer value will be restored from the temporary register. This restoring of the read pointer will cause the contents of the transmit FIFO to be cycled through repeatedly.<br>0b - Circular FIFO is disabled<br>1b - Circular FIFO is enabled |
| 7-3<br>— | Reserved |
| 2<br>HRSEL | Host Request Select<br>Selects the source of the host request input. When the host request function is enabled with the LPSPI_HREQ pin, the LPSPI_PCS[1] function is disabled.<br>0b - Host request input is the LPSPI_HREQ pin<br>1b - Host request input is the input trigger |
| 1<br>HRPOL | Host Request Polarity<br>Configures the polarity of the host request pin.<br>0b - Active low<br>1b - Active high |
| 0<br>HREN | Host Request Enable<br>When enabled in master mode, the LPSPI will only start a new SPI bus transfer if the host request input is asserted. When the LPSPI is busy, the host request input is ignored.<br>0b - Host request is disabled<br>1b - Host request is enabled |

## 57.3.4.9 Configuration Register 1 (CFGR1)

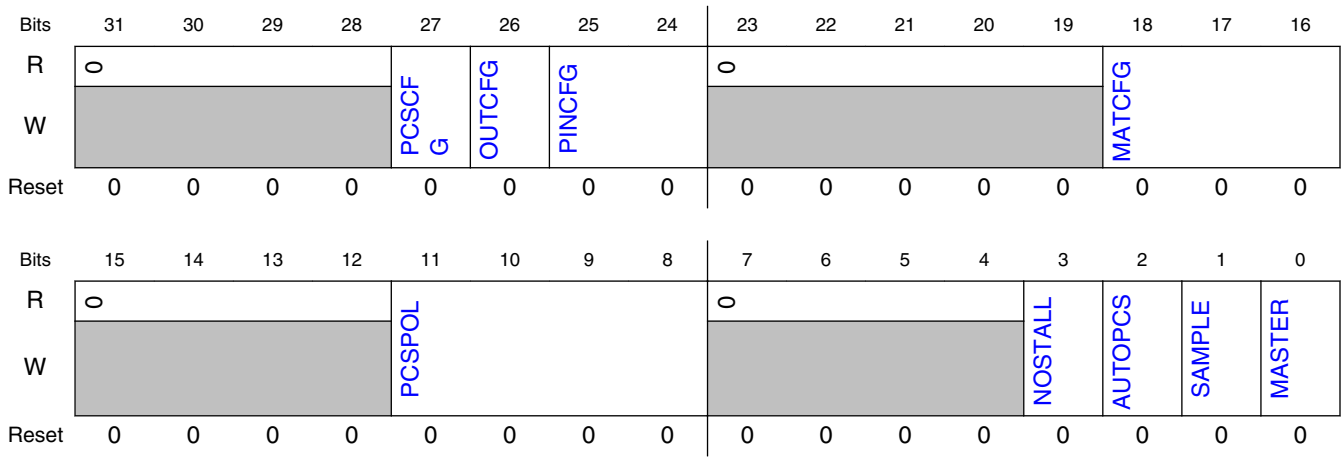
### 57.3.4.9.1 Offset

| Register | Offset |
|---|---|
| CFGR1 | 24h |

### 57.3.4.9.2 Function

The CFGR1 should only be written when the LPSPI is disabled.

### 57.3.4.9.3 Diagram



### 57.3.4.9.4 Fields

| Field | Function |
|---|---|
| 31-28<br>— | Reserved |
| 27<br>PCSCFG | Peripheral Chip Select Configuration<br>If performing 4-bit transfers, the Peripheral Chip Select Configuration bit must be set.<br>0b - PCS[3:2] are enabled<br>1b - PCS[3:2] are disabled |
| 26<br>OUTCFG | Output Config<br>Configures if the output data is tristated between accesses (LPSPI_PCS is negated).<br>0b - Output data retains last value when chip select is negated<br>1b - Output data is tristated when chip select is negated |
| 25-24<br>PINCFG | Pin Configuration<br>Configures which pins are used for input and output data during single bit transfers.<br>00b - SIN is used for input data and SOUT is used for output data<br>01b - SIN is used for both input and output data<br>10b - SOUT is used for both input and output data<br>11b - SOUT is used for input data and SIN is used for output data |
| 23-19<br>— | Reserved |
| 18-16<br>MATCFG | Match Configuration<br>Configures the condition that will cause the DMF to set.<br>**NOTE:** *Syntax:* * is boolean AND, + is boolean OR<br>000b - Match is disabled<br>001b - Reserved<br>010b - 010b - Match is enabled, if 1st data word equals MATCH0 OR MATCH1, i.e., (1st data word = MATCH0 + MATCH1) |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 011b - 011b - Match is enabled, if any data word equals MATCH0 OR MATCH1, i.e., (any data word = MATCH0 + MATCH1)<br>100b - 100b - Match is enabled, if 1st data word equals MATCH0 AND 2nd data word equals MATCH1, i.e., [(1st data word = MATCH0) * (2nd data word = MATCH1)]<br>101b - 101b - Match is enabled, if any data word equals MATCH0 AND the next data word equals MATCH1, i.e., [(any data word = MATCH0) * (next data word = MATCH1)]<br>110b - 110b - Match is enabled, if (1st data word AND MATCH1) equals (MATCH0 AND MATCH1), i.e., [(1st data word * MATCH1) = (MATCH0 * MATCH1)]<br>111b - 111b - Match is enabled, if (any data word AND MATCH1) equals (MATCH0 AND MATCH1), i.e., [(any data word * MATCH1) = (MATCH0 * MATCH1)] |
| 15-12<br>— | Reserved |
| 11-8<br>PCSPOL | Peripheral Chip Select Polarity<br>Configures the polarity of each Peripheral Chip Select pin.<br>0000b - The Peripheral Chip Select pin PCSx is active low<br>0001b - The Peripheral Chip Select pin PCSx is active high |
| 7-4<br>— | Reserved |
| 3<br>NOSTALL | No Stall<br>In master mode, the LPSPI will stall transfers when the transmit FIFO is empty or when the receive FIFO is full, ensuring that no transmit FIFO underrun or receive FIFO overrun can occur. Setting the No Stall bit will disable this functionality.<br>0b - Transfers will stall when the transmit FIFO is empty or the receive FIFO is full<br>1b - Transfers will not stall, allowing transmit FIFO underruns or receive FIFO overruns to occur |
| 2<br>AUTOPCS | Automatic PCS<br>For correct operations, the LPSPI slave normally requires the PCS to negate between frames. Setting the Automatic PCS bit will cause the LPSPI to generate an internal PCS signal at the end of each transfer word when the Clock Phase bit TCR[CPHA] = 1.<br>• When the Automatic PCS bit is set, the SCK must remain idle for at least 4 LPSPI functional clock cycles (divided by the Prescaler Value TCR[PRESCALE] configuration) between each word, to ensure correct operations<br>• In master mode, the Automatic PCS bit is ignored<br>0b - Automatic PCS generation is disabled<br>1b - Automatic PCS generation is enabled |
| 1<br>SAMPLE | Sample Point<br>When set, the LPSPI master will sample the input data on a delayed LPSPI_SCK edge, which improves the setup time when sampling data.<br>• The input data setup time in master mode with delayed LPSPI_SCK edge is equal to the input data setup time in slave mode<br>• In slave mode, the SAMPLE bit is ignored<br>0b - Input data is sampled on SCK edge<br>1b - Input data is sampled on delayed SCK edge |
| 0<br>MASTER | Master Mode<br>Configures the LPSPI in master or slave mode. The Master Mode bit directly controls the direction of the LPSPI_SCK and LPCPI_PCS pins.<br>0b - Slave mode<br>1b - Master mode |

## 57.3.4.15 Transmit Command Register (TCR)

### 57.3.4.15.1 Offset

| Register | Offset |
|---|---|
| TCR | 60h |

### 57.3.4.15.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that the data are written. Command Register writes will be tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. Changing the command word will cause all subsequent SPI bus transfers to be performed using the new command word.

- **In master mode,** writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware will clear TXMSK when the LPSPI_PCS negates.
- **In master mode,** if the command word is changed before an existing frame has completed, then the existing frame will terminate and the command word will then update. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In slave mode,** the command word should be changed only when the LPSPI is idle and there is no SPI bus transfer.

**Avoid register reading problems:** Reading the Transmit Command Register will return the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- to either read the Transmit Command Register when the transmit FIFO is empty,
- or to read the Transmit Command Register more than once and then compare the returned values.

# 57.4 Functional description

## 57.4.1 Clocking and resets

**Table 57-4. Clocks**

| | |
|---|---|
| LPSPI Functional clock | • The LPSPI functional clock is asynchronous to the bus clock.<br>• If the LPSPI functional clock remains enabled in low power modes, then LPSPI can perform SPI bus transfers and low power wakeups, in both master and slave modes.<br>• The LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least 2 times faster than the SPI external clock frequency (LPSPI_SCK). |
| External clock | • The LPSPI shift register is clocked directly by the LPSPI_SCK clock.<br>• How the LPSPI_SCK clock is generated or supplied depends upon the mode (master or slave):<br>  • in master mode: the LPSPI_SCK clock is generated internally.<br>  • in slave mode: the LPSPI_SCK clock is supplied externally. |

*Table continues on the next page...*

**Table 57-4. Clocks (continued)**

| | |
|---|---|
| Bus clock | The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs. |

**Table 57-5. Resets**

| | |
|---|---|
| Chip reset | Resets the LPSPI logic and registers to their default state. |
| Software reset | • Resets the LPSPI logic and registers to their default state, except for the Control Register.<br>• The LPSPI software reset is in the Control Register CR[RST]. |
| FIFO resets | • Resets the transmit/command FIFO and the receive FIFO.<br>• Control Register CR[RTF](Reset Transmit FIFO) and CR[RRF] (Reset Receive FIFO) are write-only bits.<br>• After being reset,a FIFO is empty. |

## 57.4.2 Master Mode

### 57.4.2.1 Transmit and Command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words.

- Transmit data words are stored to the transmit/command FIFO, by writing the Transmit Data Register (TDR).
- Command words are stored to the transmit/command FIFO, by writing the Transmit Command Register (TCR).

When a command word is at the top of the transmit/command FIFO, the actions that can occur depend upon whether the LPSPI module is either busy or between frames, the Continuous Transfer bit (TCR[CONT]), and the Continuing Command bit (TCR[CONTC]).

**Table 57-6. Possible actions when a command word is at the top of the transmit/command FIFO**

| Condition | Action |
|---|---|
| If the LPSPI is between frames | then the command word is pulled from the FIFO, and that command word controls all subsequent transfers. |
| If LPSPI is busy and the Continuous Transfer bit (TCR[CONT]) is set or cleared and the Continuing Command bit (TCR[CONTC]) is cleared | then the SPI frame will complete at the end of the existing word, ignoring the FRAMESZ configuration. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with CONTC=0 will always terminate (stop) the existing transfer regardless of the previous CONT value. |

*Table continues on the next page...*

**Table 57-6. Possible actions when a command word is at the top of the transmit/command FIFO (continued)**

| Condition | Action |
|---|---|
| If the LPSPI is busy and the existing Continuous Transfer bit (TCR[CONT]) is set or cleared and the new Continuing Command bit (TCR[CONTC]) value is set | then the command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last LPSPI_SCK pulse of the existing frame (based on the FRAMESZ configuration), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When the Continuing Command bit (TCR[CONTC]) is set, only the lower 24-bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. |

**NOTE**

About the Continuous Transfer bit (CONT) and Continuing Command bit (CONTC):

- Continuous Transfer bit (CONT)=1 is used to keep PCS asserted at end of frame, allowing the transfer to continue.
- Continuing Command bit (CONTC)=1 is used to indicate that this command word should not terminate the existing frame, and the transfer can continue using the new command word.

The Continuing Command bit (CONTC)=1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary, is when the previous command has the Continuous Transfer bit (CONT)=1.

The current state of the existing command word can be read by reading the Transmit Command Register (TCR). It requires at least 3 LPSPI functional clock cycles for the transmit command register to update after the transmit command register is written (assuming an empty FIFO) and the LPSPI must be enabled (Module Enable CR[MEN] bit is set).

Writing the transmit command register does not initiate a SPI bus transfer, unless the Transmit Data Mask (TCR[TXMSK]) bit is set. When the Transmit Data Mask bit is set, a new command word will not be loaded until the end of the existing frame (based on FRAMESZ configuration); at the end of the transfer, the TXMSK bit will be cleared.

In master mode, the LPSPI command word in the Transmit Command Register (TCR) controls SPI attributes (using bits and fields in registers).

## Table 57-7. LPSPI Command Word in Master Mode

| Transmit Command Register (TCR) | | Description | Can this bit/ field be modified during a data transfer? |
|---|---|---|---|
| Bit/Field | Name | | |
| CPOL | Clock Polarity | Configures the polarity of the LPSPI_SCK pin. Any change of CPOL value will cause a transition on the LPSPI_SCK pin. | N |
| CPHA | Clock Phase | Configures the clock phase of the transfer. | N |
| PRESCALE | Prescaler Value | Configures a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables the LPSPI module to connect to different slave devices at different frequencies. | N |
| PCS | Peripheral Chip Select | Configures which LPSPI_PCS asserts for the transfer; the polarity of LPSPI_PCS is static and configured by PCSPOL. If PCSCFG is set, then PCS[3:2] should not be selected. | N |
| LSBF | LSB First | Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first. | Y |
| BYSW | Byte Swap | Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian. | Y |
| CONT | Continuous Transfer | Configures for a continuous transfer that keeps PCS asserted between frames (as configured by FRAMESZ). A new command word is required to cause PCS to negate. Also supports changing the command word at the frame size boundaries. | Y |
| CONTC | Continuing Command | Indicates that this is a new command word for the existing continuous transfer. The CONTC bit when set must only be written to the transmit/ command FIFO on a frame bounday. | Y |
| RXMSK | Receive Data Mask | Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching. | Y |
| TXMSK | Transmit Data Mask | Masks the transmit data, so that masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by Output Config CFGR1[OUTCFG]). Useful for half-duplex transfers. | Y |
| WIDTH | Transfer Width | Configures the number of bits shifted on each LPSPI_SCK pulse.<br>• 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.<br>• 2-bit and 4-bit transfers are useful for interfacing to QuadSPI memory devices, and only support half-duplex data formats, and at least one bit (Transmit Data Mask (TCR[TXMSK] or Receive Data Mask TCR[RXMSK]) must also be set. | Y |
| FRAMESZ | Frame Size | Configures the frame size in number of bits equal to (FRAMESZ + 1).<br>• The minimum frame size is 8 bits.<br>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported.<br>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.<br>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit. | Y |

**SPI bus transfers:**

- The LPSPI initiates a SPI bus transfer when:
  - data is written to the transmit FIFO
  - and the HREQ pin is asserted (or disabled)
  - and the LPSPI is enabled
- To perform the SPI bus transfer, LPSPI uses the attributes configured in the Transmit Command Register (TCR) and uses the timing parameters in the Clock Configuration Register (CCR).
- The SPI bus transfer ends after the FRAMESZ configuration is reached, or at the end of a word when a new transmit command word is at the top of the transmit/command FIFO.
- The HREQ input is only checked on the next time that the LPSPI goes idle (the LPSPI completes the current transfer and the Transmit Command Register (TCR) is empty).

**Circular FIFO:** The transmit/command FIFO also supports a Circular FIFO feature, which enables the LPSPI master to (periodically) repeat a short data transfer that can fit within the transmit/command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled, the current state of the FIFO read pointer is saved and the status flags do not update. After the transmit/command FIFO is considered empty and the LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit/command FIFO are not permanently pulled from the FIFO while circular FIFO mode is enabled.

#### 57.4.2.2 Receive FIFO and Data Match

The receive FIFO is used to store receive data during SPI bus transfers. When the Receive Data Mask TCR[RXMSK] bit is set, the receive data is discarded instead of being stored in the receive FIFO.

- The receive data is written to the receive FIFO at the end of the frame.
- During a multiple word or continuous transfer, the receive data is also written to the receive FIFO at the same time as the new transmit data is read from the transmit FIFO.
- During a continuous transfer, if the transmit FIFO is empty, then the receive data is only written to the receive FIFO after the transmit FIFO is written or after the Transmit Command Register (TCR) is written to end the frame.

Receive data supports a receive data match function that can match received data against one of two words or against a masked data word. The receive data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded due to the Receive Data Mask TCR[RXMSK] bit cannot cause the data match to set, and will delay the receive data match on the first received data word, until all discarded data is received.
- The receiver data match function can also be configured to discard all received data until a data match is detected, using the Receive Data Match Only CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the Receive Data Match Only CFGR0[RDMO] bit, then clear the Data Match Flag SR[DMF] bit.

### 57.4.2.3 Timing Parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the PRESCALE configuration. Although the Clock Configuration Register (CCR) cannot be changed when the LPSPI module is busy, to support interfacing to different slave devices at different frequencies, the Prescaler Value TCR[PRESCALE] configuration can be changed between SPI bus transfers using the Transmit Command Register (TCR).

**Table 57-8. LPSPI Timing Parameters**

| Clock Configuration Register (CCR) | | Description | Min | Max |
|---|---|---|---|---|
| Bit/Field | Name | | | |
| SCKDIV | SCK Divider | Configures the LPSPI_SCK clock period to (SCKDIV +2) cycles. When SCK Divider is configured to an odd number of cycles, the first half of the LPSPI_SCK cycle is one cycle longer than the second half of the LPSPI_SCK cycle. | 0 (2 cycles) | 255 (257 cycles) |
| DBT | Delay Between Transfers | Configures the minimum delay between PCS negation and the next PCS assertion to (DBT + 2) cycles. When the command word is updated between transfers, there is a minimum of (DBT/2)+1 cycles between the command word update and any change on LPSPI_PCS pins. | 0 (2 cycles) | 255 (257 cycles) |
| DBT | Delay Between Transfers | Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (DBT + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer. | 0 (1 cycle) | 255 (256 cycles) |
| PCSSCK | PCS-to-SCK Delay | Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles. | 0 (1 cycle) | 255 (256 cycles) |
| SCKPCS | SCK-to-PCS Delay | Configures the minimum delay between the last SCK edge and the PCS assertion to (SCKPCS + 1) cycles. | 0 (1 cycle) | 255 (256 cycles) |

#### 57.4.2.4 Pin Configuration

- To swap directions or support half-duplex transfers on the same pin, the LPSPI_SIN and LPSPI_SOUT pins can be configured using the Pin Configuration CFGR1[PINCFG].
- To determine if an output data pin (like LPSPI_SOUT) will tristate when the LPSPI_PCS is negated, or if the output data pin will simply retain the last value, use the Output Config CFGR1[OUTCFG].
- When configuring for half-duplex transfers using the same data pin in single-bit transfer mode, or when configuring any transfer in 2-bit and 4-bit transfer modes, the output data pins must be configured to tristate when LPSPI_PCS is negated; use the Output Config CFGR1[OUTCFG].
- When performing quad-data transfers, the Peripheral Chip Select Configuration CFGR1[PCSCFG] must be enabled. The Peripheral Chip Select Configuration CFGR1[PCSCFG] is also used to disable LPSPI_PCS[3:2] functions.

#### 57.4.2.5 Clock Loopback

The LPSPI master can be configured to use 1 of 2 clocks to sample the input data (for example, LPSPI_SIN):

- either the LPSPI_SCK output clock directly
- or a delayed version of the LPSPI_SCK output clock

The delayed version of the LPSPI_SCK is delayed by the LPSPI_SCK pin output delay, plus the LPSPI_SCK pin input delay, and is configured by setting CFGR1[SAMPLE]. Enabling the loopback version of the LPSPI_SCK can improve the setup time of the input data from the slave.

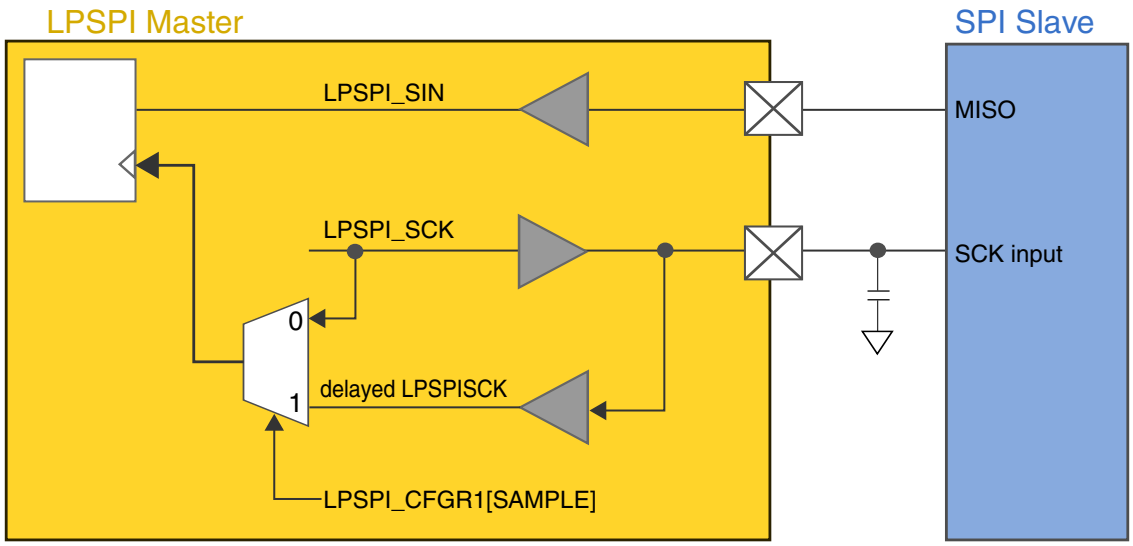

**Figure 57-7. Clock Loopback**

See the device datasheet for the specific input setup time in master loopback mode.

## 57.4.3 Slave Mode

LPSPI slave mode:

- uses the same shift register and logic that master mode uses
- does not use the Clock Configuration Register (CCR)
- during SPI bus transfers, requires that the Transmit Command Register (TCR) remain static (unchanging)

### 57.4.3.1 Transmit and Command FIFO commands

Before enabling the LPSPI in slave mode, the Transmit Command Register (TCR) should be initialized, although the Transmit Command Register register will not update until after the LPSPI is enabled. After being enabled, the Transmit Command Register should only be changed if the LPSPI is idle. In slave mode, the LPSPI command word in the Transmit Command Register (TCR) controls SPI attributes (using bits and fields in registers). Before the LPSPI_PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag will set.

**Table 57-9. LPSPI Command Word in Slave Mode**

| Transmit Command Register (TCR) | | Description |
|---|---|---|
| Bit/Field | Name | |
| CPOL | Clock Polarity | Configures the polarity of the external LPSPI_SCK input. |
| CPHA | Clock Phase | Configures the clock phase of transfer. |
| PRESCALE | Prescaler Value | Configures the LPSPI functional clock prescaler. |
| PCS | Peripheral Chip Select | Configures which LPSPI_PCS is used, the polarity of LPSPI_PCS is static and configured by PCSPOL. If PCSCFG is set, then PCS[3:2] should not be selected. |
| LSBF | LSB First | Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first. |
| BYSW | Byte Swap | Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing to devices that organize data as big-endian. |
| CONT | Continuous Transfer | When Continuous Transfer is set, only the first FRAMSZ bits will be transmitted/ received by the LPSPI module. |
| CONTC | Continuing Command | CONTC bit is reserved (in slave mode). |
| RXMSK | Receive Data Mask | Masks the receive data and does not store the masked receive data to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching. |
| TXMSK | Transmit Data Mask | Masks the transmit data, so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is tristated (unless configured by Output Config CFGR1[OUTCFG]). Useful for half-duplex transfers. |
| WIDTH | Transfer Width | Configures the number of bits shifted on each LPSPI_SCK pulse.<br>• 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.<br>• 2-bit and 4-bit transfers are useful for interfacing to QuadSPI memory devices, and only support half-duplex data formats, and at least one bit (Transmit Data Mask TCR[TXMSK] or Receive Data Mask (TCR[RXMSK]) must also be set. |
| FRAMESZ | Frame Size | Configures the frame size in number of bits equal to (FRAMESZ + 1).<br>• The minimum frame size is 8 bits.<br>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported.<br>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.<br>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit. |

## 57.4.3.2 Receive FIFO and Data Match

The receive FIFO is used to store received data during SPI bus transfers. When the Receive Data Mask TCR[RXMSK] is set, the received data is discarded (instead of storing the received data in the receive FIFO).

Receive data supports a receive data match function that can match received data against one of two words or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded (because the Receive Data Mask TCR[RXMSK] is set) cannot cause the data match to set, and will delay the match on the first received data word, until all discarded data is received.
- The receiver match function can also be configured to discard all received data until a data match is detected, using the Receive Data Match Only CFGR0[RDMO] bit.
- After a receive data match, to allow all subsequent data to be received, first clear the Receive Data Match Only CFGR0[RDMO] bit, then clear the Data Match Flag SR[DMF] bit.

#### 57.4.3.3 Clocked Interface

The LPSPI module supports interfacing to external masters that provide only clock and data pins (LPSPI_PCS is not required). This interface requires:

- using Clock Phase TCR[CPHA] = 1 (data is changed on the leading edge of SCK and captured on the following edge)
- configuring the LPSPI_PCS input to be always asserted (configure the Peripheral Chip Select Polarity CFGR1[PCSPOL[n]] = 1). For example, to configure PCS[0] to be always asserted, set PCSPOL[0] = 1, and don't configure PCS[0] in the pin muxing.
- setting the Automatic PCS CFGR1[AUTOPCS] bit = 1 (Automatic PCS generation is enabled). When Automatic PCS generation (AUTOPCS) is set, a minimum of 4 LPSPI functional clock cycles (divided by PRESCALE configuration) is required between the last LPSPI_SCK edge of one word and the first LPSPI_SCK edge of the next word.

### 57.4.4 Interrupts and DMA Requests

The next table lists the slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit/receive DMA requests.

**Table 57-10. LPSPI Interrupts and DMA Requests**

| Status Register (SR) | | Description | Can generate | | |
|---|---|---|---|---|---|
| Status Flag | Name | | Interrupt? | DMA Request? | Low Power Wakeup? |
| TDF | Transmit Data Flag | Data can be written to transmit FIFO, as configured by the Transmit FIFO Watermark FCR[TXWATER] | Y | TX | Y |
| RDF | Receive Data Flag | Data can be read from the receive FIFO, as configured by the Receive FIFO Watermark FCR[RXWATER] | Y | RX | Y |
| WCF | Word Complete Flag | Word is complete, the last bit of the word has been sampled | Y | N | Y |
| FCF | Frame Complete Flag | Frame is complete, and PCS has negated | Y | N | Y |
| TCF | Transfer Complete Flag | Transfer is complete, PCS has negated, and the transmit/command FIFO is empty | Y | N | Y |
| TEF | Transmit Error Flag | Indicates a transmit/command FIFO underrun. In master mode when the No Stall CFGR1[NOSTALL] bit is clear (0, transfers will stall when transmit FIFO is empty or receive FIFO is full), the Transmit Error Flag bit cannot set. | Y | N | Y |
| REF | Receive Error Flag | Receive error flag, indicates a receive FIFO overflow. In master mode when the No Stall CFGR1[NOSTALL] bit is clear (0, transfers will stall when transmit FIFO is empty or receive FIFO is full), the Receive Error Flag bit cannot set. | Y | N | Y |
| DMF | Data Match Flag | Indicates that the received data has matched the configured data match value | Y | N | Y |
| MBF | Module Busy Flag | LPSPI is busy performing a SPI bus transfer | N | N | N |

## 57.4.5 Peripheral Triggers

The connection of the LPSPI peripheral triggers to other peripherals depend upon the specific device being used.

**Table 57-11. LPSPI Triggers**

| Trigger | Description |
|---|---|
| Frame Output Trigger | The frame output trigger:<br>• asserts at the end of each frame (when PCS negates)<br>• remains asserted until PCS next asserts |
| Word Output Trigger | The word output trigger: |

*Table continues on the next page...*

## Table 57-11. LPSPI Triggers (continued)

| Trigger | Description | |
|---|---|---|
| | • asserts at the end of each received word<br>• remains asserted for 1 LPSPI_SCK period | The LPSPI generates 2 output triggers that can be connected to other peripherals on the device. |
| Input Trigger | To control the start of a LPSPI bus transfer, the LPSPI input trigger can be selected instead of the LPSPI_HREQ input.<br>• The LPSPI input trigger is synchronized, and must assert for at least 2 cycles of the LPSPI functional clock divided by the PRESCALE configuration, so that the input trigger can be detected.<br>• When the LPSPI module is busy, the LPSPI_HREQ input (and therefore the LPSPI input trigger) is ignored . | |

# Chapter 58
# Flexible I/O (FlexIO)

## 58.1 Chip-specific FlexIO information

### 58.1.1 FlexIO overview

The FlexIO is a highly configurable module providing a wide range of functionality including:

- Flexible shift registers for emulation of a variety of serial/parallel communication protocols
- Programmable logic arrays allowing the integration of external digital logic functions on-chip
- Up to 16-bit timer or pulse counters with trigger/interrupt generation on compare match
- DMA support

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- Camera IF
- LCD RGB
- PWM / Waveform generation

The module can remain functional in VLPS mode provided the clock it is using remains enabled.

### 58.1.2 FlexIO Instantiation

This section summarize the features and module configurations of FlexIO

Amongst other features, the FlexIO module in this device supports:
1. Emulation in serial/parallel communication protocols
2. Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules

## 58.2 Introduction

### 58.2.1 Overview

The FlexIO is a highly configurable module providing a wide range of functionality including:
- Emulation of a variety of serial/parallel communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

### 58.2.2 Features

The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:

- UART
- I2C
- SPI
- I2S
- Camera IF
- Motorola 68K/Intel 8080 bus
- PWM/Waveform generation

The following key features are provided:

- Array of 32-bit shift registers with transmit, receive and data match modes

- Double buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes
- Automatic start/stop bit generation
- 1, 2, 4, 8, 16 or 32 multi-bit shift widths for parallel interface support
- Interrupt, DMA or polled transmit/receive operation
- Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during stop modes
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions
- Programmable logic mode for integrating external digital logic functions on-chip or combining pin/shifter/timer functions to generate complex outputs
- Programmable state machine for offloading basic system control functions from CPU with support for up to 8 states, 8 outputs and 3 selectable inputs per state

## 58.2.3 Block Diagram

The following diagram gives a high-level overview of the configuration of FlexIO timers and shifters.

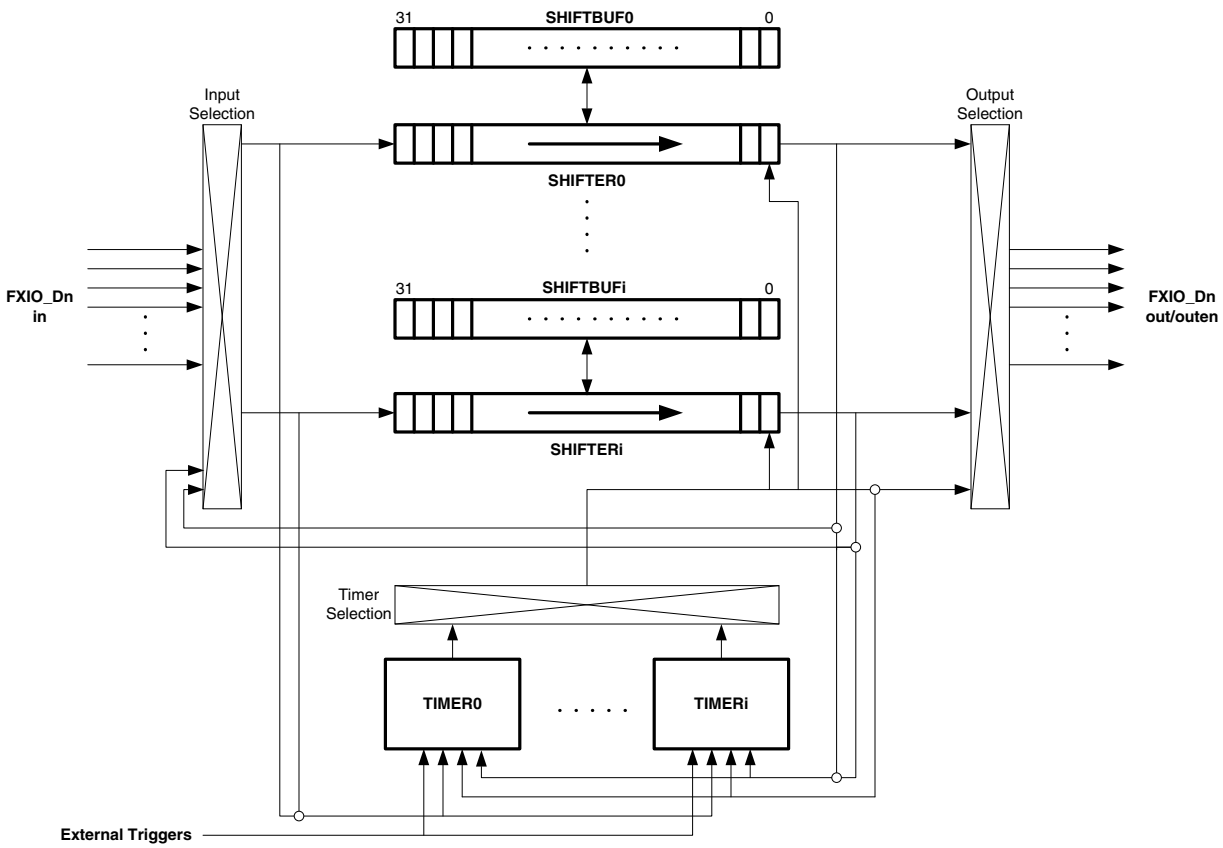

**Figure 58-1. FlexIO block diagram**

### 58.2.4 Modes of operation

The FlexIO module supports the chip modes described in the following table.

**Table 58-1. Chip modes supported by the FlexIO module**

| Chip mode | FlexIO Operation |
|---|---|
| Run | Normal operation |
| Stop/Wait | Can continue operating provided the Doze Enable bit (CTRL[DOZEN]) is clear and the FlexIO is using an external or internal clock source which remains operating during stop/wait modes. |
| LLS | The Doze Enable (CTRL[DOZEN]) bit is ignored and the FlexIO will wait for all Timers to complete any pending operation before acknowledging LLS mode entry. |
| Debug | Can continue operating provided the Debug Enable bit (CTRL[DBGE]) is set. |

### 58.2.5 FlexIO Signal Descriptions

| Signal | Description | I/O |
|---|---|---|
| FXIO_Dn (n=0...31) | Bidirectional FlexIO Shifter and Timer pin inputs/outputs | I/O |

## 58.3 Memory Map and Registers

### 58.3.1 FLEXIO register descriptions

#### 58.3.1.1 FLEXIO Memory map

FLEXIO0 base address: 4003_9000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID Register (VERID) | 32 | RO | 0101_0001h |
| 4h | Parameter Register (PARAM) | 32 | RO | 0420_0808h |
| 8h | FlexIO Control Register (CTRL) | 32 | RW | 0000_0000h |
| Ch | Pin State Register (PIN) | 32 | RO | 0000_0000h |

*Table continues on the next page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 10h | Shifter Status Register (SHIFTSTAT) | 32 | W1C | 0000_0000h |

# 58.4 Functional description

## 58.4.1 Clocking and Resets

### 58.4.1.1 Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers. Provided the FlexIO functional clock is at least two times faster than the bus clock, the CTRL[FASTACC] bit can be set to support fast register accesses.

### 58.4.1.2 Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

### 58.4.1.3 Chip reset

The logic and registers for the FlexIO are reset to their default state on a chip reset.

### 58.4.1.4 Software reset

The FlexIO implements a software reset bit in its Control Register. The CTRL[RST] will reset all logic and registers to their default state, except for the CTRL itself.

## 58.4.2 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

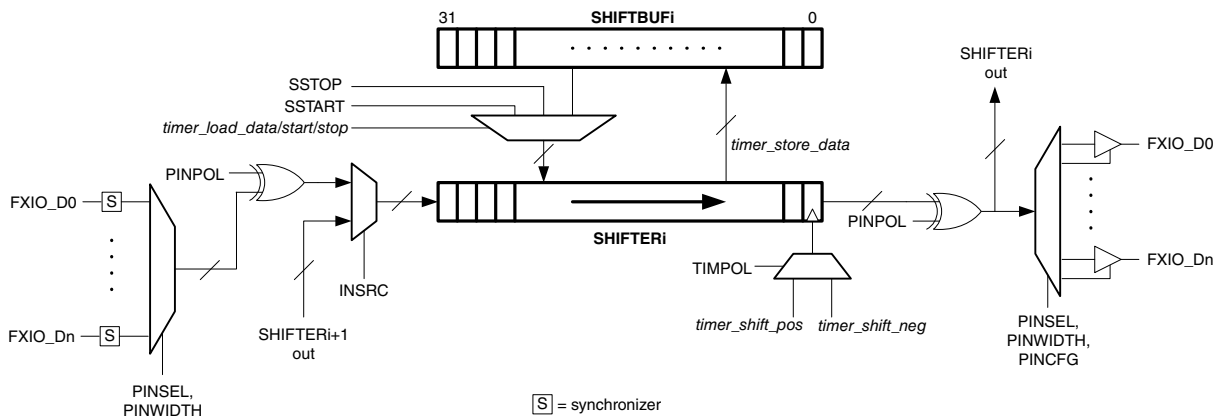

**Figure 58-2. Shifter Microarchitecture**

### 58.4.2.1 Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter will load data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/after SHIFTBUF data by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Note that the shifter will immediately load a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag will clear when new data has been written into the SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

### 58.4.2.2 Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD]=Receive), the shifter will shift data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

### 58.4.2.3 Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter will shift data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the matched data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

### 58.4.2.4 Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter will shift data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs. The flag will clear automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when a match occurs. The flag will clear when there is a read from the SHIFTBUF register or it written with logic 1.

### 58.4.2.5 State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which could potentially remain in a STOP/VLPS low power mode.

When configured for State mode (SHIFTCTL[SMOD]=State), the SHIFTBUF register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (SHIFTSTATE[STATE]). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

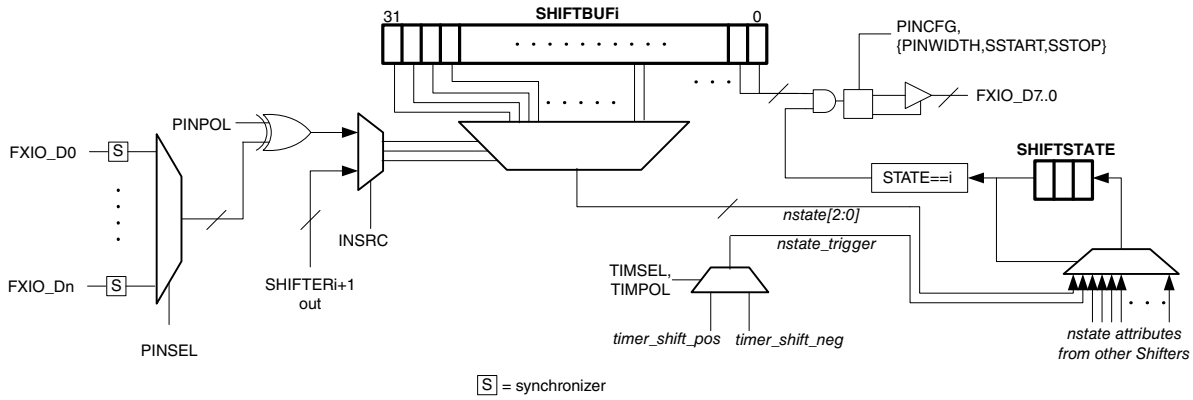

**Figure 58-3. State Microarchitecture**

When Shifter i has been selected by the current state pointer, output pins FXIO_D[7:0] will be driven by SHIFTBUFi[31:24] using the configuration set by SHIFTCTLi[PINCFG]. When set, SHIFTCFGi{PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} are respectively used to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by SHIFTCTLi[PINSEL] together with SHIFTBUFi[23:0]. Note that each state could potentially use a different set of 3 input pins. The following table details how the next state value is computed when the current state pointer is pointing to Shifter i.

**Table 58-2. Next State computation for SHIFTSTATE[STATE]=i**

| FXIO_D[PINSEL+2] | FXIO_D[PINSEL+1] | FXIO_D[PINSEL] | Next State Value |
|---|---|---|---|
| 0 | 0 | 0 | SHIFTBUFi[2:0] |
| 0 | 0 | 1 | SHIFTBUFi[5:3] |
| 0 | 1 | 0 | SHIFTBUFi[8:6] |
| 0 | 1 | 1 | SHIFTBUFi[11:9] |
| ... | ... | ... | ... |
| 1 | 1 | 1 | SHIFTBUFi[23:21] |

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by SHIFTCTLi[TIMSEL] with polarity controlled by SHIFTCTLi[TIMPOL]. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see Timer section for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs will not be driven and a next state transition is never triggered.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set whenever the Shifter has been selected by the current state pointer. The flag will clear when the current state pointer is updated to a different Shifter.

### 58.4.2.6 Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter.

When configured for Logic mode (SHIFTCTL[SMOD]=Logic), the SHIFTBUF register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

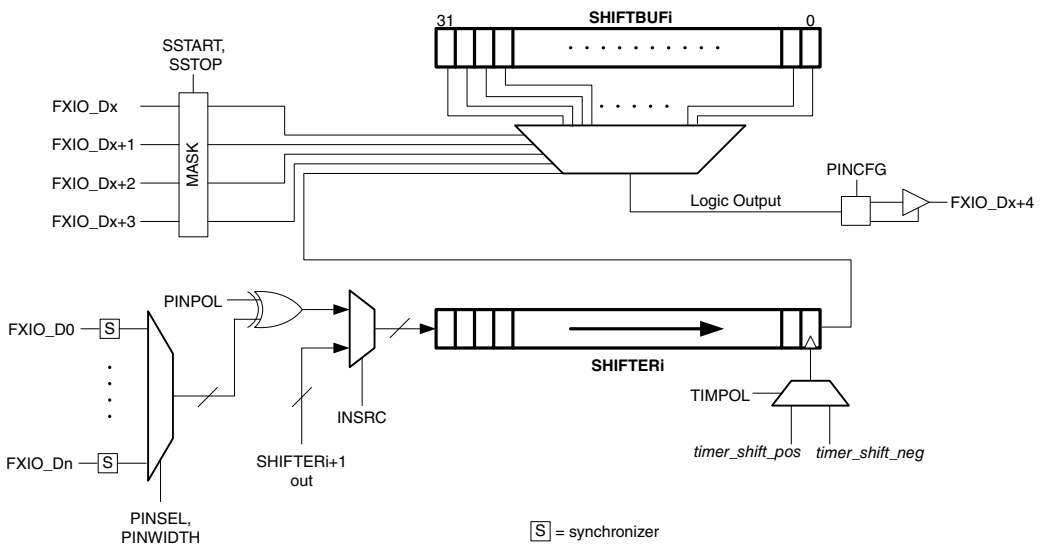

**Figure 58-4. Logic Microarchitecture**

The look-up table is driven using 4 pin inputs (maskable using SHIFTCFG[SSTOP] and SHFITCFG[SSTART]) plus 1 input from the internal shifter and can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

**Table 58-3. Logic Look-up table for Shifter 'i'**

| SHIFTERi[0] | FXIO_D[x+3][1] | FXIO_D[x+2] | FXIO_D[x+1] | FXIO_D[x] | Logic Output to FXIO_D[x+4] |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | SHIFTBUFi[0] |
| 0 | 0 | 0 | 0 | 1 | SHIFTBUFi[1] |
| 0 | 0 | 0 | 1 | 0 | SHIFTBUFi[2] |
| 0 | 0 | 0 | 1 | 1 | SHIFTBUFi[3] |
| ... | ... | ... | ... | ... | ... |
| 1 | 1 | 1 | 1 | 1 | SHIFTBUFi[31] |

1. for Shifter i=0...3, x=i

   for Shifter i=4...7, x=i+4

To minimize output glitches, SHIFTCFG[SSTOP] and SHIFTCFG[SSTART] can be used to mask unused input pins. When set, {SSTOP[1:0], SSTART[1:0]} will mask FXIO_D[x+3]...FXIO_D[x] inputs respectively, so that any transitions on these pins will not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table, allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

SHIFTCFG[PWIDTH] will control the number of delay stages introduced by the internal shifter input (SHIFTERi[0]). For example, when configured for 1-bit shift (PWIDTH=0), the internal shifter will introduce a 32 Shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the look-up table. When configured for 32-bit shift (PWIDTH=16...31), the internal shifter will introduce a 1 Shift clock delay to its input.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag will clear when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when the output pin allocated to the logic look-up table has a value of 1. The flag can be cleared by writing it with logic 1.

## 58.4.3 Timer Operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a

trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip-specific FlexIO information for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

#### 58.4.3.1 Timer 8-bit Baud Counter Mode

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number of shift clock edges in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits only decrement when the lower 8-bits equal zero and decrement.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

#### 58.4.3.2 Timer 8-bit High PWM Mode

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

### 58.4.3.3 Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

### 58.4.3.4 Timer Enable and Start Bit

When the TIMOD is configured for the desired mode, and the condition configured by timer enable (TIMENA) is detected then the following events occur.

- Timer counter will load the current value of the compare Register and start decrementing as configured by TIMDEC.
- Timer output may update to its initial state depending on the TIMOUT configuration. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer will either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the Timer start bit is enabled, the timer counter will reload with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift will not load correctly.

### 58.4.3.5 Timer Decrement and Reset

The Timer will then generate the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11). When TIMDEC is configured to decrement from a pin or trigger, the timer will decrement on both rising and falling edges.

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter will load the current value of the compare register again, the timer output may also be affected by the reset as configured in TIMOUT.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event will cause the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the timer mode, the timer status flag may also be set.

### 58.4.3.6 Timer Disable and Stop Bit

When the is Timer is configured to add a stop bit on each compare, the following additional events will occur.

- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.
- On the first rising edge of the shifter clock after the compare, the timer counter will reload the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter will reload the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output will clear. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock would otherwise generate one.
- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter will continue decrementing until the next rising edge of the shift clock is detected, at which point it will finish. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit, but does not generate shift events.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). Receive shift registers with stop bit enabled will store the contents of the shift register into the shift buffer and verify the state of the input data

on the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

## 58.4.4 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

### 58.4.4.1 Parallel Interface

Shifters can be configured to use multiple FlexIO pins in parallel using the SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a shifter:

1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC]=1), the least significant 4, 8, 16 or 32-bits from the adjacent shifter will be sampled on each Shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be configured to sample multiple pins (SHIFTCFG[INSRC]=0), with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant bits will be masked with 0 e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[31:24] will sample {0,0,FXIO_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be configured to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

Note that if PWIDTH is less than the number of bits being shifted on each Shift clock, then the most significant pins will not be driven e.g. if PINSEL=7 and PWIDTH=6, then SHIFTER[5:0] will drive only FXIO_D[12:7] on each Shift clock.

#### 58.4.4.2 Pin Synchronization

When configuring a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized to the FlexIO clock before the signal is used by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin will make an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:

1. 0.5 – 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the FlexIO Application Information Section.

### 58.4.5 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the FlexIO interrupt and DMA requests.

**Table 58-4. FlexIO Interrupts and DMA Requests**

| Flag | Description | Interrupt | DMA Request | Low Power Wakeup |
|---|---|---|---|---|
| SSF | Shifter Status Flag. | Y | Y | Y |
| SEF | Shifter Error Flag. | Y | N | Y |

### 58.4.6 Peripheral Triggers

The connection of the FlexIO peripheral triggers with other peripherals are device specific.

#### 58.4.6.1 Output Triggers

Each FlexIO Timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

#### 58.4.6.2 Input Trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

## 58.5 Application Information

This section provides examples for a variety of FlexIO module applications.

### 58.5.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the SSTART and SSTOP fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to SHIFTBUFn (or SHIFTBUFBIS for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

**Table 58-5. UART Transmit Configuration**

| Register | Value | Comments |
|---|---|---|
| SHIFTCFGn | 0x0000_0032 | Configure start bit of 0 and stop bit of 1. |
| SHIFTCTLn | 0x0003_0002 | Configure transmit using Timer 0 on posedge of clock with output data on Pin 0. Can invert output data by setting PINPOL, or can support open drain by setting PINPOL=0x1 and PINCFG=0x1. |
| TIMCMPn | 0x0000_0F01 | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFGn | 0x0000_2222 | Configure start bit, stop bit, enable on trigger asserted and disable on compare. Can support CTS by configuring TIMEN=0x3. |
| TIMCTLn | 0x01C0_0001 | Configure dual 8-bit counter using Shifter 0 status flag as inverted internal trigger source. Can support CTS by configuring PINSEL=0x1 (for Pin 1) and PINPOL=0x1. |
| SHIFTBUFn | Data to transmit | Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS[7:0] register instead. |

## 58.5.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters will cause the error flag to set and the shifter buffer register will return 0x00.

FlexIO does not support automatic verification of parity bits.

**Table 58-6. UART Receiver Configuration**

| Register | Value | Comments |
|---|---|---|
| SHIFTCFGn | 0x0000_0032 | Configure start bit of 0 and stop bit of 1. |
| SHIFTCTLn | 0x0080_0001 | Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL. |
| TIMCMPn | 0x0000_0F01 | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFGn | 0x0204_2422 | Configure start bit, stop bit, enable on pin posedge and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4. |
| TIMCTLn | 0x0000_0081 | Configure dual 8-bit counter using inverted Pin 0 input. |
| SHIFTBUFn | Data to receive | Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead. |

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS will assert when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit will be detected while the RTS is asserted, the received data is simply ignored.

**Table 58-7. UART Receiver with RTS Configuration**

| Register | Value | Comments |
|---|---|---|
| SHIFTCFGn | 0x0000_0032 | Configure start bit of 0 and stop bit of 1. |
| SHIFTCTLn | 0x0080_0001 | Configure receive using Timer 0 on negedge of clock with input data on Pin 0. Can invert input data by setting PINPOL. |
| TIMCMPn | 0x0000_0F01 | Configure 8-bit transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of bits x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFGn | 0x0204_2522 | Configure start bit, stop bit, enable on pin posedge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT=0x2 and TIMRST=0x4. |

*Table continues on the next page...*

**Table 58-7. UART Receiver with RTS Configuration (continued)**

| Register | Value | Comments |
|---|---|---|
| TIMCTLn | 0x02C0_0081 | Configure dual 8-bit counter using inverted Pin 0 input. Trigger is internal using inverted Pin 1 input. |
| TIMCMP(n+1) | 0x0000_FFFF | Never compare. |
| TIMCFG(n+1) | 0x0030_6100 | Enable on Timer N enable and disable on trigger falling edge. Decrement on trigger to ensure no compare. |
| TIMCTL(n+1) | 0x0143_0003 | Configure 16-bit counter and output on Pin 1. Trigger is internal using Shifter 0 flag. |
| SHIFTBUFn | Data to receive | Received data can be read from SHIFTBUFBYS[7:0], use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS[7:0] register instead. |

## 58.5.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

**Table 58-8. SPI Master (CPHA=0) Configuration**

| Register | Value | Comments |
|---|---|---|
| SHIFTCFGn | 0x0000_0000 | Start and stop bit disabled. |
| SHIFTCTLn | 0x0083_0002 | Configure transmit using Timer 0 on negedge of clock with output data on Pin 0. |
| SHIFTCFG(n+1) | 0x0000_0000 | Start and stop bit disabled. |
| SHIFTCTL(n+1) | 0x0000_0101 | Configure receive using Timer 0 on posedge of clock with input data on Pin 1. |

*Table continues on the next page...*

**Table 58-9. SPI Master (CPHA=1) Configuration (continued)**

| Register | Value | Comments |
|---|---|---|
| TIMCFGn | 0x0100_2222 | Configure start bit, stop bit, enable on trigger high and disable on compare, initial clock state is logic 0. |
| TIMCTLn | 0x01C3_0201 | Configure dual 8-bit counter using Pin 2 output (shift clock), with Shifter 0 flag as the inverted trigger. Set PINPOL to invert the output shift clock. Set TIMDIS=3 to keep slave select asserted for as long as there is data in the transmit buffer. |
| TIMCMP(n+1) | 0x0000_FFFF | Never compare. |
| TIMCFG(n+1) | 0x0000_1100 | Enable when Timer 0 is enabled and disable when Timer 0 is disabled. |
| TIMCTL(n+1) | 0x0003_0383 | Configure 16-bit counter (never compare) using inverted Pin 3 output (as slave select). |
| SHIFTBUFn | Data to transmit | Transmit data can be written to SHIFTBUF, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. Can support MSB first transfer by writing to SHIFTBUFBBS register instead. |
| SHIFTBUF(n+1) | Data to receive | Received data can be read from SHIFTBUFBYS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support MSB first transfer by reading from SHIFTBUFBIS register instead. |

## 58.5.4 SPI Slave

SPI slave mode can be supported using one Timer, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The transmit data must be written to the transmit buffer register before the external slave select asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

## Table 58-10. SPI Slave (CPHA=0) Configuration

| Register | Value | Comments |

## 58.5.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/ STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter will load 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register will assert an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.

Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

**Table 58-12. I2C Master Configuration**

| Register | Value | Comments |
|---|---|---|
| SHIFTCFGn | 0x0000_0032 | Start bit enabled (logic 0) and stop bit enabled (logic 1). |

## 58.5.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

**Table 58-13. I2S Master Configuration**

| SHIFTBUF(n+1) | Data to receive | Received data can be read from SHIFTBUFBIS, use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. Can support LSB first transfer by reading from SHIFTBUF register instead. |

### 58.5.7 I2S Slave

I2S slave mode can be supported using three Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until falling edge of bit clock (when frame sync is normally sampled). Timer 0 detects falling edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects rising edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

**Table 58-14. I2S Slave Configuration**

## 58.5.8 Camera Interface

Camera Interface can be supported using one Timer, one or more Shifters and multiple Pins. Multiple transfers can be supported using DMA controller.

The example below describes FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer, however a bigger or smaller buffer may be used depending on system DMA performance and FlexIO resource usage by other applications. Note that additional timers may be used to track number of pixels per row and number of rows per frame or HREF/VSYNC may be assigned as GPIO interrupts for software tracking.

**Table 58-15. Camera Interface Configuration for 8-bit CMOS sensor**

| Register | Value | Comments |

## 58.5.9 Motorola 68K/Intel 8080 Bus Interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. In conjunction with GPIO, FlexIO is able to drive these interfaces using one Timer and one Shifter, although additional Shifters could be used to support large transfers via the DMA controller.

The configuration below provides an example of how to drive a 16-bit 68K or 8080 bus. For a 8080 bus, two GPIO are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

**Table 58-16. Motorola 68K/Intel 8080 Write Configuration**

| Register | Value | Comments |
|---|---|---|
| SHIFTCFG0...7 | 0x000F_0100 | Configure 16-bit parallel shift in from adjacent shifter. |
| SHIFTCTL0 | 0x0003_0002 | Configure transmit using Timer 0 on posedge of clock with data output to FXIO_D[15:0]. |
| SHIFTCTL1...7 | 0x0000_0002 | Configure transmit using Timer 0 on posedge of clock. |
| TIMCMP0 | 0x0000_0101 (1-beat)<br>0x0000_1F01 (16-beats) | Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFG0 | 0x0000_2200 | Configure enable on trigger high and disable on compare. Timer output high on enable. |
| TIMCTL0 | 0x01C3_1001 (Motorola 68K, 1-beat)<br>0x1DC3_1001 (Motorola 68K, 16-beats)<br>0x01C3_1081 (Intel 8080, 1-beat)<br>0x1DC3_1081 (Intel 8080, 16-beats) | Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with Shifter 0 (1-beat) or Shifter 7 (16-beats) flag as the inverted trigger. |
| SHIFTBUF0...7 | Data to transmit | Transmit data can be written to SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer, use the Shifter Status Flag to indicate when data can be written using interrupt or DMA request. |

**Table 58-17. Motorola 68K/Intel 8080 Read Configuration**

| Register | Value | Comments |
|---|---|---|
| SHIFTCFG0...6 | 0x000F_0100 | Configure 16-bit parallel shift in from adjacent shifter. |
| SHIFTCFG7 | 0x000F_0000 | Configure 16-bit parallel shift in from pin. |
| SHIFTCTL0...7 | 0x0080_0001 | Configure receive using Timer 0 on negedge of clock with data input from FXIO_D[15:0]. |
| TIMCMP0 | 0x0000_0101 (1-beat)<br>0x0000_1F01 (16-beats) | Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FlexIO clock. Set TIMCMP[15:8] = (number of beats x 2) - 1. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFG0 | 0x0000_2220 | Configure stop_bit, enable on trigger high and disable on compare. Timer output high on enable. |
| TIMCTL0 | 0x1DC3_1001 (Motorola 68K, 1 beat)<br>0x01C3_1001 (Motorola 68K, 16 beats)<br>0x1DC3_1181 (Intel 8080, 1 beat)<br>0x01C3_1181 (Intel 8080, 16 beats) | Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with Shifter 7 flag (1-beat) or Shifter 0 flag (16-beats) as the inverted trigger. |
| SHIFTBUF0...7 | Data received | Received data can be read from SHIFTBUF0 (1-beat) or SHIFTBUF0...7 (16-beats), use the Shifter Status Flag to indicate when data can be read using interrupt or DMA request. |

In general, any operation to a 68K/8080 bus slave will begin with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow should be used:

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (e.g. 1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to/from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

## 58.5.10 Low Power State Machine

The configuration below details a hypothetical state machine example to illustrate the flexibility allowed when using Shifter state mode.

In this example, FlexIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted (This assumes comparator is connected to external trigger 15. See the chip-specific FlexIO information for actual FlexIO trigger mappings). Throughout this operation, the CPU can be kept in a STOP/ VLPS mode, by clearing the CTRL[DOZEN] bit and ensuring the FLEXIO_CLK is enabled. The state diagram below shows the states and transitions implemented by this example.

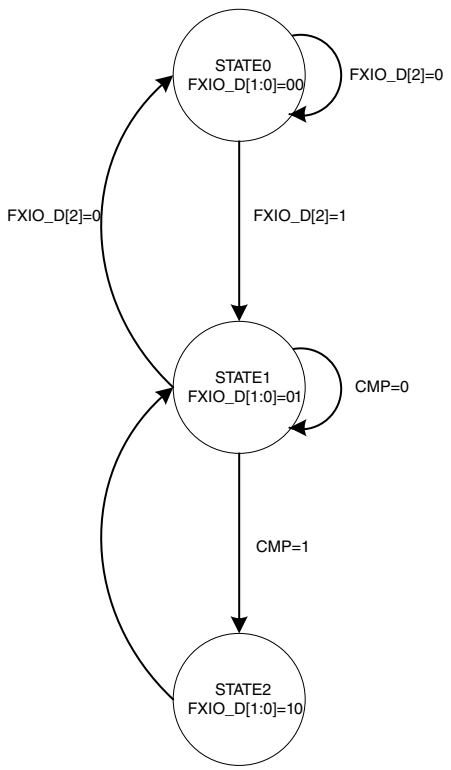

**Figure 58-5. State Diagram**

**Table 58-18. State Machine Configuration**

| Register | Value | Comments |
|---|---|---|
| SHIFTCFG0...2 | 0x0000_0003 | Enable FXIO_D[1:0] as outputs. |
| SHIFTCTL0 | 0x0080_0206 | Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state. |
| SHIFTBUF0 | 0x0020_8208 | State0: Drive FXIO_D[1:0]=00, transition to State0 if FXIO_D[2]=0, State1 if FXIO_D[2]=1. |

*Table continues on the next page...*

## Table 58-18. State Machine Configuration (continued)

| Register | Value | Comments |
|---|---|---|
| SHIFTCTL1 | 0x0000_0206 | Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output high to trigger next state. |
| SHIFTBUF1 | 0x0140_8408 | State1: Drive FXIO_D[1:0]=01, transition to State0 if FXIO_D[2]=0, State1 if CMP=0, State2 if CMP=1 (FXIO_D[3]=1) |
| SHIFTCTL2 | 0x0080_0206 | Configure for State mode using FXIO_D[4:2] as inputs to select next state and Timer0 output low to trigger next state. |
| SHIFTBUF2 | 0x0224_9249 | State2: Drive FXIO_D[1:0]=10, transition to State1 when Timer0 output low |
| TIMCMP0 | 0x0000_FFFF | Configure baud rate of divide by 131072 of the FlexIO clock. Set TIMCMP[7:0] = (baud rate divider / 2) - 1. |
| TIMCFG0 | 0x0000_0000 | Configure timer always enabled. |
| TIMCTL0 | 0x0000_0003 | Configure single 16-bit counter. |
| TIMCFG1 | 0x0010_7600 | Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge. |
| TIMCTL1 | 0x0F03_0303 | Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected. |

# Chapter 59
# Inter-IC Sound (I2S)

## 59.1 Chip-specific I2S information

### 59.1.1 Instantiation information

This device contains 1 $I^2S$ module.

As configured on the device, module features include:

- TX data lines: 2
- RX data lines: 2
- FIFO size (words): 8 word
- Maximum words per frame: 32
- Maximum bit clock divider: 512

### 59.1.2 $I^2S$/SAI operation in low power modes

#### 59.1.2.1 Stop and very low power modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In VLPS mode, the module behaves as it does in stop mode if VLPS mode is entered from run mode. However, if VLPS mode is entered from VLPR mode, the FIFO might underflow or overflow before wakeup from stop mode due to the limits in bus bandwidth. In VLPW and VLPR modes, the module is limited by the maximum bus clock frequencies.

When operating from an internally generated bit clock or Audio Master Clock that is disabled in stop modes:

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented–not acknowledged–while waiting for the transmitter and receiver to be disabled at the end of the current frame.

#### 59.1.2.2 Low-leakage modes

When entering low-leakage modes, the Stop Enable (TCSR[STOPE] and RCSR[STOPE]) bits are ignored, and the SAI is disabled after completing the current transmit and receive Frames. Entry into stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

## 59.2 Introduction

The $I^2S$ (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as $I^2S$, AC97, TDM, and codec/DSP interfaces.

### 59.2.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 2 data lines
- Receiver with independent bit clock and frame sync supporting 2 data lines
- Each data line can support a maximum Frame size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame

- Asynchronous 8 × 32-bit FIFO for each transmit and receive data line
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word
- Supports combining multiple data line FIFOs into single data line FIFO

## 59.2.2 Block diagram

The following block diagram also shows the module clocks.

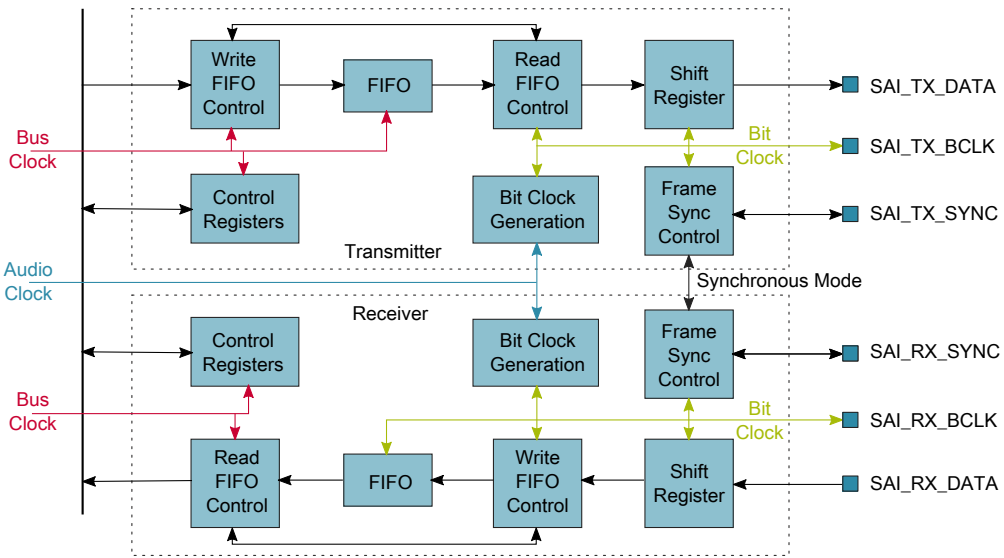

**Figure 59-1. I²S/SAI block diagram**

## 59.2.3 Modes of operation

Module power modes include Run mode, Stop modes, low-leakage stop modes, and Debug mode.

### 59.2.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

### 59.2.3.2 Stop modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented–not acknowledged–while waiting for the transmitter and receiver to be disabled at the end of the current frame.

### 59.2.3.3 Low-leakage stop modes

When entering low-leakage stop modes, the Stop Enable (TCSR[STOPE] and RCSR[STOPE]) bits are ignored and the SAI is disabled after completing the current transmit and receive Frames. Entry into stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

### 59.2.3.4 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

## 59.3 External signals

| Name | Function | I/O |
|---|---|---|
| SAI_TX_BCLK | Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated. | I/O |
| SAI_TX_SYNC | Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated | I/O |

*Table continues on the next page...*

| Name | Function | I/O |
|---|---|---|
| | synchronously by the bit clock when internally generated. | |
| SAI_TX_DATA[1:0] | Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word. | O |
| SAI_RX_BCLK | Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated. | I/O |
| SAI_RX_SYNC | Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated. | I/O |
| SAI_RX_DATA[1:0] | Receive Data. The receive data is sampled synchronously by the bit clock. | I |

## 59.4 Memory map and register definition

A read or write access to an address from offset 0x100 and above will result in a bus error.

### 59.4.1 I2S register descriptions

When configured for a synchronous mode of operation, the receiver or other SAI peripheral must be configured for asynchronous operation.<br>00b - Asynchronous mode.<br>01b - Synchronous with receiver.<br>10b - Synchronous with another SAI transmitter.<br>11b - Synchronous with another SAI receiver. |
| 29<br>BCS | Bit Clock Swap<br>This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC).<br>When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC).<br>This field has no effect when synchronous to another SAI peripheral.<br>0b - Use the normal bit clock source.<br>1b - Swap the bit clock source. |
| 28<br>BCI | Bit Clock Input<br>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. |

*Table continues on the next page...*

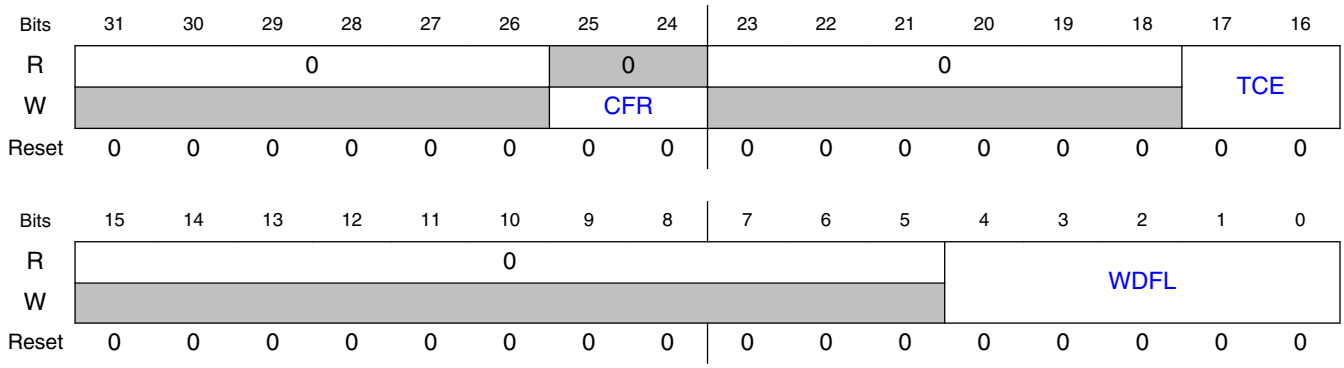
| Field | Function |
|---|---|
| | The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral .<br>0b - No effect.<br>1b - Internal logic is clocked as if bit clock was externally generated. |
| 27-26<br>MSEL | MCLK Select<br>Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.<br>**NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option.<br>00b - Bus Clock selected.<br>01b - Master Clock (MCLK) 1 option selected.<br>10b - Master Clock (MCLK) 2 option selected.<br>11b - Master Clock (MCLK) 3 option selected. |
| 25<br>BCP | Bit Clock Polarity<br>Configures the polarity of the bit clock.<br>0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge.<br>1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge. |
| 24<br>BCD | Bit Clock Direction<br>Configures the direction of the bit clock.<br>0b - Bit clock is generated externally in Slave mode.<br>1b - Bit clock is generated internally in Master mode. |
| 23-8<br>— | Reserved |
| 7-0<br>DIV | Bit Clock Divide<br>Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2. |

## 59.4.1.7 SAI Transmit Configuration 3 Register (TCR3)

### 59.4.1.7.1 Offset

| Register | Offset |
|---|---|
| TCR3 | 14h |

## 59.4.1.7.2 Diagram



## 59.4.1.7.3 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-24<br>CFR | Channel FIFO Reset<br>Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set.<br>The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer.<br>0b - No effect.<br>1b - Transmit data channel N FIFO is reset. |
| 23-18<br>— | Reserved |
| 17-16<br>TCE | Transmit Channel Enable<br>Enables the corresponding data channel for transmit operation. Changing TCE field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation.<br>The width of TCE field = the number of transmit channels (call it N). For example, if TCE field is 2 bits wide, then bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Setting bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Setting bit N will enable transmit channel N.<br>0b - Transmit data channel N is disabled.<br>1b - Transmit data channel N is enabled. |
| 15-5<br>— | Reserved |
| 4-0<br>WDFL | Word Flag Configuration<br>Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set. |

## 59.4.1.8 SAI Transmit Configuration 4 Register (TCR4)

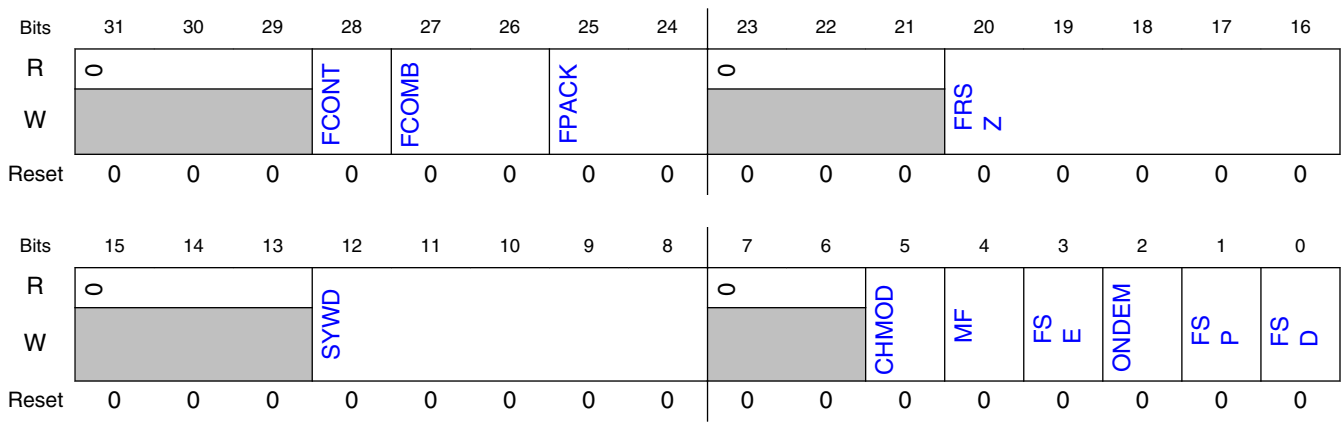
### 59.4.1.8.1 Offset

| Register | Offset |
|---|---|
| TCR4 | 18h |

### 59.4.1.8.2 Function

This register must not be altered when TCSR[TE] is set.

### 59.4.1.8.3 Diagram



### 59.4.1.8.4 Fields

| Field | Function |
|---|---|
| 31-29<br>— | Reserved |
| 28<br>FCONT | FIFO Continue on Error<br>Configures when the SAI will continue transmitting after a FIFO error has been detected.<br>0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.<br>1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared. |
| 27-26<br>FCOMB | FIFO Combine Mode |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel.<br>When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.<br>00b - FIFO combine mode disabled.<br>01b - FIFO combine mode enabled on FIFO reads (from transmit shift registers).<br>10b - FIFO combine mode enabled on FIFO writes (by software).<br>11b - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software). |
| 25-24<br>FPACK | FIFO Packing Mode<br>Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software.<br>00b - FIFO packing is disabled<br>01b - Reserved<br>10b - 8-bit FIFO packing is enabled<br>11b - 16-bit FIFO packing is enabled |
| 23-21<br>— | Reserved |
| 20-16<br>FRSZ | Frame size<br>Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words. |
| 15-13<br>— | Reserved |
| 12-8<br>SYWD | Sync Width<br>Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame. |
| 7-6<br>— | Reserved |
| 5<br>CHMOD | Channel Mode<br>Configures if transmit data pins are configured for TDM mode or Output mode.<br>0b - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled.<br>1b - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled. |
| 4<br>MF | MSB First<br>Configures whether the LSB or the MSB is transmitted first.<br>0b - LSB is transmitted first. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - MSB is transmitted first. |
| 3<br>FSE | Frame Sync Early<br>0b - Frame sync asserts with the first bit of the frame.<br>1b - Frame sync asserts one bit before the first bit of the frame. |
| 2<br>ONDEM | On Demand Mode<br>When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear.<br>0b - Internal frame sync is generated continuously.<br>1b - Internal frame sync is generated when the FIFO warning flag is clear. |
| 1<br>FSP | Frame Sync Polarity<br>Configures the polarity of the frame sync.<br>0b - Frame sync is active high.<br>1b - Frame sync is active low. |
| 0<br>FSD | Frame Sync Direction<br>Configures the direction of the frame sync.<br>0b - Frame sync is generated externally in Slave mode.<br>1b - Frame sync is generated internally in Master mode. |

### 59.4.1.9.4 Fields

| Field | Function |
|---|---|
| 31-29<br>— | Reserved |
| 28-24<br>WNW | Word N Width<br>Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported. |
| 23-21<br>— | Reserved |
| 20-16<br>W0W | Word 0 Width<br>Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame. |
| 15-13<br>— | Reserved |
| 12-8<br>FBT | First Bit Shifted<br>Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First. |
| 7-0<br>— | Reserved |

## 59.4.1.10 SAI Transmit Data Register (TDR0 - TDR1)

### 59.4.1.10.1 Offset

For a = 0 to 1:

| Register | Offset |
|---|---|
| TDRa | 20h + (a × 4h) |

#### 59.4.1.10.2 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | | | | | | | | | |
| W | TDR | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | | | | | | | | | |
| W | TDR | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### 59.4.1.10.3 Fields

| Field | Function |
|---|---|
| 31-0<br>TDR | Transmit Data Register<br>Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored. |

### 59.4.1.11 SAI Transmit FIFO Register (TFR0 - TFR1)

#### 59.4.1.11.1 Offset

For a = 0 to 1:

| Register | Offset |
|---|---|
| TFRa | 40h + (a × 4h) |

#### 59.4.1.11.2 Function

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

### 59.4.1.11.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 59.4.1.11.4 Fields

| Field | Function |
|---|---|
| 31<br>WCP | Write Channel Pointer<br>When FIFO Combine mode is enabled for writes, indicates that this data channel is the next FIFO to be written.<br>0b - No effect.<br>1b - FIFO combine is enabled for FIFO writes and this FIFO will be written on the next FIFO write. |
| 30-20<br>— | Reserved |
| 19-16<br>WFP | Write FIFO Pointer<br>FIFO write pointer for transmit data channel. |
| 15-4<br>— | Reserved |
| 3-0<br>RFP | Read FIFO Pointer<br>FIFO read pointer for transmit data channel. |

## 59.4.1.12 SAI Transmit Mask Register (TMR)

### 59.4.1.12.1 Offset

| Register | Offset |
|---|---|
| TMR | 60h |

### 59.4.1.12.2 Function

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

### 59.4.1.12.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

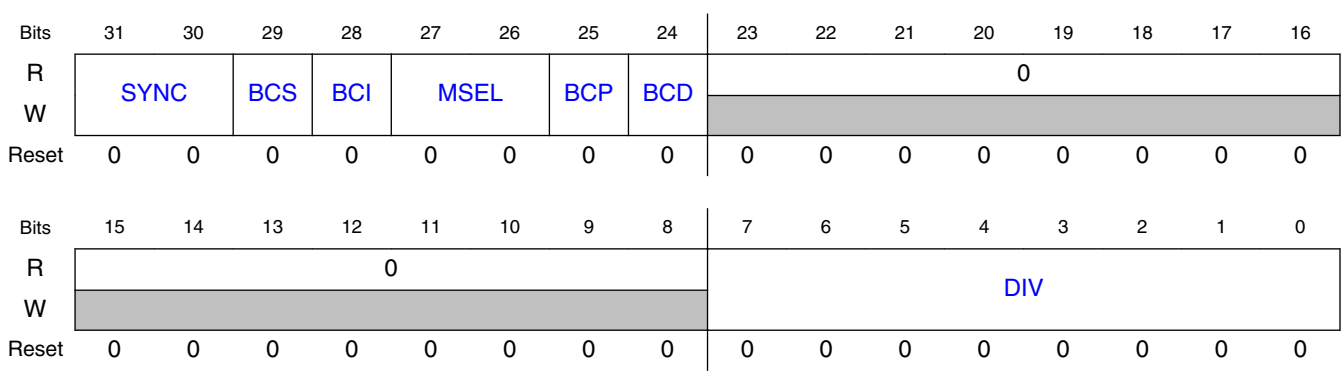
### 59.4.1.15.1 Offset

| Register | Offset |
|---|---|
| RCR2 | 90h |

### 59.4.1.15.2 Function

This register must not be altered when RCSR[RE] is set.

### 59.4.1.15.3 Diagram



### 59.4.1.15.4 Fields

| Field | Function |
|---|---|
| 31-30<br>SYNC | Synchronous Mode<br>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter or other SAI peripheral must be configured for asynchronous operation. |

*Table continues on the next page...*

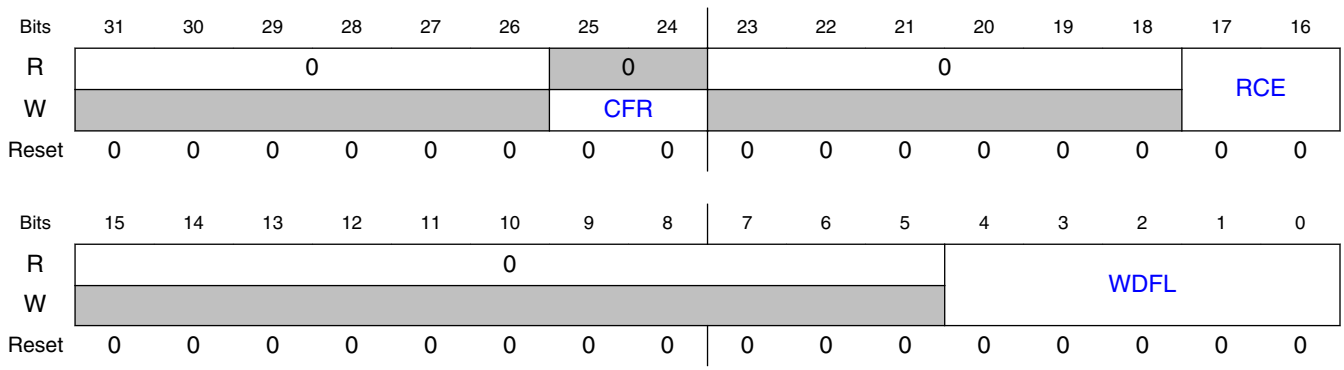
| Field | Function |
|---|---|
| | 00b - Asynchronous mode.<br>01b - Synchronous with transmitter.<br>10b - Synchronous with another SAI receiver.<br>11b - Synchronous with another SAI transmitter. |
| 29<br>BCS | Bit Clock Swap<br>This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (SAI_TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (SAI_RX_SYNC).<br>When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (SAI_RX_BCLK) but use the transmitter frame sync (SAI_TX_SYNC).<br>This field has no effect when synchronous to another SAI peripheral.<br>0b - Use the normal bit clock source.<br>1b - Swap the bit clock source. |
| 28<br>BCI | Bit Clock Input<br>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.<br>The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral .<br>0b - No effect.<br>1b - Internal logic is clocked as if bit clock was externally generated. |
| 27-26<br>MSEL | MCLK Select<br>Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.<br>**NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option.<br>00b - Bus Clock selected.<br>01b - Master Clock (MCLK) 1 option selected.<br>10b - Master Clock (MCLK) 2 option selected.<br>11b - Master Clock (MCLK) 3 option selected. |
| 25<br>BCP | Bit Clock Polarity<br>Configures the polarity of the bit clock.<br>0b - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge.<br>1b - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge. |
| 24<br>BCD | Bit Clock Direction<br>Configures the direction of the bit clock.<br>0b - Bit clock is generated externally in Slave mode.<br>1b - Bit clock is generated internally in Master mode. |
| 23-8<br>— | Reserved |
| 7-0<br>DIV | Bit Clock Divide<br>Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2. |

# 59.4.1.16 SAI Receive Configuration 3 Register (RCR3)

## 59.4.1.16.1 Offset

| Register | Offset |
|---|---|
| RCR3 | 94h |

## 59.4.1.16.2 Diagram



## 59.4.1.16.3 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-24<br>CFR | Channel FIFO Reset<br>Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set.<br>The width of CFR field = the number of receive channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to receive channel 1 FIFO pointer and bit position 25 refers to receive channel 2 FIFO pointer. Setting bit 24 resets receive channel 1 FIFO pointer, and setting bit 25 enables receive channel 2 FIFO pointer. Setting bit N will reset receive channel N FIFO pointer.<br>0b - No effect.<br>1b - Receive data channel N FIFO is reset. |
| 23-18<br>— | Reserved |
| 17-16<br>RCE | Receive Channel Enable<br>Enables the corresponding data channel for receive operation. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for receive operation. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | The width of RCE field = the number of receive channels (call it N). For example, if RCE field is 2 bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Setting bit 16 enables receive channel 1, and setting bit 17 enables receive channel 2. Setting bit N will enable receive channel N.<br>0b - Receive data channel N is disabled.<br>1b - Receive data channel N is enabled. |
| 15-5<br>— | Reserved |
| 4-0<br>WDFL | Word Flag Configuration<br>Configures which word the start of word flag is set. The value written should be one less than the word number (for example, write zero to configure for the first word in the frame). When configured to a value greater than the Frame Size field, then the start of word flag is never set. |

## 59.4.1.17 SAI Receive Configuration 4 Register (RCR4)

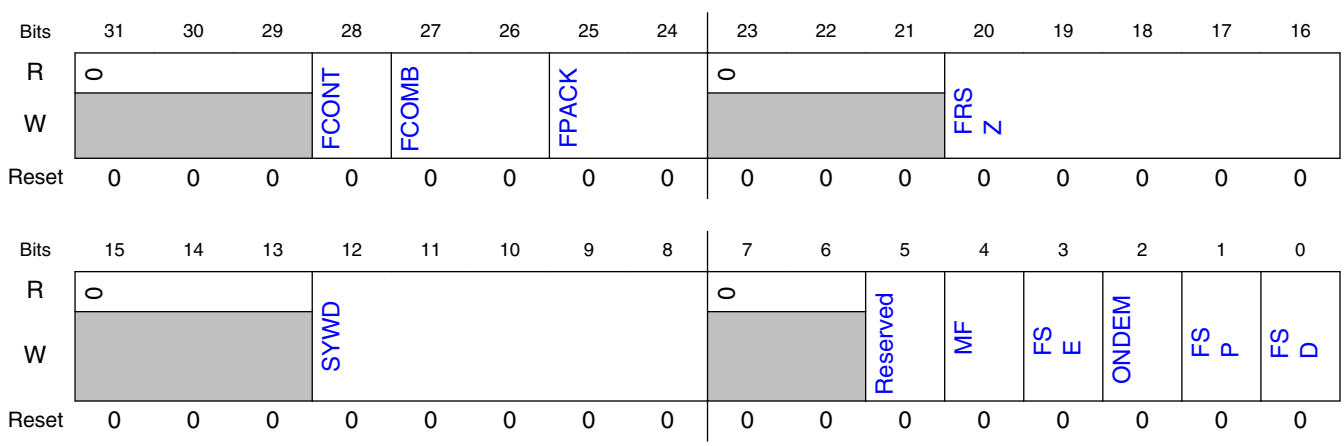
### 59.4.1.17.1 Offset

| Register | Offset |
|---|---|
| RCR4 | 98h |

### 59.4.1.17.2 Function

This register must not be altered when RCSR[RE] is set.

### 59.4.1.17.3 Diagram



## 59.4.1.17.4 Fields

| Field | Function |
|---|---|
| 31-29<br>— | Reserved |
| 28<br>FCONT | FIFO Continue on Error<br>Configures when the SAI will continue receiving after a FIFO error has been detected.<br>0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.<br>1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared. |
| 27-26<br>FCOMB | FIFO Combine Mode<br>When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel.<br>When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.<br>00b - FIFO combine mode disabled.<br>01b - FIFO combine mode enabled on FIFO writes (from receive shift registers).<br>10b - FIFO combine mode enabled on FIFO reads (by software).<br>11b - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software). |
| 25-24<br>FPACK | FIFO Packing Mode<br>Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software.<br>00b - FIFO packing is disabled<br>01b - Reserved.<br>10b - 8-bit FIFO packing is enabled<br>11b - 16-bit FIFO packing is enabled |

## 59.5 Functional description

This section provides a complete functional description of the block.

### 59.5.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

#### 59.5.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

#### 59.5.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

#### 59.5.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

**NOTE**

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

### 59.5.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

#### 59.5.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

#### 59.5.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

### 59.5.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other or synchronously to other SAI peripherals.

#### 59.5.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

#### 59.5.3.2 Multiple SAI Synchronous mode

Synchronous operation between multiple SAI peripherals is not supported on all devices. This mode requires the source of the bit clock and frame sync to be configured for asynchronous operation and the remaining users of the bit clock and frame sync to be configured for synchronous operation.

Synchronous operation between multiple SAI transmitters or receivers also requires the source of the bit clock and frame sync to be enabled for any of the synchronous transmitters or receivers to also be enabled. It is recommended that the source of the bit clock and frame sync is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The separate SAI peripherals otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

### 59.5.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

## 59.5.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 8 × 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

### 59.5.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 59-2 for LSB First configurations and Figure 59-3 for MSB First configurations.

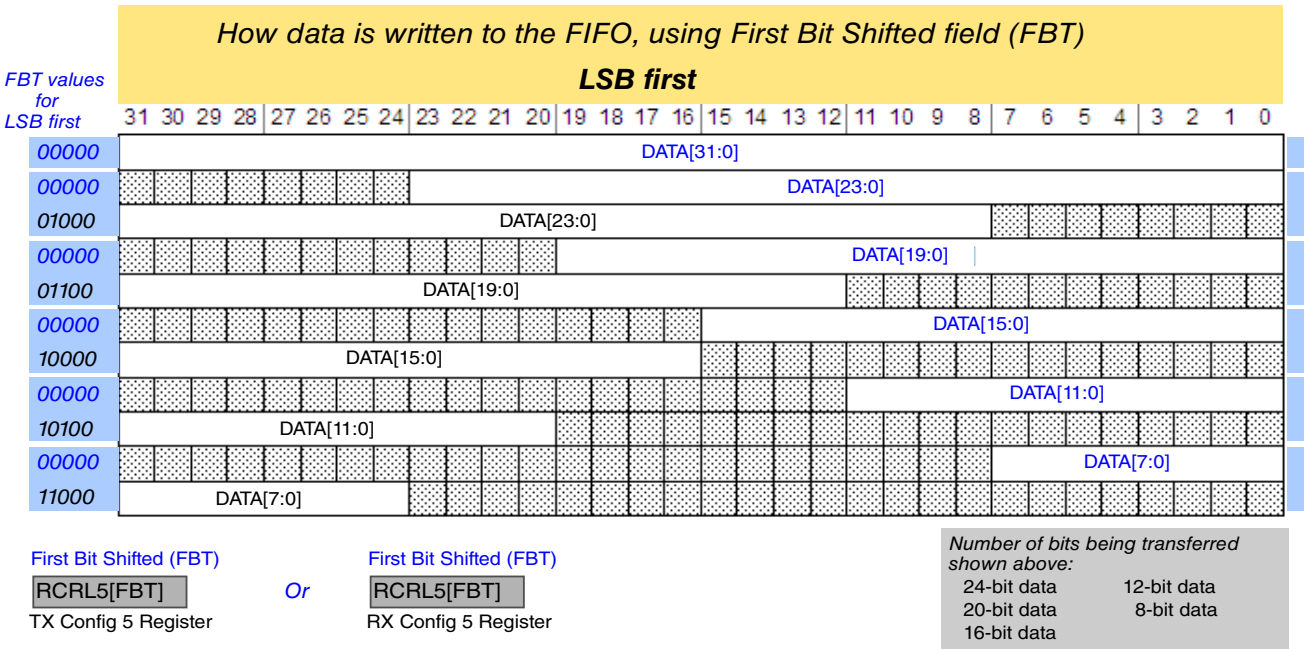

**Figure 59-2. SAI first bit shifted, LSB first**

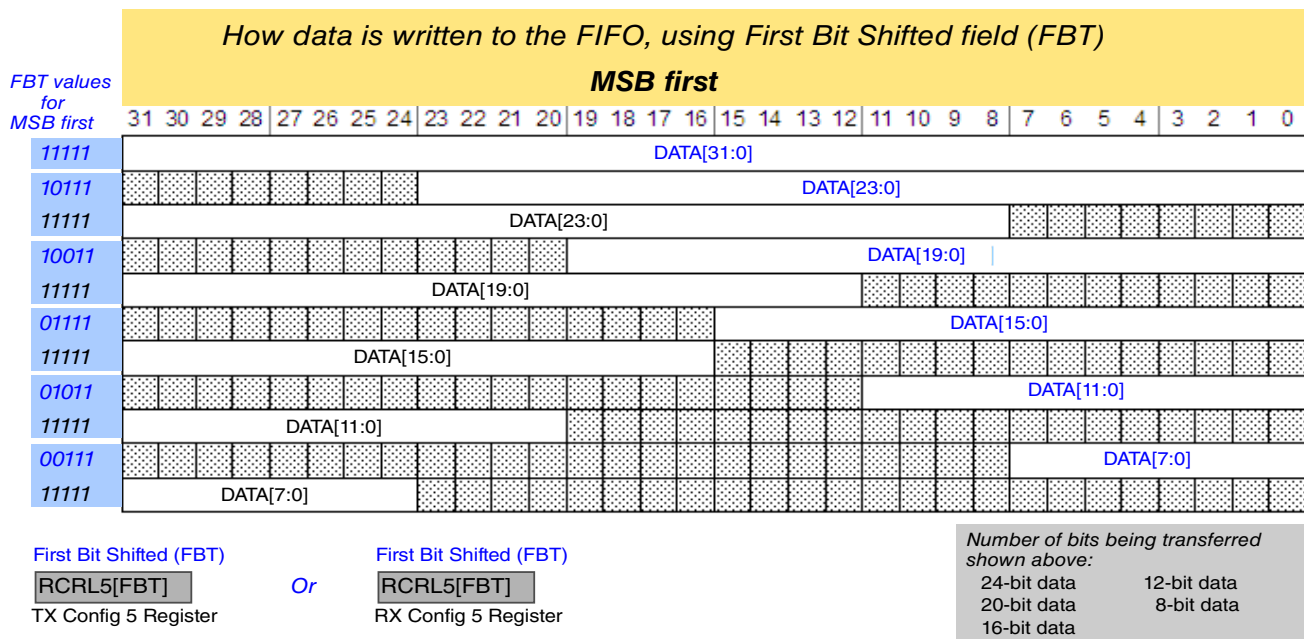

**Figure 59-3. SAI first bit shifted, MSB first**

### 59.5.5.2 FIFO pointers

When writing to a Transmit Data Register (TDR*n*), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR*n*) increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the Transmit Data Register and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, then writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, then to avoid a FIFO underrun, the Transmit Data Register must be written at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, the Transmit FIFO should be initialized with data (since after the transmitter is enabled, the transmitter will start a new frame, and if no data is in the FIFO, then the transmitter will immediately give an error).

When reading a Receive Data Register (RDR*n*), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR*n*) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, then reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, then to avoid a FIFO overrun, the Receive Data Register must be read at least 3 bit clocks before the end of an unmasked word.

### 59.5.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset $0 (first bit is selected by TCFG5[FBT] must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset $2 (first bit is selected by TCSR5[FBT][3:0]). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset $0 (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset $2 (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset $0, second word in byte offset $1, third word in byte offset $2 and fourth word in byte offset $3. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset $0.

### 59.5.5.4 FIFO Combine

FIFO combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when FIFO Combine mode is enabled.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register will access the first enabled channel FIFO, while the second access to a FIFO register will access the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable the FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels are loaded at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted is loaded from the first enabled channel FIFO, while the second word transmitted is loaded from the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always loaded from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received is stored to the first enabled channel FIFO, while the second word received is stored to the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always stored the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels will load or store each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags will assert if any of the enabled data channel meets the warning flag or request flag conditions.

## 59.5.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

## 59.5.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous versions of the transmitter and receiver interrupts are generated to wake up the CPU from stop mode.

### 59.5.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

### 59.5.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

### 59.5.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCONT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

#### 59.5.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

#### 59.5.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

# Chapter 60
# Smart Card Interface Module (EMV SIM)

## 60.1 Chip-specific EMV SIM information

### 60.1.1 EMV_SIM overview

The Euro/Mastercard/Visa Serial Interface Module (EMV_SIM) is a module that supports ISO-7816 protocol. For more information, please see Introduction

### 60.1.2 EMV_SIM Instantiation

This device contains 1 EMV_SIM module. This section describes how each module is configured on this device.

## 60.2 Introduction

The Euro, MasterCard, Visa Subscriber Identification Module (EMV SIM) is designed to facilitate communication to Smart Cards compatible to the EMV ver4.3 standard (Book 1) and Smart Cards compatible with ISO/IEC 7816-3 Standard.

### 60.2.1 Features

The EMV SIM module supports the following features:

- Supports Smart Cards based on the EMV Standard v4.3 and ISO 7816-3 standard

- Independent clock for SIM logic (transmitter + receiver) and independent clock for register read-write interface
- 16 byte deep FIFO for transmitter and receiver
- Automatic NACK generation on parity error and receiver FIFO overflow error
- Support for both Inverse and Direct conventions
- Re-transmission of byte upon Smart Card NACK request with programmable threshold of re-transmissions
- Auto detection of Initial Character in receiver and setting of data format (inverse or direct)
- NACK detection in receiver
- Independent timers to measure character wait time, block wait time and block guard time
- Two general purpose counters available for use by software application with programmable clock selection for the counters
- DMA support available to transfer data to/from FIFOs. Programmable option available to select interrupt or DMA feature
- Programmable Prescaler to generate the desired frequency for Card Clock and Baud Rate Divisor to generate the internal ETU clocks for transmitter and receiver for any F/D ratio
- Deep sleep wake-up via Smart Card presence detect interrupt
- Manual control of all Smart Card interface signals
- Automatic power down of port logic on Smart Card presence detect
- Support for 8-bit LRC and 16-bit CRC generation for bytes sent out from transmitter and checking incoming message checksum for receiver

## 60.3 Block Diagram

Figure below shows the block diagram for the EMV SIM module.

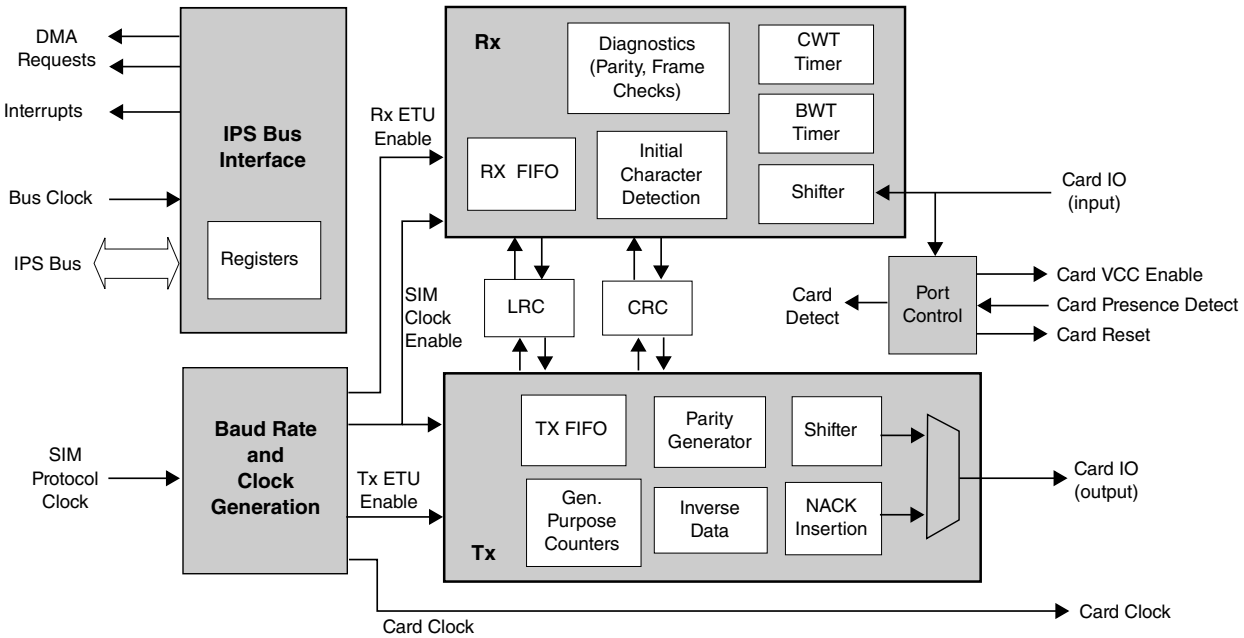

**Figure 60-1. EMV SIM Block Diagram**

## 60.4 Design Overview

The EMV SIM is designed to be compliant to the EMV ICC Specifications ver. 4.3 (dated Nov 2011) and the ISO-7816-3 standard.

The EMV SIM module is a block that is configured via the device's peripheral bus interface. The module has 32-bit aligned memory mapped registers that are used to configure and control the operations of the module. The software can write the transmit bytes or read the received bytes using either interrupt operation or DMA operation. The module can generate necessary DMA requests for the operation.

The module interfaces to the external card (Smart Card) via card clock, card reset, card $V_{CC}$ enable and IO pins. The transmitter output from the module and the receiver input to the module are connected to the same IO pin and used in the open drain configuration. A pull-up resistor must be connected to the IO pin on board to allow proper functioning.

The key functional blocks in the module are clocking, transmitter and receiver which control the interactions with the Smart Card. These blocks function on a clock that is different and asynchronous to the register read/write clock. In order for the transmitter and receiver to function properly, the respective configuration must be done before enabling the transmitter or receiver.

The clocking module generates the card clock (output to Smart Card), and the internal clocks for the transmitter and receiver. The internal clocks control the ETU period and the sampling and driving of data on the IO line. The receive operation uses an internal over-sampled clock that oversamples the received input at 16x times the ETU rate. The prescaler generates the card clock in the range of 1 to 5 MHz with near 50% duty cycle and the baud divider generates the internal ETU clocks for transmitter and receiver.

The transmitter comprises of a 16-byte deep FIFO to store the bytes to be sent to the Smart Card. These bytes are sent to the Smart Card serially by the transmitter. The data format (i.e. inverse or direct conversion) is supported and the byte is converted into the right data format before being shifted out serially. The transmitter also supports retransmission of the current byte on the reception of a NACK. The transmitter automatically inserts NACK when the receiver indicates a parity or FIFO overflow error, if configured to do so by software. The transmitter is not required to be enabled for this. The transmitter also includes timer to insert the programmable guard time between the transmitter bytes and general purpose timers to allow software performs certain measurements. The status of the transmitter operation is intimated to software via maskable interrupts.

The receiver comprises of a 16-byte deep FIFO to store the correctly received bytes from the Smart Card. Software must ensure that it reads out the data from FIFO to prevent any overflow when more bytes are sent from the card. The receiver can be configured to detect the initial character. When configured to do so, the data format (direct or inverse convention) is also determined by the receiver and appropriate bit is set in the register map. Internal timers in the receiver measure the various wait times (Character, Block and Guard). On reception of a byte, the receiver checks the byte for Parity Error (in T=0 mode) and Framing Error. It can then direct the transmitter to insert NACK on parity error detection. For a block of bytes received, the receiver checks for LRC or CRC errors (in T=1 mode). Other errors are stored as status for software to be aware of their occurrence. The status of the receiver operation is intimated to software via maskable interrupts.

In addition to the above blocks, the module also contains the 8-bit LRC and the 16-bit CRC blocks that are common to the transmitter and receiver. Both transmitter and receiver can use the LRC and CRC blocks and can insert the LRC or CRC into the byte stream or check the validity of the input stream using the LRC and CRC values received. Since transmit and receive operations are mutually exclusive, common LRC and CRC blocks for the transmitter and receiver can be used.

The Smart Card interface signals, except IO, which is controlled by the transmitter and receiver; are generated by the port control block which controls the assertion and de-assertion of the clock, reset and VCC signals to Smart Card. It can do so manually (software needs to explicitly write the necessary bits) or using auto power down wherein

the module can itself power down the Smart Card when configured to do so by software. The port control block can also detect the Smart Card presence and generate necessary interrupts to indicate the same.

## 60.5 Signal Description

The following table shows the user-accessible signals available on EMV SIM. See the chip-level specification to find out which signals are connected to the external pins.

**Table 60-1. EMV SIM Signal Description**

| Signal | Description | I/O |
|---|---|---|
| EMVSIM_SCLK | Card Clock. Clock to Smart Card. | O |
| EMVSIM_SRST | Card Reset. Reset signal to Smart Card | O |
| EMVSIM_VCC_EN | Card Power Enable. This signal controls the power to Smart Card | O |
| EMVSIM_IO | Card Data Line. Bi-directional data line. | I/O |
| EMVSIM_PD | Card Presence Detect. Signal indicating presence or removal of card | I |

## 60.6 Memory Map and Registers

### 60.6.1 EMVSIM register descriptions

The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s.The module will not check for correctness of programmed values in the registers and software must ensure that correct values are being written.

#### 60.6.1.1 EMVSIM Memory map

EMVSIM0 base address: 4003_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID Register (VER_ID) | 32 | RO | 0000_0000h |

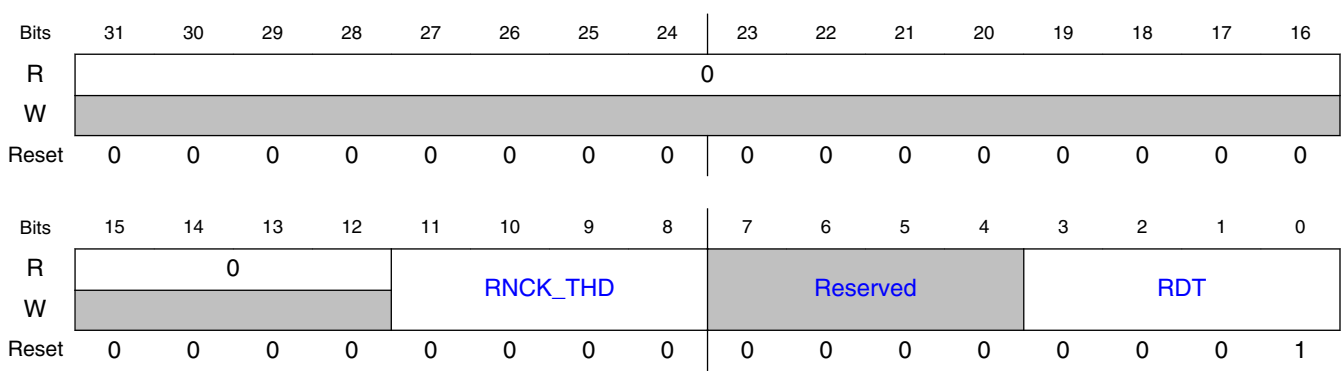
## 60.6.1.8 Receiver Threshold Register (RX_THD)

### 60.6.1.8.1 Offset

| Register | Offset |
|---|---|
| RX_THD | 18h |

### 60.6.1.8.2 Diagram



### 60.6.1.8.3 Fields

| Field | Function |
|---|---|
| 31-12<br>— | Reserved |
| 11-8 | Receiver NACK Threshold Value |

*Table continues on the next page...*

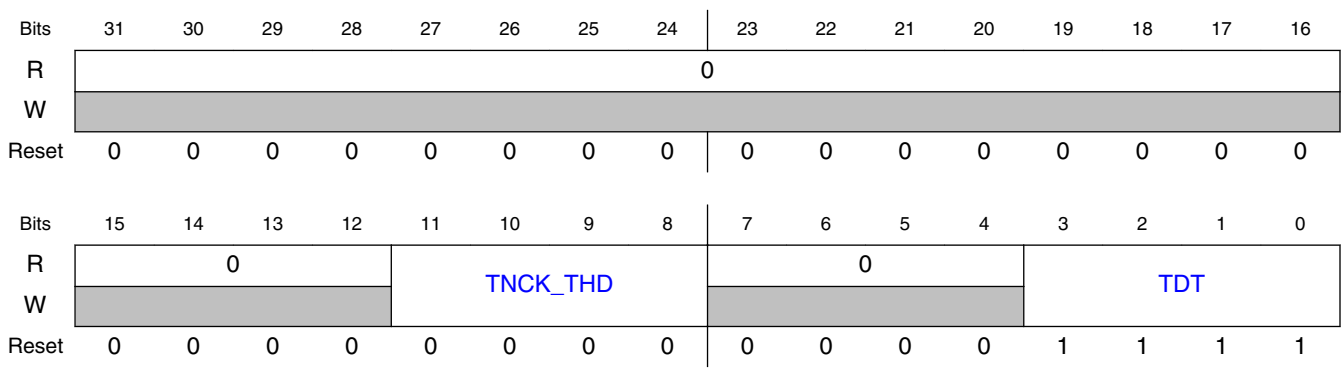
| Field | Function |
|---|---|
| RNCK_THD | Used to specify the number of consecutive NACK's transmitted by the EMV SIM module, for a given character, before the receive threshold error (RTE) flag is triggered. A value of 0 indicates that RTE is never set. When a valid character is received by the EMV SIM, the internal counter keeping track of the NACK count resets to zero for the subsequent byte being received. If the ANACK bit is clear in the CNTL register, RNCK_THD has no effect.<br>0000b - Zero Threshold. RTE will not be set |
| 7-4<br>— | Reserved |
| 3-0<br>RDT | Receiver Data Threshold Value<br>Determines the number of bytes that must exist in the Receive FIFO to trigger the receive data threshold interrupt flag (RDTF). Value must not exceed the total bytes that can be stored in the Receive FIFO. |

## 60.6.1.9 Transmitter Threshold Register (TX_THD)

### 60.6.1.9.1 Offset

| Register | Offset |
|---|---|
| TX_THD | 1Ch |

### 60.6.1.9.2 Diagram



### 60.6.1.9.3 Fields

| Field | Function |
|---|---|
| 31-12<br>— | Reserved |
| 11-8 | Transmitter NACK Threshold Value |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TNCK_THD | Used to set the NACK threshold for the transmitter. Once the threshold number set by TNCK_THD has been reached for the current byte being transmitted, the error flag TNTE in the TX_STATUS register will be set. Setting of TNTE causes the remaining transmissions queued in the transmit FIFO to be aborted and no more transmissions to occur until software clears TNTE. To trigger TNTE, a given byte being transmitted must reach the TNCK_THD threshold itself. Transmit NACKs accumulated on one byte are not carried over to the next.<br>0000b - TNTE will never be set; retransmission after NACK reception is disabled.<br>0001b - TNTE will be set after 1 nack is received; 0 retransmissions occurs.<br>0010b - TNTE will be set after 2 nacks are received; at most 1 retransmission occurs.<br>0011b - TNTE will be set after 3 nacks are received; at most 2 retransmissions occurs.<br>1111b - TNTE will be set after 15 nacks are received; at most 14 retransmissions occurs. |
| 7-4<br>— | Reserved |
| 3-0<br>TDT | Transmitter Data Threshold Value<br>Used to set the threshold value for the Transmit FIFO at which the TDTF bit in the TX_STATUS register will be set. When the number of bytes in the Transmit FIFO is less than or equal to TDT[3:0], TDTF will be set. |

## 60.6.1.10.3 Fields

| Field | Function |
|---|---|
| 31-28<br>— | Reserved |
| 27-24<br>RX_CNT | Receive FIFO Byte Count<br>These bits indicate the number of bytes stored in the receive FIFO.<br>0000b - FIFO is emtpy |
| 23-20<br>— | Reserved |
| 19-16<br>RX_WPTR | Receive FIFO Write Pointer Value<br>Value of write pointer of Receive FIFO |
| 15-14<br>— | Reserved |
| 13<br>FEF | Frame Error Flag<br>Used to indicate if the current received byte did not have proper STOP bits. This will not cause a NACK transmission.<br>This bit will not cause an interrupt assertion. It is simply an indication that a framing error has occured.<br>0b - No frame error detected<br>1b - Frame error detected |
| 12<br>PEF | Parity Error Flag<br>Used to indicate if a received byte had a parity error or not. A parity error will cause transmission of NACK if ANACK bit is set in CTRL register and PEF bit will not be asserted. When ANACK is *not* set, PEF will be asserted.<br>This bit will also not assert when ICM bit is set; however parity is checked in ICM = 1 mode. It is simply an indication that a parity error has occured.<br>0b - No parity error detected<br>1b - Parity error detected |
| 11<br>BGT_ERR | Block Guard Time Error Flag<br>Used to indicate if the block guard time was too small. The threshold is set by the block guard time register.<br>0b - Block guard time was sufficient<br>1b - Block guard time was too small |
| 10<br>BWT_ERR | Block Wait Time Error Flag<br>Used to indicate if the block wait time has been exceeded. The threshold is set by the block wait time registers.<br>0b - Block wait time not exceeded<br>1b - Block wait time was exceeded |
| 9<br>RTE | Received NACK Threshold Error Flag<br>Used to indicate whether the number of consecutive NACK's generated by the EMV SIM module in response to receive parity errors, for the byte being received, equals the value programmed in the RTH[3:0] in the RX_THRESHOLD register. This bit will never set unless the ANACK bit is set in the CNTL register. The SAPDx bit in the CNTL resister must be set to enable the threshold error to trigger the auto power down sequence. RTE is a write once to clear bit. Clearing this bit also resets the internal counter for consecutive NACK's being transmitted for a given byte.<br>0b - Number of NACKs generated by the receiver is less than the value programmed in RTH[3:0] |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - Number of NACKs generated by the receiver is equal to the value programmed in RTH[3:0] |
| 8<br>CWT_ERR | Character Wait Time Error Flag<br>Used to indicate when the time between received characters is equal to or greater than the value programmed in the CHAR_WAIT register.<br>0b - No CWT violation has occurred (default).<br>1b - Time between two consecutive characters has exceeded the value in CHAR_WAIT. |
| 7<br>CRC_OK | CRC Check OK Flag<br>Used to indicate when the calculated 16-bit CRC value matches the expected value for the current input data stream. The value is calculated across all received characters from the point the CRC_EN bit is set in the CTRL register. The current CRC residual can be reset by three mechanisms:<br>• Clear CRC_EN bit in CTRL register<br>• Set XMT_EN bit in ENABLE register<br>• Automatically by hardware when ETC flag is set at the end of a transmission.<br>0b - Current CRC value does not match remainder.<br>1b - Current calculated CRC value matches the expected result. |
| 6<br>LRC_OK | LRC Check OK Flag<br>Used to indicate when the calculated 8-bit LRC value is correct for the current input data stream. The value is calculated across all received characters from the point the LRC_EN bit is set in the CTRL register. The current LRC residual can be reset by three mechanisms:<br>• Clear LRC_EN bit in CTRL register<br>• Set XMT_EN bit in ENABLE register<br>• Automatically by hardware when ETC flag is set at the end of a transmission.<br>0b - Current LRC value does not match remainder.<br>1b - Current calculated LRC value matches the expected result (i.e. zero). |
| 5<br>RDTF | Receive Data Threshold Interrupt Flag<br>Interrupt flag asserted when total bytes in the Receive FIFO equal or is greater than the programmed receive threshold RDT[3:0]. The RDTF flag will be set any time the number of unread bytes in the receive FIFO is equal to or greater than the value set by RDT[3:0].<br>The flag can be cleared by reading enough bytes out of the receive FIFO so as to bring the number of bytes left in the FIFO below the RDT[3:0] level. Another way to clear the flag is to set the RDT[3:0] level higher than the number of unread bytes currently in the FIFO.<br>The RDTF flag will create an interrupt if the RDT_IM bit in the INT_MASK register is cleared.<br>0b - Number of unread bytes in receive FIFO less than the value set by RDT[3:0] (default).<br>1b - Number of unread bytes in receive FIFO greater or than equal to value set by RDT[3:0]. |
| 4<br>RX_DATA | Receive Data Interrupt Flag<br>Interrupt asserted when a new data byte is received and entered into the Receive FIFO.<br>0b - No new byte is received<br>1b - New byte is received ans stored in Receive FIFO |
| 3-1<br>— | Reserved |
| 0<br>RFO | Receive FIFO Overflow Flag<br>Used to indicate that the EMV SIM was unable to store received data due to already unread bytes in the FIFO (FIFO full or almost full). It does not necessarily indicate that data has been lost. If the ONACK control bit in the CNTL register is set, there will be a NACK pulse generated on bytes that would otherwise cause a loss of data due to a full FIFO. These bytes should be retransmitted by the Smart Card which implies that no data has actually been lost. In this case, the RFO flag is just an indicator that this situation has occurred which may be helpful in system debug. For the case where ONACK is not set, a set RFO flag does indicate a loss of data since all bytes received with the OEF flag set will indeed be lost |

| Field | Function |
|---|---|
| | (including the byte that caused the bit to be set). The RFO flag will cause an interrupt if the RFO_IM bit in the INT_MASK register. The RFO flag is a write-one-to-clear bit.<br>0b - No overrun error has occurred (default)<br>1b - A byte was received when the received FIFO was already full |

### 60.6.1.11.3 Fields

| Field | Function |
|---|---|
| 31-28<br>— | Reserved |
| 27-24<br>TX_CNT | Transmit FIFO Byte Count<br>These bits indicate the number of bytes stored in the transmit FIFO.<br>0000b - FIFO is emtpy |
| 23-20 | Reserved |

*Table continues on the next page...*

| Field | Function |
|---|---|
| — | |
| 19-16<br>TX_RPTR | Transmit FIFO Read Pointer<br>Value of the read pointer of transmit FIFO. |
| 15-10<br>— | Reserved |
| 9<br>GPCNT1_TO | General Purpose Counter 1 Timeout Flag<br>Used to indicate when the General Purpose Counter 1 has reached the GPCNT1_VAL value in the GPCNT_VAL register.<br>0b - GPCNT1_VAL time not reached, or bit has been cleared. (default)<br>1b - General Purpose counter has reached the GPCNT1_VAL value |
| 8<br>GPCNT0_TO | General Purpose Counter 0 Timeout Flag<br>Used to indicate when the General Purpose Counter 0 has reached the GPCNT0_VAL value in the GPCNT_VAL register.<br>0b - GPCNT0_VAL time not reached, or bit has been cleared. (default)<br>1b - General Purpose counter has reached the GPCNT0_VAL value |
| 7<br>TDTF | Transmit Data Threshold Flag<br>Interrupt flag asserted when total bytes in the Transmit FIFO is less than or equal to the programmed transmit data threshold TDT[3:0]. The TDTF flag will be set any time the number of bytes in the transmit FIFO is less than or equal to the value set by TDT[3:0]. The flag can be cleared by writing enough bytes into the transmit FIFO so as to take the number of bytes in the FIFO above the TDT[3:0] level. Another way to clear the flag is to set the TDT[3:0] level lower than the number of bytes currently in the FIFO.The TDTF flag will create an interrupt if the TDT_IM bit in the INT_MASK register is cleared.<br>0b - Number of bytes in FIFO is greater than TDT[3:0], or bit has been cleared<br>1b - Number of bytes in FIFO is less than or equal to TDT[3:0] (default) |
| 6<br>TFF | Transmit FIFO Full Flag<br>Used to indicate when the Transmit FIFO has been written with maximum number of bytes that it can store. Subsequent writes may get ignored. The TFF bit can only be cleared by writing 1 to this bit or setting the FLUSH_XMT or SOFT_RESET bit in the RESET_CNTL register.<br>0b - Transmit FIFO Full condition has *not* occurred (default)<br>1b - A Transmit FIFO Full condition has occurred |
| 5<br>TCF | Transmit Complete Flag<br>Used to indicate whether the EMV SIM transmitter is ready for a new transmission. The TC flag becomes set when the guard time has expired after the last byte in the transmit FIFO (if XMT_CRC_LRC = 0) or the LRC or CRC byte (if XMT_CRC_LRC bit = 1) has been transmitted. The TC flag will create an interrupt if TC_IM in the INT_MASK register is low. The TC bit is a write-one-to-clear bit.<br>0b - Transmit pending or in progress<br>1b - Transmit complete (default) |
| 4<br>ETCF | Early Transmit Complete Flag<br>Used to indicate that the EMV SIM transmitter has finished sending the last byte in transmit FIFO (if XMT_CRC_LRC = 0) or finished sending the LRC or CRC byte (if XMT_CRC_LRC = 1). This bit differs from the TC bit in that it is set before the guard time of the last byte has elapsed. The ETC flag will create an interrupt if ETC_IM in the INT_MASK register is low. The ETC bit is a write-one-to-clear bit.<br>0b - Transmit pending or in progress<br>1b - Transmit complete (default) |
| 3<br>TFE | Transmit FIFO Empty Flag<br>Used to indicate that the EMV SIM transmit FIFO has been emptied. This bit will be set when the last byte in the transmit FIFO has been transferred out of the EMV SIM transmitter to the Smart Card successfully. TFE will also be set when the TNTE flag is set. The TFE flag will create an interrupt if TFE_IM in the INT_MASK register is low. The TFE bit is a write-one-to-clear bit. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 0b - Transmit FIFO is not empty<br>1b - Transmit FIFO is empty (default) |
| 2-1<br>— | Reserved |
| 0<br>TNTE | Transmit NACK Threshold Error Flag<br>Used to indicate the transmit NACK threshold has been reached. When TNTE is high, no further transmissions will be done until the TNTE flag is cleared. Any data transmissions still pending in the transmit FIFO will be aborted, and the TC, ETC, and TFE flags will be set. The TNTE flag will create an interrupt if TNACK_IM in the INT_MASK register is low. The TNTE bit is a write-one-to-clear bit.<br>0b - Transmit NACK threshold has not been reached (default)<br>1b - Transmit NACK threshold reached; transmitter frozen |

| | Write to this register to fill the transmit FIFO with the bytes to be transmitted. The Tx FIFO can be written to only when the transmitter is enabled. Writing to this register while transmitter is disabled will lead to ignoring of all write accesses to this register. Reads to this register will return zeros.<br>**NOTE:** Writing more data to the transmit FIFO than it can hold, will cause a Transmit FIFO Full (TFF) error. |

# 60.7 Functional Description

## 60.7.1 Initialization

### 60.7.1.1 Configuring EMV SIM

The first operation that must be done is to configure the EMV SIM interface signals to allow the EMV SIM Transmit or Receive operation to commence. The following steps describe a typical way to enable the Smart Card:

- Configure prescaler by programming the desired value in PRSC register to generate the card clock. The card clock frequency is calculated as:
  - $f_{SIM}$ / (PRSC[7:0]); where $f_{SIM}$ is the EMV SIM Clock Frequency
  - Prescaler value must be set such that the maximum card clock frequency specification set by EMV & ISO-7816 specifications are not violated

- Configure the DIVISOR_VALUE in the Baud Rate Divisor Register. This value determines the ETU period to be used by the transmitter or receiver
- Enable power to the Smart Card by setting the VCC_EN bit in PCSR register
- Enable the Smart Card clock by setting the SCEN bit in PCSR register
- Release Smart Card reset using the SRST bit in PCSR register to bring the Smart Card out of reset
- Program the power down functionality i.e. if Auto Power Down of Smart Card is required or not
- Select the Data Format type for the EMV SIM
  - Either set the IC bit to the desired data format (inverse or direct) OR
  - Set the ICM bit to allow automatic detection of Initial Character. IC bit will be updated to desired data format upon valid Initial Character detection
- Configure if the EMV SIM module is enabled to run in STOP and DOZE modes by setting the STOP_EN and DOZE_EN bits as desired
- Enable DMA request generation for Transmitter or Receiver as desired

Once the above configuration is complete, the receiver or transmitter can be configured depending on the operation to be carried out on the Smart Card.

**NOTE**

XMT_EN and RCV_EN bits should not be changed in the same write cycle. Software should attempt separate write accesses to CTRL register for updating these bits, one by one. For example, if XMT_EN = 1 and RCV_EN = 0 and in order to enable the receiver, first write to CTRL register should make XMT_EN = 0 and second write to CTRL register should make RCV_EN = 1.

### 60.7.1.2 Configuring Receiver

The following is a list of configurations that need to be performed (after the "Configuring EMV SIM" step) in order to configure the EMV SIM receiver for operation:

- Enable NACK generation capability
  - To generate NACK on parity errors and invalid initial characters, set the ANACK bit in CTRL register
  - To generate NACK on receiver FIFO overflow error, set the ONACK bit in CTRL register
- Configure the desired threshold for NACK generation and data threshold in the RX_THD register. These are the thresholds at which the RTE and RDTF flags will be set, respectively.
  - If auto power down is desired on RTE flag assertion, then write to SAPD bit PCSR to initiate the Smart Card power down

- Configure the timeout values for Character Wait Time Counter, the Block Wait Timer Counter and the Block Guard Time Counter
- Enable necessary interrupts by clearing respective bits in the INT_MASK register
- Configure the General Purpose Counter as needed and select desired clock source (GPCNT0/1_CLKSEL in the CLKCFG register)
- Enable Receiver by setting RCV_EN bit to 1 in CTRL register
- Receiver will enter Initial Character Detection mode if ICM bit is set or enter normal receive mode if ICM bit is not set
- Enable LRC or CRC as desired

#### 60.7.1.3 Configuring Transmitter

The following is a list of configurations that need to be performed (after the "Configuring EMV SIM" step) in order to configure the EMV SIM transmitter for operation:

- Select desired re-transmission threshold for NACKed characters in TX_THD register
  - This is the threshold at which the TNTE flag will be set by using the TNACK_THD[3:0] bits
- Configure the desired Guard Time between the characters transmitted by writing to the GETU[7:0] bits in TX_GETU register
- Configure the desired data threshold in TX_THD register.
- Enable necessary interrupts by clearing respective bits in the INT_MASK register
- Configure the General Purpose Counter as needed and select desired clock source (GPCNT0/1_CLKSEL in the CLKCFG register)
- Enable Transmitter by setting the XMT_EN in the CTRL register
- Enable LRC & CRC as desired
- Program bytes to be transmitted into the Tx FIFO. If DMA is enabled, DMA request will get asserted automatically.

**NOTE**

Tx FIFO can be written to after the transmitter is enabled (XMT_EN = 1). Writing to Tx FIFO while transmitter is disabled will not be successful and write access will be ignored.

**NOTE**

The Transmit and Receive operations are mutually exclusive and should not be enabled together.

### 60.7.2 Smart Card Interface and Control

The EMV SIM module controls the all the interface signals for the Smart Card. The Smart Card clock is generated using the prescaler (PRSC register) and the ETU periods are generated using the baud rate divisor (DIVISOR register). The Smart Card Reset and Voltage Enable are controlled by software through the PCSR register. The message bytes are transmitted and received on the Card IO device pin which is used in open drain configuration.

### 60.7.2.1 Smart Card Presence Detect

The Smart Card Presence Detect pin (SIMPD) allows for detection of the insertion or removal of a Smart Card. The SPDES bit in the PCSR register allows the software to configure which edge of the SIMPD pin will cause a presence detect interrupt flag to be asserted.

An internal pull-down is required on SIMPD pin to allow a high to low transition on this pin when the Smart Card is removed.

### 60.7.2.2 Powering Up

The first step to communicating with a Smart Card is to provide power and a clock signal to the card. Once the card is detected as present (using the presence detect features, or some other method), the Smart Card should be powered up according to the power up sequence specified in the ISO 7816-3 specification.

1. Apply voltage to the Smart Card by setting the VCC_EN bit in the PCSR register.
2. Select the appropriate clock frequency for the Smart Card by programming the CLKCFG and DIVISOR registers.
3. Enable the clock to the Smart Card by setting the SCEN bit in the PCSR register.
4. Remove the card from reset by setting the SRST bit in the PCSR register.

### 60.7.2.3 Automatic Power Down

Smart Cards require a proper sequence of operations to be followed to allow them to be powered down. The power down sequence as per ISO 7816 specifications is:

- Smart Card Reset (RST) pin transitions from high to low
- Smart Card Clock (CLK) is turned off to low
- Smart Card IO (IO) is transitioned from high impedance to low
- Smart Card Voltage Enable (VCC_EN) to turned off (pin driven low)

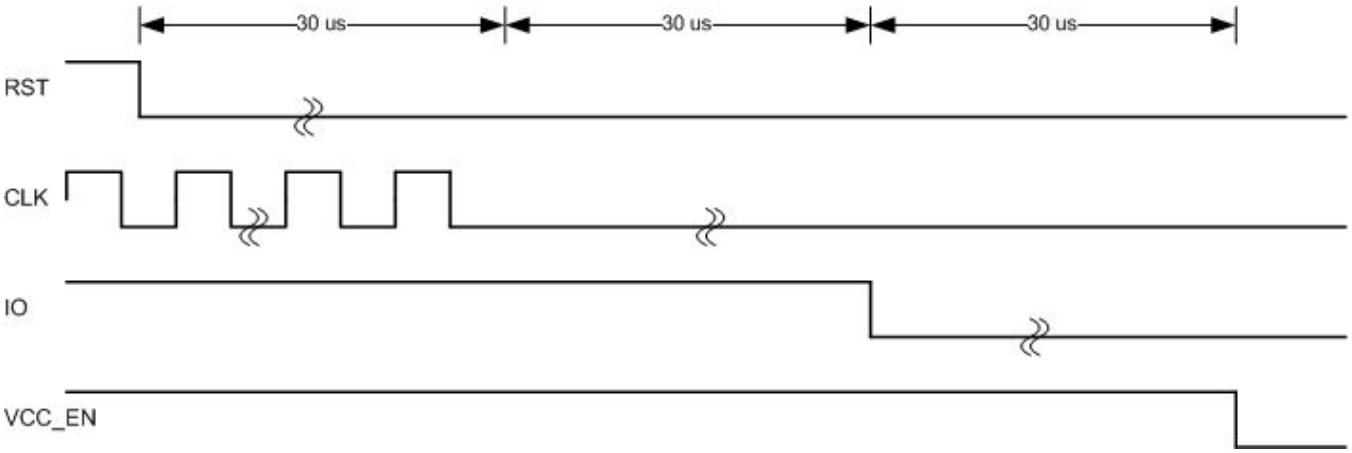

**Figure 60-2. Auto Power Down Sequence**

These operations can be done manually by software by writing to appropriate bits (SCEN, SRST and VCC_EN) in the PCSR register or automatically by hardware under the following conditions provided the auto power down feature is enabled in the PCSR register.

- Setting the SPD bit in PSCR register by software
- Assertion of RTE bit in RX_STATUS register
- Assertion of SPDIF bit in PCSR register when configured to detect card removal

**NOTE**

The SPDES bit in PCSR register determines which edge transition of the Smart Card Presence Detect pin is used for Smart Card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the edge specified by SPDES bit will cause the following: SPDIF to be set; if the SPDIM mask is clear, an interrupt to the CPU; and if SAPD in the PCSR register is set, an auto power down sequence to begin. If Smart card insertion is expected, SAPD can be set low to avoid the auto power down sequence from falsely triggering. The bit SPDP can be used to determine the current state of the Smart Card Presence Detect pin.

**NOTE**

The auto power down operation requires a low frequency clock (usually 32 kHz clock source) to be active on the device.

The auto power down sequence will clear the following register bits upon power down sequence completion:

- SPD bit in PCSR register
- SCEN bit in PCSR register

- SRST bit in PCSR register
- VCC_EN bit in PCSR register
- XMT_EN and RCV_EN bits in CTRL register

## 60.7.3 EMV SIM Receiver

The EMV SIM Receiver is designed to receive all message bytes and store valid bytes into the receive FIFO. It performs checks on the incoming messages and indicates the transmitter to enable NACK insertion for each message. In addition, the receiver automatically detects NACKs received when the transmitter is sending out message bytes.

### 60.7.3.1 Data Sampling

The incoming data is internally synchronized and sampled using a 16x oversampled clock, called the EMV SIM logic clock. The frequency of this clock is 16 times the ETU Clock (1/ETU Period). The whole receiver works on this EMV SIM logic clock.

### 60.7.3.2 Initial Character Detection

The EMV SIM module supports the detection of the Initial Character and determine the data format when it is placed in the initial character mode by setting the ICM bit in CTRL register. When placed in this mode, the EMV SIM module samples in the input line and waits for one of the initial characters to be detected. Once detected, the ICM bit is cleared and the data format bit, IC bit, is set to appropriate value depending on the data format detected using the initial character.

The two possible data formats are inverse convention and direct convention. Figures below illustrate the differences between the two formats. Essentially, inverse convention differs from direct convention in that the order of the bits is flipped (i.e. MSB for LSB) and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

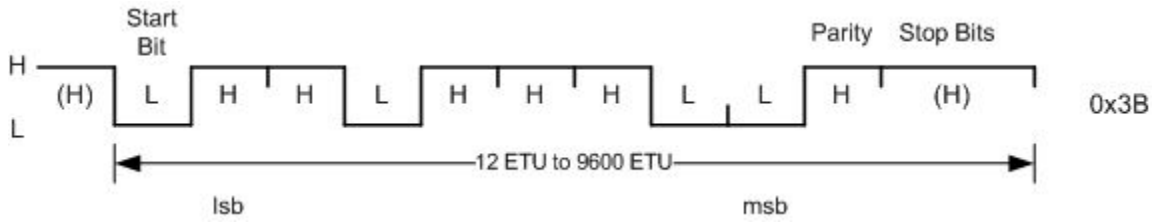

**Figure 60-3. Initial Character in Direct Conversion**

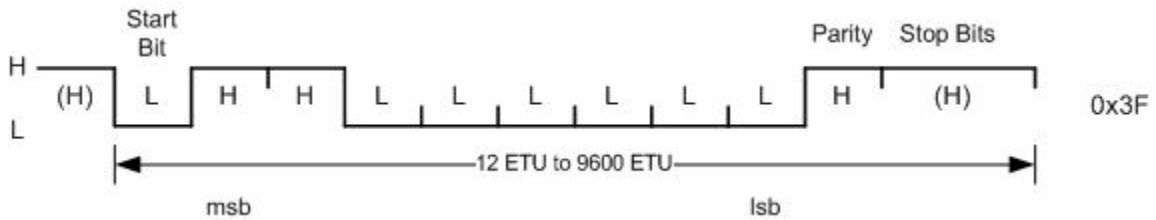

**Figure 60-4. Initial Character in Inverse Conversion**

To place the EMV SIM into initial character mode, set the ICM bit in the CTRL register. Once a valid initial character is received, the IC bit in the CTRL register will be set accordingly by the hardware, and the ICM bit will be cleared. Software can read the state of the IC bit to determine which mode the EMV SIM is currently using. The 0x3B (as decoded by direct convention) with parity bit high will cause direct convention to be used (IC set to logic 0), whereas a 0x3F (as decoded by inverse convention) with parity bit high will cause inverse convention to be used (IC set to logic 1).

The receiver remains in initial character mode until disabled by software or a valid initial character is detected. Upon detection of valid character, the receiver enters data receive mode. It is recommended to use one of the general purpose counter as a timeout during initial character mode.

When the receiver is in initial character mode, all received bytes will continue to be placed into the receive FIFO whether they be valid initial characters or not. If a valid initial character is received that causes the data format being used to change, all subsequent bytes will be decoded with that format before being placed into the FIFO, including the initial character byte itself. That is, if the IC bit is low, and the correct initial character for setting inverse convention is received, that character and all subsequently received characters will be stored in the FIFO after having been decoded using inverse convention (for example, the initial character will be stored as 0x3F).

**NOTE**

There is a condition where a parity error in the initial byte for direct convention (0x3B) could be decoded as what appears to be a valid initial character for inverse convention (that is, 0x3F). The EMV SIM module will not recognize this as a valid

initial character for inverse convention and will set the PEF flag.

### 60.7.3.3 Receiver Diagnostics

The EMV SIM module performs diagnostic checks on the incoming messages. These checks include parity check and message frame checks.

***Parity Error Detection:*** The receiver is responsible for detecting parity errors in the received data. Data is always transmitted with even parity, except when in inverse convention mode. In inverse convention mode, all data bits and the parity bit are complemented making the data appear to be odd parity. The parity bit is defined as the 10th bit of the received data. The parity of the 2nd through 10th received bits is calculated by the receiver parity logic. This logic determines if the parity of the 9 received bits is correct.

When a parity error is detected on a given byte, the parity error flag (PEF bit) is asserted in the RX_STATUS register if NACK generation on errors is disabled (ANACK = 0 in CTRL register). The parity error flag does not generate an interrupt to the system, however, the module can cause the transmitter to transmit a NACK (if ANACK = 1 in CTRL register) without software needed to enable transmitter for this and request re-transmission of the current byte.

***Framing Error Detection:*** The receiver is responsible for detecting framing errors in the received data. Data is always transmitted with 2 STOP bits, except when in 11 ETU mode, where there is one STOP bit. The STOP bits are defined as high state at the 11th and 12th bit positions in the received data. In either mode, the receiver expects to see a high at the 11th bit position in the received data. If a low is detected at the 11th bit position, the receiver indicates a framing error for that byte.

When a framing error is detected on a given byte, the FEF bit is set in the RX_STATUS register. A framing error cannot cause an interrupt, nor can it create a NACK pulse to the Smart Card asking for a retransmission of the corrupted data.

***LRC & CRC:*** The receiver also checks the LRC or CRC on the incoming block of bytes (if LRC or CRC is enabled). The result of the CRC or LRC check is updated in the RX_STATUS register once the complete message block is received.

### 60.7.3.4 NACK Detection

During transmission of message bytes, the receiver automatically checks for NACKs sent by the Smart Card. The software does not need to enable receiver for this. The NACK is detected by sampling the IO line at 11 ETUs after the falling edge of the START bit. Once a NACK is detected, the transmitter is signaled and the transmitter will retransmit the current byte after two ETU time (as per ISO 7816 specification).

### 60.7.3.5 Using EMV SIM Receiver with "T=1" Smart Cards

The EMV SIM module provides hardware support for “T=1” type Smart Cards. These type of cards present several requirements above and beyond the standard “T=0” cards. The features provided to meet the requirements that pertain to the EMV SIM receiver are as follows:

- 11 ETU Characters
  - “T=1” cards can transmit with character lengths of 11 ETUs (that is, one STOP bit). The EMV SIM module provides the RCVR11 bit in the CTRL register in order to configure the receiver state machine to accept 11 ETU characters.
- Character Wait Time Counter
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters received from the Smart Card. The value of CWT can range from 12 ETU to 32779 ETU. The EMV SIM module provides a 16-bit counter with programmable comparator clocked at the ETU bit rate to identify when the CWT has been exceeded by the Smart Card.
- Block Wait Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The block wait time must not exceed a value that is programmable. The EMV SIM module provides a 32-bit Block Wait Timer that can be used to identify when the BWT has been violated.
- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The block guard must be greater than a value that is programmable. The EMV SIM module provides a 16-bit Block Guard Timer that can be used to identify when the BGT has been violated.
- Error Detection Code
  - “T=1” cards can specify LRC or CRC error detection codes to be used. The EMV SIM module provides hardware support for both the LRC and CRC operations.

## 60.7.4 EMV SIM Transmitter

The transmitter is responsible for reading the message bytes from the Tx FIFO, adding the LRC or CRC at the end of the message block and re-transmit any byte on reception of a NACK. It assists the receive operation by inserting NACKs when directed by the receiver.

### 60.7.4.1 Message Transmission

The transmitter operation does not start until the Tx FIFO is empty. Software can configure the EMV SIM module and enable the transmitter but unless a byte is written into the Tx FIFO, no transmission will start. Clearing the XMT_EN bit while the transmitter is in operation, will halt any transmission in progress, flush the transmit FIFO. Refer Message Handling section for more details on using the Tx FIFO.

The transmitter continuously transmits the messages from the Tx FIFO. Upon NACK detection, the transmitter resends the same byte until the Transmitter NACK Threshold limit is reached. When TNTE is set, the EMV SIM transmitter is halted, and all pending transfers are aborted, and the TC, ETC, AND TFE flags are set. All bytes remaining in the transmit FIFO are lost. There is no way to restart the transmission on the next byte in the FIFO. The transmitter remains frozen until TNTE is cleared by software. The only way to clear TNTE is to write a 1 to the TNTE bit in the TX_STATUS register. It is possible to disable the detection of NACKs from the Smart Card by setting TNCK_THD[3:0] to 0x0. By setting TNCK_THD[3:0] to 0x1, it is possible to disable all retransmissions while still setting TNTE on the first NACK received. In general, TNTE is set on the NACK that causes the threshold set by TNCK_THD[3:0] to be reached. This final NACK will not cause a retransmission, whereas all previous NACKs will cause a retransmission.

If all bytes are successfully transmitted and the Tx FIFO is empty, the transmitter send the check byte (i.e. LRC or CRC) if the XMT_CRC_LRC and LRC_EN or CRC_EN bits are set. The transmitter sends each byte to the LRC or CRC block to allow the check byte generation.

At the end of each byte, the transmitter inserts the programmed Guard ETUs. Refer to Protocol Timers section for more details on Guard Time Counter.

### 60.7.4.2 NACK Insertion

The transmitter is responsible for driving the output low during the STOP bit time to signify an error was detected in the received data from the Smart Card. This logic responds to a NACK request generated by the receiver block.

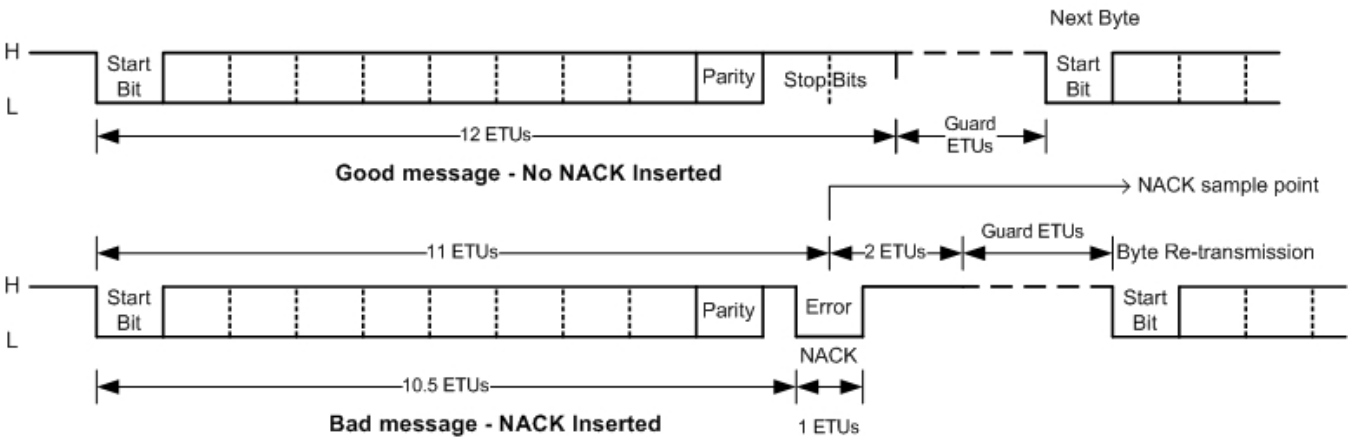

**Figure 60-5. NACK Insertion**

The NACK generation logic is also responsible for keeping track of the number of NACKs received during a transmit operation. The receiver detects NACKs generated by the Smart Card, and reports them to the transmit NACK logic. Once the number of detected NACKs has reached the programmed threshold (TNCK_THD[3:0]), an interrupt flag (TNTE) is generated, the transmit FIFO is flushed, and the transmitter is disabled.

### 60.7.4.3 Using EMV SIM Transmitter with "T=1" Smart Cards

The EMV SIM module provides hardware support for “T=1” type Smart Cards. These type of cards present several requirements above and beyond the standard “T=0” cards. The features provided to meet the requirements that pertain to the EMV SIM transmitter are as follows:

- 11 ETU Characters
  - The EMV SIM module transmitter has a programmable guard time register that allows the programmer to specify the number of ETUs between character transmissions. Programming a value of 255 (0xFF) in the GETU[7:0] bits in the GUARD_CNTL register will set the number of ETUs per character transmitted to 11.
- Character Waiting Time
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters. The value of CWT can range from 12 ETU to 32779 ETU. The time between transmitted characters is controlled by the

programmable guard time in the GETU register. However, the time between the last byte in the transmit FIFO, and the next transmitted byte can be largely affected by software response time to the transmit interrupts. The EMV SIM transmitter provides a Transmit FIFO threshold (TDTF) interrupt to signal the system when the expected number of characters have been transmitted from the transmit FIFO. The minimum CWT is achieved only if the software can respond to the TDTF interrupt and write new data to the transmit FIFO before the last character in the Transmit FIFO has been sent.

- Block Waiting Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BWT is always greater than 1800 ETU. The EMV SIM transmitter provides two General Purpose Counter(s) either of which can be used to track the BWT. The BWT is purely determined by software response time to the transmit interrupts.
- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BGT is 22 ETU. The EMV SIM module supports the BGT by providing the ability to generate an interrupt when the last byte is received, and transmitting within 2 ETU after the XMT_EN bit is set. The BGT will be determined by the speed at which the software can react to an interrupt and enable the transmitter.
- Error Detection Code
  - “T=1” cards can specify LRC or CRC error detection codes to be used. The EMV SIM module provides hardware support for both the LRC and CRC operation.

## 60.7.5 LRC and CRC

### 60.7.5.1 LRC Block

The EMV SIM module provides an 8-bit Linear Redundancy Check (LRC) generator / checker. The block is provided for use with T=1 Smart Cards that support LRC. This block can be enabled through the LRC_EN bit in the CNTL register. This block performs an 8-bit exclusive-OR on all received or transmitted characters. At the end of the reception of a block of characters, the result is expected to be 00. If so, the LRC_OK bit is set in the RX_STATUS register. During transmission, the LRC block Exclusive-ORs

each character that is transmitted with the current value of the LRC. If the XMT_CRC_LRC bit in the CTRL register is set, the LRC value will automatically be sent by the transmitter as the final character when the transmit FIFO empties.

The LRC value can be reset in multiple ways. Clearing the LCR_EN bit in the CTRL register will reset the LRC value. At the end of a transmission (either after the LRC byte is transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the LRC value is automatically reset by the EMV SIM hardware. Finally, when setting the XMT_EN bit, the EMV SIM hardware resets the LRC value.

Summary of configuration needed to use LRC block:

- Use the LRC_EN bit in CTRL register to enable the LRC block
- Use the XMT_CRC_LRC bit to enable the transmission of the LRC Character after the last character in the Transmit FIFO is sent.

### 60.7.5.2 CRC Block

The EMV SIM module provides an 16-bit Cyclic Redundancy Check (CRC) generator / checker. The block is provided for use with T=1 Smart Cards that support CRC. This block can be enabled through the CRC_EN bit in the CTRL register. This block performs a polynomial based check on all received or transmitted characters. The polynomial used for calculating the CRC is $G(x) = x^{16} + x^{12} + x^5 + 1$. The CRC register is initialized to all "1" before the data is shifted in. The CRC block can be configured to compute using the ISO 7816 CRC method or the 16-bit CCITT CRC method. The software can select the following bits: CRC_IN_FLIP, CRC_OUT_FLIP, and INV_CRC_VAL of the CTRL register.

- To select CCITT CRC method, set
  - CRC_IN_FLIP = 1
  - CRC_OUT_FLIP = 1
  - INV_CRC_VAL = 1
- To select normal CRC method (i.e. ISO 7816 CRC method), set
  - CRC_IN_VAL = 0
  - CRC_OUT_VAL = 0
  - INV_CRC_VAL = 1

During transmission, the CRC block updates the current value of the CRC using each character. If the XMT_CRC_LRC bit in the CTRL register is set, the CRC value will automatically be formatted as per the selected CRC method (CCITT or normal) and sent by the EMV SIM transmitter as the final two characters when the transmit FIFO empties. At the end of the reception of a block of characters, the residual from the CRC calculation is compared and the CRC_OK bit is set in the RX_STATUS register.

**NOTE**

Setting any other value for CRC_IN_FLIP, CRC_OUT_FLIP and INV_CRC_VAL will cause CRC value to be formatted accordingly; however the CRC will not be compliant to the standard CRC used in Smart Cards.

The CRC value can be reset/initialized in multiple ways. Clearing the CRC_EN bit in the CTRL register will reset the CRC value. At the end of a transmission (either after the CRC characters are transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the CRC value is automatically reset by the EMV SIM hardware. Finally, when setting the XMT_EN bit, the EMV SIM hardware resets the CRC value.

Summary of configuration needed to use CRC block:

- Use CRC_IN_FLIP, CRC_OUT_FLIP and INV_CRC_VAL bits in CTRL register to select the desired CRC method (CCITT or normal)
- Use the CRC_EN bit in CTRL register to enable the CRC block
- Use the XMT_CRC_LRC bit to enable the transmission of the CRC Characters after the last character in the Transmit FIFO is sent.

## 60.7.6 Message Handling

The EMV SIM module has FIFOs on both transmit and receive side for handling all message bytes.

### 60.7.6.1 Transmit FIFO

A 16-byte deep FIFO is implemented in the transmitter. The transmit FIFO can be written into by the software but reads to this FIFO will return zeros. To take care of clock synchronization, each write access will have wait states inserted by the module but this is transparent to the software. The Tx FIFO can be written to while the transmitter is enabled, however, the transmitter does not start transmitting while the FIFO is empty. A write to the Tx FIFO will initiate the transmit operation. Software can store more bytes into the Tx FIFO until the programmed threshold is reached. Software can enable DMA operation by setting TX_DMA_EN = 1 in the CTRL register. On setting this bit, a DMA request will be asserted and remain asserted till the number of bytes in FIFO reached the programmed threshold value (TDT[3:0] in the TX_THD register).

The transmit FIFO can be flushed by setting the FLSH_TX bit in the CTRL register. A transmit NACK threshold error (TNTE) will halt the transmitter, and flush the transmit FIFO. The flush operation resets the transmit read and write pointers to equal values. Everything in the transmitter block is reset by the transmit flush operation. This does not include the control registers associated with the transmitter. The Transmit data threshold flag (TDTF) does not get cleared by the FLSH_TX operation.

### 60.7.6.2 Receive FIFO

A 16-byte deep FIFO is implemented in the receiver. Since more than 16-bytes can be received in the FIFO, the software must ensure that the Rx FIFO is periodically read. The Rx FIFO can be read by software via normal CPU accesses on interrupt (RX_DATA interrupt flag) or via DMA by setting the DMA_RX_EN bit in CTRL register. The software cannot write to this register. A write access may terminate in a transfer error.

The Rx FIFO is loaded by the receiver when it receives an error free message byte with correct parity. The FIFO stores the message byte only. When the total bytes in the Rx FIFO equals the programmed threshold value (RDT[3:0] in RX_THD register), the RDTF bit is asserted in the RX_STATUS register. An interrupt will be asserted if the RDT_IM bit in the INT_MASK is cleared. If DMA access to RX_FIFO is enabled, the DMA request to read the Rx FIFO will be asserted when the threshold flag is set and will clear when all the bytes are read out from the Rx FIFO.

The receive FIFO can be flushed by setting the FLSH_RX bit in the CTRL register. The flush operation resets the receiver except for receiver control registers.

**NOTE**

Since the register bits and the receiver logic are in different clock domains, the software needs to make sure to allow clock synchronization time when sampling the RDTF bit. One proposed method could be to read one byte at a time (from Rx FIFO) when RDTF is asserted, allow a time of 3 bus clock cycles after Rx FIFO read and then check the status of the RDTF bit and repeat as necessary. Alternatively, one could set the receiver threshold one more than actually needed.

***Rx FIFO Overflow Detection:*** When a byte is received by the receiver and the Rx FIFO is not read and already contains 16 bytes, a FIFO overflow error will be asserted (RFO bit set to 1 in RX_STATUS register). The received byte will be discarded leaving the FIFO with the first 16 bytes received. If the ONACK bit in the CTRL register is asserted, the

transmitter will generate a NACK for the overflow condition every time a new byte is received that cannot be stored in the Rx FIFO. The EMV SIM module will continually send NACKs till the Rx FIFO is read or NACK transmit threshold is reached.

## 60.7.7 Protocol Timers

The EMV SIM module has several 16-bit and 32-bit timers to allow the software perform protocol timing checks and measurements like:

- Guard Time
- Character Wait Time
- Block Wait Time
- Block Guard Time
- Work Wait Time

In addition to the above, the EMV SIM module also contains two 32-bit general purpose counters which can be used by software for any application specific time measurement.

### 60.7.7.1 Transmit Guard Time

The Transmit Guard time is the number of ETUs inserted by the transmitter between each character being transmitted. The number of ETUs is controlled by programming the TX_GETU register. The Guard Time is measured as the time (in ETUs) between the STOP bits of previous character and the START bit of next character.

For a Guard Time programmed as 0xFF in GETU[7:0] bits of TX_GETU register, the transmitter inserts one STOP bit instead of two.

### 60.7.7.2 Character Wait Time

The EMV SIM receiver block includes a 16-bit counter that counts the number of bit times (ETUs) between received characters (i.e. time between start bits in the consecutive characters received). When enabled, the Character Wait Time Counter (CWT) will not start counting until after the START bit(s) of a valid character has been received. The counter is synchronized to the receive character bit positions so that an accurate count of the number of ETUs between characters can be made. The Character Wait Time Counter has a 16-bit programmable comparator. Software can write the expected number of ETUs between characters to the comparator. If the time between characters exceeds this value, an interrupt flag will be set and an interrupt generated if the mask is clear. The CWT can be configured as follows:

- Program the CWT_VAL register to the value that needs to be enforced
- Activate CWT function by setting the CWT_EN bit in the CTRL register
- Enable the CWT_ERR interrupt by clearing the CWT_IM bit in the INT_MASK register
- If an interrupt occurs, then the software should read the RX_STATUS register to determine if the error was caused by a CWT_ERR violation. The software should clear the CWT_ERR interrupt by writing a “1” to the CWT_ERR bit in the RX_STATUS register
- Software can disable the CWT counter by clearing the CWT_EN bit in the CTRL register at any time

#### 60.7.7.3 Block Wait Time and Block Guard Time

A 32-bit timer is used to measure both Block Wait Time (BWT) and Block Guard Time (BGT). The BWT and BGT timer are used to measure the delay between the leading edge of the last character of the block received by the card and the leading edge of the first character of the next block sent by the card. If this time measured is larger than the value in BWT_VAL register, then the BWT_ERR flag will be set and an interrupt generated. If the time is less than the value in the BGT_VAL register, then the BGT_ERR flag will be set and an interrupt generated. The block wait timer can be configured as follows:

- Program the BWT_VAL and BGT_VAL registers to the value that need to be enforced
- Activate the block wait timer by writing '1' to BWT_EN bit in the CTRL register
- Enable the BWT_ERR and BGT_ERR interrupts by clearing the BWT_IM and BGT_IM bits in the INT_MASK register
- If an interrupt occurs, then the software should read the RX_STATUS register to determine if the error was caused by a BWT_ERR or BGT_ERR violation. The software should clear the interrupt status bit by writing a “1” to the BWT_ERR bit or BGT_ERR, respectively, in the RX_STATUS register
- Software can disable the BWT counter by clearing the BWT_EN bit in the CTRL register at any time

**NOTE**

BWT should be enabled after all bytes are written to in Tx FIFO. This is necessary to avoid the condition where writes to Tx FIFO are very slow (more than 1 ETU time apart) and if BWT is enabled earlier, then BWT error can trigger falsely.

### 60.7.7.4 Work Wait Time

There is no separate counter to measure the work wait time (WWT). Work wait time is a combination of BWT and CWT. To measure WWT, software must configure both CWT_VAL and BWT_VAL to the value to enforced. When measuring WWT, the BGT timer will not be used so it should be masked (inactive) by the BGT_IM bit. Below is the sequence to program the EMV SIM to send and receive data while checking WWT:

- Program both the CWT_VAL and the BWT_VAL registers to the WWT (work wait time) value that needs to be enforced. Set BGT register to 0 (this is the default value).
- Activate both the CWT and BWT functions by setting the CWT_EN and BWT_EN bit in the CTRL register
- Enable the CWT_ERR and BWT_ERR interrupts by clearing the CWT_IM and BWT_IM bits in the INT_MASK register
- Program the EMV SIM module to enable Receiver or Transmitter as desired by application
- If an interrupt occurs, then the software should consider that a WWT violation if the CWT_ERR or BWT_ERR bits are asserted. The software should clear the CWT_ERR or BWT_ERR interrupt by writing a “1” to the BWT_ERR or CWT_ERR bit in the RX_STATUS register

### 60.7.7.5 General Purpose Timers

The EMV SIM module provides TWO 16-bit counters for use, when timing events during Smart Card communication. The clock source for the counter is selectable between three sources: Card Clock, Receiver Clock (16 times the ETU clock) or ETU Clock (for Transmitter). The GPCNT0/1_CLKSEL[1:0] bits in the CTRL register are used to select the clock input. The counter is enabled as soon as the input clock is selected. The starting of the counter is immediate once the input clock is running. Software can control the three input clock sources by using the SCEN, KILL_CLOCKS, RCV_EN and XMT_EN bits provided in the CTRL register.

To run the counters from the card clock source the following conditions must be met:

- ‘KILL_CLOCKS = 0’ in the CTRL register
- ‘RCV_EN = 1’ or XMT_EN = 1 in the CTRL register
- 'SCEN = 1' in the PCSR register
- ‘GPCNT_CLKSET[1:0] = 01’ in the CLKCFG register

The counter will begin to count at the card clock rate as soon as these conditions are met.

To run the counters from the receive clock source the following conditions must be met:

- ‘KILL_CLOCKS = 0’ in the CTRL register.

- ‘RCV_EN = 1’ or XMT_EN = 1 in the CTRL register
- ‘GPCNT0/1_CLKSET[1:0] = 10’ in the CLKCFG register

The counter will begin to count at the receive clock rate as soon as these conditions are met.

To run the counters from the ETU (transmit) clock source the following conditions must be met:

- ‘KILL_CLOCKS = 0’ in the CTRL register.
- ‘RCV_EN = 1’ or XMT_EN = 1 in the CTRL register
- ‘GPCNT0/1_CLKSET[1:0] = 11’ in the CLKCFG register

The counters will begin to count at the ETU clock rate as soon as these conditions are met.

The counters can be reset by setting GPCNT0/1_CLKSEL[1:0] to 00. A 16-bit comparator value (GPCNT0/1_VAL register) is provided that allows the software to select a count value at which the interrupt flags (GPCNT0/1_TO bit in TX_STATUS register) can be set and an interrupt generated if the mask (GPCNT0/1_IM bits in INT_MASK register) are clear.

The following sequence should be followed to configure both general purpose timers:

- Program counter comparator using the GPCNT0/1_VAL register
- Enable the conditions described above using the CTRL register
- Select desired clock source for the General Purpose Counter using the CLKCFG register
- Enable interrupts in the INT_MASK register

## 60.7.8 Answer To Reset (ATR) Detection

The first communication that occurs between the Smart Card and the EMV SIM module will be a block of data sent from the Smart Card to the EMV SIM module after the card is powered up and the card reset is removed (As described in Smart Card Interface and Control Section). This block is called the Answer To Reset (ATR). To receive the ATR, the EMV SIM module should be configured for 12 ETU character reception. According to the ISO 7816-3 spec, both “T=0” and “T=1” cards will communicate initially using 12 ETU character durations.

The following steps provide a suggested approach to configure the EMV SIM module to receive the ATR.

- Clear RCVR11 bit in the CTRL register

- Set ANACK bit in the CTRL register to enable NACK generation. The ISO 7816-3 spec allows the EMV SIM module to NACK any communication errors that occur during the initial communication at 12 ETU.

**NOTE**

The Europay MasterCard and VISA (EMV) cards are similar to “T=1”, but do not allow the EMV SIM module to NACK during the initial communication

- Enable RDTF and RFO interrupts by setting RDT_IM and RFO_IM bits in INT_MASK register. These interrupts are enabled to notify the software when characters are received. A threshold can be set for the number of characters to receive before generating an interrupt.
- Set desired threshold for received characters by writing RDT in RX_THD register

The EMV SIM should be setup to perform in initial character mode during ATR detection. This will cause the hardware to identify the first valid character sent during the ATR as an initial character. This character will automatically configure the hardware for the data convention used by the Smart Card.

- Set Initial Character Mode by setting the ICM bit in the CTRL register

The ISO 7816-3 spec requires that Smart Cards meet certain timing restrictions. One of these is the time from the de-assertion of the card reset to the beginning of the ATR sequence. The EMV SIM module's General Purpose Counter can be used to verify that the Smart Card begins its ATR within the 400 to 40,000 card clock cycle range.

- Set the General Purpose Counter 0 or 1 Timeout Value to 0x9C40 using GPCNT0/1_VAL register.
- Enable General Purpose Counter Interrupt by clearing GPCNT0/1_IM in INT_MASK register.
- Enable General Purpose Counter by programming the GPCNT0/1_CLKSEL[1:0] bits to 01, so that the card clock is used for counting.

The ISO7816-3 spec states that the maximum allowed time between two characters during the ATR is 9600 ETUs (Initial Waiting Time). The Character Wait Time Counter should be setup to detect any errors for this condition.

- Set Character Wait Time Counter Comparator to 9600 using the CWT_VAL register
- Enable the Character Wait Time Counter Interrupt by clearing CWT_ERR_IM in INT_MASK register
- Enable the Character Wait Time Counter by setting the CWT_EN bit in the CTRL register

The last step in preparing for ATR reception is to enable the receiver.

- Set RCV_EN bit in CTRL register

The EMV SIM module will generate interrupts once a threshold number of characters is received. The software should react to these interrupts and read the characters from the receive FIFO (RX_BUF) until the complete ATR has been received. If a General Purpose Counter interrupt occurs before the final ATR character is received, then the card should be deactivated according to the ISO 7816-3 spec (See Section Smart Card Interface and Control). Otherwise, once a valid ATR is received, the software will know from the ATR information the specific characteristics for this card (refer to the ISO 7816-3 spec for details).

#### 60.7.8.1 Programming Considerations for T=0 Smart Cards

If the card is of type T=0, the software should adjust the following parameters according to the information in the ATR:

- Adjust the baud rate by changing the values of DIVISOR register based on the values of 'F' and 'D' received in the ATR.
- Adjust the guard time between characters by changing the value of GETU[7:0] in the TX_GETU register.
- Adjust NACK capability by modifying the values of the ONACK and ANACK bits in the CTRL register.
- Adjust the stop clock polarity by modifying the value of the SCSP bit in the PCSR register.
- Adjust the level of transmit NACK re-transmissions allowed by modifying the value of the TNCK_THD[3:0] bits in the TX_THD register.
- Adjust the level for the Receive NACK threshold by modifying the RNCK_THD[3:0] bits in the RX_THD register.

If a negotiation with the Smart Card is desired, the software sends a PPS response to the Smart Card. To send the response, the following steps should be performed:

- Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the TX_THD register.
- Clear all transmit interrupt flags in the TX_STATUS register by writing a one to the bits of the register.
- Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 characters are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the Smart Card.
- Enable the transmitter by setting the XMT_EN bit in the CTRL register.
- Write the characters to be sent as response (max 16) to the transmit FIFO using the TX_BUF register.

At this point, the EMV SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the Smart Card.

Once the transmission is complete, the EMV SIM module should be completely configured for standard operation with the T=0 Smart Card. The software can continue to service RDTF interrupts for received characters, and TDTF interrupts for transmitted characters.

### 60.7.8.2 Programming Considerations for T=1 Smart Cards

If the card is of type T=1, the software should adjust the following parameters according to the information in the ATR:

- Adjust the baud rate by changing the values of DIVISOR register based on the values of 'F' and 'D' received in the ATR.
- Adjust the guard time between characters by changing the value of GETU[7:0] in the TX_GETU register. Setting GETU[7:0] to 0xFF configures the SIM transmitter for 11 ETU transmissions.
- Disable NACK capability by clearing the ONACK and ANACK bits in the CTRL register. T=1 cards do not allow NACKs.
- Adjust the stop clock polarity by modifying the value of the SCSP bit in the PCSR register.
- Set Character Wait Time Counter Timeout Value to value specified in the ATR by using the CWT_VAL register.
- Enable the Character Wait Time Counter Interrupt by clearing CWT_ERR_IM in INT_MASK register.
- Enable the Character Wait Time Counter by setting the CWT_EN bit in the CTRL register.
- Enable CRC or LRC error checking according to the ATR information by setting either the CRC_EN or LRC_EN bit in the CTRL register. These bits should never be set at the same time!

For T=1 cards, the ATR is sent using a T=0 type of structure (12 ETU, no LRC or CRC). If a negotiation with the Smart Card is desired, the software will send a PPS response to the Smart Card. Otherwise, the protocol is initiated with a block transfer from the EMV SIM module. In order to send the response or the first block, the following steps should be performed:

- Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the TX_THD register.

- Clear all transmit interrupt flags in the TX_STATUS register by writing a one to the bits of the register.
- Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 characters are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the Smart Card.
- Enable the transmission of the error checking characters (LRC or CRC) by setting the XMT_CRC_LRC bit in the CTRL register.

**NOTE**

If the card supports PPS, the software may not be allowed to send the LRC/CRC information until the PPS exchange is completed. If so, do not set the XMT_CRC_LRC bit during the PPS exchange.

- Enable the transmitter by setting the XMT_EN bit in the CTRL register.
- Write the characters to be sent as response (max 16) to the transmit FIFO using the TX_BUF register.

At this point, the EMV SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the Smart Card.

Once the transmission is complete, the EMV SIM module should be completely configured for standard operation with the T=1 Smart Card. The software can continue to service RDTF interrupts for received characters, and TDTF interrupts for transmitted characters.

# Chapter 61
# Universal Serial Bus Full Speed Controller (USBFS)

## 61.1 Chip-specific USB information

In this chapter, the term IRC48M refers to the Fast Internal Reference Clock (FIRC) discussed in the other chapters.

This MCU only supports Full Speed Device Mode.

### 61.1.1 USB wakeup

When the USB detects that there is no activity on the USB bus for more than 3 ms, the INT_STAT[SLEEP] bit is set. This bit can cause an interrupt and software decides the appropriate action.

Waking from a low power mode (except in LLS/VLLS mode where USB is not powered) occurs through an asynchronous interrupt triggered by activity on the USB bus. Setting the USBTRC0[USBRESMEN] bit enables this function.

The following wakeup functionality is also supported:

- In Stop/VLPS, the USB controller can generate an interrupt on VREGIN detection.
- In LLS/VLLS except VLLS1/0, VREGIN is an input pin to the LLWU and a transition on it can generate a wakeup.
- In LLS/VLLS, USB0_DP and USB0_DM are input pins to the LLWU and a transition on those pins can generate a wakeup provided the USB is powered and in host mode.

### 61.1.2 LPUART over USB capability

This device supports a connection whereby LPUART2 may be connected to the FS USB physical layer (and the USB controller disconnected) to allow simple debugging capabilities for applications which do not have direct physical access to LPUART2.

By setting the USBx_USBCTRL[UARTSEL] bit, LPUART2 will be connected to the FS USB physical layer. This configures the FS USB DP/DM signals to be configured as normal LPUART2 signals, which do not operate in differential mode.

## 61.1.3 USB Power Distribution

This chip includes an internal 5 V to 3.3 V USB regulator that powers the USB transceiver or the MCU (depending on the application).

### 61.1.3.1 AA/AAA cells power supply

The chip can be powered by two AA/AAA cells. In this case, the MCU is powered through VDD which is within the 1.8 to 3.0 V range. After USB cable insertion is detected, the USB regulator is enabled to power the USB transceiver.

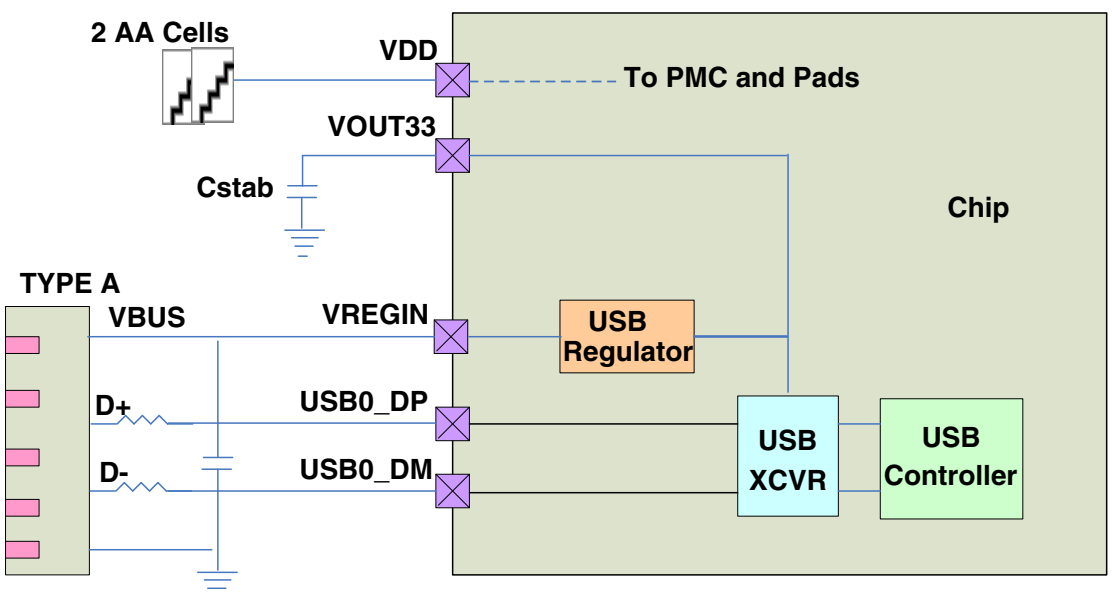

**Figure 61-1. USB regulator AA cell usecase**

### 61.1.3.2 Li-Ion battery power supply

The chip can also be powered by a single Li-ion battery. In this case, VOUT33 is connected to VDD. The USB regulator must be enabled by default to power the MCU. When connected to a USB host, the input source of this regulator is switched to the USB bus supply from the Li-ion battery.

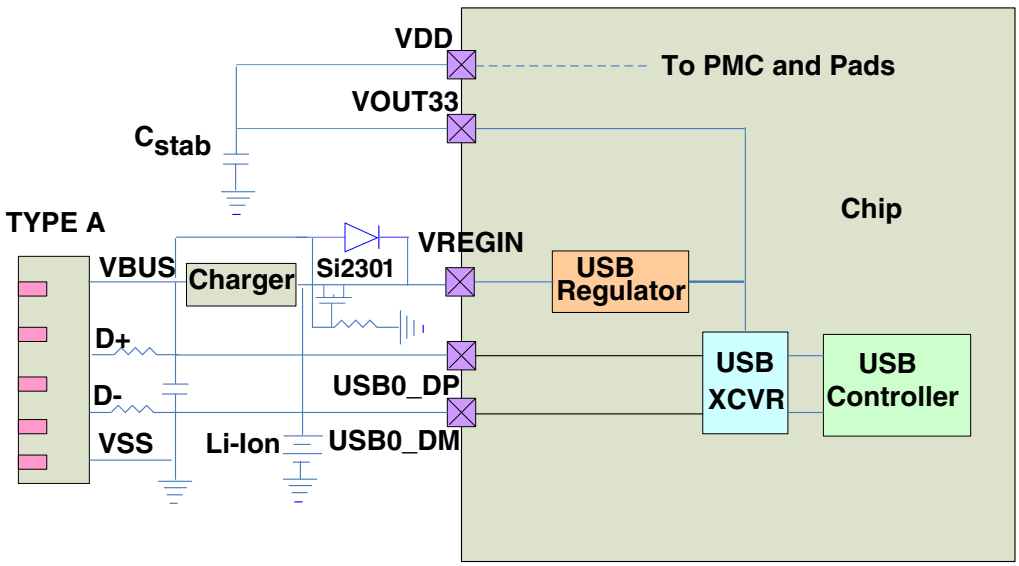

**Figure 61-2. USB regulator Li-ion usecase**

### 61.1.3.3 USB bus power supply

The chip can also be powered by the USB bus directly. In this case, VOUT33 is connected to VDD. The USB regulator must be enabled by default to power the MCU, then to power USB transceiver or external sensor.

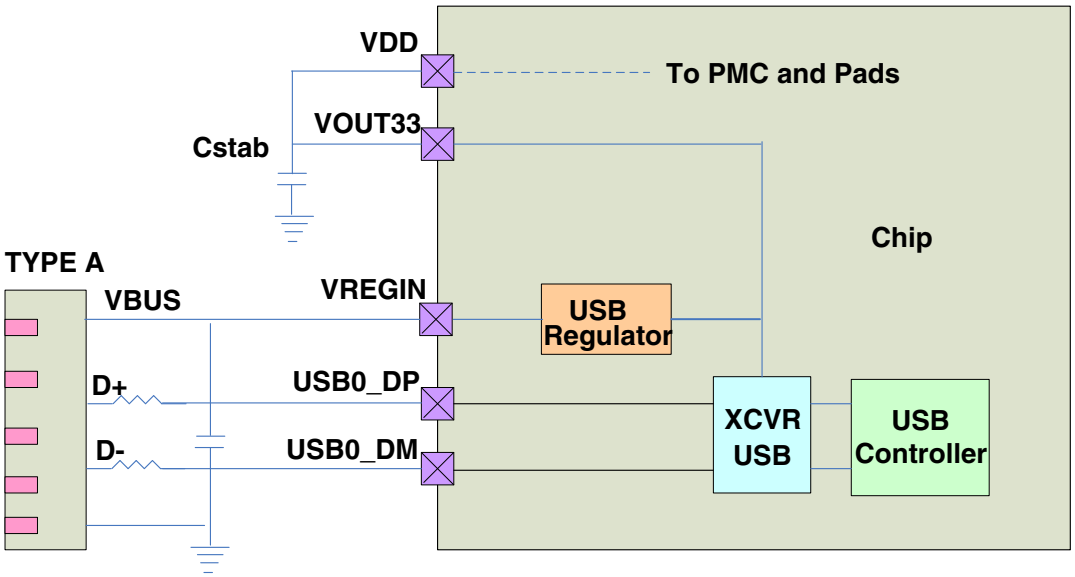

**Figure 61-3. USB regulator bus supply**

## 61.1.4 USB controller configuration

This section summarizes how the module has been configured in the chip.

**NOTE**

When USB is not used in the application, it is recommended to connect VOUT33 and VREGIN together and tie to ground through a 10 kΩ resistor. Do not tie directly to ground, because this causes a latch-up risk.

## 61.1.5 Keep Alive Mode and IRC48M operation

### 61.1.5.1 Entering Keep Alive mode

**To enter Keep Alive mode:**

1. Enter either VLPS mode or Stop mode, ensuring that the USB 48 MHz functional clock source remains enabled in either mode (VLPS mode or Stop mode):
   - **To enter VLPS mode:** set
     - KEEP_ALIVE_CTRL[KEEP_ALIVE_EN] = 1 (Keep Alive mode enable)
     - CLK_RECOVER_IRC_EN[IRC_EN] = 1 (IRC48M enable bit)
     - SPM_CORELPCNFG[CORELPCNFG_BGEN] = 1 (Bandgap Enable In VLPx Operation)

    - SPM_CORELPCNFG[SBDIS] = 1 (Source Bias Disable)
    - SPM_CORELPCNFG[WBDIS] = 1 (Well Bias Disable)
  - **To enter Stop mode:** set only
    - KEEP_ALIVE_CTRL[KEEP_ALIVE_EN] = 1 (Keep Alive mode enable)
    - CLOCK_RECOVER_IRC_EN[IRC_EN] = 1 (IRC48M enable bit)
2. To initialize the BDT in USB RAM, within each BDT set OWN=0 for every endpoint, except for EP0. The buffer address for EP0 must be configured to an address within the USB SRAM, ensuring that received data is placed within the USB SRAM. The USB cannot access other memory locations within USB Keep Alive mode.
3. Enable the wakeup interrupt, by setting KEEP_ALIVE_CTRL[WAKE_INT_EN] = 1.
4. Set KEEP_ALIVE_WKCTRL[WAKE_ON_THIS] appropriately to configure what received token will generate the wakeup from Keep Alive mode. Software then enters Stop mode and the USB is in Keep Alive mode.

### 61.1.5.2 Exiting Keep Alive mode

Any enabled interrupt generates a wakeup from STOP/VLPS mode; this causes an exit from USB Keep Alive mode. The USB can also be configured to generate an interrupt when it receives a particular token (for example, SETUP), as configured by KEEP_ALIVE[WAKE_ON_THIS]. Other USB interrupts can also remain enabled and can be generated in USB Keep Alive mode.

### 61.1.5.3 Device mode IRC48M operation

The following are the IRC48M initialization code steps:

1. Select the clock source and configure the clock divider for FIRC: SCG_FIRCDIV[FIRCDIV1] = 1, SCG_FIRCCFG[RANGE] = 0.
2. Enable FIRC: SCG_FIRCCSR [FIRCEN] = 1
3. Select FIRC as the system clock source: SCG_RCCR[SCS] = 0011

For chip-specific details, see the USBFS controller clocking information in the *Clock Distribution* chapter.

## 61.2 Introduction

This chapter describes the USB full speed controller. The USBFS controller provides functionality for implementing a USB2.0 full-speed compliant peripheral and interfaces to a USBFS transceiver.

**NOTE**

This chapter describes the following registers that have similar names: USB_CTL, USB_CTRL, and USB_CONTROL. These are all separate registers.

## 61.2.2 USB—Overview

The USB is a cable bus that supports data exchange between a host computer and a wide range of simultaneously accessible peripherals. The attached peripherals share USB bandwidth through a host-scheduled, token-based protocol. The bus allows peripherals to be attached, configured, used, and detached while the host and other peripherals are in operation.

USB software provides a uniform view of the system for all application software, hiding implementation details to make application software more portable. It manages the dynamic attach and detach of peripherals.

There is only one host in any USB system. The USB interface to the host computer system is referred to as the Host Controller.

There may be multiple USB devices in any system such as human interface devices, speakers, printers, etc. USB devices present a standard USB interface in terms of comprehension, response, and standard capability.

The host initiates transactions to specific peripherals, whereas the device responds to control transactions. The device sends and receives data to and from the host using a standard USB data format. USB 2.0 full-speed /low-speed peripherals operate at 12Mbit/s or 1.5 Mbit/s.

For additional information, see the USB 2.0 specification.

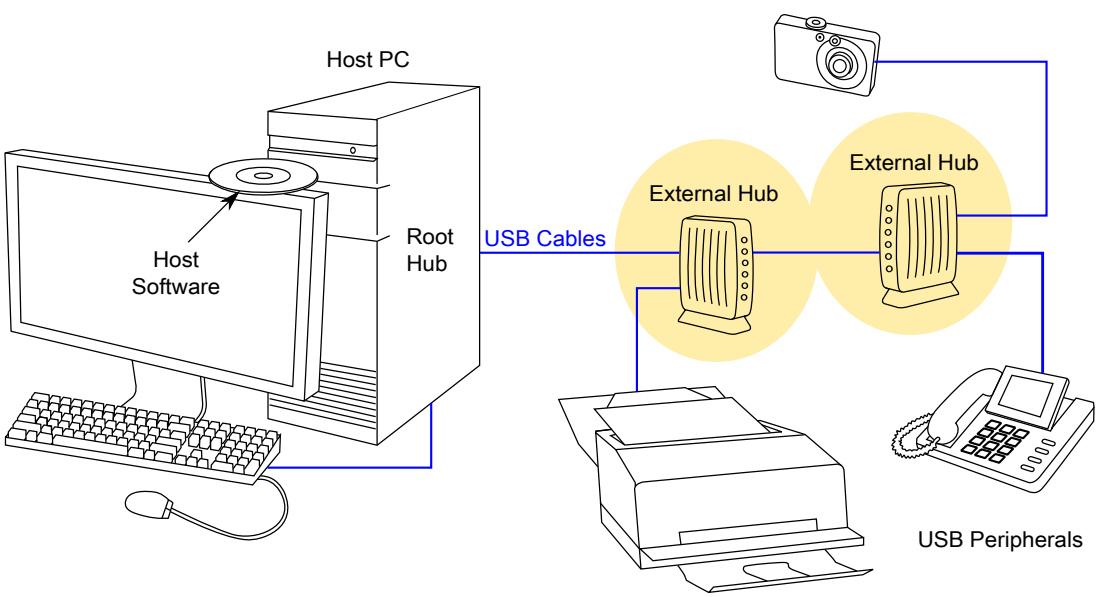

**Figure 61-4. Example USB 2.0 system configuration**

### 61.2.3 USBFS Features

- USB 1.1 and 2.0 compatible FS device controller
- 16 bidirectional endpoints
- DMA or FIFO data stream interfaces
- Low-power consumption
- IRC48M with clock-recovery is supported to eliminate the 48 MHz crystal. It is used for USB device-only implementation.
- Keep-alive feature is supported to power down system bus and CPU. USB can respond to IN with NAK and wake up for SETUP/OUT.

## 61.3 Functional description

USBFS communicates with the processor core through status registers, control registers, and data structures in memory.

### 61.3.1 Data Structures

To efficiently manage USB endpoint communications, USBFS implements a Buffer Descriptor Table (BDT) in system memory. See Figure 61-6.

### 61.3.2 On-chip transceiver required external components

USB system operation requires external components to ensure that driver output impedance, eye diagram, and VBUS cable fault tolerance requirements are met. DM and DP I/O pads must connect through series resistors (approximately 33 Ω each) to the USB connector on the application printed circuit board (PCB). Additionally, signal quality optimizes when these 33 Ω resistors are mounted closer to the processor than to the USB board-level connector. The USB transceiver includes:

- An internal 1.5 kΩ pullup resistor on the USB_DP line for full-speed device (controlled by USB_CONTROL[DPPULLUPNONOTG]
- Internal 15 kΩ pulldown resistors on the USB_DP and USB_DM signals, which are primarily intended for Host mode operation but are also useful in Device mode as explained below.

**NOTE**

For device operation, the internal 15 kΩ pulldowns should be enabled to keep the DP and DM ports in a known quiescent state when the VBUS detection software determines that the USB connection is not activated, including the cases when no cable to a host is present or when the USB port is not used. The internal 15 kΩ pulldowns should be controlled by USB_CTRL[PDE] in this case.

The following diagram provides an overview of device-only connections. For more details, see the *Kinetis Peripheral Module Quick Reference*(KQRUG).

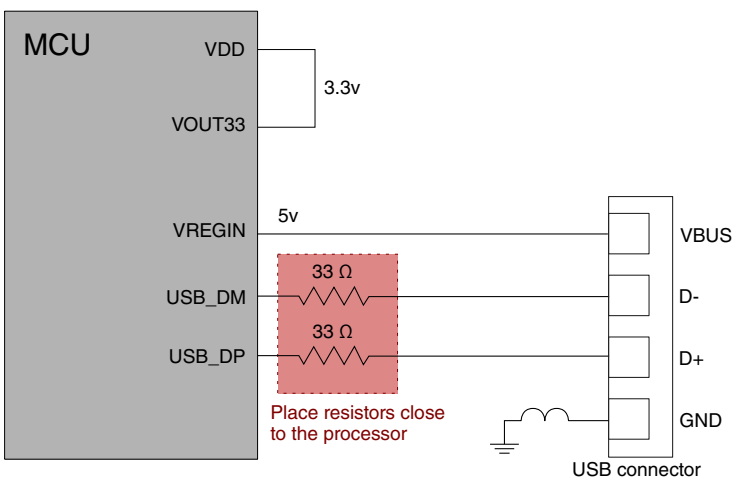

**Figure 61-5. Typical Device-only diagram (bus-powered)**

## 61.4 Programmers interface

This section discusses the major components of the programming model for the USB module.

### 61.4.1 Buffer Descriptor Table

To efficiently manage USB endpoint communications USBFS implements a Buffer Descriptor Table (BDT) in system memory.

- The BDT resides on a 512-byte boundary in system memory and is pointed to by the BDT Page Registers.
- Every endpoint direction requires two 8-byte Buffer Descriptor (BD) entries.

Therefore, a system with 16 fully bidirectional endpoints would require 512 bytes of system memory to implement the BDT. The two BD entries allows for an EVEN BD and ODD BD entry for each endpoint direction, which allows the microprocessor to process one BD while USBFS is processing the other BD. Double buffering BDs in this way allows USBFS to transfer data easily at the maximum throughput provided by USB.

Software should manage buffers for USBFS by updating the BDT when needed. This allows USBFS to efficiently manage data transmission and reception, while the microprocessor performs communication overhead processing and other function-dependent applications.

Because the buffers are shared between the microprocessor and USBFS, a simple semaphore mechanism is used to distinguish who is allowed to update the BDT and buffers in system memory. A semaphore (the OWN bit) is cleared to 0 when the BD entry is owned by the microprocessor.

- When OWN bit is 0, the microprocessor is allowed read and write access to the BD entry and the buffer in system memory.
- When OWN bit is 1, the BD entry and the buffer in system memory are owned by USBFS. USBFS now has full read and write access and the microprocessor must not modify the BD or its corresponding data buffer.

The BD also contains indirect address pointers to where the actual buffer resides in system memory. This indirect address mechanism is shown in the following diagram.

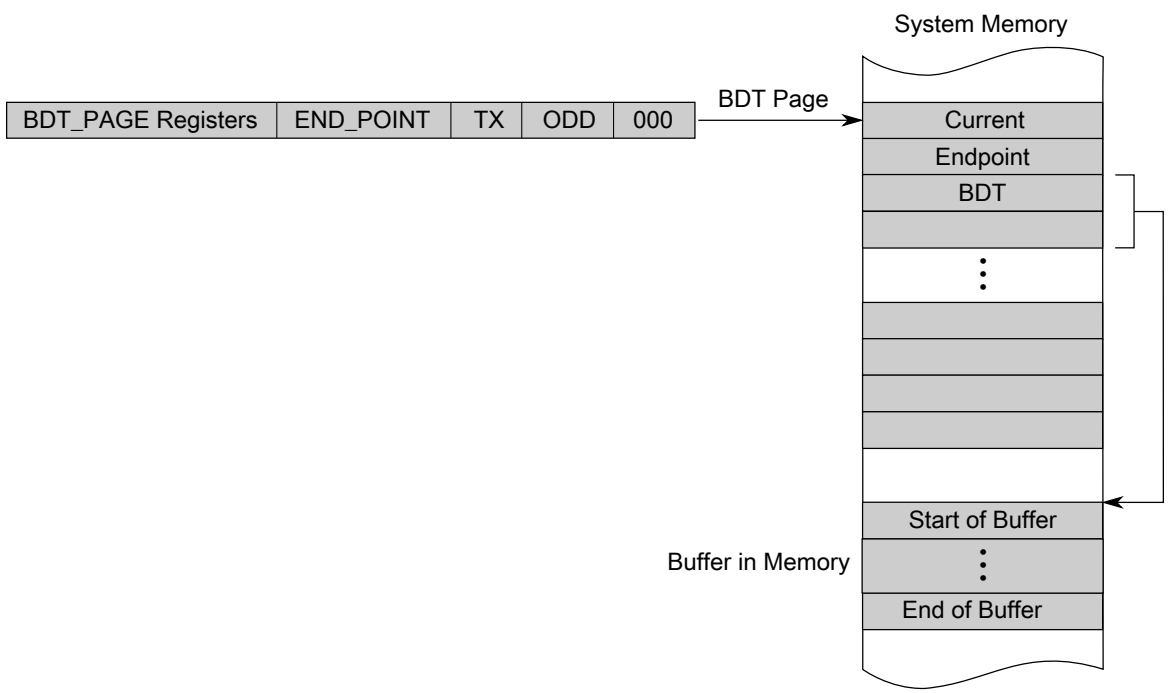

**Figure 61-6. Buffer descriptor table**

## 61.4.2 USB data transfers—Receive (Rx) and Transmit (Tx)

A USBFS core-centric nomenclature is used to describe the direction of the data transfer between USBFS core and USB. Throughout this chapter:

- "RX" (or "receive") describes transfers that move data from USB to memory.
- "TX" (or "transmit") describes transfers that move data from memory to USB.

The following table shows the data directions for USBFS.

**Table 61-1. Data direction for USB host or USB target**

| RX | TX |
|---|---|
| OUT or SETUP | IN |

## 61.4.3 Addressing BDT entries

An understanding of the addressing mechanism of the Buffer Descriptor Table is useful when accessing endpoint data via USBFS or microprocessor:

- The BDT occupies up to 512 bytes of system memory.
- 16 bidirectional endpoints can be supported with a full BDT of 512 bytes.
- 16 bytes are needed for each USB endpoint direction.
- Applications with fewer than 16 endpoints require less RAM to implement the BDT.
- The BDT Page Registers (BDT_PAGE) point to the starting location of the BDT.
- The BDT must be located on a 512-byte boundary in system memory.
- All enabled TX and RX endpoint BD entries are indexed into the BDT to allow easy access via USBFS or MCU core.

When a USB token on an enabled endpoint is received, USBFS uses its integrated DMA controller to interrogate the BDT. USBFS reads the corresponding endpoint BD entry to determine whether it (USBFS) owns the BD and corresponding buffer in system memory.

To compute the entry point into the BDT, the BDT_PAGE registers are concatenated with the current endpoint and the TX and ODD fields, to form a 32-bit address. This address mechanism is shown in the following tables:

**Table 61-2. BDT Address Calculation**

| 31:24 | 23:16 | 15:9 | 8:5 | 4 | 3 | 2:0 |
|---|---|---|---|---|---|---|
| BDT_PAGE_03 | BDT_PAGE_02 | BDT_PAGE_01[7:1] | Endpoint | TX | ODD | 000 |

**Table 61-3. BDT address calculation fields**

| Field | Description |
|---|---|
| BDT_PAGE | BDT_PAGE registers in the Control Register Block |
| ENDPOINT | ENDPOINT field from the USB TOKEN |
| TX | 1 for transmit transfers; 0 for receive transfers |
| ODD | It corresponds to the buffer currently in use; the buffers are used in a ping-pong fashion. Maintained within the USBFS SIE. |

## 61.4.4 Buffer Descriptors (BDs)

A buffer descriptor provides endpoint buffer control information for USBFS and the processor. The Buffer Descriptors have different meanings, depending on whether it is the USBFS or the processor reading the BD in memory.

The USBFS controller uses the data stored in the BDs to determine:

- Who owns the buffer in system memory
- Data0 or Data1 PID
- Whether to release ownership upon packet completion
- No address increment (FIFO mode)
- Whether data toggle synchronization is enabled
- How much data is to be transmitted or received
- Where the buffer resides in system memory

The processor uses the data stored in the BDs to determine:

- Who owns the buffer in system memory
- Data0 or Data1 PID
- The received TOKEN PID
- How much data was transmitted or received
- Where the buffer resides in system memory

The format for the BD is shown in the following table.

## Table 61-4. Buffer descriptor format

| 31:26 | 25:16 | 15:8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|
| RSVD | BC (10 bits) | RSVD | OWN | DATA0/1 | KEEP/ TOK_PID[3] | NINC/ TOK_PID[2] | DTS/ TOK_PID[1] | BDT_STALL/ TOK_PID[0] | 0 | 0 |
| Buffer Address (32-Bits) | | | | | | | | | | |

## Table 61-5. Buffer descriptor fields

| Field | Description |
|---|---|
| 31–26<br>RSVD | Reserved |
| 25–16<br>BC | Byte Count<br>Represents the 10-bit byte count. The USBFS SIE changes this field upon the completion of a RX transfer with the byte count of the data received. |
| 15–8<br>RSVD | Reserved |
| 7<br>OWN | Determines whether the processor or USBFS currently owns the buffer. Except when KEEP = 1, the SIE hands ownership back to the processor after completing the token by clearing this bit.<br>This must always be the last byte of the BD that the processor updates when it initializes a BD.<br>0 The processor has access to the BD. USBFS ignores all other fields in the BD.<br>1 USBFS has access to the BD. While USBFS owns the BD, the processor should not modify any other fields in the BD. |
| 6<br>DATA0/1 | Defines whether a DATA0 field (DATA0/1=0) or a DATA1 (DATA0/1=1) field was transmitted or received. It is unchanged by USBFS. |
| 5<br>KEEP/<br>TOK_PID[3] | This bit has two functions (KEEP or TOK_PID[3]):<br>• KEEP bit—When written by the processor, it serves as the KEEP bit. Typically, this bit is 1 with ISO endpoints feeding a FIFO. The microprocessor is not informed that a token has been processed; the data is simply transferred to or from the FIFO. When KEEP is set, normally the NINC bit is also set to prevent address increment.<br>0 Allows USBFS to release the BD when a token has been processed.<br>1 This bit is unchanged by USBFS. Bit 3 of the current token PID is written back to the BD by USBFS.<br>• TOK_PID[3]—If the OWN bit is also set, then the BD remains owned by USBFS indefinitely; when written by USB, it serves as the TOK_PID[3] bit. Typically, this bit is 1 with ISO endpoints feeding a FIFO. The microprocessor is not informed that a token has been processed; the data is simply transferred to or from the FIFO. When KEEP is set, normally the NINC bit is also set to prevent address increment.<br>0 or 1 Bit 3 of the current token PID is written back to the BD by USBFS. |
| 4<br>NINC/<br>TOK_PID[2] | No Increment (NINC)<br>Disables the DMA engine address increment. This forces the DMA engine to read or write from the same address. This is useful for endpoints when data needs to be *read from* or *written to* a single location (such as a FIFO). Typically this bit is set with the KEEP bit for ISO endpoints that are interfacing to a FIFO.<br>0 USBFS writes bit 2 of the current token PID to the BD. |

*Table continues on the next page...*

**Table 61-5. Buffer descriptor fields (continued)**

| Field | Description |
|---|---|
| | 1 This bit is unchanged by USBFS. |
| 3<br>DTS/<br>TOK_PID[1] | Setting this bit enables USBFS to perform Data Toggle Synchronization.<br>• If KEEP = 0, then bit 1 of the current token PID is written back to the BD.<br>• If KEEP = 1, then this bit is unchanged by USBFS.<br><br>0 Data Toggle Synchronization is disabled.<br><br>1 Enables USBFS to perform Data Toggle Synchronization. |
| 2<br>BDT_STALL<br>TOK_PID[0] | Setting this bit causes USBFS to issue a STALL handshake if a token is received by the SIE that would use the BDT in this location. The BDT is not consumed by the SIE (the owns bit remains set and the rest of the BDT is unchanged) when a BDT_STALL bit is set.<br>• If KEEP = 0, then bit 0 of the current token PID is written back to the BD.<br>• If KEEP = 1, then this bit is unchanged by USBFS.<br><br>0 No stall issued.<br><br>1 The BDT is not consumed by the SIE (the OWN bit remains set and the rest of the BDT is unchanged).<br><br>Setting BDT_STALL also causes the corresponding USB_ENDPT*n*[EPSTALL] bit to set. This causes USBOTG to issue a STALL handshake for both directions of the associated endpoint. To clear the stall condition:<br>1. Clear the associated USB_ENDPT*n*[EPSTALL] bit.<br>2. Write the BDT to clear OWN and BDT_STALL. |
| TOK_PID[n] | Bits [5:2] can also represent the current token PID. The current token PID is written back in to the BD by USBFS when a transfer completes. The values written back are the token PID values from the USB specification:<br>• 0x1 for an OUT token.<br>• 0x9 for an IN token.<br>• 0xD for a SETUP token. |
| 1–0<br>Reserved | Reserved, should read as zeroes. |
| ADDR[31:0] | Address<br><br>Represents the 32-bit buffer address in system memory; this address must also be 32-bit aligned. These bits are unchanged by USBFS. |

## 61.4.5 USB transaction

When USBFS transmits or receives data, it computes the BDT address using the address generation shown in "Addressing Buffer Descriptor Entries" table.

If OWN =1, then the following process occurs:

1. USBFS reads the BDT.
2. The SIE transfers the data via the DMA to or from the buffer pointed to by the ADDR field of the BD.
3. When the TOKEN is complete, USBFS updates the BDT, and if KEEP=0, then USBFS changes the OWN bit to 0.

4. The STAT register is updated and the TOK_DNE interrupt is set.
5. When the processor processes the TOK_DNE interrupt, it reads from the status register all the information needed to process the endpoint.
6. At this point, the processor allocates a new BD, so that additional USB data can be transmitted or received for that endpoint, and then processes the last BD.

The following figure shows a timeline of how a typical USB token is processed after the BDT is read and OWN=1.

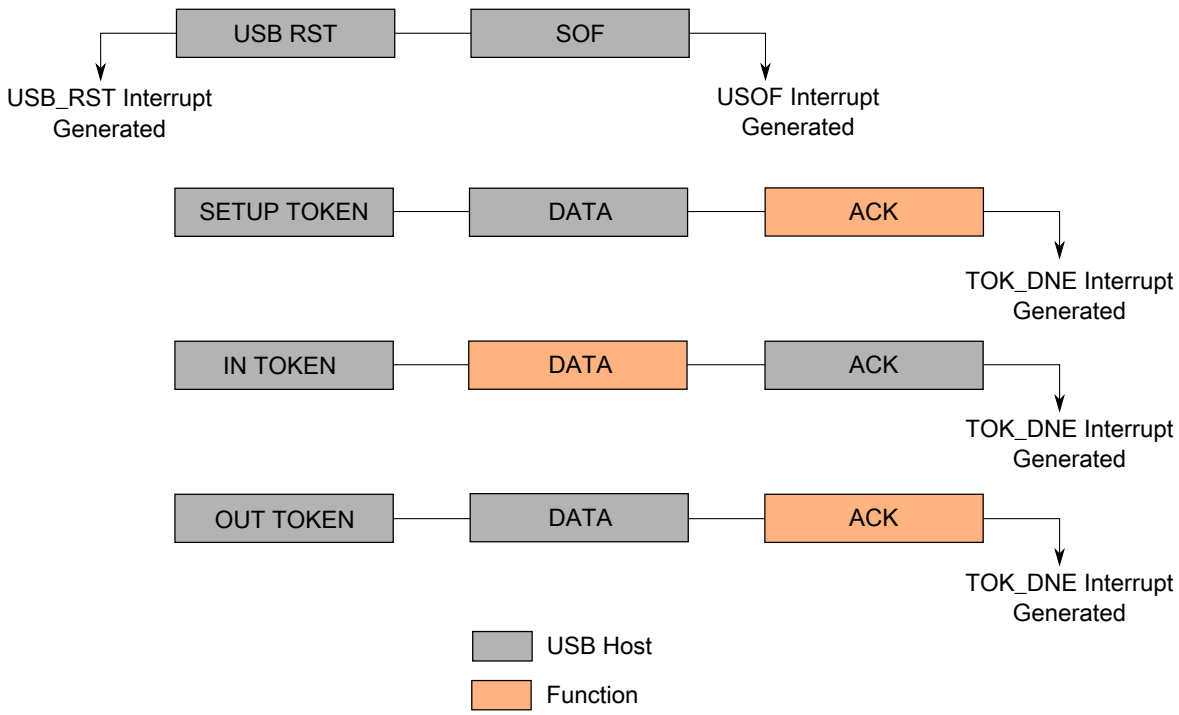

**Figure 61-7. USB token transaction**

The USB has two sources for the DMA overrun error: memory latency and oversized packets.

- **Memory Latency:** The memory latency may be too high and cause the receive FIFO to overflow. This is predominantly a hardware performance issue, usually caused by transient memory access issues.
- **Oversized Packets:** The packet received may be larger than the negotiated *MaxPacket* size. Typically, this is caused by a software bug. For DMA overrun errors due to oversized data packets, the USB specification is ambiguous, because it assumes correct software drivers on both sides. NAKing the packet can result in retransmission of the already oversized packet data. Therefore, in response to oversized packets, the USB core continues ACKing the packet for non-isochronous transfers.

**Table 61-6. USB responses to DMA overrun errors**

| Errors due to Memory Latency | Errors due to Oversized Packets |
|---|---|
| Non-Acknowledgment (NAK) or Bus Timeout (BTO) — See bit 4 in "Error Interrupt Status Register (ERRSTAT)" as appropriate for the class of transaction. | Continues acknowledging (ACKing) the packet for non-isochronous transfers. |
| — | The data written to memory is clipped to the MaxPacket size so as not to corrupt system memory. |
| The DMAERR bit is set in the ERRSTAT register for host and device modes of operation. Depending on the values of the INTENB and ERRENB register, the core may assert an interrupt to notify the processor of the DMA error. | Asserts ERRSTAT[DMAERR] ,which can trigger an interrupt and TOKDNE interrupt fires. Note: The TOK_PID field of the BDT is not 1111 because the DMAERR is not due to latency. |
| • In Host mode: the TOKDNE interrupt is generated and the TOK_PID field of the BDT is 1111 to indicate the DMA latency error. Host mode software can decide to retry or move to next scheduled item.<br>• In device mode: the BDT is not written back nor is the TOKDNE interrupt triggered because it is assumed that a second attempt is queued and will succeed in the future. | The packet length field written back to the BDT is the MaxPacket value that represents the length of the clipped data actually written to memory. |
| From here, the software can decide an appropriate course of action for future transactions, such as stalling the endpoint, canceling the transfer, disabling the endpoint, and others. | |

## 61.5 Memory map/Register definitions

This section provides the memory map and detailed descriptions of all USB interface registers.

### 61.5.1 USBFS memory mapping

The address space occupied by the USBFS registers is followed by 2048 bytes of embedded RAM used in Keep Alive mode. This USB RAM can also be used in Run mode.

### 61.5.2 USB register descriptions

#### 61.5.2.1 USB Memory map

USB0 base address: 4004_5000h

#### 61.5.2.7.1 Offset

| Register | Offset |
|---|---|
| ISTAT | 80h |

#### 61.5.2.7.2 Function

Contains fields for each of the interrupt sources within the USB Module. Each of these fields are qualified with their respective interrupt enable bits.

- After an interrupt bit has been set to "1", the interrupt bit can only be cleared by writing a "1" to the interrupt bit.
- This register contains the value of 0x00 after a reset.

#### 61.5.2.7.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | STALL | 0 | RESUME | SLEEP | TOKDNE | SOFTOK | ERROR | USBRST |
| W | W1C | | W1C | W1C | W1C | W1C | W1C | W1C |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### 61.5.2.7.4 Fields

| Field | Function |
|---|---|
| 7<br>STALL | Stall Interrupt<br>In Device mode, STALL bit is asserted when a STALL handshake is sent by the SIE. |
| 6<br>— | Reserved |
| 5<br>RESUME | RESUME<br>RESUME bit is set when a K-state is observed on the DP/DM signals for 2.5 µs. When not in Suspend mode, this interrupt must be disabled. |
| 4<br>SLEEP | Sleep<br>SLEEP bit is set when the USB Module detects a constant idle on the USB bus for 3 ms. The sleep timer is reset by activity on the USB bus. |
| 3<br>TOKDNE | Current token processing<br>TOKDNE bit is set when the current token being processed has completed. The processor must immediately read the STATUS (STAT) register to determine the EndPoint and BD used for this token. Clearing TOKDNE bit:<br>• causes STAT to be cleared<br>• or the STAT holding register to be loaded into the STAT register. |
| 2<br>SOFTOK | Start Of Frame (SOF) token<br>SOFTOK bit is set when the USB Module receives a Start Of Frame (SOF) token. |
| 1<br>ERROR | Error<br>ERROR bit is set when any of the error conditions within Error Interrupt Status (ERRSTAT) register occur. The processor must then read the ERRSTAT register to determine the source of the error. |
| 0<br>USBRST | USB Reset<br>USBRST bit is set when the USB Module has decoded a valid USB reset. This informs the processor that it should write 0x00 into the address register and enable endpoint 0.<br>USBRST is set after a USB reset has been detected for 2.5 microseconds. USBRST is not asserted again until the USB reset condition has been removed and the USB reset condition is reasserted. |

## 61.5.2.8 Interrupt Enable register (INTEN)

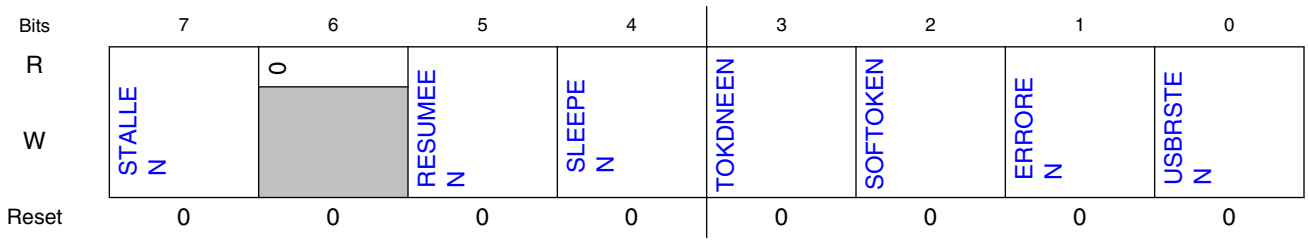
### 61.5.2.8.1 Offset

| Register | Offset |
|---|---|
| INTEN | 84h |

### 61.5.2.8.2 Function

Contains enable fields for each of the interrupt sources within the USB Module. Setting any of these bits enables the respective interrupt source in the ISTAT register. After a reset, INTEN register contains value 0x00.

### 61.5.2.8.3 Diagram



### 61.5.2.8.4 Fields

| Field | Function |
|---|---|
| 7<br>STALLEN | STALL Interrupt Enable<br>0b - Diasbles the STALL interrupt.<br>1b - Enables the STALL interrupt. |
| 6<br>— | Reserved |
| 5<br>RESUMEEN | RESUME Interrupt Enable<br>0b - Disables the RESUME interrupt.<br>1b - Enables the RESUME interrupt. |
| 4<br>SLEEPEN | SLEEP Interrupt Enable<br>0b - Disables the SLEEP interrupt.<br>1b - Enables the SLEEP interrupt. |
| 3<br>TOKDNEEN | TOKDNE Interrupt Enable<br>0b - Disables the TOKDNE interrupt.<br>1b - Enables the TOKDNE interrupt. |
| 2<br>SOFTOKEN | SOFTOK Interrupt Enable<br>0b - Disbles the SOFTOK interrupt.<br>1b - Enables the SOFTOK interrupt. |
| 1<br>ERROREN | ERROR Interrupt Enable<br>0b - Disables the ERROR interrupt.<br>1b - Enables the ERROR interrupt. |
| 0<br>USBRSTEN | USBRST Interrupt Enable<br>0b - Disables the USBRST interrupt.<br>1b - Enables the USBRST interrupt. |

# 61.5.2.9 Error Interrupt Status register (ERRSTAT)

## 61.5.2.9.1 Offset

| Register | Offset |
|---|---|
| ERRSTAT | 88h |

## 61.5.2.9.2 Function

Contains enable bits for each of the error sources within the USB Module. Each of these bits are qualified with their respective error enable bits.

- All bits of this register are logically OR'd together and the result placed in the ERROR bit of the ISTAT register.
- After an interrupt bit has been set it may only be cleared by writing a one to the respective interrupt bit.
- Each bit is set as soon as the error condition is detected; therefore, the interrupt does not typically correspond with the end of a token being processed.
- After a reset, ERRSTAT register contains value 0x00.

## 61.5.2.9.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | BTSER R | OWNERR | DMAERR | BTOER R | DFN8 | CRC16 | CRC5EOF | PIDER R |
| W | W1C | W1C | W1C | W1C | W1C | W1C | W1C | W1C |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

## 61.5.2.9.4 Fields

| Field | Function |
|---|---|
| 7<br>BTSERR | Bit stuff error<br>BTSERR bit is set when a bit stuff error is detected. If BTSERR is set, then the corresponding packet is rejected due to the error. |
| 6<br>OWNERR | OWNERR<br>OWNERR bit is valid when the USB Module is operating in Peripheral mode (CTL[HOSTMODEEN] = 0). OWNERR is set (to 1) if the USB Module requires a new BD for SETUP, ISO IN, or ISO OUT transfer while a new BD is not available. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 5<br>DMAERR | DMAERR<br>DMAERR bit is set if the USB Module has requested a DMA access to read a new BDT, but has not been given the bus before it needs to receive or transmit data.<br>• If processing a TX transfer, this would cause a transmit data underflow condition.<br>• If processing a RX transfer, this would cause a receive data overflow condition.<br><br>DMAERR interrupt is useful when developing device arbitration hardware for the microprocessor and the USB module, to minimize bus request and bus grant latency. DMAERR bit is also set if a data packet to or from the host is larger than the buffer size allocated in the BDT; in this case, the data packet is truncated as it is put in buffer memory. |
| 4<br>BTOERR | Bus turnaround timeout error<br>BTOERR bit is set when a bus turnaround timeout error occurs. The USB module contains a bus turnaround timer that keeps track of the amount of time elapsed between the token and data phases of a SETUP or OUT TOKEN or the data and handshake phases of a IN TOKEN. If more than 16 bit times are counted from the previous EOP before a transition from IDLE, then a bus turnaround timeout error occurs. |
| 3<br>DFN8 | Data field not 8 bits (in length)<br>DFN8 bit is set if the data field received was not 8 bits in length. USB Specification 1.0 requires that data fields be an integral number of bytes. If the data field was not an integral number of bytes, then DFN8 bit is set (to 1). |
| 2<br>CRC16 | CRC16 error<br>CRC16 bit is set (to 1) when a data packet is rejected due to a CRC16 error. |
| 1<br>CRC5EOF | CRC5 error or end of frame error<br>This error interrupt has two functions:<br>• When the USB Module is operating in Peripheral mode (CTL[HOSTMODEEN] = 0), this interrupt detects CRC5 errors in the token packets generated by the host. If CRC5EOF is 1, then the token packet was rejected due to a CRC5 error.<br>• When the USB Module is operating in Host mode (CTL[HOSTMODEEN] = 1), this interrupt detects End Of Frame (EOF) error conditions. This type of error occurs when the USB Module is transmitting or receiving data and the SOF counter reaches zero. This interrupt is useful when developing USB packet scheduling software, to ensure that no USB transactions cross the start of the next frame. |
| 0<br>PIDERR | PID error<br>PIDERR bit is set when the PID check field fails. |

## 61.5.2.10 Error Interrupt Enable register (ERREN)

### 61.5.2.10.1 Offset

| Register | Offset |
|---|---|
| ERREN | 8Ch |

### 61.5.2.10.2 Function

Contains enable bits for each of the error interrupt sources within the USB module.

- Setting any of these bits enables the respective interrupt source in ERRSTAT.
- Each bit is set as soon as the error condition is detected; therefore, the interrupt does not typically correspond with the end of a token being processed.
- After a reset, ERREN register contains value 0x00.

### 61.5.2.10.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R<br>W | BTSERREN | OWNERREN | DMAERREN | BTOERREN | DFN8EN | CRC16EN | CRC5EOFEN | PIDERREN |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 61.5.2.10.4 Fields

| Field | Function |
|---|---|
| 7<br>BTSERREN | BTSERR Interrupt Enable<br>0b - Disables the BTSERR interrupt.<br>1b - Enables the BTSERR interrupt. |
| 6<br>OWNERREN | OWNERR Interrupt Enable<br>This field is valid when the USB module is operating in Peripheral mode (CTL[HOSTMODEEN] = 0).<br>0b - Disables the OWNERR interrupt.<br>1b - Enables the OWNERR interrupt. |
| 5<br>DMAERREN | DMAERR Interrupt Enable<br>0b - Disables the DMAERR interrupt.<br>1b - Enables the DMAERR interrupt. |
| 4<br>BTOERREN | BTOERR Interrupt Enable<br>0b - Disables the BTOERR interrupt.<br>1b - Enables the BTOERR interrupt. |
| 3<br>DFN8EN | DFN8 Interrupt Enable<br>0b - Disables the DFN8 interrupt.<br>1b - Enables the DFN8 interrupt. |
| 2<br>CRC16EN | CRC16 Interrupt Enable<br>0b - Disables the CRC16 interrupt.<br>1b - Enables the CRC16 interrupt. |
| 1<br>CRC5EOFEN | CRC5/EOF Interrupt Enable<br>0b - Disables the CRC5/EOF interrupt.<br>1b - Enables the CRC5/EOF interrupt. |
| 0<br>PIDERREN | PIDERR Interrupt Enable<br>0b - Disables the PIDERR interrupt.<br>1b - Enters the PIDERR interrupt. |

## 61.5.2.11 Status register (STAT)

### 61.5.2.11.1 Offset

| Register | Offset |
|---|---|
| STAT | 90h |

### 61.5.2.11.2 Function

Reports the transaction status within the USB module.

When the processor's interrupt controller has received a TOKDNE, the Interrupt Status Register must be read to determine the status of the previous endpoint communication. The data in the status register is valid when the TOKDNE interrupt is asserted. The Status register is actually a read window into a status FIFO maintained by the USB module. When the USB module uses a BD, it updates the Status register.

If another USB transaction is performed before the TOKDNE interrupt is serviced, then the USB module stores the status of the next transaction in the STAT FIFO. Thus, STAT is actually a 4-byte FIFO that allows the processor core to process one transaction while the SIE is processing the next transaction. Clearing the TOKDNE bit in the ISTAT register causes the SIE to update STAT with the contents of the next STAT value. If the data in the STAT holding register is valid, then the SIE immediately reasserts to TOKDNE interrupt.

### 61.5.2.11.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | ENDP | | | | TX | ODD | 0 | |
| W | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 61.5.2.11.4 Fields

| Field | Function |
|---|---|
| 7-4<br>ENDP | ENDP<br>This 4-bit field encodes the endpoint address that received or transmitted the previous token. This allows the processor core to determine the BDT entry that was updated by the last USB transaction. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 3<br>TX | Transmit Indicator<br>0b - The most recent transaction was a receive operation.<br>1b - The most recent transaction was a transmit operation. |
| 2<br>ODD | Odd bank<br>ODD bit is set (to 1) if the last buffer descriptor *that was updated*, was in the odd bank of the BDT. |
| 1-0<br>— | Reserved |

## 61.5.2.12 Control register (CTL)

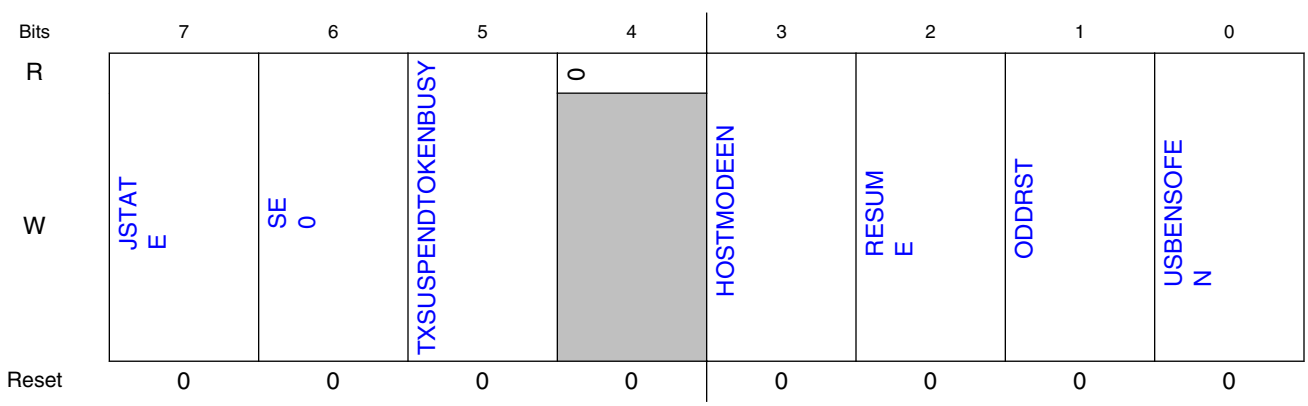
### 61.5.2.12.1 Offset

| Register | Offset |
|---|---|
| CTL | 94h |

### 61.5.2.12.2 Function

Provides various control and configuration information for the USB module.

### 61.5.2.12.3 Diagram



### 61.5.2.12.4 Fields

| Field | Function |
|---|---|
| 7 | Live USB differential receiver JSTATE signal |

*Table continues on the next page...*

| Field | Function |
|---|---|
| JSTATE | The polarity of this signal is affected by the current state of LSEN . |
| 6<br>SE0 | Live USB Single-Ended Zero signal |
| 5<br>TXSUSPENDTOKENBUSY | TXSUSPEND or TOKENBUSY<br>In Device mode, TXD_SUSPEND is set when the SIE has disabled packet transmission and reception. Clearing TXD_SUSPEND bit allows the SIE to continue token processing. TXD_SUSPEND bit is set to 1 by the SIE when a SETUP Token is received, allowing software to dequeue any pending packet transactions in the BDT before resuming token processing. |
| 4<br>— | Reserved |
| 3<br>HOSTMODEEN | Host mode enable<br>0b - USB Module operates in Device mode.<br>1b - USB Module operates in Host mode. In Host mode, the USB module performs USB transactions under the programmed control of the host processor. |
| 2<br>RESUME | Resume<br>When set to 1, RESUME bit enables the USB Module to execute resume signaling, this allows the USB Module to perform remote wake-up. Software must set RESUME to 1 for the required amount of time, and then clear RESUME to 0. If HOSTMODEEN is set, then the USB module appends a Low Speed End-of-Packet to the Resume signaling when the RESUME bit is cleared (to 0). |
| 1<br>ODDRST | ODDRST<br>Setting this bit to 1 resets all the BDT ODD ping/pong fields to 0, which then specifies the EVEN BDT bank. |
| 0<br>USBENSOFEN | USB Enable<br>Setting USBENSOFEN bit to 1 enables the USB-FS to operate; clearing USBENSOFEN bit (to 0) disables the USB-FS. Setting USBENSOFEN bit to 1 causes the SIE to reset all of its ODD bits to the BDTs; therefore, setting USBENSOFEN bit resets much of the logic in the SIE.<br>0b - Disables the USB Module.<br>1b - Enables the USB Module. |

## 61.5.2.13 Address register (ADDR)

### 61.5.2.13.1 Offset

| Register | Offset |
|---|---|
| ADDR | 98h |

### 61.5.2.13.2 Function

In Peripheral mode (CTL[HOSTMODEEN] = 0), ADDR holds the unique USB address that the USB module decodes. CTL[USBEN] must be 1.

After the reset input becomes active or the USB module decodes a USB reset signal, the Address register is reset to 0x00. This action initializes the Address register to decode address 0x00, as required by the USB specification.

### 61.5.2.13.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | 0 | ADDR | | | | | | |
| W | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 61.5.2.13.4 Fields

| Field | Function |
|---|---|
| 7<br>— | Reserved |
| 6-0<br>ADDR | USB Address<br>Defines the USB address that the USB module decodes in Peripheral mode. |

## 61.5.2.14 BDT Page register 1 (BDTPAGE1)

### 61.5.2.14.1 Offset

| Register | Offset |
|---|---|
| BDTPAGE1 | 9Ch |

### 61.5.2.14.2 Function

Provides address bits 15 through 9 of the base address where the current Buffer Descriptor Table (BDT) resides in system memory. See Buffer Descriptor Table. The 32-bit BDT Base Address is always aligned on 512-byte boundaries, so bits 8 through 0 of the base address are always zero.

### 61.5.2.14.3 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|

|---|---|
| 7-0<br>BDTBA | BDTBA<br>Provides address bits 31 through 24 of the BDT base address that defines the location of Buffer Descriptor Table resides in system memory. |

### 61.5.2.19 Endpoint Control register (ENDPT0 - ENDPT15)

#### 61.5.2.19.1 Offset

For a = 0 to 15:

| Register | Offset |
|---|---|
| ENDPTa | C0h + (a × 4h) |

#### 61.5.2.19.2 Function

Contains the endpoint control bits for each of the 16 endpoints available within the USB module for a decoded address. The format for these registers is shown in the following figure.

- Endpoint 0 (ENDPT0) is associated with control pipe 0, which is required for all USB functions. Therefore, after a USBRST interrupt occurs, the processor core should set ENDPT0 to contain 0x0D. In Host mode, ENDPT0 is used to determine the handshake, retry and low speed characteristics of the host transfer. Common

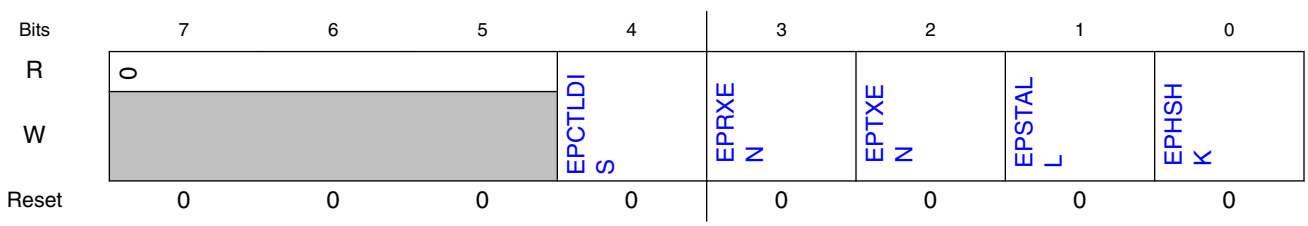
values to use for ENDPT0 in Host mode are 0x4D for Control, Bulk, and Interrupt transfers, and 0x4C for Isochronous transfers.

- For Control, Bulk and Interrupt transfers, the EPHSHK bit should be 1. For Isochronous transfers, EPHSHK bit should be 0.
- The 3 bits EPCTLDIS, EPRXEN, and EPTXEN define if an endpoint is enabled and also define the direction of the endpoint. The endpoint enable/direction control is defined in the next table.

**Table 61-7. Endpoint enable and direction control**

| EPCTLDIS | EPRXEN | EPTXEN | Endpoint enable/direction control |
|---|---|---|---|
| X | 0 | 0 | Disable endpoint |
| X | 0 | 1 | Enable endpoint for Tx transfers only |
| X | 1 | 0 | Enable endpoint for Rx transfers only |
| 1 | 1 | 1 | Enable endpoint for Rx and Tx transfers |
| 0 | 1 | 1 | Enable Endpoint for RX and TX as well as control (SETUP) transfers. |

## 61.5.2.19.3 Diagram



## 61.5.2.19.4 Fields

| Field | Function |
|---|---|
| 7-5<br>— | Reserved |
| 4<br>EPCTLDIS | Control (SETUP) transfer disable<br>• When EPCTLDIS bit is set to 1, it disables control (SETUP) transfers.<br>• When EPCTLDIS bit is cleared (to 0), control transfers are enabled, but only if the EPRXEN and EPTXEN bits are also set. See Table 61-7. |
| 3<br>EPRXEN | Endpoint for RX transfers enable<br>When EPRXEN bit is set to 1, it enables the endpoint for RX transfers. See Table 61-7. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 2<br>EPTXEN | Endpoint for TX transfers enable<br>When EPTXEN bit is set to 1, it enables the endpoint for TX transfers. See Table 61-7. |
| 1<br>EPSTALL | Endpoint stalled<br>When EPSTALL bit is set to 1, it indicates that the endpoint is stalled.<br>• EPSTALL bit has priority over all other control bits in this register, but the EPSTALL bit is only valid if EPTXEN=1 or EPRXEN=1.<br>• Any access to this endpoint causes the USB Module to return a STALL handshake.<br>• After an endpoint is stalled, intervention is required from the Host Controller. |
| 0<br>EPHSHK | Endpoint handshaking enable<br>When EPHSHK bit is set to 1, it enables an endpoint to perform handshaking during a transaction to this endpoint. EPHSHK bit is generally 1 unless the endpoint is Isochronous. |

## 61.5.2.20 USB Control register (USBCTRL)

### 61.5.2.20.1 Offset

| Register | Offset |
|---|---|
| USBCTRL | 100h |

| Field | Function |
|---|---|
| 7-5<br>— | Reserved |
| 4<br>DPPULLUPNONOTG | DPPULLUPNONOTG<br>Provides control of the DP Pullup in USB, if USB is configured in non-OTG Device mode.<br>0b - DP Pullup in non-OTG Device mode is not enabled.<br>1b - DP Pullup in non-OTG Device mode is enabled. |
| 3-0<br>— | Reserved |

### 61.5.2.23 USB Transceiver Control register 0 (USBTRC0)

#### 61.5.2.23.1 Offset

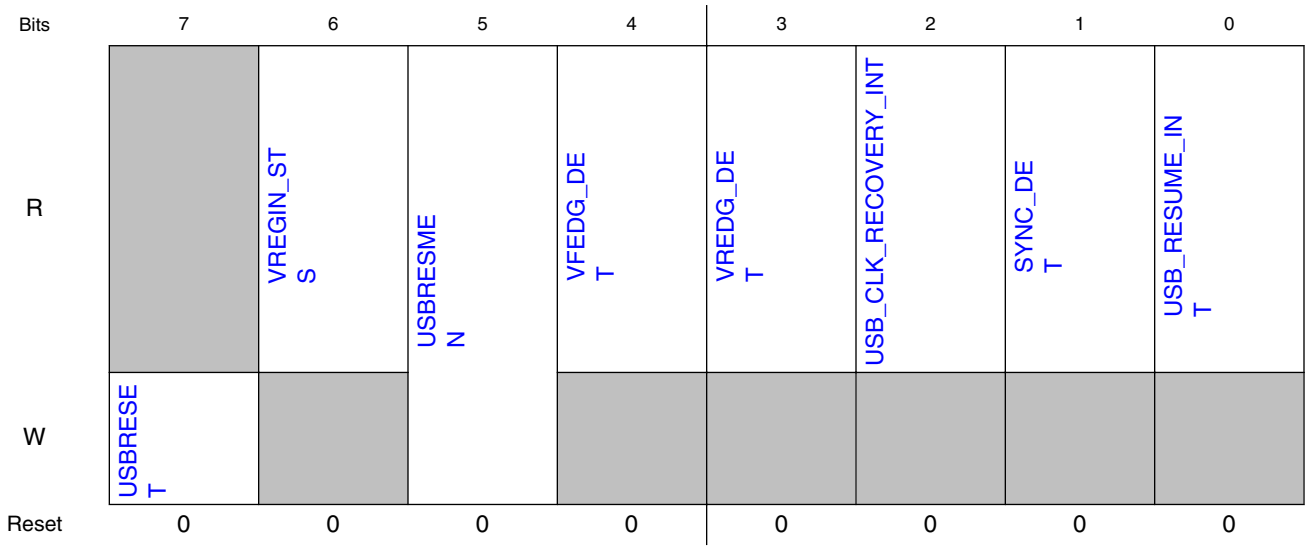
| Register | Offset |
|---|---|
| USBTRC0 | 10Ch |

#### 61.5.2.23.2 Function

Includes signals for basic operation of the on-chip USB Full Speed transceiver and for configuration of the USB data connection (that are not otherwise included in the USB Full Speed controller registers).

In bus-powered device use cases when the USB receptacle VBUS pin is connected to VREGIN, VREGIN interrupt detection using the VFEDG_DET and VREDG_DET bits may be used for VBUS detection.

## 61.5.2.23.3 Diagram



## 61.5.2.23.4 Fields

| Field | Function |
|---|---|
| 7<br>USBRESET | USB Reset<br>Generates a hard reset to USB. After USBRESET bit is set (to 1) and the reset occurs, the USBRESET bit is automatically cleared.<br>**NOTE: USBRESET bit always reads 0. After setting USBRESET bit, wait 2 USB clock cycles before accessing other USB register bit fields.**<br>0b - Normal USB module operation.<br>1b - Returns the USB module to its reset state. |
| 6<br>VREGIN_STS | VREGIN_STS<br>Indicates the VREGIN status, and is a read-only bit. |
| 5<br>USBRESMEN | Asynchronous Resume Interrupt Enable<br>When USBRESMEN bit is set to 1, after detection of resume signaling on the USB bus, it allows the USB module to send an asynchronous wakeup event to the MCU. The MCU then re-enables clocks to the USB module. This is used for low-power Suspend mode when USB module clocks are stopped or when the USB transceiver is in Suspend mode. Async wakeup only works in Device mode.<br>• The asynchronous resume interrupt differs from the synchronous resume interrupt, in that it asynchronously detects K-state using the unfiltered state of the D+ and D– pins.<br>• The asynchronous resume interrupt should only be enabled when the Transceiver is suspended.<br>0b - USB asynchronous wakeup from Suspend mode is disabled.<br>1b - USB asynchronous wakeup from Suspend mode is enabled. |
| 4<br>VFEDG_DET | VREGIN Falling Edge Interrupt Detect<br>To enable VFEDG_DET bit, use USB*x*_MISCCTRL[VFEDG_EN].<br>0b - VREGIN falling edge interrupt has not been detected.<br>1b - VREGIN falling edge interrupt has been detected. |
| 3<br>VREDG_DET | VREGIN Rising Edge Interrupt Detect<br>To enable VREDG_DET bit, use USB*x*_MISCCTRL[VREDG_EN]. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 0b - VREGIN rising edge interrupt has not been detected.<br>1b - VREGIN rising edge interrupt has been detected. |
| 2<br>USB_CLK_RECOVERY_INT | Combined USB Clock Recovery interrupt status<br>The read-only USB_CLK_RECOVERY_INT field will be set to 1'b1 when any of USB clock recovery interrupt conditions are detected and those interrupts are unmasked.<br>• The only unmasked USB clock recovery interrupt condition results from an overflow of the frequency trim setting values, indicating that the frequency trim calculated is out of the adjustment range of the IRC48M output clock.<br>• To clear USB_CLK_RECOVERY_INT bit after it has been set, write 0xFF to register USB_CLK_RECOVER_INT_STATUS. |
| 1<br>SYNC_DET | Synchronous USB Interrupt Detect<br>0b - Synchronous interrupt has not been detected.<br>1b - Synchronous interrupt has been detected. |
| 0<br>USB_RESUME_INT | USB Asynchronous Interrupt<br>0b - No interrupt was generated.<br>1b - Interrupt was generated because of the USB asynchronous interrupt. |

## 61.5.2.24 Keep Alive mode control (KEEP_ALIVE_CTRL)

### 61.5.2.24.1 Offset

| Register | Offset |
|---|---|
| KEEP_ALIVE_CTRL | 124h |

### 61.5.2.24.2 Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | WAKE_INT_STS | KEEP_ALIVE_STS | 0 | WAKE_INT_EN | WAKE_REQ_EN | STOP_ACK_DLY_EN | OWN_OVERRD_EN | KEEP_ALIVE_EN |
| W | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |

### 61.5.2.24.3 Fields

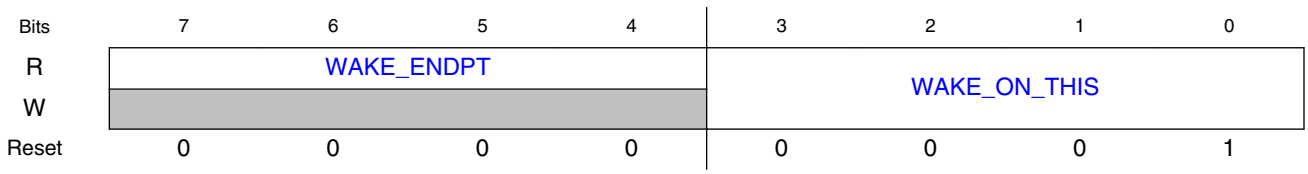
| Field | Function |
|---|---|
| 7<br>WAKE_INT_STS | Wakeup Interrupt Status<br>If KEEP_ALIVE mode is enabled and a SETUP token or software assigned token is received, then WAKE_INT_STS interrupt is set to 1 only after the token is processed and the USB state is IDLE. To clear WAKE_INT_STS bit, write 1. |
| 6<br>KEEP_ALIVE_STS | Keep Alive Status<br>Indicates if USB is in Keep Alive mode.<br>0b - USB is not in Keep Alive mode.<br>1b - USB is in Keep Alive mode. |
| 5<br>— | Reserved |
| 4<br>WAKE_INT_EN | Wakeup Interrupt Enable<br>To enable WAKE_INT_STS, set WAKE_INT_EN to 1. |
| 3<br>WAKE_REQ_EN | WAKE_REQ_EN<br>During KEEP_ALIVE mode, a bus access by the USB controller to a memory location outside the USB SRAM will cause the bus access to stall until KEEP_ALIVE mode is exited. When WAKE_REQ_EN is set to 1, a bus access by the USB controller to a memory location outside the USB SRAM will generate a wakeup, thereby allowing the bus access to complete. After the bus access finishes, the USB will reenter the KEEP_ALIVE mode if no other wakeups have been detected.<br>**NOTE:** An interrupt is not generated as a result of the wakeup request.<br>0b - USB bus wakeup request is disabled<br>1b - USB bus wakeup request is enabled |
| 2<br>STOP_ACK_DLY_EN | STOP_ACK_DLY_EN<br>• When STOP_ACK_DLY_EN is set to 1, then the module will respond to the ipg_stop *when USB core state is idle and there is no AHB transfer*.<br>• When STOP_ACK_DLY_EN is set to 0, then the module will respond to the ipg_stop *when there is no AHB transfer*.<br>0b - Enter KEEP_ALIVE mode until the USB core is idle and there is no USB AHB transfer.<br>1b - Enter KEEP_ALIVE mode immediately when there is no USB AHB transfer. |
| 1<br>OWN_OVERRD_EN | OWN bit override enable<br>During KEEP_ALIVE mode, when OWN_OVERRD_EN is set to 1, and if received token is not SETUP, then the OWN bit of current BD will be forced to 0, so the USB core will respond with NAK. |
| 0<br>KEEP_ALIVE_EN | Keep Alive mode enable<br>Global enable for USB_KEEP_ALIVE mode.<br>• When KEEP_ALIVE_EN is 1 (asserted), USB shall enter USB_KEEP_ALIVE mode after asserting ipg_stop;<br>• When KEEP_ALIVE_EN is 0 (de-asserted), everything is the same as before. |

## 61.5.2.25 Keep Alive mode wakeup control (KEEP_ALIVE_WKCTRL)

### 61.5.2.25.1 Offset

| Register | Offset |
|---|---|
| KEEP_ALIVE_WKCTRL | 128h |

### 61.5.2.25.2 Diagram



### 61.5.2.25.3 Fields

## 61.5.2.31 USB Clock recovery control (CLK_RECOVER_CTRL)

### 61.5.2.31.1 Offset

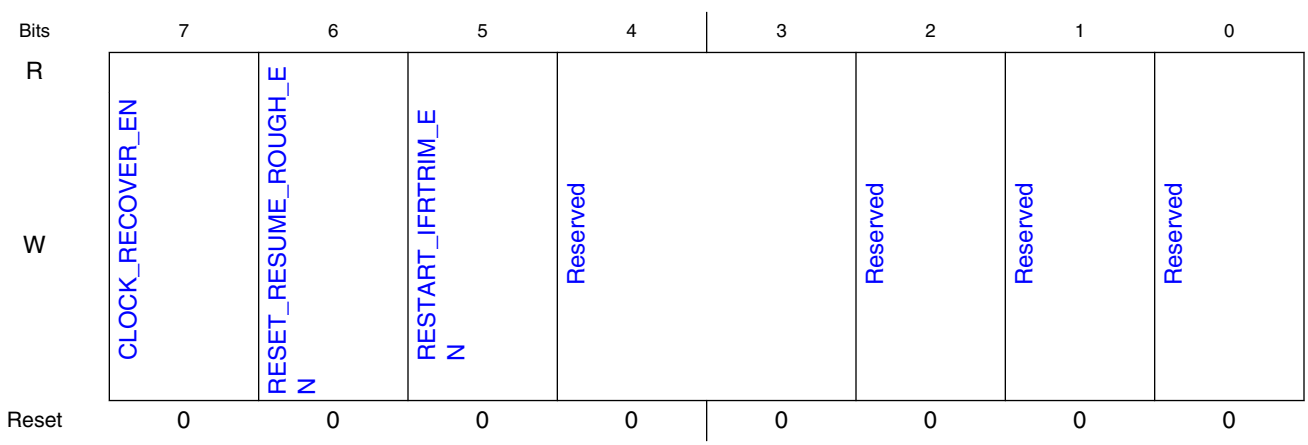
| Register | Offset |
|---|---|
| CLK_RECOVER_CTRL | 140h |

### 61.5.2.31.2 Function

Signals in CLK_RECOVER_CTRL register control the crystal-less USB clock mode in which the internal IRC48M oscillator is tuned to match the clock extracted from the incoming USB data stream.

**The IRC48Minternal oscillator module must be enabled in register USB_CLK_RECOVER_IRC_EN for this mode.**

### 61.5.2.31.3 Diagram



### 61.5.2.31.4 Fields

| Field | Function |
|---|---|
| 7<br>CLOCK_RECOVER_EN | Crystal-less USB enable<br>CLOCK_RECOVER_EN bit must be enabled if user wants to use the crystal-less USB mode for the Full Speed USB controller and transceiver.<br>**NOTE: CLOCK_RECOVER_EN bit should not be set for USB Host mode or OTG.**<br>0b - Disable clock recovery block (default) |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1b - Enable clock recovery block |
| 6<br>RESET_RESUME_ROUGH_EN | Reset/resume to rough phase enable<br>The clock recovery block tracks the IRC48M to get an accurate 48 MHz clock. It has 2 phases after user enables clock_recover_en bit, rough phase and tracking phase. The step to fine tune the IRC48M by adjusting the trim fine value is different during these 2 phases. The step-in rough phase is larger than that in tracking phase. Switch back to the rough stage whenever a USB bus reset or bus resume occurs.<br>0b - Always works in tracking phase after the first time rough phase, to track transition (default).<br>1b - Go back to rough stage whenever a bus reset or bus resume occurs. |
| 5<br>RESTART_IFRTRIM_EN | Restart from IFR trim value<br>IRC48M has a default trim fine value whose default value is factory trimmed (the IFR trim value). The clock recover block tracks the accuracy of the clock 48 MHz, and keeps updating the trim fine value accordingly.<br>0b - Trim fine adjustment always works based on the previous updated trim fine value (default).<br>1b - Trim fine restarts from the IFR trim value, whenever bus_reset/bus_resume is detected or module enable is desasserted. |
| 4-3<br>— | Reserved |
| 2<br>— | Reserved<br>Customers should not change this bit from its default state. |
| 1<br>— | Reserved<br>Customers should not change this bit from its default state. |
| 0<br>— | Reserved<br>Customers should not change this bit from its default state. |

## 61.5.2.32 IRC48MFIRC oscillator enable register (CLK_RECOVER_IRC_EN)

### 61.5.2.32.1 Offset

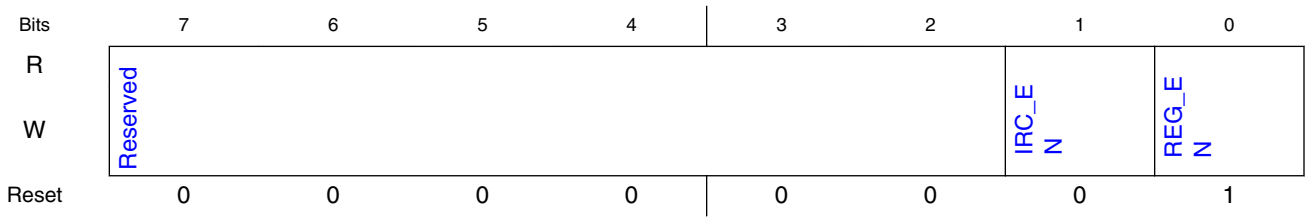
| Register | Offset |
|---|---|
| CLK_RECOVER_IRC_EN | 144h |

### 61.5.2.32.2 Function

Controls basic operation of the on-chip IRC48M module used to produce nominal 48 MHz clocks for USB crystal-less operation and other functions.

See additional information about the IRC48M operation in the Clock Distribution chapter.

### 61.5.2.32.3 Diagram



### 61.5.2.32.4 Fields

| Field | Function |
|---|---|
| 7-2<br>— | Reserved |
| 1<br>IRC_EN | IRC_EN<br>IRC48M enable bit is used to enable the on-chip IRC48M module to generate clocks for crystal-less USB, and it can be used for FS USB Device mode operation. IRC_EN bit must be set before using the crystal-less USB clock configuration.<br>0b - Disable the IRC48M module (default)<br>1b - Enable the IRC48M module |
| 0<br>REG_EN | Regulator enable<br>IRC48M regulator enable bit is used to enable the local analog regulator for IRC48M module. REG_EN bit must be set if user wants to use the crystal-less USB clock configuration.<br>0b - IRC48M local regulator is disabled<br>1b - IRC48M local regulator is enabled (default) |

## 61.5.2.33 Clock recovery combined interrupt enable (CLK_RECOVER_INT_EN)

### 61.5.2.33.1 Offset

| Register | Offset |
|---|---|
| CLK_RECOVER_INT_EN | 154h |

### 61.5.2.33.2 Function

Enables or masks the individual interrupt flags which are logically OR'ed together, to produce the combined interrupt indication at USB_USBTRC0[USB_CLK_RECOVERY_INT] bit, if the indicated conditions have been detected in the USB clock recovery algorithm operation.

### 61.5.2.33.3 Diagram

| 3-0<br>— | Reserved<br>Should always be written as 0. |

## 61.6 Keep Alive mode

Keep Alive mode is for chips with *device-only* USB implementations.

**NOTE**

The address range 0x4010_0000 to 0x4010_07FF consists of 2 KB of on-chip USB RAM in Run mode. Due to a design limitation, only the bottom half of the USB RAM (0x4010_0000 to 0x4010_03FF) can be accessed by the USB core in Keep Alive Mode.

When entering Keep Alive Mode, all USB buffers (and BDT) *that will be accessed during Keep Alive mode* will be placed in the bottom half of USB RAM.

Keep Alive mode keeps USB active in STOP/VLPS low-power modes so there is no need to re-start USB after exiting low power modes. When connected to the host and when there is no data to transfer, to save power, the software can power down the system bus and the CPU, keeping only the USB power on. In Keep Alive mode, only the USB 48 MHz functional clock is required by the USB controller; the rest of the device enters Stop mode. When the SETUP token or a software-assigned token is received, the USB core wakes up and responds NAK to all other packets.

Because the USB core must access the BDT in Keep Alive mode, the bottom half of 2KB on-chip USB RAM (located from 0x4010_0000 to 0x4010_03FF) is used for the BDT and small data packets during Keep Alive mode. Software puts the BDT into this RAM in Keep Alive mode and changes all OWN bits to 0 (except the SETUP endpoint). This can be done by setting USB_KEEP_ALIVE_CTRL[OWN_OVERRD_EN].

**NOTE**

For more about entering/exiting Keep Alive mode and device mode IRC48M operations, see the chip-specific section in the front of this chapter.

# Chapter 62
# USB Voltage Regulator (USBVREG)

## 62.1 Chip-specific USBVREG information

### 62.1.1 USB Voltage Regulator Configuration

This section summarizes how the module has been configured in the chip.

**NOTE**

When USB is not used in the application, it is recommended to connect VOUT33 and VREGIN together and tie to ground through a 10kΩ resistor. Do not tie directly to ground, as this causes a latch-up risk.

## 62.2 Introduction

This section provides an introduction to the USB_VREG module.The USB voltage regulator module (USB_VREG) provides USB regulator control registers.

### 62.2.1 Features

The USB_VREG includes the following features:

- USB regulator control

# Chapter 63
# Ultra Secured Digital Host Controller (uSDHC)

## 63.1 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 63-1.

The uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by the uSDHC:

The Multi Media Card (MMC) is a universal low cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly-emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward-compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the following figure does not show cards with reduced size or mini cards.

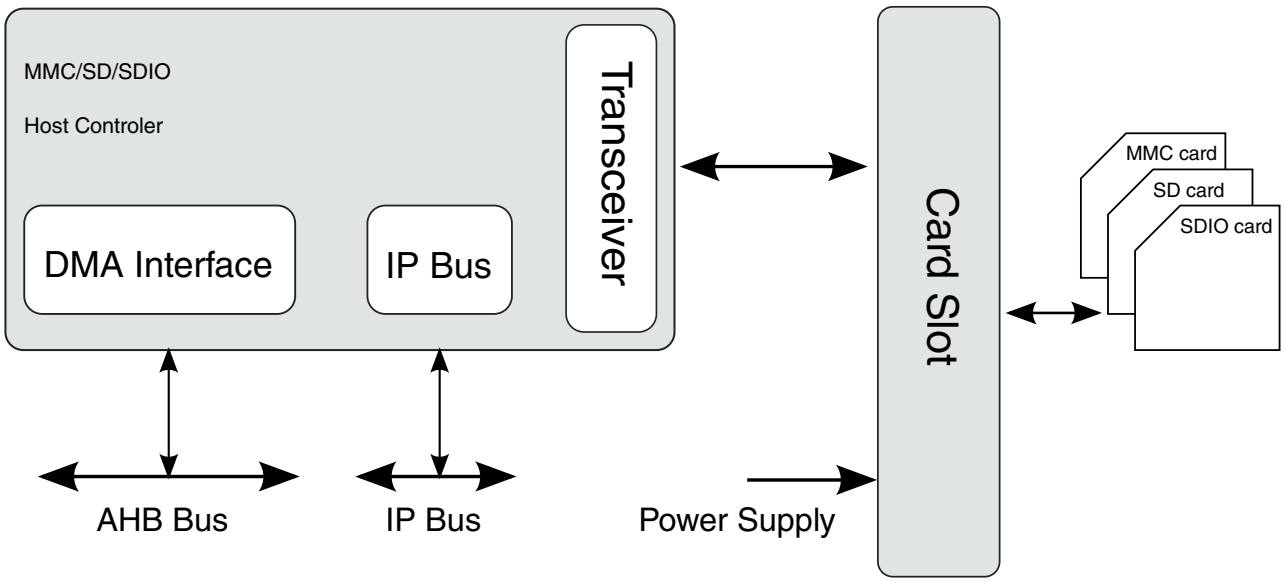

**Figure 63-1. System Connection of the uSDHC**

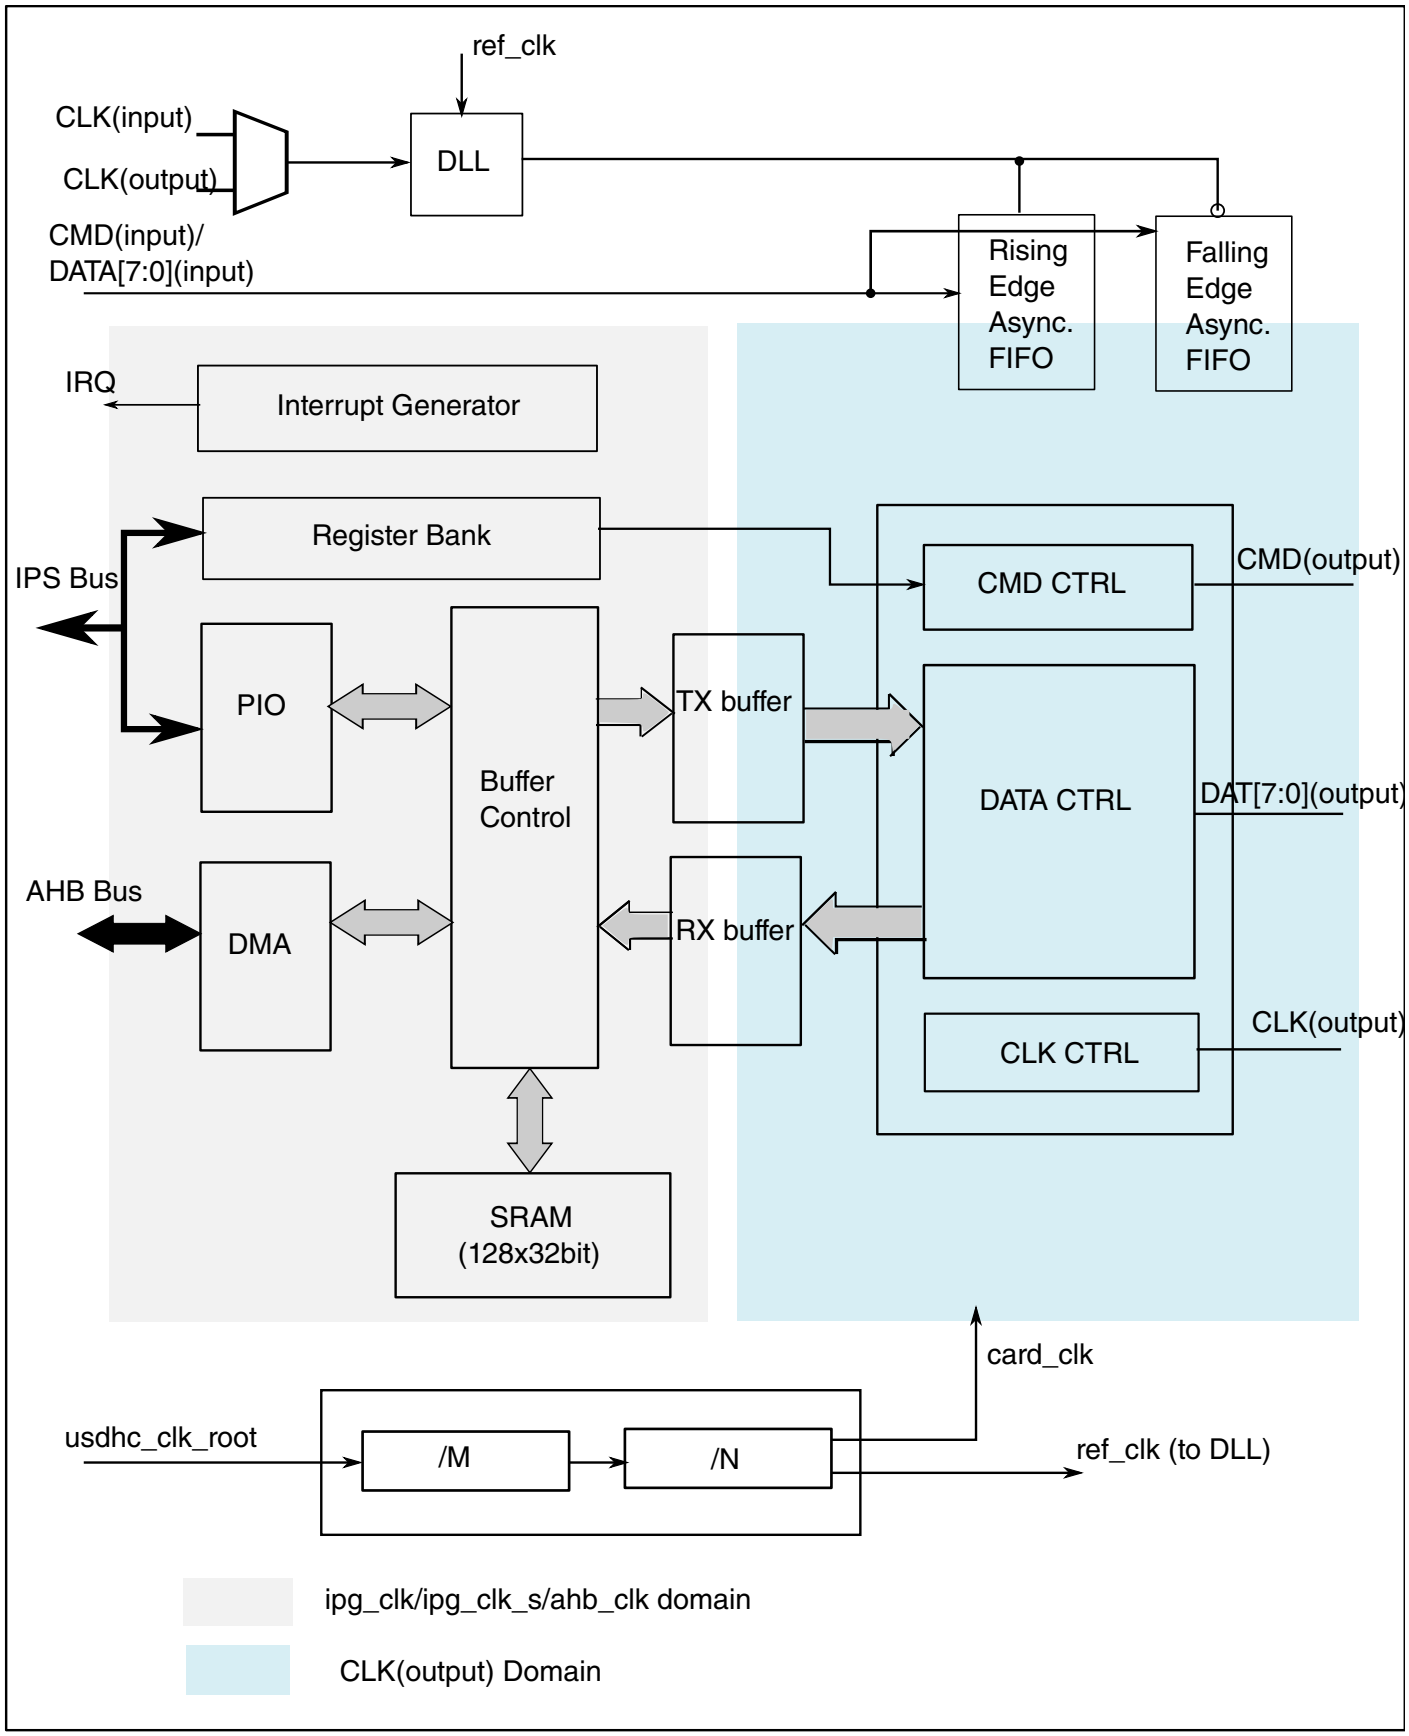

**Figure 63-2. ultra Secure Digital Host Controller Block Diagram**

### 63.1.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 52 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
  - Up to 200 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 200 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR(Single Data Rate) mode
  - Up to 832 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR(Dual Data Rate) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Support voltage selection by configuring vendor specific register bit
- Supports Advanced DMA to perform linked memory access

Note: IP can support above listed speed mode and max data throughput. For SOC, speed mode and data throughput should be Chip-specific.Pls check corresponding SOC description.

### 63.1.2 Modes and Operations

#### 63.1.2.1 Data transfer Modes

The uSDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 26 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC HS200 mode(up to 200 Mhz)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)

Note: IP can support above listed speed mode and max clock frequency. For SOC, speed mode and max clock frequency should be Chip-specific.Pls check corresponding SOC description.

## 63.2 External Signals

The following table describes the external signals of uSDHC:

**Table 63-1. uSDHC External Signals**

| Signal | Description | Direction |
|---|---|---|
| CLK | Clock for MMC/SD/SDIO card | O |
| CMD | CMD line connect to card | I/O |
| DATA7 | DAT7 line in 8-bit mode<br>Not used in other modes | I/O |
| DATA6 | DAT6 line in 8-bit mode | I/O |

*Table continues on the next page...*

**Table 63-1. uSDHC External Signals (continued)**

| Signal | Description | Direction |
|---|---|---|
| | Not used in other modes | |
| DATA5 | DAT5 line in 8-bit mode<br>Not used in other modes | I/O |
| DATA4 | DAT4 line in 8-bit mode<br>Not used in other modes | I/O |
| DATA3 | DAT3 line in 4/8-bit mode or configured as card detection pin<br>May be configured as card detection pin in 1-bit mode | I/O |
| DATA2 | DAT2 line or Read Wait in 4-bit mode<br>Read Wait in 1-bit mode | I/O |
| DATA1 | DAT1 line in 4/8-bit mode<br>Also used to detect interrupt in 1/4-bit mode | I/O |
| DATA0 | DAT0 line in all modes<br>Also used to detect busy state | I/O |
| CD_B | Card detection pin<br>If not used(for the embedded memory),tie low to indicate there is a card attached. | I |
| WP | Card write protect detect<br>If not used(for the embedded memory), tie low to indicate it's not write protected. | I |
| LCTL | LED control used to drive an external LED Active high<br>Fully controlled by the driver<br>Optional output | O |
| RESET_B | Card hardware reset signal, active LOW | O |
| VSELECT | IO power voltage selection signal | O |

## 63.2.1 Signals Overview

The uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC and the card.
- The CD and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD# means that a card is inserted, and a high on WP means that the write protect switch is active.
- LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.

- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST and VSELECT are all optional for system implementation. If the uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.If the uSDHC does not support HS400 mode, STROBE can also be optional and tied to low.

## 63.3 Clocks

The table found here describes the clock sources for uSDHC.

**Table 63-2. uSDHC Clocks**

| Clock name | Clock Root | Description |
|---|---|---|
| hclk | ahb_clk_root | AHB bus clock |
| ipg_clk | ipg_clk_root | Peripheral clock |
| ipg_clk_perclk | usdhc_clk_root | Base clock |
| ipg_clk_s | ipg_clk_root | Peripheral access clock for register accesses |

## 63.4 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

### 63.4.1 Data Buffer

The uSDHC uses one configurable data buffer to transfer data between the system bus (IP Bus or AHB Bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable and can be from 1 to 128 words.The burst lengths for read and write are also configurable and can be from 1 to 31 words.

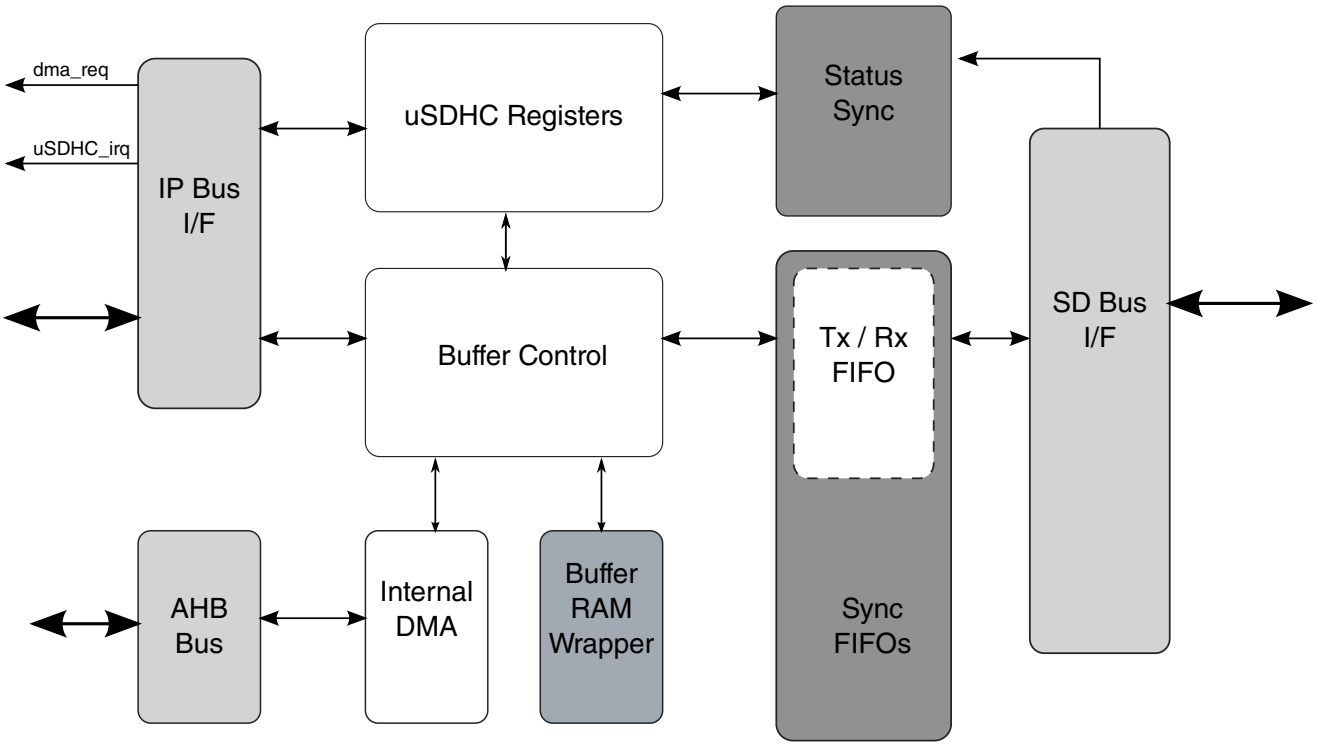

**Figure 63-3. uSDHC Buffer Scheme**

There are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark Level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored in the buffer.

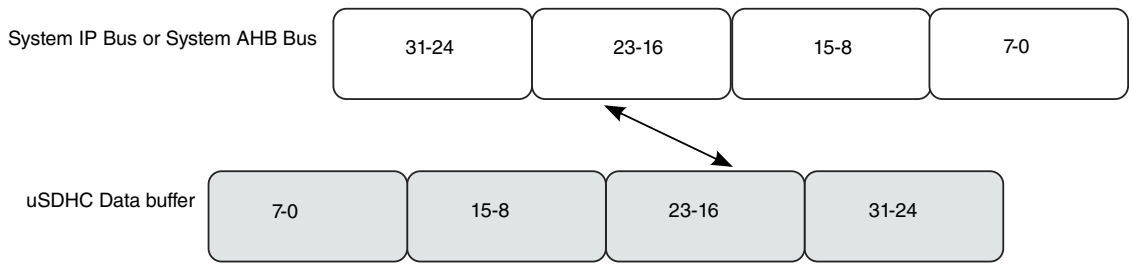

**Figure 63-4. Data Swap between System Bus and uSDHC Data Buffer in Byte Little Endian Mode**

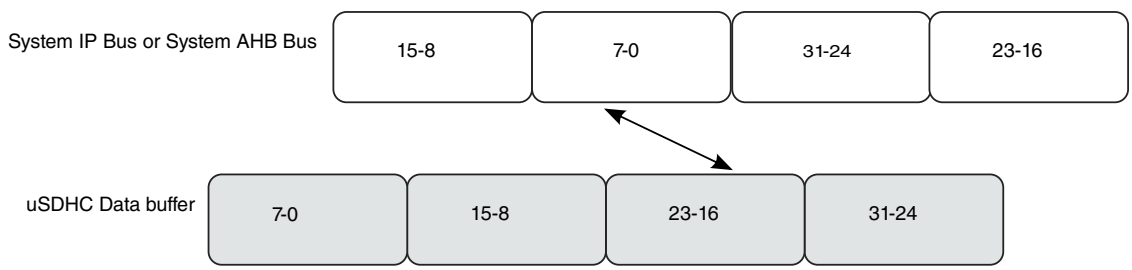

**Figure 63-5. Data Swap between System Bus and uSDHC Data Buffer in Half Word Big Endian Mode**

### 63.4.1.1 Write Operation Sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, (the DMAEN bit in the Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the uSDHC sets the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

The uSDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the uSDHC will stop the CLK to avoid the data buffer under-run situation.

#### 63.4.1.2 Read Operation Sequence

There are 2 ways to read data from the buffer when the user transfers data to the card:

- Processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, that is available and ready for system fetching data. At the same time, the uSDHC sets the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

For any write transfer mode, the uSDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the uSDHC will stop the CLK to avoid the data buffer over-run situation.

#### 63.4.1.3 Data Buffer and Block Size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can be from 1 to 128 words. For both read and write the burst length can be from 1 to 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned) stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block the ending byte will be abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

#### 63.4.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the dividing of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size up to 64 bytes. Although the uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided (see example below).

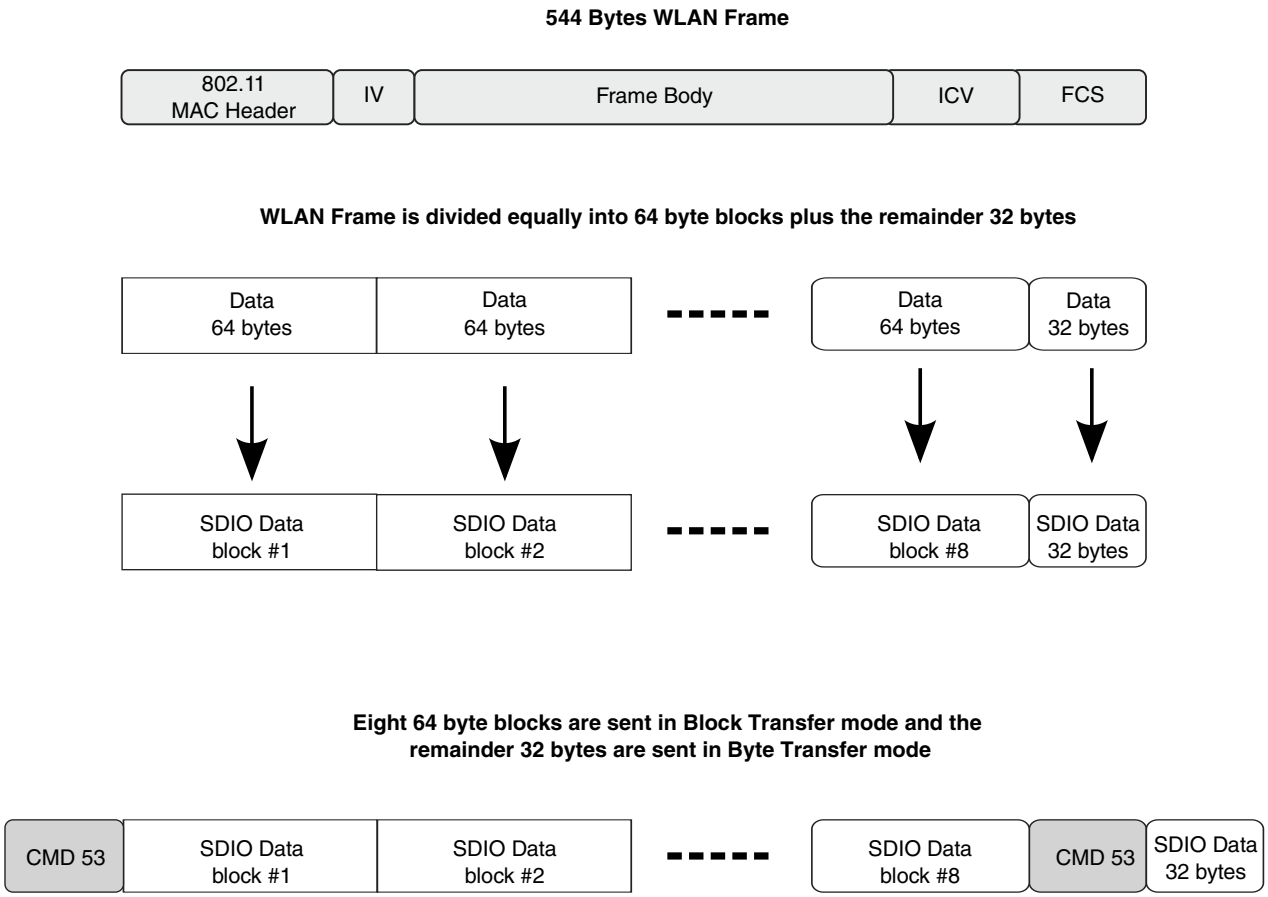

**Figure 63-6. Example for Dividing Large Data Transfers**

## 63.4.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the uSDHC_dreq_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

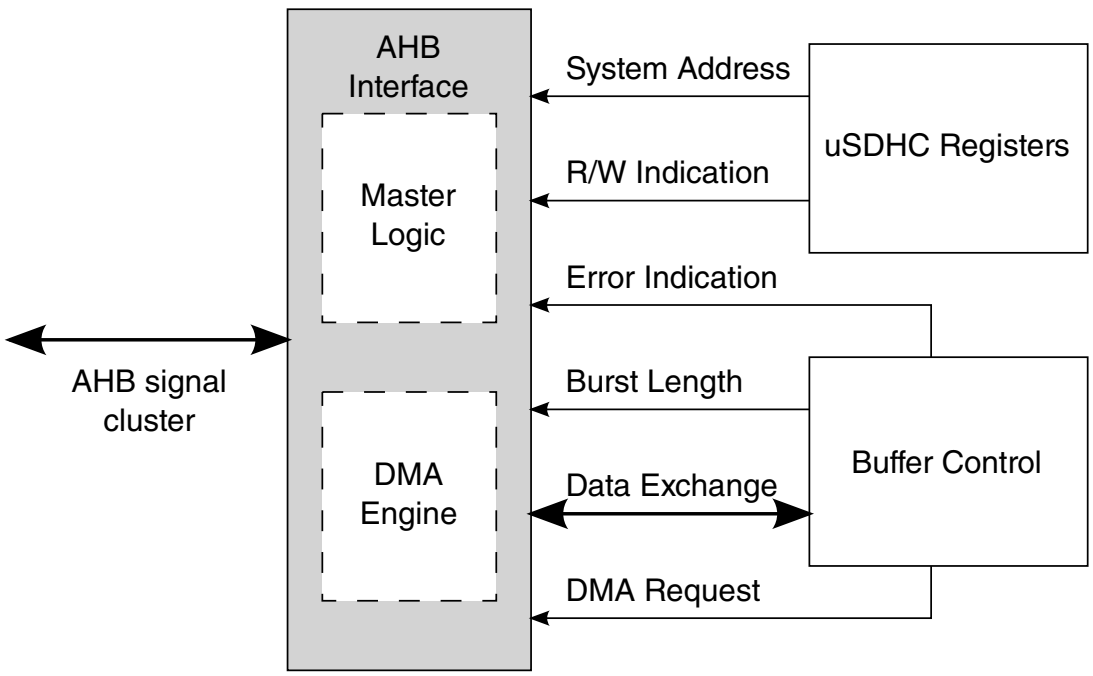

**Figure 63-7. DMA AHB Interface Block**

### 63.4.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request if the data buffer space(for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The uSDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuffed byte.

#### 63.4.2.2 DMA Burst Length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in Internal DMA Request. After 6 words are read, the burst length will be 2 words, then the next burst length will be 6 words. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

#### 63.4.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state.At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register will be generated to host CPU to report a bus error condition.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block. DMA operation will resume when the interrupt is serviced by software.

#### 63.4.2.4 ADMA Engine

In the SD Host Controller Standard, a new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver.

The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

#### 63.4.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer

See the figure below for the format of the descriptor table for ADMA1.

| Address/ Page Field | | Address/ Page Field | | Attribute Field | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| 31 | 12 | 11 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Address or Data Length | | 000000 | | Act 2 | Act 1 | 0 | Int | End | Valid |

| Act 2 | Act1 | Symbol | Comment | 31- 28 | 27- 12 |
|---|---|---|---|---|---|
| 0 | 0 | Nop | No Operation | Don't Care | |
| 0 | 1 | Set | Set Data Length | 0000 | Data Length |
| 1 | 0 | Tran | Transfer Data | Data Address | |
| 1 | 1 | Link | Link Descriptor | Descriptor Address | |

| | |
|---|---|
| Valid | Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA. |
| End | End = 1 indicates current descriptor is the ending one. |
| Int | Int = 1 generates DMA Interrupt when this descriptor is processed. |

**Figure 63-8. Format of the ADMA1 Descriptor Table**

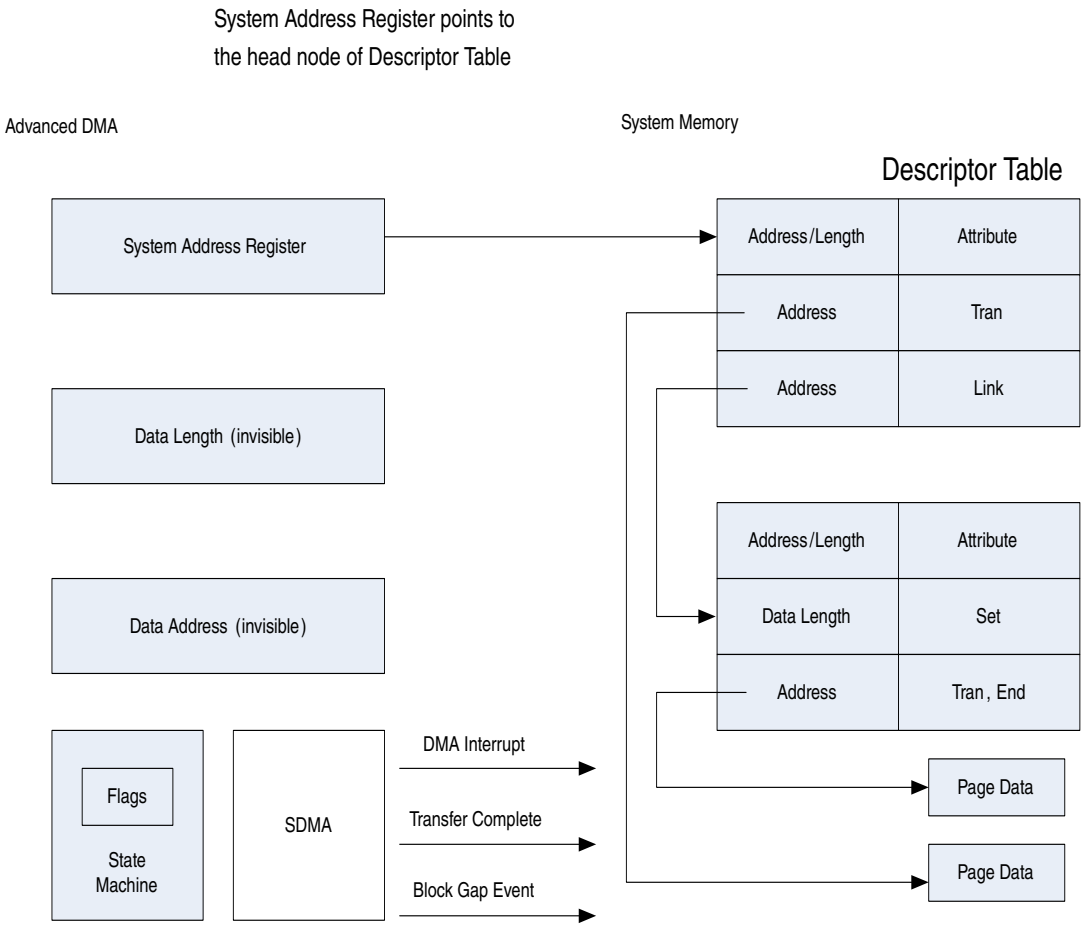

**Figure 63-9. Concept and Access Method of ADMA1 Descriptor Table**

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned(lower 2-bit is always set to 0). Data length is in byte unit.

| Address Field | | Length | | Reserved | | Attribute Field | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 63 | 32 | 31 | 16 | 15 | 06 | 05 | 04 | 03 | 02 | 01 | 00 |
| 32-bit Address | | 16-bit length | | 0000000000 | | Act 2 | Act 1 | 0 | Int | End | Valid |

| Act 2 | Act1 | Symbol | Comment | Operation |
|---|---|---|---|---|
| 0 | 0 | Nop | No Operation | Don't Care |
| 0 | 1 | Rsv | Reserved | Same as Nop. Read this line and go to next one |
| 1 | 0 | Tran | Transfer Data | Transfer data with address and length set in this descriptor line |
| 1 | 1 | Link | Link Descriptor | Link to another descriptor |

| | |
|---|---|
| Valid | Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA. |
| End | End = 1 indicates current descriptor is the ending one. |
| Int | Int = 1 generates DMA Interrupt when this descriptor is processed. |

**Figure 63-10. Format of the ADMA2 Descriptor Table**

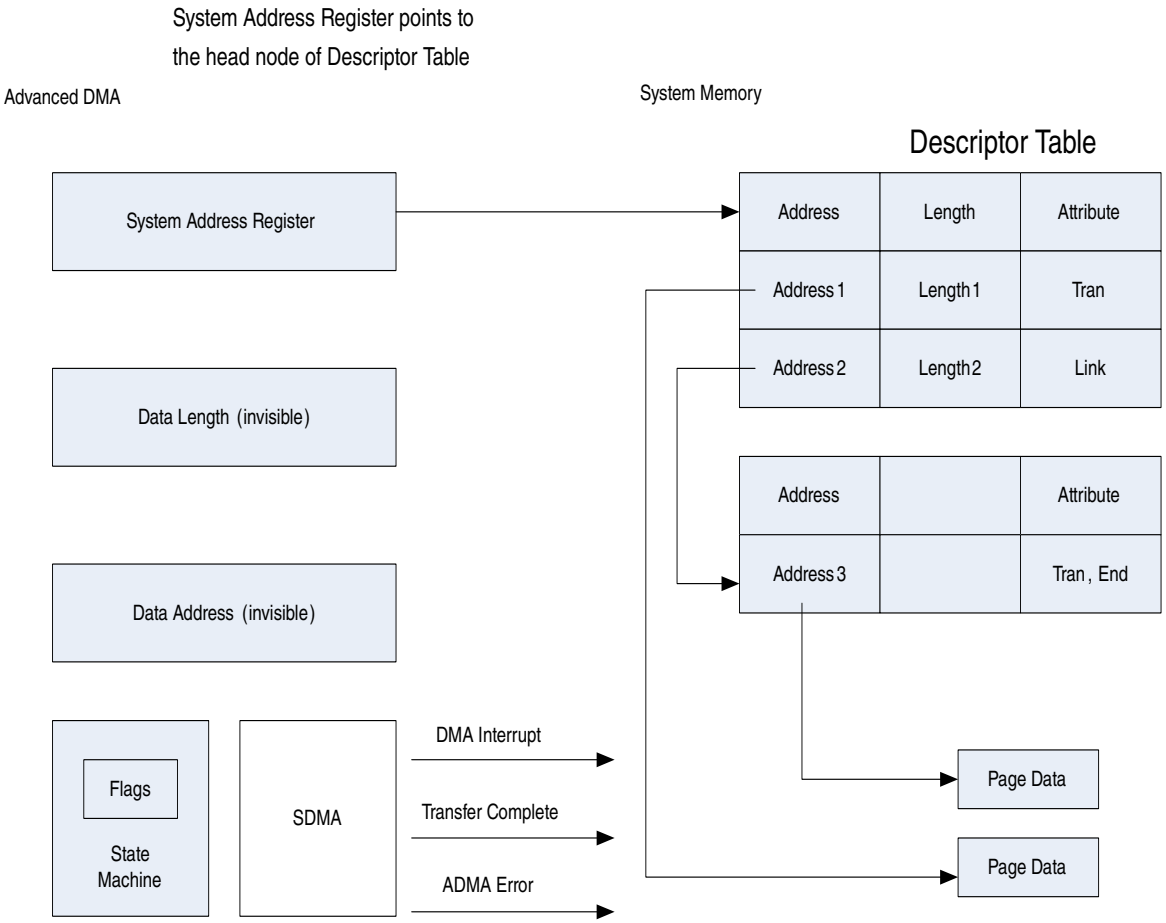

**Figure 63-11. Concept and Access Method of ADMA2 Descriptor Table**

### 63.4.2.4.2 ADMA Interrupt

If the interrupt flag descriptor is set, ADMA will generate an interrupt according to various types of descriptors:

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

#### 63.4.2.4.3 ADMA Error

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error will be generated when it fails to detect a 'Valid' flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

When BLKCNTEN bit is not set, then whole data length set in descriptor should be a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors will occur.

### 63.4.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank.

See the figure below for the block diagram.

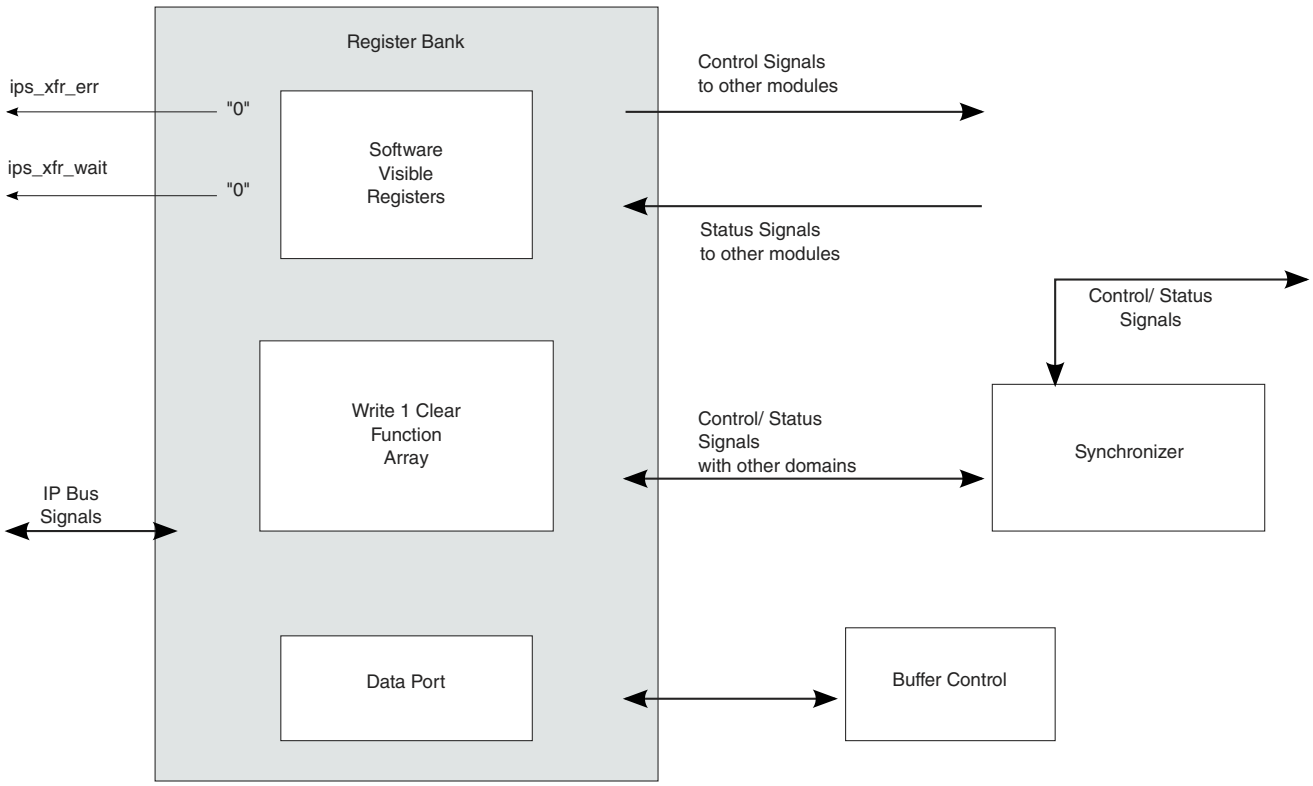

**Figure 63-12. Register Bank Diagram**

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

### 63.4.3.1 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub modules:

1. SD control misc.

2. Command control.
3. Data control.
4. Clock control

### 63.4.3.2 SD control misc

In the SD control misc unit, the card detect(include the CD_B and DATA3 used as Card Detection), write protection and card interrupt are implemented.

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The module also detects the WP (Write Protect) line. If WP is active, writes to the register bank will be ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

### 63.4.3.3 SD Clock control

If the internal data buffer is near full(for read) or near empty(for write), the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer has space(for read) or has data(for write), the clock gate of this module will open and the SD clock will be active again.

### 63.4.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC Shift Register.

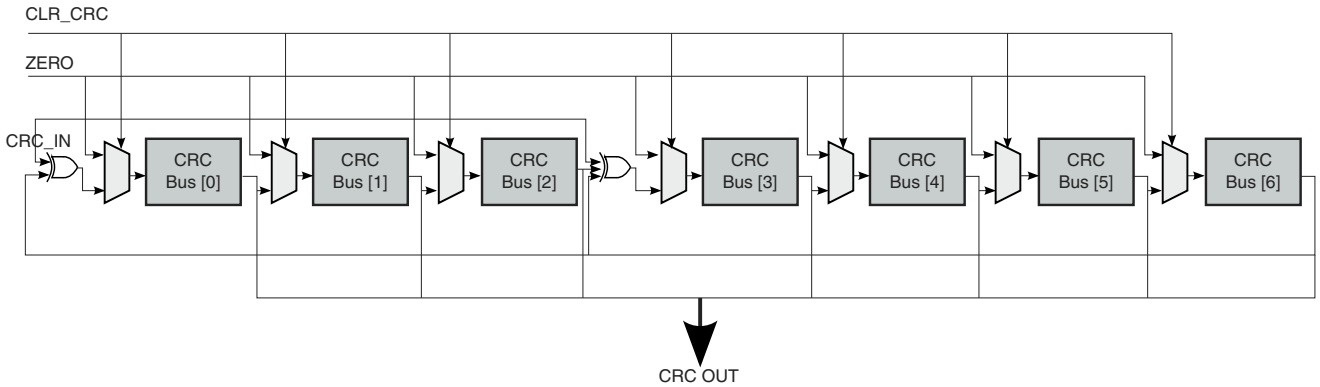

**Figure 63-13. Command CRC Shift Register**

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

### 63.4.3.5 Data control

The Data Agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the Read Wait state by the request from the Transceiver.

The CRC polynomials for the DATA are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

## 63.4.4 Clock & Reset Manager

This module controls all the reset signals within the uSDHC.

There are four kinds of reset signals within uSDHC:

1. Hardware reset.
2. Software reset for all logic.
3. Software reset for the data logic.
4. Software reset for the command logic.

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

## 63.4.5 Clock Generator

The Clock Generator generates the card CLK by peripheral source clock in two stages.

Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

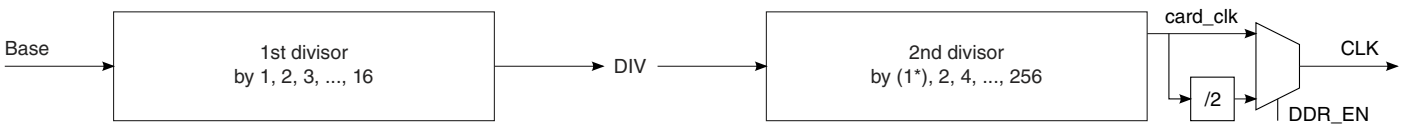

**Figure 63-14. Two Stages of the Clock Divider**

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual internal working clock (card_clk). This clock is the driving clock for all sub modules of the SD Protocol Unit, and the sync FIFOs (see Figure 63-3) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4,..., or DIV/256. Thus the highest frequency of the card_clk is Base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of Base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

Please note, in SDR mode and DDR mode, the CLK are different.

- In SDR mode, CLK is equal to the internal working clock(card_clk).

- In DDR mode, CLK is equal to the card_clk/2.

## 63.4.6 SDIO Card Interrupt

Information on Interrupts in 1-bit Mode, Interrupts in 4-bit Mode, and Card Interrupt Handling are detailed in the sections below.

### 63.4.6.1 Interrupts in 1-bit Mode

In this case the DATA1 pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

### 63.4.6.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The uSDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line will be held low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the Interrupt Period, the card releases the DATA1 line into the high Z state. The uSDHC samples the DATA1 during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

### 63.4.6.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the uSDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. In 1-bit mode, the uSDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the

SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1, and the uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

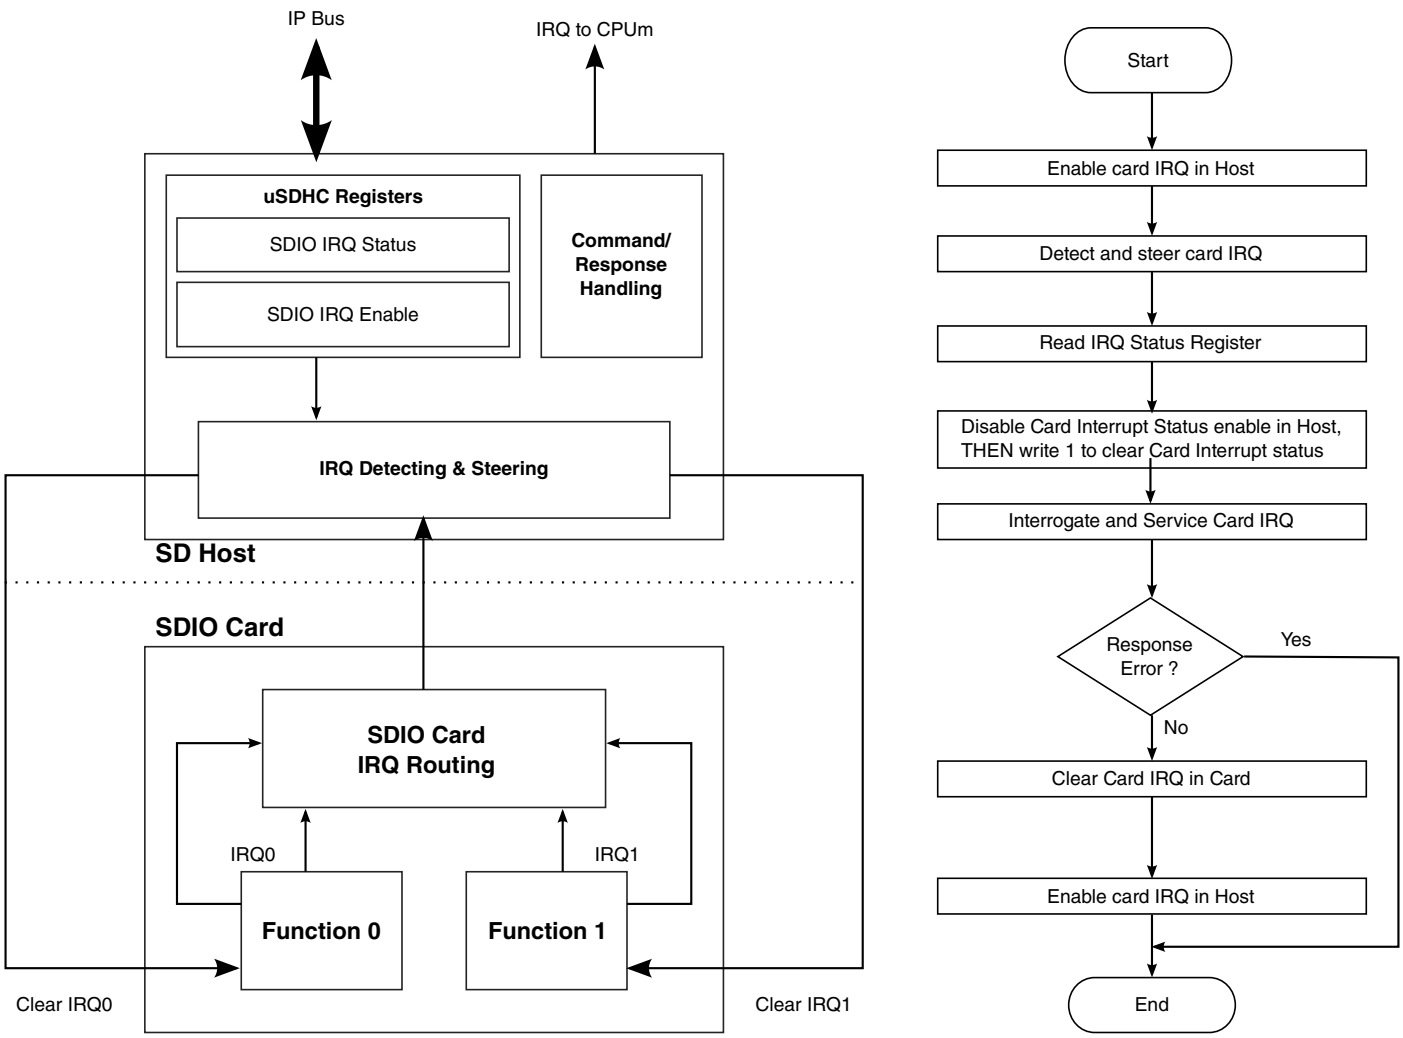

**Figure 63-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure**

### 63.4.7 Card Insertion and Removal Detection

The uSDHC uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 will be pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, the uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, the uSDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

### 63.4.8 Power Management and Wake Up Events

When there is no operation between the uSDHC and the card through the SD bus, the user can completely disable the ipg_clk and ipg_perclk in the chip level clock control module to save power. When the user needs to use the uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the uSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The uSDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register, the clocks are gated in the low position to the uSDHC. For maximum power saving, the user can disable all the clocks to the uSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

**NOTE**

To make the interrupt a wakeup event, when all the clocks to the uSDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be

set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

#### 63.4.8.1 Setting Wake Up Events

For the uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

### 63.4.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature which requires hardware support. There are two types of fast boot mode, boot operation, and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

**NOTE**

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

#### 63.4.9.1 Boot operation

**NOTE**

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

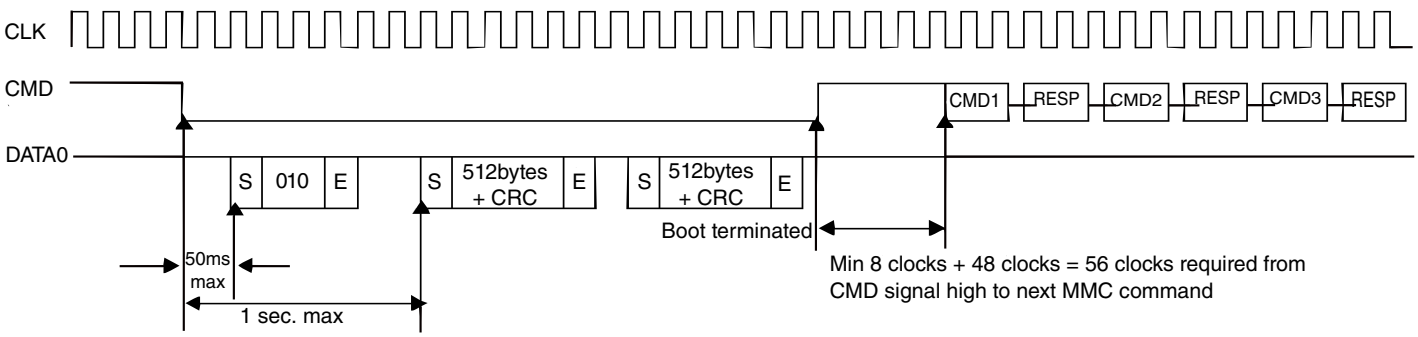

**Figure 63-16. MultiMediaCard state diagram (normal boot mode)**

### 63.4.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

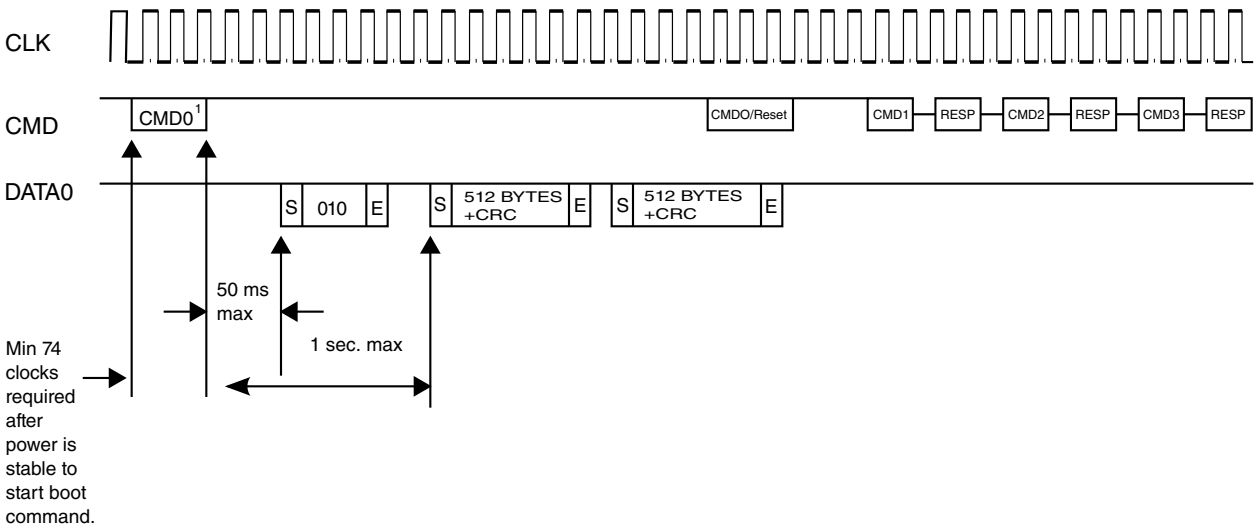
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, theslave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE 1. CMD0 with argument 0xFFFFFFFA

**Figure 63-17. MultiMediaCard state diagram (alternative boot mode)**

## 63.5 Initialization/Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, ALL_SEND_CID. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

### 63.5.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver will deal with "fake" errors like this with caution.

### 63.5.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

#### 63.5.2.1 Card Detect

See the figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the uSDHC.

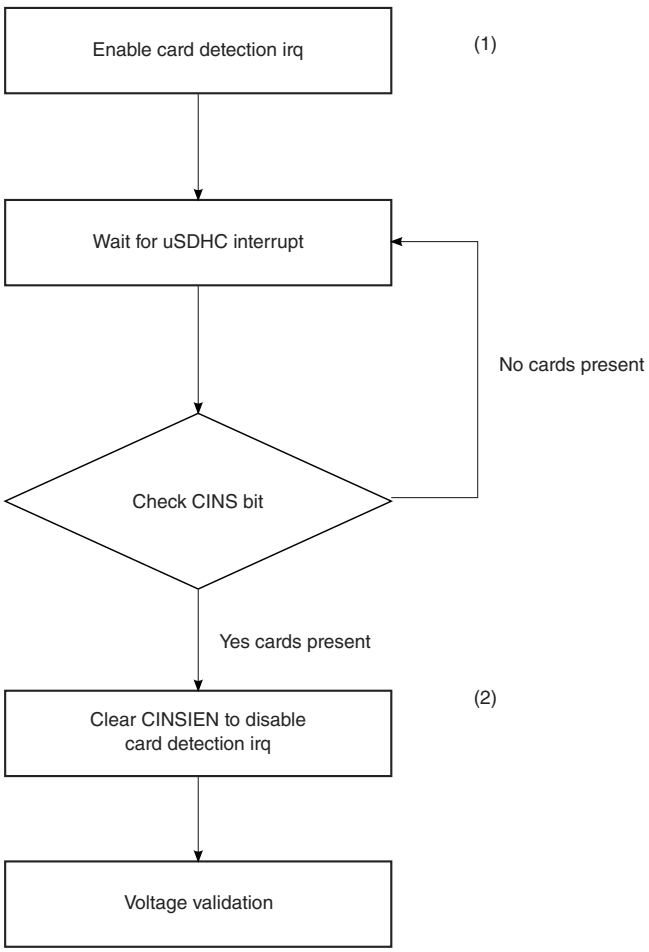


**Figure 63-18. Flow Diagram for Card Detection**

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

### 63.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)

- Software reset (Host Only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both the uSDHC and the card.

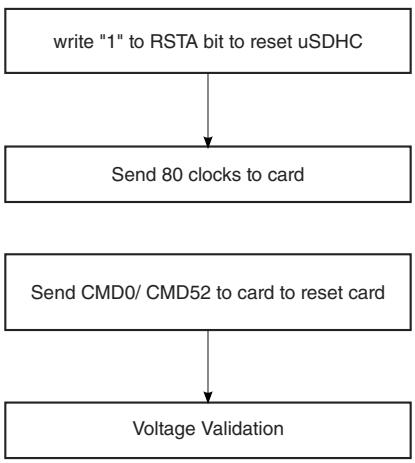

**Figure 63-19. Flow Chart for Reset of the uSDHC and SD I/O Card**

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

### 63.5.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for Vdd are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card  if (card is already labelled as SDCombo)
{ //
change label
```

```
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
} // of else
}
```

### 63.5.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different. For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards

(the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC) {
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

## 63.5.3 Card Access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

### 63.5.3.1 Block Write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

#### 63.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DATA line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DATA line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DATA to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET_BLOCKLEN (CMD16)
- For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

#### 63.5.3.1.2 DDR Write

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

#### 63.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the Stop At Block Gap Request(SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16)
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the uSDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The uSDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to

send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

### 63.5.3.2 Block Read

Information about Normal Read, DDR Read, Read with Pause, and DLL (Delay Line) in Read Path are detailed in the sections below.

#### 63.5.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16)
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

#### 63.5.3.2.2 DDR Read

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

#### 63.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the uSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in Normal Read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16)
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

5. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the uSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the uSDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the uSDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

#### 63.5.3.2.4 DLL (Delay Line) in Read Path

The DLL(Delay Line) is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT).

The reasons why the DLL is needed for uSDHC are 1.) the path of read data traveling from card to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL will automatically adjust the number of delay cells according to target value set by user and PVT changes. Be aware that target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns, setting target value of 16 means 5ns =(16/32)*10ns. Software can disable automatic update by setting dll_gate_update bit.

Since the user may change the frequency of the card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. The following is the correct flow, which should be ignored if DLL_CTRL_ENABLE is not set.

Step 1: Set DLL_CTRL_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: clear DLL_CTRL_RESET bit

Step 5: Wait until both DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: set DLL_CTRL_SLV_FORCE_UPD

Step 7: clear DLL_CTRL_SLV_FORCE_UPD

**NOTE**

Software should make sure the DLL_CTRL_SLV_FORCE_UPD is lasted for at least one card_clk. So software may need to add some delay between Step6 and Step7.

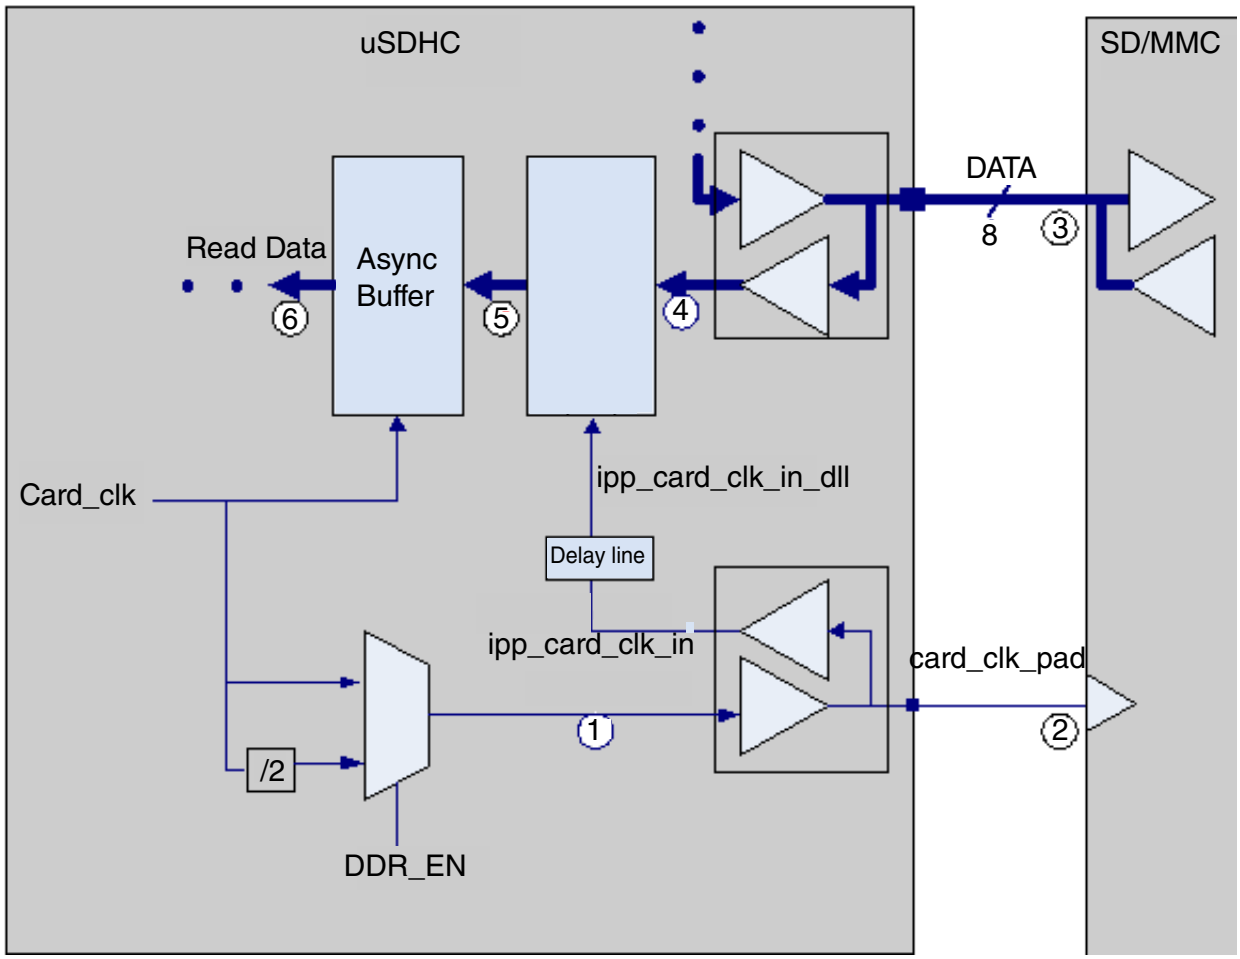

**Figure 63-20. DLL(Delay Line) in Read Path**

### 63.5.3.3 Suspend Resume

The uSDHC supports the Suspend Resume operations of SDIO cards, although slightly differently than the suggested implementation of Suspend in the SDIO card specification.

#### 63.5.3.3.1 Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the Driver shall not mark the Suspend command as a "Suspend", (i.e. setting the CMDTYP bits to 01). Instead, the Driver shall send this command as if it were a normal command, and only

when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform the uSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

#### 63.5.3.3.2 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

### 63.5.3.4 ADMA Usage

To use the ADMA in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.

4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

#### 63.5.3.5 Transfer Error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 Errors are detailed in the sections below.

##### 63.5.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the uSDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

##### 63.5.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs.

The start address can be calculated by either:

1. Reading the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the

next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Reading the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

#### 63.5.3.5.3 Transfer ADMA Error

There are 3 kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

#### 63.5.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

#### 63.5.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DATA1 line during some special period. The uSDHC only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the uSDHC, and the Host System is informed by the uSDHC asserting the uSDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to Card Interrupt Handling for the card interrupt handling flow.

### 63.5.4 Switch Function

A switch command shall be issued by the Host Driver to enable new features added to the SD/MMC spec. SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed mode are also defined. To enable these features, a switch command shall be issued by the Host Driver.

For SDIO cards, the high speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards , the high speed mode/HS200 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit ,DDR4-bit and DDR8-bit width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

### 63.5.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

### 63.5.4.2 Query, Enable and Disable SD High Speed Mode/SDR50/ SDR104/DDR50

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100Mhz for SDR50, 200Mhz for SDR104, 50Mhz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
```

```
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

### 63.5.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

### 63.5.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

## 63.5.5 ADMA Operation

Code for ADMA1 Operation and ADMA2 Operation can be found here.

### 63.5.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

### 63.5.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

## 63.5.6 Fast Boot Operation

### 63.5.6.1 Normal fast boot flow

1. Software must configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If the data will be sent through DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept at the default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.
7. DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt will be triggered, and software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
10. Reset the host and then can begin the normal process.

### 63.5.6.2 Alternative fast boot flow

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
7. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host will send out the interrupt and software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process..
8. If there is no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

### 63.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow is described below:

1. Software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1).Here VALUE1 is the value of the block count that needs to transfer the first time, so that that the hostwill stop at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. Software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enbable ADMA2 by configuring Protocol Control Register bits [9-8].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (ie, in IRAM, at least 6 word). The first pair descriptor define the start address (ie, IRAM)and data length(ie,512byte*VALUE1) of fisrt part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word(record as VALUE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data_length data transfer descriptor.
7. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot, and don't need set in normal fast boot.
8. Software needs to configure Transfer Type Register to start the boot process . CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure blk no in Bock Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.
9. When the step 8 is configured, boot process will begin, the first VALUE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.

10. When TC, BGE bit is 1, . SW can analyzes the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code(VALUE3 the remain boot code block). Remeber set the last descriptor with END.
11. Software needs to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the *(BLK_CNT - (VALUE1+1+VALUE3))*, that host will stop at block gap when *the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9*. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequence. Please note, Software doesn't need to configure the *BLK_CNT* again, because it's counted down automatically by the uSDHC controller.
12. Software needs to clear TC and BGE bit. And software needs to clear SABGREQ(bit 16 in Protocol control register), and set CREQ(bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow is started, for uSDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

## 63.6 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards can be found here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DATA.
4. addressed (point-to-point) data transfer commands (adtc).

Response: a response is a token which is sent from the card to the host as an answner to a previously received command. A response is transferred serially on the CMD line.

**Table 63-3. Commands for MMC/SD/SDIO Cards**

| CMD INDEX | Type | Argument | Response type | Abbreviation | Description |
|---|---|---|---|---|---|
| CMD0 | bc | [31:0] stuff bits | - | GO_IDLE_STATE | Resets all MMC and SD memory cards to idle state. |
| CMD1 | bcr | [31:0] OCR without busy | R3 | SEND_OP_COND | Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line. |
| CMD2 | bcr | [31:0] stuff bits | R2 | ALL_SEND_CID | Asks all cards to send their CID numbers on the CMD line. |
| CMD3[1] | ac | [31:6] RCA<br>[15:0] stuff bits | R1<br>R6 (SDIO) | SET/ SEND_RELATIVE_ADDR | Assigns relative address to the card. |
| CMD4 | bc | [31:0] DSR<br>[15:0] stuff bits | - | SET_DSR | Programs the DSR of all cards. |
| CMD5 | bc | [31:0] OCR without busy | R4 | IO_SEND_OP_COND | Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line. |
| CMD6[2] | adtc | [31] Mode<br>0: Check function<br>1: Switch function<br>[30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF)<br>[7:4] Function group1 for command system<br>[3:0] Function group2 for access mode | R1 | SWITCH_FUNC | Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details. |
| CMD6[3] | ac | [31:26] Set to 0<br>[25:24] Access<br>[23:16] Index<br>[15:8] Value<br>[7:3] Set to 0<br>[2:0] Cmd Set | R1b | SWITCH | Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details. |
| CMD7 | ac | [31:6] RCA<br>[15:0] stuff bits | R1b | SELECT/ DESELECT_CARD | Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all. |

*Table continues on the next page...*

## Table 63-3. Commands for MMC/SD/SDIO Cards (continued)

| CMD INDEX | Type | Argument | Response type | Abbreviation | Description |
|---|---|---|---|---|---|
| CMD8 | adtc | [31:0] stuff bits | R1 | SEND_EXT_CSD | The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes. |
| CMD9 | ac | [31:6] RCA<br>[15:0] stuff bits | R2 | SEND_CSD | Addressed card sends its card-specific data (CSD) on the CMD line. |
| CMD10 | ac | [31:6] RCA<br>[15:0] stuff bits | R2 | SEND_CID | Addressed card sends its card-identification (CID) on the CMD line. |
| CMD11 | adtc | [31:0] data address | R1 | READ_DAT_UNTIL_STOP | Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows. |
| CMD12 | ac | [31:0] stuff bits | R1b | STOP_TRANSMISSION | Forces the card to stop transmission. |
| CMD13 | ac | [31:6] RCA<br>[15:0] stuff bits | R1 | SEND_STATUS | Addressed card sends its status register. |
| CMD14 | Reserved | | | | |
| CMD15 | ac | [31:6] RCA<br>[15:0] stuff bits | - | GO_INACTIVE_STATE | Sets the card to inactive state in order to protect the card stack against communication breakdowns. |
| CMD16 | ac | [31:0] block length | R1 | SET_BLOCKLEN | Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD. |
| CMD17 | adtc | [31:0] data address | R1 | READ_SINGLE_BLOCK | Reads a block of the size selected by the SET_BLOCKLEN command. |
| CMD18 | adtc | [31:0] data address | R1 | READ_MULTIPLE_BLOCK | Continuously transfers data blocks from card to host until interrupted by a stop command. |
| CMD19 | Reserved | | | | |
| CMD20 | adtc | [31:0] data address | R1 | WRITE_DAT_UNTIL_STOP | Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows. |
| CMD21 | adtc | [31:0] stuff bits | R1 | SEND_TUNING_BLOCK | 128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection. |
| CMD22-23 | Reserved | | | | |
| CMD24 | adtc | [31:0] data address | R1 | WRITE_BLOCK | Writes a block of the size selected by the SET_BLOCKLEN command. |
| CMD25 | adtc | [31:0] data address | R1 | WRITE_MULTIPLE_BLOCK | Continuously writes blocks of data until a STOP_TRANSMISSION follows. |
| CMD26 | adtc | [31:0] stuff bits | R1 | PROGRAM_CID | Programming of the card identification register. This command shall be issued only |

*Table continues on the next page...*

## Table 63-3. Commands for MMC/SD/SDIO Cards (continued)

| CMD INDEX | Type | Argument | Response type | Abbreviation | Description |
|---|---|---|---|---|---|
| | | | | | once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer. |
| CMD27 | adtc | [31:0] stuff bits | R1 | PROGRAM_CSD | Programming of the programmable bits of the CSD. |
| CMD28 | ac | [31:0] data address | R1b | SET_WRITE_PROT | If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE). |
| CMD29 | ac | [31:0] data address | R1b | CLR_WRITE_PROT | If the card provides write protection features, this command clears the write protection bit of the addressed group. |
| CMD30 | adtc | [31:0] write protect data address | R1 | SEND_WRITE_PROT | If the card provides write protection features, this command asks the card to send the status of the write protection bits. |
| CMD31 | Reserved | | | | |
| CMD32 | ac | [31:0] data address | R1 | TAG_SECTOR_START | Sets the address of the first sector of the erase group. |
| CMD33 | ac | [31:0] data address | R1 | TAG_SECTOR_END | Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase. |
| CMD34 | ac | [31:0] data address | R1 | UNTAG_SECTOR | Removes one previously selected sector from the erase selection. |
| CMD35 | ac | [31:0] data address | R1 | TAG_ERASE_GROUP_START | Sets the address of the first erase group within a range to be selected for erase. |
| CMD36 | ac | [31:0] data address | R1 | TAG_ERASE_GROUP_END | Sets the address of the last erase group within a continuous range to be selected for erase. |
| CMD37 | ac | [31:0] data address | R1 | UNTAG_ERASE_GROUP | Removes one previously selected erase group from the erase selection. |
| CMD38 | ac | [31:0] stuff bits | R1b | ERASE | Erase all previously selected sectors. |
| CMD39 | ac | [31:0] RCA<br>[15] register write flag<br>[14:8] register address<br>[7:0] register data | R4 | FAST_IO | Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This |

*Table continues on the next page...*

## Table 63-3. Commands for MMC/SD/SDIO Cards (continued)

| CMD INDEX | Type | Argument | Response type | Abbreviation | Description |
|---|---|---|---|---|---|
| | | | | | command accesses application dependent registers which are not defined in the MMC standard. |
| CMD40 | bcr | [31:0] stuff bits | R5 | GO_IRQ_STATE | Sets the system into interrupt mode. |
| CMD41 | Reserved | | | | |
| CDM42 | adtc | [31:0] stuff bits | R1b | LOCK_UNLOCK | Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command. |
| CMD43~51 | Reserved | | | | |
| CMD52 | ac | [31:0] stuff bits | R5 | IO_RW_DIRECT | Access a single register within the total 128k of register space in any I/O function. |
| CMD53 | ac | [31:0] stuff bits | R5 | IO_RW_EXTENDED | Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers. |
| CMD54 | Reserved | | | | |
| CMD55 | ac | [31:16] RCA<br>[15:0] stuff bits | R1 | APP_CMD | Indicates to the card that the next command is an application specific command rather that a standard command. |
| CMD56 | adtc | [31:1] stuff bits<br>[0]: RD/WR | R1b | GEN_CMD | Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command. |
| CMD57-59 | Reserved | | | | |
| CMD60 | adtc | [31] WR<br>[30:24] stuff bits<br>[23:16] address<br>[15:8] stuff bits<br>[7:0] byte count | R1b | RW_MULTIPLE_REGISTER | These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers. |
| CMD61 | adtc | [31] WR<br>[30:16] stuff bits<br>[15:0] data unit count | R1b | RW_MULTIPLE_BLOCK | The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer. |
| CMD62-63 | Reserved | | | | |
| ACMD6[4] | ac | [31:2] stuff bits<br>[1:0] bus width | R1 | SET_BUS_WIDTH | Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register. |

*Table continues on the next page...*

**Table 63-3. Commands for MMC/SD/SDIO Cards (continued)**

| CMD INDEX | Type | Argument | Response type | Abbreviation | Description |
|---|---|---|---|---|---|
| ACMD13[4] | adtc | [31:0] stuff bits | R1 | SD_STATUS | Send the SD Memory Card status. |
| ACMD22[4] | adtc | [31:0] stuff bits | R1 | SEND_NUM_WR_SECTORS | Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block. |
| ACMD23[4] | ac | [31:23] stuff bits<br>[22:0] Number of blocks | R1 | SET_WR_BLK_ERASE_COUNT | Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block). |
| ACMD41[4] | bcr | [31:0] OCR | R3 | SD_APP_OP_COND | Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line. |
| ACMD42[4] | ac | [31:1] stuff bits<br>[0] set_cd | R1 | SET_CLR_CARD_DETECT | Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card. |
| ACMD51[4] | adtc | [31:0] stuff bits | R1 | SEND_SCR | Reads the SD Configuration Register (SCR). |

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards . The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 2.
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT_CSD Access Modes are shown below.

**Table 63-4. EXT_CSD Access Modes**

| Bits | Access Name | Operation |
|---|---|---|
| 00 | Command Set | The command set is changed according to the Cmd Set field of the argument |
| 01 | Set Bits | The bits in the pointed byte are set, according to the 1 bits in the Value field. |
| 10 | Clear Bits | The bits in the pointed byte are cleared, according to the 1 bits in the Value field. |
| 11 | Write Byte | The Value field is written into the pointed byte. |

# 63.7 Software Restrictions

### 63.7.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared.

### 63.7.2 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

### 63.7.3 Suspend Operation

In order to suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended trasnfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, uSDHC will regard the current transfer is aborted and change BLKCNT register to its original value, instead of keeping the remained number of blocks.

### 63.7.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

### 63.7.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

### 63.7.6 Data Port Access

Data Port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or internal DMA. Otherwise the data would be corrupted inside the uSDHC buffer.

### 63.7.7 Change Clock Frequency

uSDHC does not automatically gate off the card clock when the Host Driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing clock divisor value(SDCLKFS or DVS in System Control Register) or setting RSTA bit.

Also before changing the clock divisor value, Host Driver should make sure the SDSTB bit is high.

### 63.7.8 Multi-block Read

For pre-defined multi-block read operation, i.e., the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

## 63.8 uSDHC Memory Map/Register Definition

## 63.8.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map for the uSDHC. All these registers only support 32-bit accesses.

**NOTE**

The uSDHC registers are 32-bit wide and only support 32-bit access.

### 63.8.1.1 uSDHC Memory map

USDHC0 base address: 4003_E000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | DMA System Address (DS_ADDR) | 32 | RW | 0000_0000h |
| 4h | Block Attributes (BLK_ATT) | 32 | RW | 0000_0000h |
| 8h | Command Argument (CMD_ARG) | 32 | RW | 0000_0000h |
| Ch | Command Transfer Type (CMD_XFR_TYP) | 32 | RW | 0000_0000h |
| 10h | Command Response0 (CMD_RSP0) | 32 | RO | 0000_0000h |
| 14h | Command Response1 (CMD_RSP1) | 32 | RO | 0000_0000h |

### 63.8.1.2.4 Fields

| Field | Function |
|---|---|
| 31-0<br>DS_ADDR | DS_ADDR<br>**DMA System Address / Argument 2** |

| Field | Function |
|---|---|
| | When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23.<br>1. **SDMA System Address**<br>Since the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When the uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register.<br>This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until the DLA bit in the Present State register is cleared, before writing to this register.<br>The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC will automatically change SEQ burst type to NSEQ.<br>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions.<br>2. **Argument 2**<br>This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23.<br>If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case. |

## 63.8.1.3 Block Attributes (BLK_ATT)

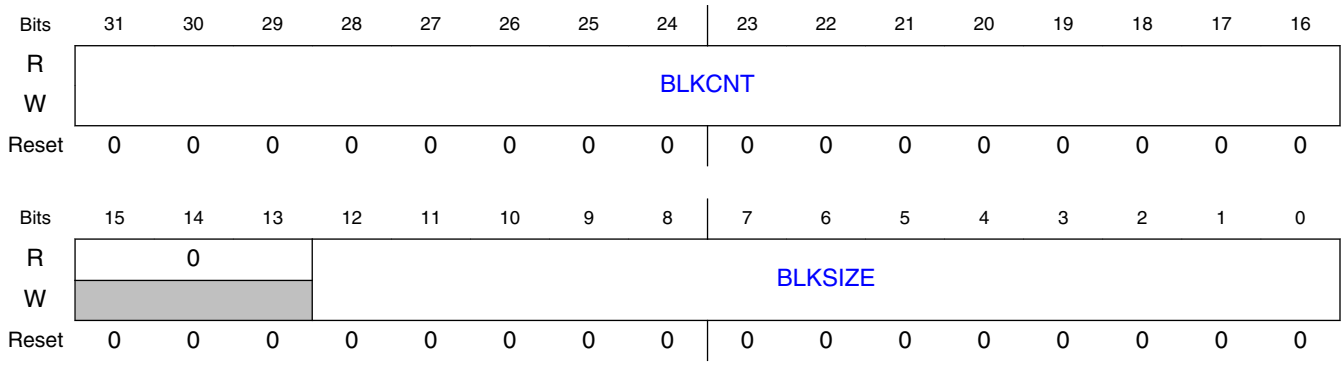
### 63.8.1.3.1 Offset

| Register | Offset |
|---|---|
| BLK_ATT | 4h |

### 63.8.1.3.2 Function

This register is used to configure the number of data blocks and the number of bytes in each block.

### 63.8.1.3.3 Diagram



### 63.8.1.3.4 Fields

| Field | Function |
|---|---|
| 31-16<br>BLKCNT | Block Count<br>Blocks Count For Current Transfer:<br>This register is enabled when the Block Count Enable bit in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The uSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.<br>This register should be accessed only when no transaction is executing (i.e. after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.<br>When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when Suspend command is sent out, uSDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count.<br>When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count.<br>**NOTE:** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL bit is indicating a single block transfer, the read value of BLKCNT is always 1.<br>0000000000000000b - Stop Count<br>0000000000000001b - 1 block<br>0000000000000010b - 2 blocks<br>1111111111111111b - 65535 blocks |

| Field | Function |
|---|---|
| | This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored.<br>0000000000000b - No data transfer<br>0000000000001b - 1 Byte<br>0000000000010b - 2 Bytes<br>0000000000011b - 3 Bytes<br>0000000000100b - 4 Bytes<br>0000111111111b - 511 Bytes<br>0001000000000b - 512 Bytes<br>0100000000000b - 2048 Bytes<br>1000000000000b - 4096 Bytes |

## 63.8.1.4 Command Argument (CMD_ARG)

### 63.8.1.4.1 Offset

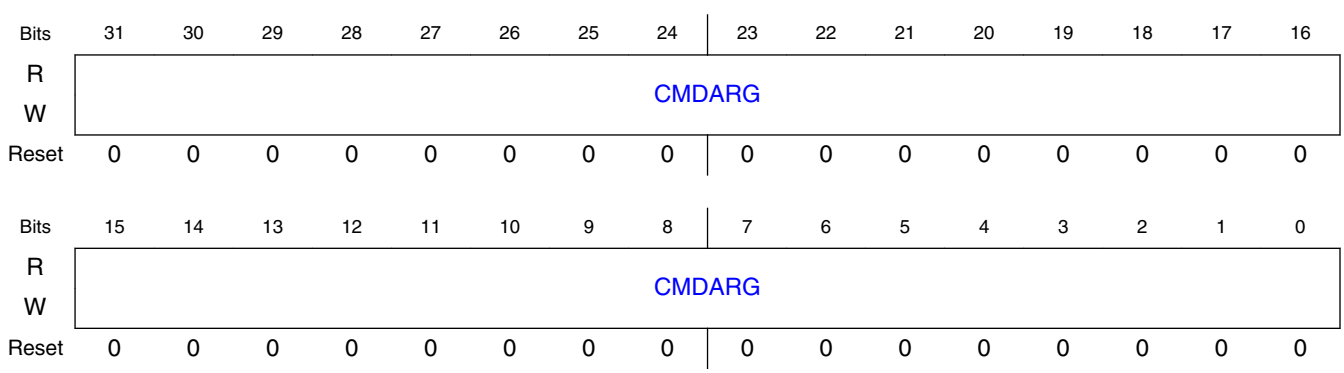
| Register | Offset |
|---|---|
| CMD_ARG | 8h |

### 63.8.1.4.2 Function

This register contains the SD / MMC Command Argument.

.

### 63.8.1.4.3 Diagram



#### 63.8.1.4.4 Fields

| Field | Function |
|---|---|
| 31-0<br>CMDARG | Command Argument<br>The SD / MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification.This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set. |

### 63.8.1.5 Command Transfer Type (CMD_XFR_TYP)

#### 63.8.1.5.1 Offset

| Register | Offset |
|---|---|
| CMD_XFR_TYP | Ch |

#### 63.8.1.5.2 Function

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the uSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer invovled, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1'), otherwise uSDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, i.e., response time-out, uSDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to

re-try the transfer. It is also possible that for some reason the card responds the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

**Table 63-5. Transfer Type Register Setting for Various Transfer Types**

| Multi/Single Block Select | Block Count Enable | Block Count | Function |
|---|---|---|---|
| 0 | Don't Care | Don't Care | Single Transfer |
| 1 | 0 | Don't Care | Infinite Transfer |
| 1 | 1 | Positive Number | Multiple Transfer |
| 1 | 1 | Zero | No Data Transfer |

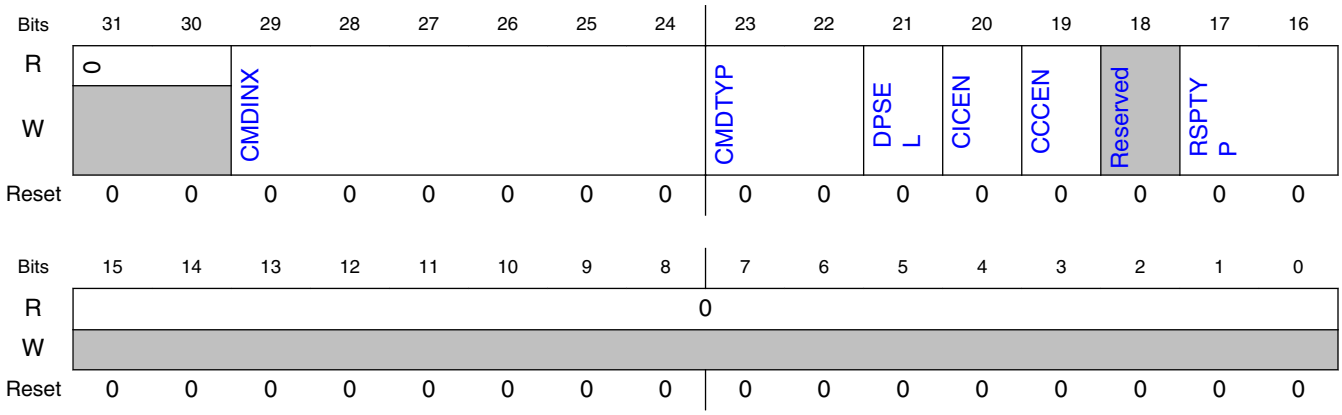
The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits as well as the name of the response type.

**Table 63-6. Relationship Between Parameters and the Name of the Response Type**

| Response Type | Index Check Enable | CRC Check Enable | Name of Response Type |
|---|---|---|---|
| 00 | 0 | 0 | No Response |
| 01 | 0 | 1 | R2 |
| 10 | 0 | 0 | R3,R4 |
| 10 | 1 | 1 | R1,R5,R6 |
| 11 | 1 | 1 | R1b,R5b |

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the uSDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

### 63.8.1.5.3 Diagram



### 63.8.1.5.4 Fields

| Field | Function |
|---|---|
| 31-30<br>— | -<br>Reserved |
| 29-24<br>CMDINX | Command Index<br>These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification. |
| 23-22<br>CMDTYP | Command Type<br>There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands.<br>• Suspend Command: If the Suspend command succeeds, the uSDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DATA line. Since the uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the Host Driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the uSDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, the uSDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the uSDHC will maintain its current state, and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.<br>• Resume Command: The Host Driver re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The uSDHC will check for a pending busy state before starting write transfers.<br>• Abort Command: If this command is set when executing a read transfer, the uSDHC will stop reads to the buffer. If this command is set when executing a write transfer, the uSDHC will stop driving the DATA line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction).<br>00b - Normal Other commands<br>01b - Suspend CMD52 for writing Bus Suspend in CCCR<br>10b - Resume CMD52 for writing Function Select in CCCR<br>11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR |

## 63.8.1.9 Command Response3 (CMD_RSP3)

### 63.8.1.9.1 Offset

| Register | Offset |
|---|---|
| CMD_RSP3 | 1Ch |

### 63.8.1.9.2 Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD Bus.

**Table 63-7. Response Bit Definition for Each Response Type**

| Response Type | Meaning of Response | Response Field | Response Register |
|---|---|---|---|
| R1,R1b (normal response) | Card Status | R[39:8] | CMDRSP0 |

*Table continues on the next page...*

**Table 63-7. Response Bit Definition for Each Response Type (continued)**

| Response Type | Meaning of Response | Response Field | Response Register |
|---|---|---|---|
| R1b (Auto CMD12 response) | Card Status for Auto CMD12 | R[39:8] | CMDRSP3 |
| R2 (CID, CSD register) | CID/CSD register [127:8] | R[127:8] | {CMDRSP3[23:0],<br>CMDRSP2,<br>CMDRSP1,<br>CMDRSP0} |
| R3 (OCR register) | OCR register for memory | R[39:8] | CMDRSP0 |
| R4 (OCR register) | OCR register for I/O etc. | R[39:8] | CMDRSP0 |
| R5, R5b | SDIO response | R[39:8] | CMDRSP0 |
| R6 (Publish RCA) | New Published RCA[31:16] and card status[15:0] | R[39:9] | CMDRSP0 |

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the uSDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the uSDHC will check R[47:1], and if the response length is 136 the uSDHC will check R[119:1].

Since the uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows the uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

### 63.8.1.9.3 Diagram

| 31-0<br>DATCONT | Data Content<br>The Buffer Data Port register is for 32-bit data access by the ARM platform. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s. |

## 63.8.1.11 Present State (PRES_STATE)

### 63.8.1.11.1 Offset

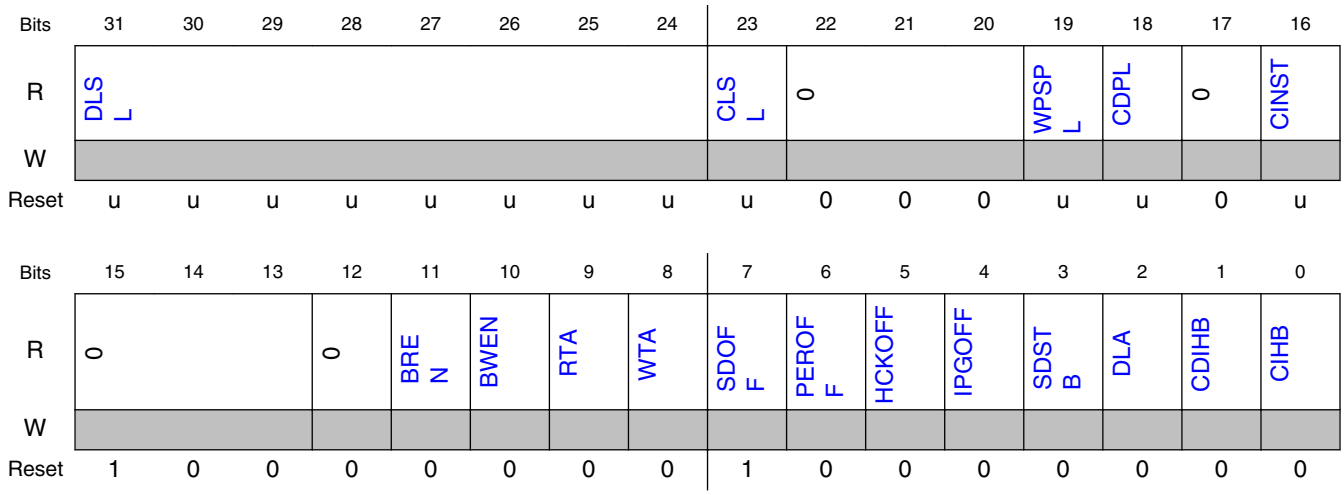
| Register | Offset |
|---|---|
| PRES_STATE | 24h |

### 63.8.1.11.2 Function

The Host Driver can get status of the uSDHC from this 32-bit read only register.

- The Host Driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.
- Note: the reset value of Present State Register depend on board connectivity.

## 63.8.1.11.3 Diagram



## 63.8.1.11.4 Fields

| Field | Function |
|---|---|
| 31-24<br>DLSL | DATA[7:0] Line Signal Level<br>This status is used to check the DATA line level to recover from errors, and for debugging.This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up.<br>00000000b - Data 0 line signal level<br>00000001b - Data 1 line signal level<br>00000010b - Data 2 line signal level<br>00000011b - Data 3 line signal level<br>00000100b - Data 4 line signal level<br>00000101b - Data 5 line signal level<br>00000110b - Data 6 line signal level<br>00000111b - Data 7 line signal level |
| 23<br>CLSL | CMD Line Signal Level<br>This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up. |
| 22-20<br>— | -<br>Reserved |
| 19<br>WPSPL | Write Protect Switch Pin Level<br>The Write Protect Switch is supported for memory and combo cards.This bit reflects the inverted value of the WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled.<br>0b - Write protected (WP = 1)<br>1b - Write enabled (WP = 0) |
| 18 | Card Detect Pin Level |

*Table continues on the next page...*

| Field | Function |
|---|---|
| CDPL | This bit reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the CD_B pin (i.e. when a card is inserted in the socket, it is 0 on the CD_B input, and consequently the CDPL reads 1.)<br>0b - No card present (CD_B = 1)<br>1b - Card present (CD_B = 0) |
| 17<br>— | -<br>Reserved |
| 16<br>CINST | Card Inserted<br>This bit indicates whether a card has been inserted. The uSDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit.<br>The Software Reset For All in the System Control register does not effect this bit. A software reset does not effect this bit.<br>0b - Power on Reset or No Card<br>1b - Card Inserted |
| 15-13<br>— | -<br>Reserved |
| 12<br>— | -<br>Reserved |
| 11<br>BREN | Buffer Read Enable<br>This status bit is used for non-DMA read transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when some reads from the buffer(read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this bit from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled.<br>0b - Read disable<br>1b - Read enable |
| 10<br>BWEN | Buffer Write Enable<br>This status bit is used for non-DMA write transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when some writes to the buffer(write DATPORT(Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled.<br>0b - Write disable<br>1b - Write enable |
| 9<br>RTA | Read Transfer Active<br>This status bit is used for detecting completion of a read transfer.<br>This bit is set for either of the following conditions: |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | • After the end bit of the read command.<br>• When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer.<br><br>A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions:<br><br>• When the last data block as specified by block length is transferred to the System, i.e. all data are read away from uSDHC internal buffer.<br>• When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1.<br><br>0b - No valid data<br>1b - Transferring data |
| 8<br>WTA | Write Transfer Active<br><br>This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the uSDHC.<br><br>This bit is set in either of the following cases:<br><br>• After the end bit of the write command.<br>• When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer.<br><br>This bit is cleared in either of the following cases:<br><br>• After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple).<br>• After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request.<br><br>During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state.<br><br>0b - No valid data<br>1b - Transferring data |
| 7<br>SDOFF | SD Clock Gated Off Internally<br><br>This status bit indicates that the SD Clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON bit is 0 to stop the SD clock in idle status. Set IPG_PERCLK_SOFT_EN and CARD_CLK_SOFT_EN to 0 also gate off SD clock. This bit is for the Host Driver to debug data transaction on the SD bus.<br><br>0b - SD Clock is active.<br>1b - SD Clock is gated off. |
| 6<br>PEROFF | IPG_PERCLK Gated Off Internally<br><br>This status bit indicates that the IPG_PERCLK is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK will be gated off, otherwise IPG_PERCLK will be always active.<br><br>0b - IPG_PERCLK is active.<br>1b - IPG_PERCLK is gated off. |
| 5<br>HCKOFF | HCLK Gated Off Internally<br><br>This status bit indicates that the HCLK is internally gated off. This bit is for the Host Driver to debug during a data transfer.<br><br>0b - HCLK is active.<br>1b - HCLK is gated off. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 4<br>IPGOFF | IPG_CLK Gated Off Internally<br>This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug.<br>0b - IPG_CLK is active.<br>1b - IPG_CLK is gated off. |
| 3<br>SDSTB | SD Clock Stable<br>This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON bit in System Control register to remove glitches on the card clock when the frequency is changing.<br>*Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.*<br>0b - Clock is changing frequency and not stable.<br>1b - Clock is stable. |
| 2<br>DLA | Data Line Active<br>This status bit indicates whether one of the DATA lines on the SD Bus is in use.<br>In the case of read transactions:<br>This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register.<br>This bit will be set in either of the following cases:<br>• After the end bit of the read command.<br>• When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer.<br>This bit will be cleared in either of the following cases:<br>(1) When the end bit of the last data block is sent from the SD Bus to the uSDHC.<br>(2) When the Read Wait state is stopped by a Suspend command and the DATA2 line is released.<br>The uSDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait.<br>In the case of write transactions:<br>This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register.<br>This bit will be set in either of the following cases:<br>• After the end bit of the write command.<br>• When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer.<br>This bit will be cleared in either of the following cases:<br>• When the SD card releases Write Busy of the last data block, the uSDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the uSDHC shall assume the card drive "Not Busy".<br>• When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request.<br>In the case of command with busy pending:<br>This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DATA0 line is released. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 0b - DATA Line Inactive<br>1b - DATA Line Active |
| 1<br>CDIHB | Command Inhibit (DATA)<br>This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register.<br>**NOTE:** The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.<br>0b - Can issue command which uses the DATA line<br>1b - Cannot issue command which uses the DATA line |
| 0<br>CIHB | Command Inhibit (CMD)<br>If this status bit is 0, it indicates that the CMD line is not in use and the uSDHC can issue a SD / MMC Command using the CMD line.<br>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the uSDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit.<br>0b - Can issue command using only CMD line<br>1b - Cannot issue command |

## 63.8.1.12 Protocol Control (PROT_CTRL)

### 63.8.1.12.1 Offset

| Register | Offset |
|---|---|
| PROT_CTRL | 28h |

### 63.8.1.12.2 Function

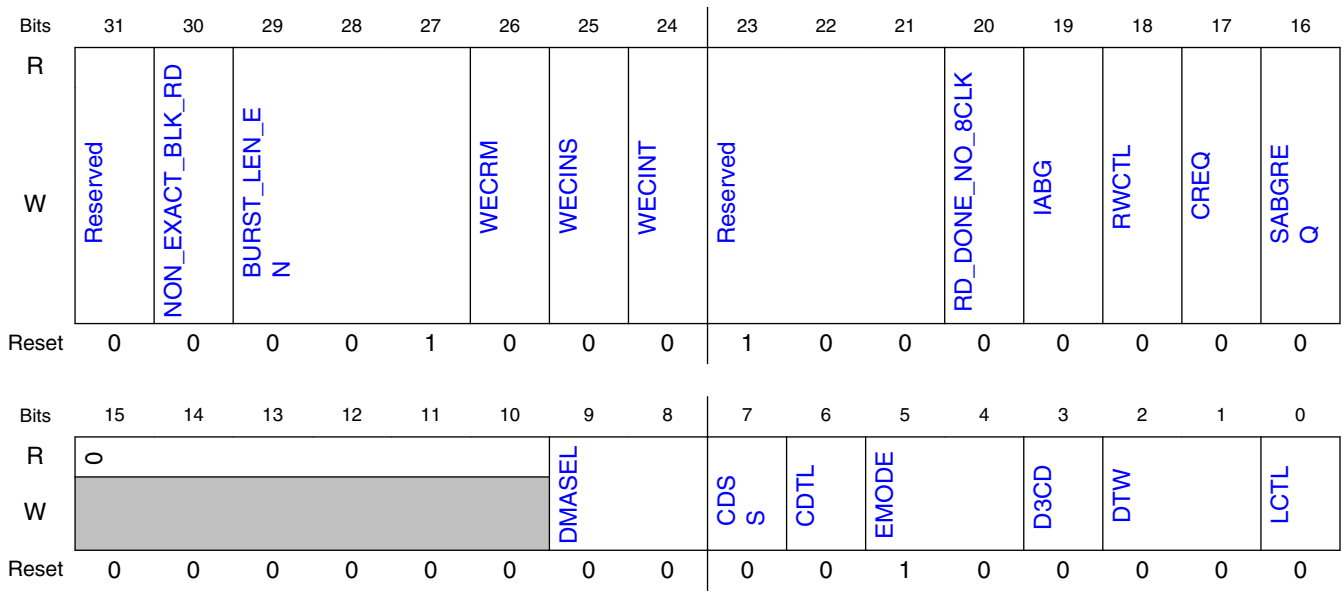
There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the uSDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request shall be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command shall be used to restart the transfer.

3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver shall wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver shall clear the Stop At Block Gap Request before or simultaneously.

### 63.8.1.12.3 Diagram



### 63.8.1.12.4 Fields

| Field | Function |
|---|---|
| 31<br>— | -<br>Reserved. Always write as 0 |
| 30<br>NON_EXACT_BLK_RD | NON_EXACT_BLK_RD<br>Current block read is non-exact block read. It is only used for SDIO.<br>0b - The block read is exact block read. Host driver doesn't need to issue abort command to terminate this multi-block read.<br>1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read. |
| 29-27<br>BURST_LEN_EN | BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP<br>This is used to enable / disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLEs on the AXI side. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 1xxb - Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP<br>x1xb - Burst length is enabled for INCR4 / INCR8 / INCR16<br>xx1b - Burst length is enabled for INCR |
| 26<br>WECRM | Wakeup Event Enable On SD Card Removal<br>This bit enables a wakeup event, via a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Removal Status and the uSDHC interrupt.<br>0b - Disable<br>1b - Enable |
| 25<br>WECINS | Wakeup Event Enable On SD Card Insertion<br>This bit enables a wakeup event, via a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Insertion Status and the uSDHC interrupt.<br>0b - Disable<br>1b - Enable |
| 24<br>WECINT | Wakeup Event Enable On Card Interrupt<br>This bit enables a wakeup event, via a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Interrupt Status and the uSDHC interrupt.<br>0b - Disable<br>1b - Enable |
| 23-21<br>— | -<br>Reserved. Always write as 3'b100 |
| 20<br>RD_DONE_NO_8CLK | RD_DONE_NO_8CLK<br>*Read done no 8 clock:*<br>*According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end bit of the last data block. So, by default(RD_DONE_NO_8CLK=0), 8 clocks will be active after the end bit of the last read data transaction.*<br>*However, this 8 clocks should not be active if user wants to use stop at block gap(include the auto stop at block gap in boot mode) feature for read and the RWCTL bit(bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid this 8 clocks. Otherwise, the device may send extra data to uSDHC while uSDHC ignores these data.*<br>*In a summary, this bit should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.* |
| 19<br>IABG | Interrupt At Block Gap<br>This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.<br>0b - Disabled<br>1b - Enabled |
| 18<br>RWCTL | Read Wait Control |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise the uSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DATA line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the uSDHC will stop the SD Clock to pause reading operation.<br>0b - Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set<br>1b - Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set |
| 17<br>CREQ | Continue Request<br>This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer.<br>The uSDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored.<br>0b - No effect<br>1b - Restart |
| 16<br>SABGREQ | Stop At Block Gap Request<br>This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver shall not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the uSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver shall not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the uSDHCs behavior is undefined.<br>This bit effects Read Transfer Active, Write Transfer Active, DATA Line Active and Command Inhibit (DATA) in the Present State register.<br>0b - Transfer<br>1b - Stop |
| 15-10<br>— | -<br>Reserved |
| 9-8<br>DMASEL | DMA Select<br>This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation.<br>00b - No DMA or Simple DMA is selected<br>01b - ADMA1 is selected<br>10b - ADMA2 is selected<br>11b - reserved |
| 7<br>CDSS | Card Detect Signal Selection<br>This bit selects the source for the card detection.<br>0b - Card Detection Level is selected (for normal purpose).<br>1b - Card Detection Test Level is selected (for test purpose). |
| 6 | Card Detect Test Level |

*Table continues on the next page...*

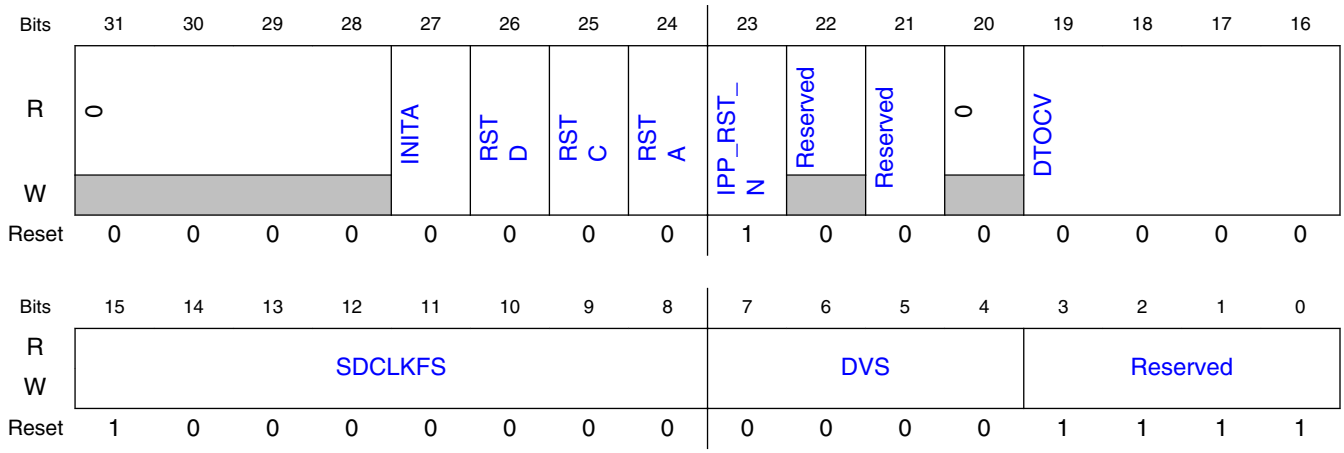
| Field | Function |
|---|---|
| CDTL | This is bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion.<br>0b - Card Detect Test Level is 0, no card inserted<br>1b - Card Detect Test Level is 1, card inserted |
| 5-4<br>EMODE | Endian Mode<br>The uSDHC supports all three endian modes in data transfer. Refer to Data Buffer for more details.<br>00b - Big Endian Mode<br>01b - Half Word Big Endian Mode<br>10b - Little Endian Mode<br>11b - Reserved |
| 3<br>D3CD | DATA3 as Card Detection Pin<br>If this bit is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the uSDHC does not support.<br>0b - DATA3 does not monitor Card Insertion<br>1b - DATA3 as Card Detection Pin |
| 2-1<br>DTW | Data Transfer Width<br>This bit selects the data width of the SD bus for a data transfer. The Host Driver shall set it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits.<br>00b - 1-bit mode<br>01b - 4-bit mode<br>10b - 8-bit mode<br>11b - Reserved |
| 0<br>LCTL | LED Control<br>This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands.<br>0b - LED off<br>1b - LED on |

## 63.8.1.13 System Control (SYS_CTRL)

### 63.8.1.13.1 Offset

| Register | Offset |
|---|---|
| SYS_CTRL | 2Ch |

## 63.8.1.13.2 Diagram



## 63.8.1.13.3 Fields

| Field | Function |
|---|---|
| 31-28<br>— | -<br>Reserved |
| 27<br>INITA | Initialization Active<br>When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (i.e. when command line or data lines are active, write to this bit is not allowed). On the otherhand, when this bit is set, i.e., during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self cleared. |
| 26<br>RSTD | Software Reset For DATA Line<br>Only part of the data circuit is reset. DMA circuit is also reset. After this bit is set, SW waits for self-clear.<br>The following registers and bits are cleared by this bit:<br>• Data Port register<br>• Buffer is cleared and initialized.<br>• Present State register<br>• Buffer Read Enable<br>• Buffer Write Enable<br>• Read Transfer Active<br>• Write Transfer Active<br>• DATA Line Active<br>• Command Inhibit (DATA) Protocol Control register<br>• Continue Request<br>• Stop At Block Gap Request Interrupt Status register<br>• Buffer Read Ready<br>• Buffer Write Ready<br>• DMA Interrupt |

|---|---|
| | This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register.<br>*In Single Data Rate mode(DDR_EN bit of MIXERCTRL is '0')*<br>Only the following settings are allowed:<br>80h) Base clock divided by 256<br>40h) Base clock divided by 128<br>20h) Base clock divided by 64<br>10h) Base clock divided by 32<br>08h) Base clock divided by 16<br>04h) Base clock divided by 8<br>02h) Base clock divided by 4<br>01h) Base clock divided by 2<br>00h) Base clock divided by 1<br>*While in Dual Data Rate mode(DDR_EN bit of MIXERCTRL is '1')*<br>*Only the following settings are allowed:*<br>*80h) Base clock divided by 512*<br>*40h) Base clock divided by 256*<br>*20h) Base clock divided by 128*<br>*10h) Base clock divided by 64*<br>*08h) Base clock divided by 32*<br>*04h) Base clock divided by 16*<br>*02h) Base clock divided by 8*<br>*01h) Base clock divided by 4*<br>*00h) Base clock divided by 2*<br>*When S/W changes the DDR_EN bit, SDCLKFS may need to be changed also!*<br>In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD Clock.<br>Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits.<br>The frequency of SDCLK is set by the following formula:<br>Clock Frequency = (Base Clock) / (prescaler x divisor)<br>For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz.<br>The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz.<br>According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit.<br>*Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.* |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | *If setting SDCLKFS and DVS can generate same clock frequency,(For example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.* |
| 7-4<br>DVS | Divisor<br>This register is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle.<br>*Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.*<br>The setting are as following:<br>0000b - Divide-by-1<br>0001b - Divide-by-2<br>1110b - Divide-by-15<br>1111b - Divide-by-16 |
| 3-0<br>— | -<br>Reserved. Always write as 1. |

## 63.8.1.14 Interrupt Status (INT_STATUS)

### 63.8.1.14.1 Offset

| Register | Offset |
|---|---|
| INT_STATUS | 30h |

### 63.8.1.14.2 Function

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

**Table 63-8. uSDHC Status for Command Timeout Error/Command Complete Bit Combinations**

| Command Complete | Command Timeout Error | Meaning of the Status |
|---|---|---|
| 0 | 0 | X |

*Table continues on the next page...*

**Table 63-8. uSDHC Status for Command Timeout Error/Command Complete Bit Combinations (continued)**

| Command Complete | Command Timeout Error | Meaning of the Status |
|---|---|---|
| X | 1 | Response not received within 64 SDCLK cycles |
| 1 | 0 | Response received |

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

**Table 63-9. uSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations**

| Transfer Complete | Data Timeout Error | Meaning of the Status |
|---|---|---|
| 0 | 0 | X |
| 0 | 1 | Timeout occurred during transfer |
| 1 | X | Data Transfer Complete |

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

**Table 63-10. uSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations**

| Command Complete | Command Timeout Error | Meaning of the Status |
|---|---|---|
| 0 | 0 | No error |
| 0 | 1 | Response Timeout Error |
| 1 | 0 | Response CRC Error |
| 1 | 1 | CMD line conflict |

### 63.8.1.14.4 Fields

| Field | Function |
|---|---|
| 31-29<br>— | -<br>Reserved |
| 28<br>DMAE | DMA Error<br>Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the Host Driver shall re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size.<br>0b - No Error<br>1b - Error |
| 27<br>— | -<br>Reserved |
| 26<br>— | Reserved. |
| 25<br>— | -<br>Reserved |
| 24<br>AC12E | Auto CMD12 Error<br>Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error.<br>0b - No Error<br>1b - Error |
| 23<br>— | -<br>Reserved |
| 22<br>DEBE | Data End Bit Error<br>Occurs either when detecting 0 at the end bit position of read data, which uses the DATA line, or at the end bit position of the CRC.<br>0b - No Error<br>1b - Error |
| 21<br>DCE | Data CRC Error<br>Occurs when detecting a CRC error when transferring read data, which uses the DATA line, or when detecting the Write CRC status having a value other than 010.<br>0b - No Error<br>1b - Error |
| 20<br>DTOE | Data Timeout Error<br>Occurs when detecting one of following time-out conditions.<br>• Busy time-out for R1b, R5b type<br>• Busy time-out after Write CRC status<br>• Read Data time-out. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | 0b - No Error<br>1b - Time out |
| 19<br>CIE | Command Index Error<br>Occurs if a Command Index error occurs in the command response.<br>0b - No Error<br>1b - Error |
| 18<br>CEBE | Command End Bit Error<br>Occurs when detecting that the end bit of a command response is 0.<br>0b - No Error<br>1b - End Bit Error Generated |
| 17<br>CCE | Command CRC Error<br>Command CRC Error is generated in two cases.<br>• If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response.<br>• The uSDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the uSDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict.<br>0b - No Error<br>1b - CRC Error Generated. |
| 16<br>CTOE | Command Timeout Error<br>Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the uSDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set (as shown in Interrupt Status (INT_STATUS) ), this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the uSDHC.<br>0b - No Error<br>1b - Time out |
| 15<br>— | -<br>Reserved |
| 14<br>— | -<br>Reserved |
| 13<br>— | -<br>Reserved |
| 12<br>— | -<br>Reserved |
| 11-9<br>— | -<br>Reserved |
| 8<br>CINT | Card Interrupt<br>This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the uSDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing this bit to 1 can clear this bit, but as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | When this status has been set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again.<br>0b - No Card Interrupt<br>1b - Generate Card Interrupt |
| 7<br>CRM | Card Removal<br>This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register.<br>0b - Card state unstable or inserted<br>1b - Card removed |
| 6<br>CINS | Card Insertion<br>This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register.<br>0b - Card state unstable or removed<br>1b - Card inserted |
| 5<br>BRR | Buffer Read Ready<br>This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information.<br>0b - Not ready to read buffer<br>1b - Ready to read buffer |
| 4<br>BWR | Buffer Write Ready<br>This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information.<br>0b - Not ready to write buffer<br>1b - Ready to write buffer: |
| 3<br>DINT | DMA Interrupt<br>Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set.<br>0b - No DMA Interrupt<br>1b - DMA Interrupt is generated |
| 2<br>BGE | Block Gap Event<br>If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1.<br>In the case of a Read Transaction: This bit is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing).<br>0b - No block gap event<br>1b - Transaction stopped at block gap |
| 1<br>TC | Transfer Complete<br>This bit is set when a read or write transfer is completed.<br>In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System).<br>In the case of a Write Transaction: This bit is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released).<br>In the case of a command with busy, this bit is set when busy is deasserted.<br>0b - Transfer not complete<br>1b - Transfer complete |
| 0<br>CC | Command Complete<br>This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register.<br>0b - Command not complete<br>1b - Command complete |

## 63.8.1.15 Interrupt Status Enable (INT_STATUS_EN)

### 63.8.1.15.1 Offset

| Register | Offset |
|---|---|
| INT_STATUS_EN | 34h |

### 63.8.1.15.2 Function

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (i.e. when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, uSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

## 63.8.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

### 63.8.1.16.1 Offset

| Register | Offset |
|---|---|
| INT_SIGNAL_EN | 38h |

### 63.8.1.16.2 Function

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

## 63.8.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

### 63.8.1.17.1 Offset

| Register | Offset |
|---|---|
| AUTOCMD12_ERR_STATUS | 3Ch |

### 63.8.1.17.2 Function

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver shall check this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in bit 04-01.This register is valid only when the Auto CMD12 Error status bit is set.

The table bwlow shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

**Table 63-11. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12**

| Auto CMD12 CRC Error | Auto CMD12 Timeout Error | Type of Error |
|---|---|---|
| 0 | 0 | No Error |
| 0 | 1 | Response Timeout Error |
| 1 | 0 | Response CRC Error |
| 1 | 1 | CMD line conflict |

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the uSDHC is going to issue an Auto CMD12.
   - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command
   - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
   - Check errors correspond to bits 1-4.
   - Set bits 1-4 corresponding to detected errors.
   - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
   - Set bit 7 to 1 if there is a command that can't be issued
   - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the Command register. So it is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

### 63.8.1.17.3 Diagram

### 63.8.1.19.4 Fields

| Field | Function |
|---|---|
| 31-29<br>— | -<br>Reserved |
| 28-24<br>WR_BRST_LEN | Write Burst Length Due to system restriction, the actual burst length may not exceed 16.<br>The number of words the uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field). |
| 23-16<br>WR_WML | Write Watermark Level<br>The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128. |
| 15-13<br>— | -<br>Reserved |
| 12-8<br>RD_BRST_LEN | Read Burst Length Due to system restriction, the actual burst length may not exceed 16.<br>The number of words the uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field). |
| 7-0<br>RD_WML | Read Watermark Level<br>The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128. |

## 63.8.1.20 Mixer Control (MIX_CTRL)

### 63.8.1.20.1 Offset

| Register | Offset |
|---|---|
| MIX_CTRL | 48h |

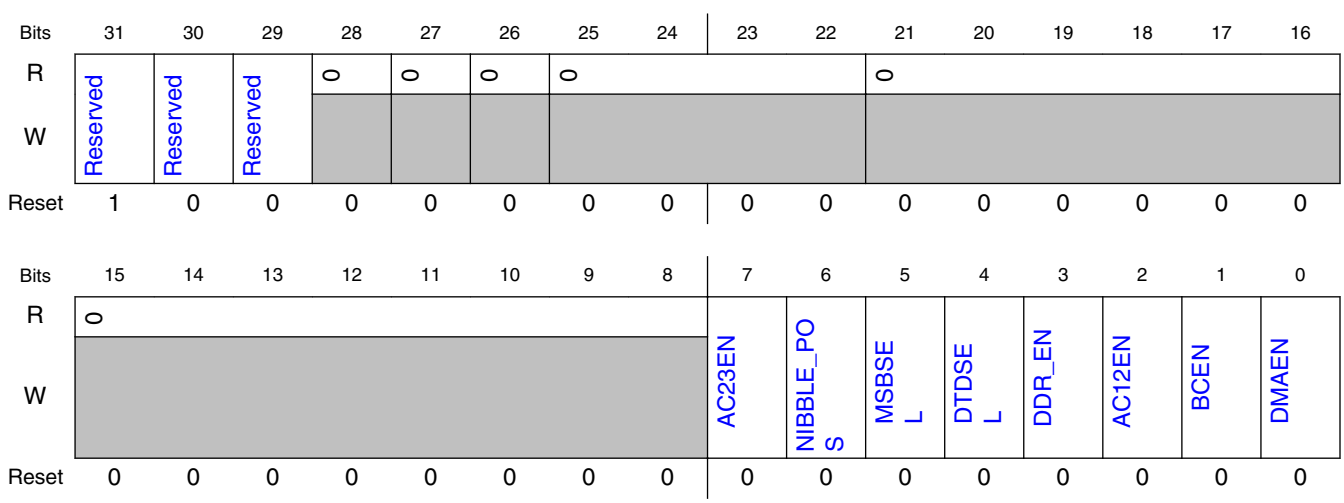
### 63.8.1.20.2 Function

This register is used to DMA and data transfer. To prevent data loss, The software should check if data transfer is active before writing this register. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

**Table 63-12. Transfer Type Register Setting for Various Transfer Types**

| Multi/Single Block Select | Block Count Enable | Block Count | Function |
|---|---|---|---|
| 0 | Don't Care | Don't Care | Single Transfer |
| 1 | 0 | Don't Care | Infinite Transfer |
| 1 | 1 | Positive Number | Multiple Transfer |
| 1 | 1 | Zero | No Data Transfer |

### 63.8.1.20.3 Diagram



## 63.8.1.20.4 Fields

| Field | Function |
|---|---|
| 31<br>— | -<br>Reserved. Always write as 1 |
| 30<br>— | -<br>Reserved. Always write as 0. |
| 29<br>— | -<br>Reserved. Always write as 0. |

| 27<br>— | -<br>Reserved |
| 26<br>— | -<br>Reserved |
| 25-22<br>— | -<br>Reserved |
| 21-8<br>— | -<br>Reserved |
| 7<br>AC23EN | Auto CMD23 Enable<br>When this bit is set to 1, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register. |
| 6<br>NIBBLE_POS | NIBBLE_POS<br>In DDR 4-bit mode nibble position indictation. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'. |
| 5<br>MSBSEL | Multi / Single Block Select<br>This bit enables multiple block DATA line data transfers. For any other commands, this bit can be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Command Transfer Type (CMD_XFR_TYP) ).<br>0b - Single Block<br>1b - Multiple Blocks |
| 4<br>DTDSEL | Data Transfer Direction Select<br>This bit defines the direction of DATA line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the uSDHC and is set to 0 for all other commands.<br>0b - Write (Host to Card)<br>1b - Read (Card to Host) |
| 3<br>DDR_EN | Dual Data Rate mode selection |
| 2<br>AC12EN | Auto CMD12 Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the uSDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the uSDHC will ignore this bit no matter it is set or not.<br>0b - Disable<br>1b - Enable |
| 1<br>BCEN | Block Count Enable<br>This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer.<br>0b - Disable<br>1b - Enable |
| 0<br>DMAEN | DMA Enable<br>This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA or the Advanced DMA is active depends on the DMA Select field of the Protocol Control register.<br>0b - Disable<br>1b - Enable |

## 63.8.1.21 Force Event (FORCE_EVENT)

### 63.8.1.21.1 Offset

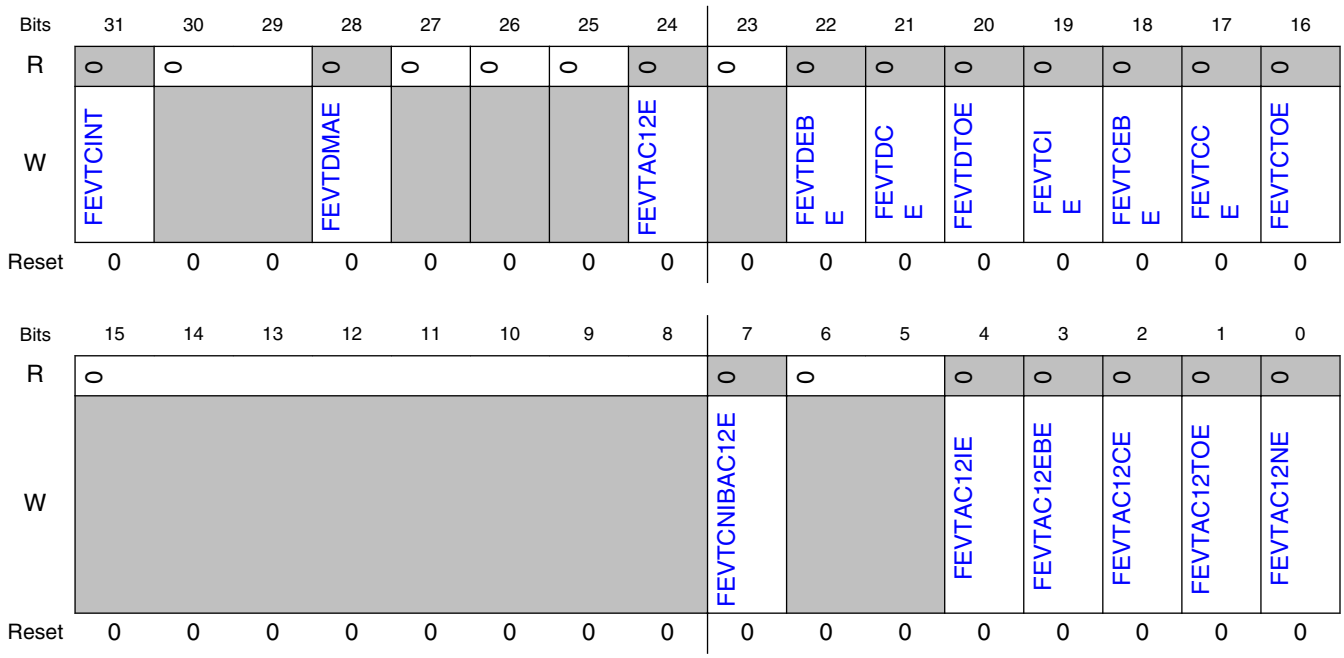
| Register | Offset |
|---|---|
| FORCE_EVENT | 50h |

### 63.8.1.21.2 Function

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, make sure to set IPGEN bit in System Control Register so that IPG_CLK is always active.

Forcing a card interrupt will generate a short pulse on the DATA1 line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is self cleared.

## 63.8.1.21.3 Diagram



## 63.8.1.21.4 Fields

| Field | Function |
|---|---|
| 31<br>FEVTCINT | Force Event Card Interrupt<br>Writing 1 to this bit generates a short low-level pulse on the internal DATA1 line, as if a self clearing interrupt was received from the external card. If enabled, the CINT bit will be set and the interrupt service routine may treat this interrupt as a normal interrupt from the external card. |
| 30-29<br>— | -<br>Reserved |

## 63.8.1.22 ADMA Error Status Register (ADMA_ERR_STATUS)

### 63.8.1.22.1 Offset

| Register | Offset |
|---|---|
| ADMA_ERR_STATUS | 54h |

### 63.8.1.22.2 Function

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

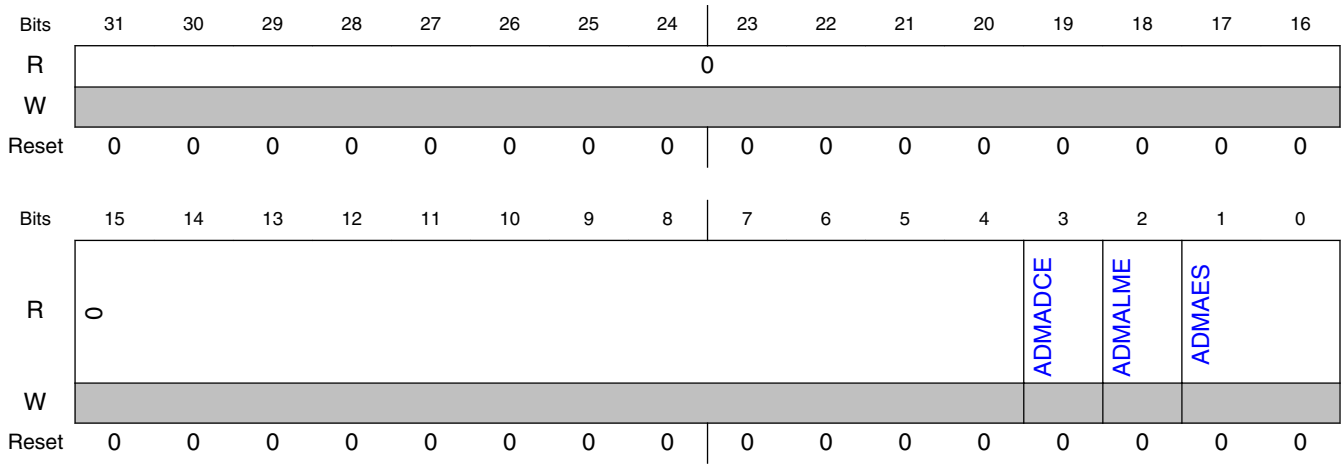
In case of a write operation, the Host Driver should use the ACMD22 to get the number of the written block, rather than using this information, since unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

**Table 63-13. ADMA Error State Coding**

| D01-D00 | ADMA Error State (when error has occurred) | Contents of ADMA System Address Register |
|---|---|---|
| 00 | ST_STOP (Stop DMA) | Holds the address of the next executable Descriptor command |
| 01 | ST_FDS (Fetch Descriptor) | Holds the valid Descriptor address |
| 10 | ST_CADR (Change Address) | No ADMA Error is generated |
| 11 | ST_TFR (Transfer Data) | Holds the address of the next executable Descriptor command |

### 63.8.1.22.3 Diagram



### 63.8.1.22.4 Fields

| Field | Function |
|---|---|
| 31-4<br>— | -<br>Reserved |
| 3<br>ADMADCE | ADMA Descriptor Error<br>This error occurs when invalid descriptor fetched by ADMA.<br>0b - No Error<br>1b - Error |
| 2<br>ADMALME | ADMA Length Mismatch Error<br>This error occurs in the following 2 cases:<br>• While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length.<br>• Total data length cannot be divided by the block length.<br>0b - No Error<br>1b - Error |
| 1-0<br>ADMAES | ADMA Error State (when ADMA Error is occurred)<br>This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to ADMA Error Status Register (ADMA_ERR_STATUS) for more details. |

## 63.8.1.23 ADMA System Address (ADMA_SYS_ADDR)

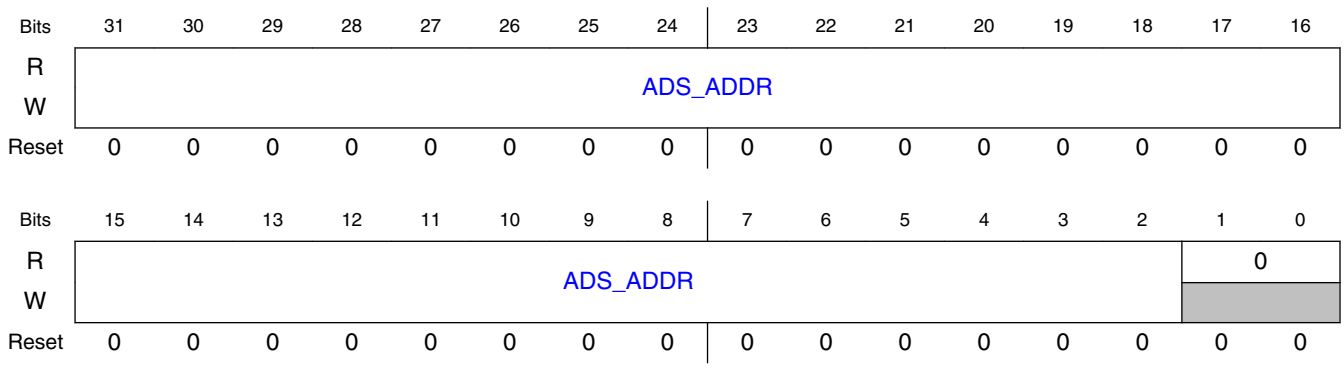
### 63.8.1.23.1 Offset

| Register | Offset |
|---|---|
| ADMA_SYS_ADDR | 58h |

### 63.8.1.23.2 Function

This register contains the physical system memory address used for ADMA transfers.

### 63.8.1.23.3 Diagram



### 63.8.1.23.4 Fields

| Field | Function |
|---|---|
| 31-2<br>ADS_ADDR | ADMA System Address<br>This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register shall hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.<br>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions . |

# Chapter 64
# 2.4 GHz Multi-Protocol Radio

## 64.1 Introduction

This document describes the 3rd generation 2.4 GHz Multi-Protocol Radio capable of supporting the modes described below in the 2.4 GHz ISM band.

- IEEE Std. 802.15.1 v4.2 Bluetooth Low Energy (BLE) single-mode device operation
- IEEE Std. 802.15.4-2006 compliant ZigBee RF4CE/IP
- IEEE Std. 802.15.4j-2012 in Medical Body Area Network (MBAN) frequency bands spanning from 2360 MHz to 2400 MHz
- Generic FSK at 1Mbps, 500Kbps, or 250Kbps
- Concurrent 802.15.4 and BLE operation

The Radio is comprised of a Constant-Envelope Transmitter and a Quadrature Zero-IF Receiver.

The Radio block diagram is provided for illustration of the internal organization of the radio.

2.4GHZ RADIO HIERARCHY DIAGRAM

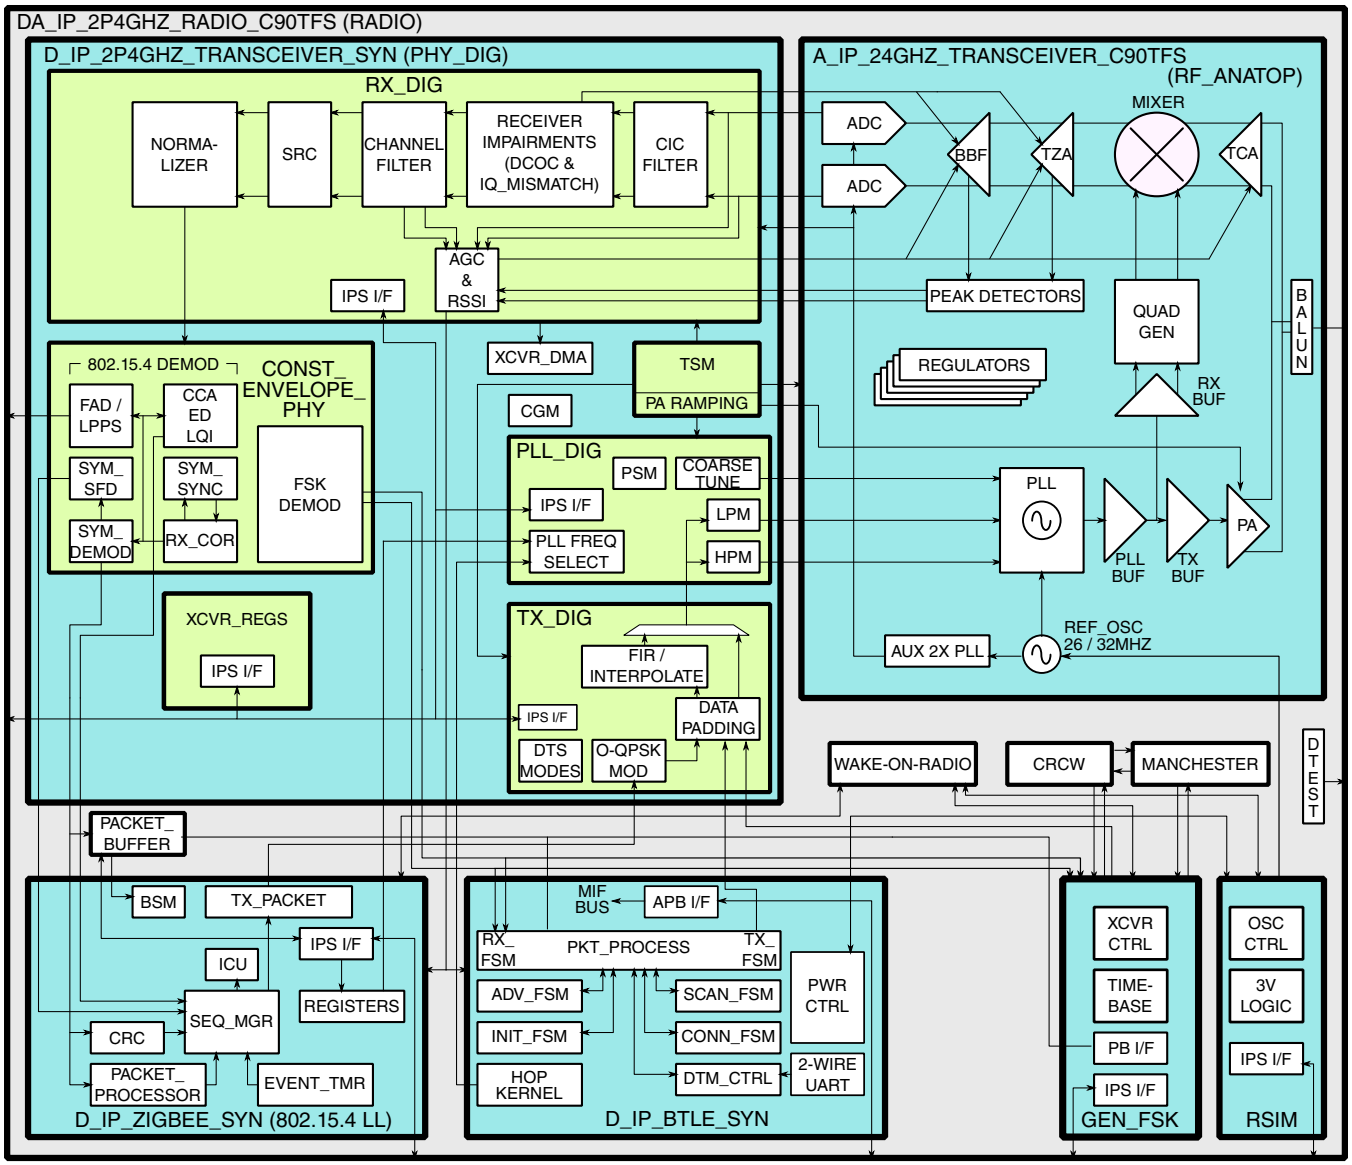

**Figure 64-1. Radio Block diagram**

# 64.2 Radio System Integration Module

## 64.2.1 Introduction

The Radio System Integration Module (RSIM) provides support for the Radio specific System Integration requirements.

#### 64.2.1.1 Features

The RSIM includes the following features:

- Status bit and enable of the BLE Ref Osc (Sysclk) Request
- Interrupt enable and flag for BLE Ref Osc (Sysclk) Request
- Power Mode specific enables for the RF Ref Osc
- Status bit and override control of the RF Ref Osc Ready signal
- Control of the SoC Platform Asynchronous Gasket Bypass
- Override control of the Stop Acknowledge signal from the Radio to the SoC
- Control bit to force BLE to exit deep sleep mode
- Control of the delay time for the BLE Active signal to the Flash
- Output enables for the two pad outputs of the BLE Active signal
- A 40-bit unique MAC address loaded from the SoC Flash IFR at Power On Reset
- SoC padring isolation controls for sensitive RF analog circuits
- Radio Reset blocking and a software Radio Reset control bit to support SoC and Radio concurrent testing
- Control Zigbee/Generic FSK + DSM related.

### 64.2.1.2 Block diagram

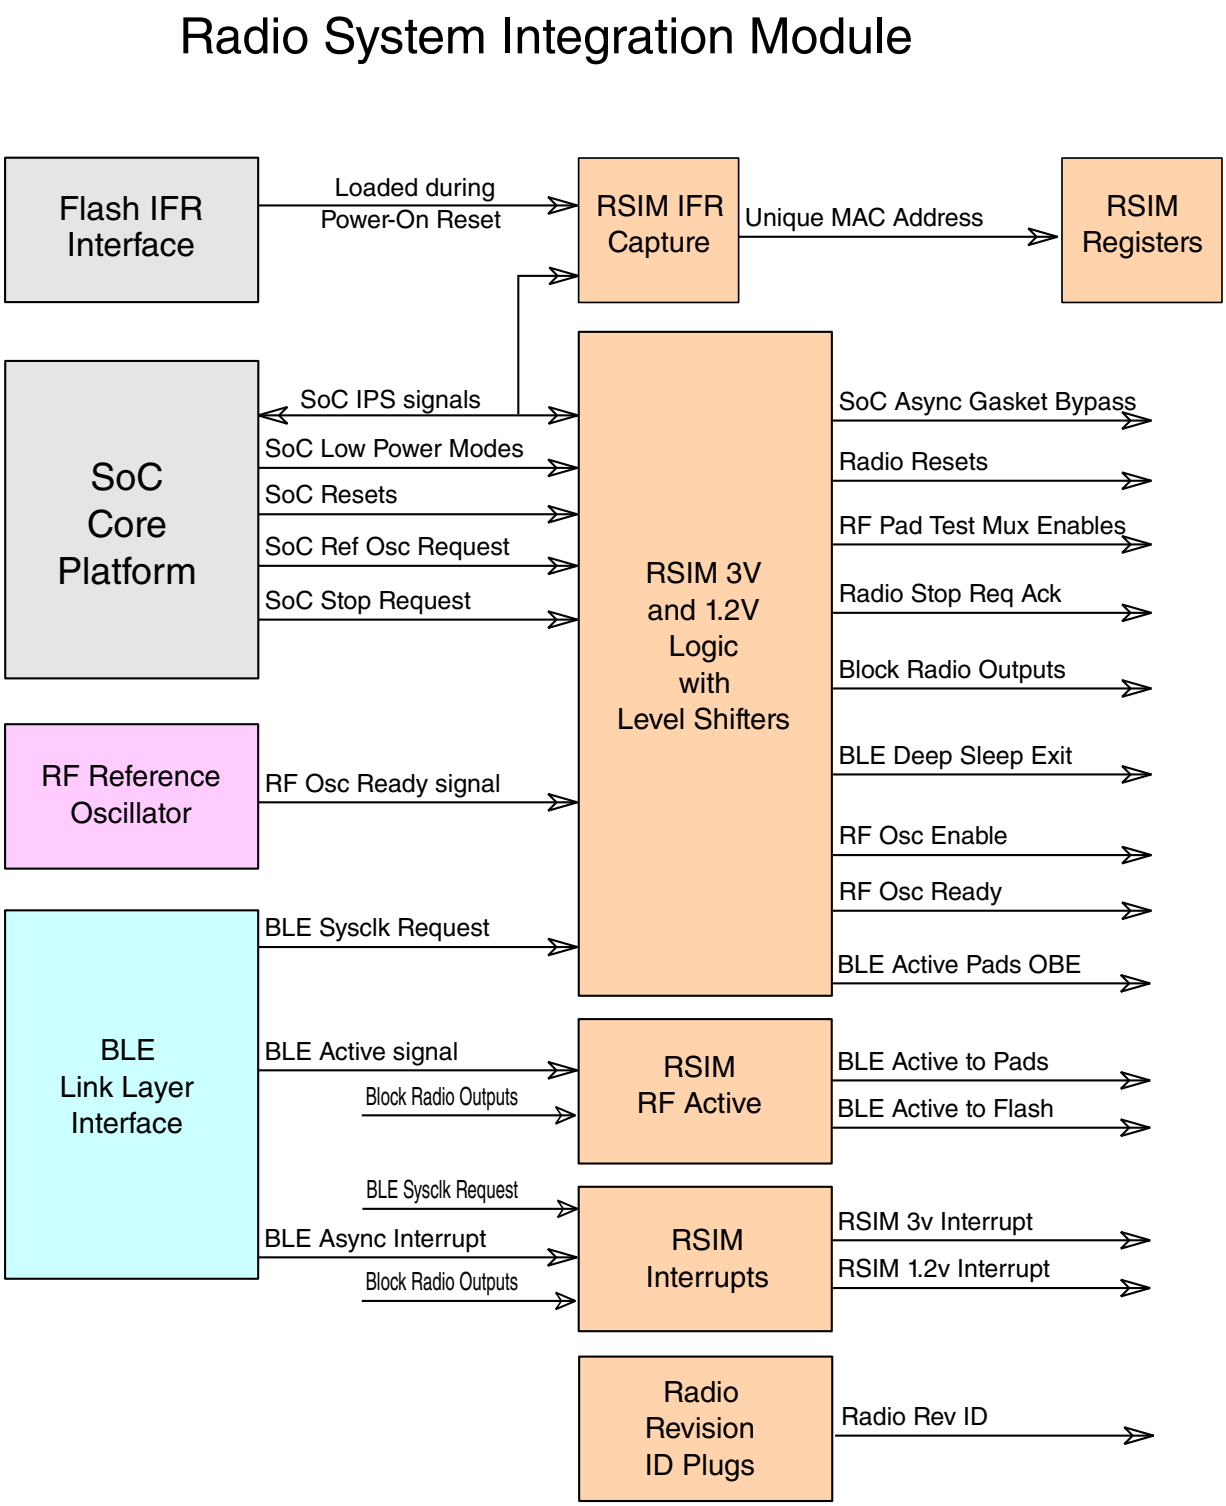

**Figure 64-2. Block diagram**

## 64.2.2 Radio Power

The Radio 1.2v digital operates as an independent power domain from the other SoC 1.2v power domains and this power domain is controlled by hardware in the Radio as described in this section.

### 64.2.2.1 Radio Power Modes

The Radio has four main Power Modes:

1. RVLLS : Radio Off Mode, this is the default mode the Radio enters after any POR, no Radio functionality is available. Whenever RVLLS is entered all of the Radio Link Layer logic will be reset to the POR state.
2. RRun : Radio Run Mode, the Radio enters this mode as described in the Radio Run Request section below.
3. RLLS : Radio State Retention Mode, the Radio digital logic retains it's state in a low power configuration, Deep Sleep Modes can be enabled, Radio Analog is inactive.
4. RLLS-OSC : Radio Osc Ready Mode, the Radio digital logic retains it's state in a low power configuration, Deep Sleep Modes can be enabled, Radio Oscillator is kept active to avoid a warmup delay before going into RRun mode.

Note that when the Radio is in Run Mode the SoC System Power Module (SPM) can be further configured into VLPS mode for some additional power savings.

The Radio Power Mode transitions are illustrated in the diagram below:

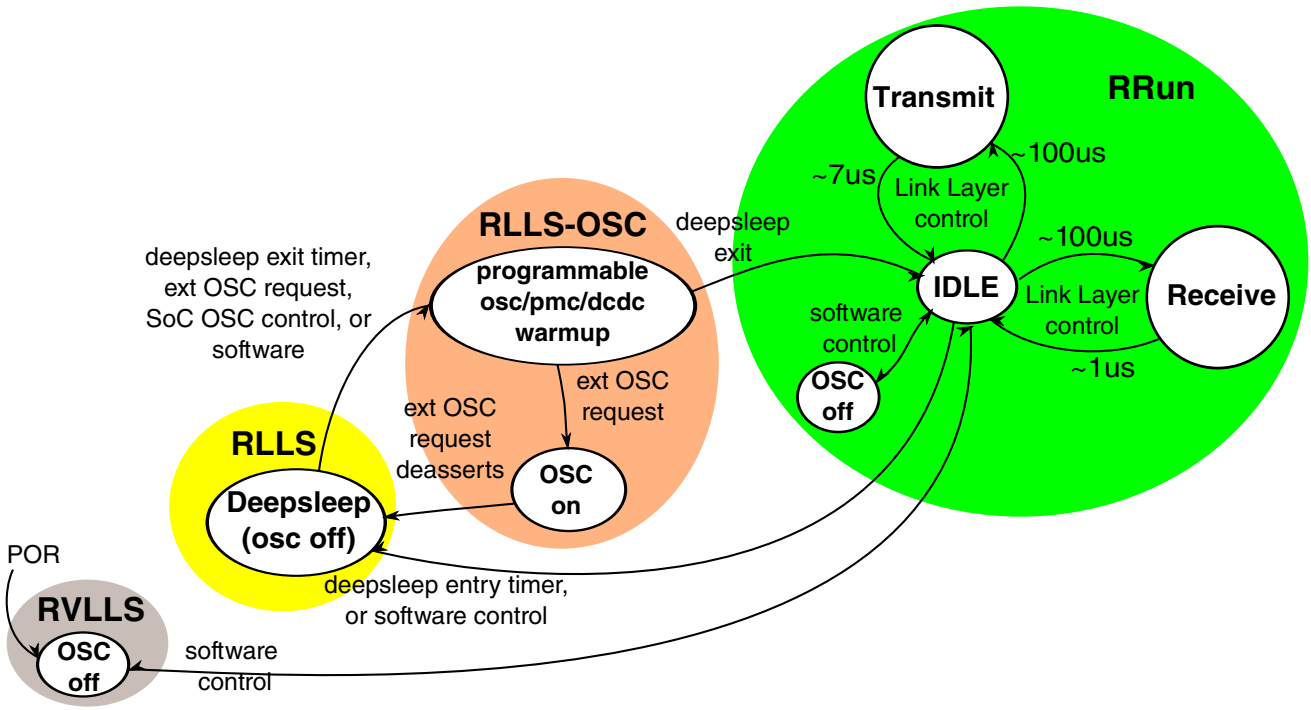

**Figure 64-3. Radio Power Mode Transitions**

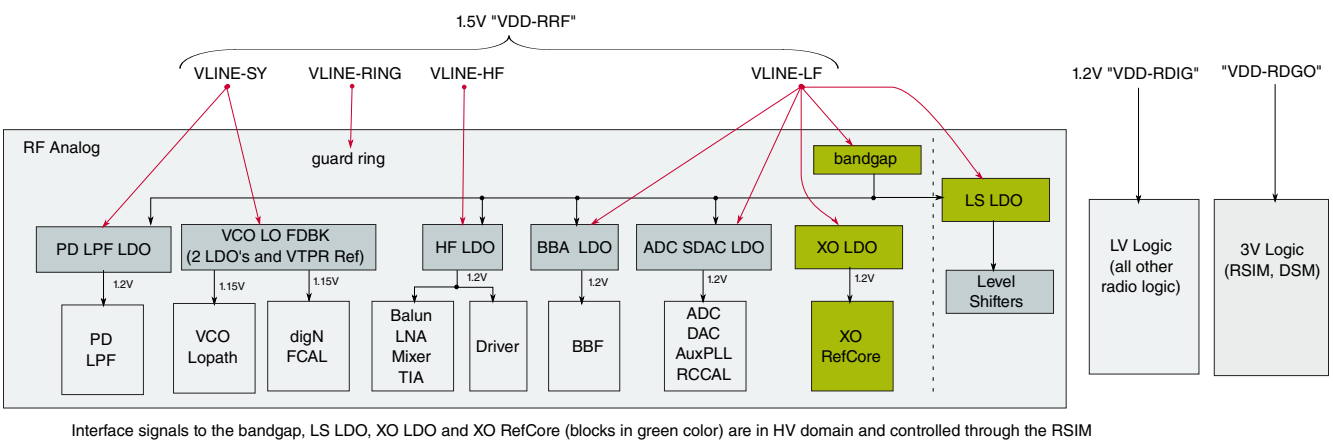
## 64.2.2.2 Radio Power Domains

The Radio has three Power Domains:

1. RF Analog Power, VDD-RRF, always powered
2. Radio 1.2v Digital Power, VDD-RDIG, only powered in RRun Mode
3. Radio 1.8v Digital Power, VDD-RDGO, always powered

The Power Domains are connected as shown in the following figure:



Interface signals to the bandgap, LS LDO, XO LDO and XO RefCore (blocks in green color) are in HV domain and controlled through the RSIM

**Figure 64-4. Radio Power Domain**

### 64.2.2.3 RF Analog Bandgap Trim

The RF Analog LDO voltage regulators use the RF Analog Bandgap as their voltage reference, this reference level is trimmed at the factory and the trim values are stored in the Flash IFR.

After any SoC POR event the Radio will load the RF Analog BG_1V_TRIM and BG_IBIAS_5U_TRIM registers with the Flash IFR values; these register values can then be overridden by software as needed.

### 64.2.2.4 Power-On Handshake

The Radio has a Power-On Handshake method with the SPM whereby the Radio asserts or de-assserts a request for the SPM to enter Full Power Run Regulation mode and the SPM acknowledges the request after the transition into or out of Run Regulation is completed.

#### 64.2.2.4.1 Radio Run Request

The Radio can request that the SPM enter Run Regulation Mode in three ways:

1. Software can set the RSIM_RUN_REQUEST register bit, which will force Radio Run mode while it is set.
2. Any of the Radio Deep Sleep State Machines can request that the Radio wakeup from DSM, and the State Machines can then automatically reenter DSM and remove the Run Request without waking up the MCU.
3. An External Osc Request can request the RF Osc which can be configured as a Radio Run Request, and the Run Request will de-assert when the External Osc Request de-asserts.

Each of the Run Request methods acts in an OR fashion so that the Radio stays in Run Mode as long as any one of these is active.

Note that the SPM can be configured in various ways to provide this Run Regulation power, including using an External Power Supply.

The RSIM has several registers that control and observe the Run Request as shown in the following table:

**Table 64-1. RSIM Run Request Bits**

| RSIM Register Field | Function | Description |
|---|---|---|

*Table continues on the next page...*

**Table 64-1. RSIM Run Request Bits (continued)**

| | | |
|---|---|---|
| RSIM_RUN_REQUEST | RSIM Run Regulator Request | When this bit is set, the RSIM will request the SPM Run Regulator to be turned on and the RSIM will then stop requesting Stop after the Run Regulator Acknowledge signal is received from the SPM module. |
| RADIO_RUN_REQ_STAT | Radio Run Request Status | This is the value of the Radio Run Request signal being sent to the SPM module, including any overrides. |
| RSIM_RUN_REQ_OVRD | RSIM Run Request Override | This bit directly controls the RSIM Run Request signal to the SPM when the RSIM Run Request Override is enabled. |
| RSIM_RUN_REQ_OVRD_EN | RSIM Run Request Override Enable | This bit enables the RSIM Run Request Override bit. |

#### 64.2.2.4.2 SPM Observe and Overrides

The RSIM has several registers that observe and override the SPM signals as shown in the following table:

**Table 64-2. RSIM SPM Run Acknowledge Bits**

| RSIM Register Field | Function | Description |
|---|---|---|
| SPM_RUN_ACK_STAT | SPM Run Request Acknowledge Status | This is the value of the SPM Run request Acknowledge signal being sent to the Radio. |
| SPM_RUN_REQ_ACK_OVRD | SPM Run Request Acknowledge Override | This bit directly controls the SPM Run Request Acknowledge signal when the SPM Run Request Acknowledge Override is enabled. |
| SPM_RUN_REQ_ACK_OVRD_EN | SPM Run Request Acknowledge Override Enable | This bit enables the SPM Run Request Acknowledge Override bit. |

#### 64.2.2.4.3 Radio Run Acknowledged

After the Radio has requested that the SPM enter Run Regulation Mode, software can poll the SPM_RUN_ACK_STAT bit to confirm that the SPM has completed the Radio request.

### 64.2.2.5 Power-On Sequencer

The RSIM has a Power-On Sequencer that requests Radio Run Mode, enables the RF Osc, and signals RF_Active. The Power-On Sequencer is programmable and has hardware connections to all of the Radio's Deep Sleep State Machines.

When enabled, the Radio will use the same Radio Power-On Sequence, regardless of the Radio Protocol. The timing of the sequence is controlled by the RSIM DSM_PWR_OFFSET register where the POWER_OFFSET, COARSE_DELAY, FINE_DELAY, and ACTIVE_WARNING values are programmed, and by the BLE WAKEUP_CONFIG and WAKEUP_CONFIG2 registers.

The Power-On timing will always be the same prior to the exit from Deep Sleep Mode, even if the Radio Power is already on. This is needed to support all the various Deep Sleep Modes that each requires precise On-Air timing and co-existence with each other, as well as the case where software may be turning the Radio Power on and off.

Software can always directly turn on the Radio Power by setting the RSIM_POWER register bit RSIM_RUN_REQUEST, and can then directly turn on the RF OSC by setting the RSIM_CTRL bit RF_OSC_EN

The Radio Power-On Sequence can also be used when the SoC External Osc Request pin is used to request the RF OSC by setting the RSIM OSC_CONTROL bit EXT_ACTIVE_EN.

The Radio Power-On Sequence is illustrated in the following diagram.

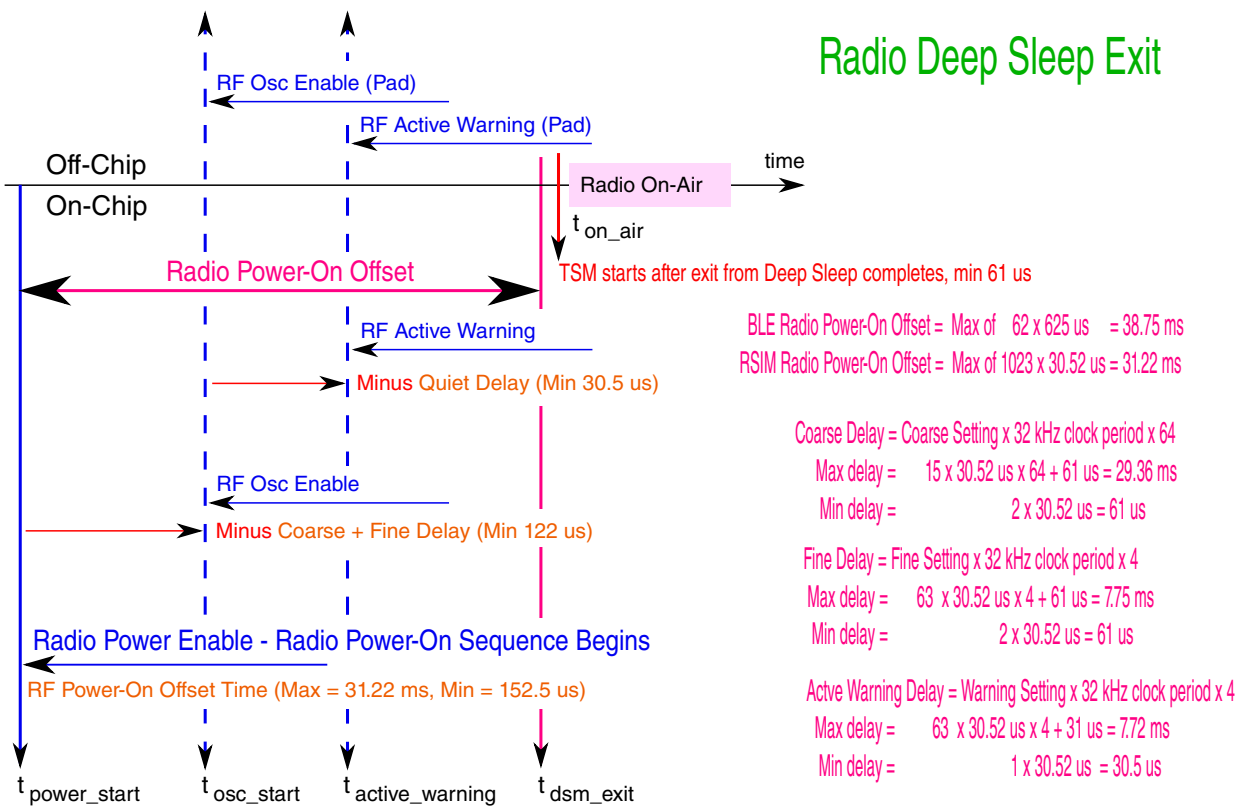


**Figure 64-5. Radio Power-On Sequence Diagram**

#### 64.2.2.5.1 Milestones

The Radio Power-On Sequence has four timing milestones:

1. $\mathbf{T_{power_start}}$ : A Run Request is sent to request the SPM to enter full power Run Mode
2. $\mathbf{T_{osc_start}}$ : The RF Analog controls are set to warm-up the RF OSC and a signal is presented on the RF_OSC_EN SoC pin
3. $\mathbf{T_{active_warning}}$ : A signal is presented on the RF_ACTIVE SoC pin to indicate the upcoming Radio Operation
4. $\mathbf{T_{dsm_exit}}$ : Link Layer exits Deep Sleep mode
5. $\mathbf{T_{on_air}}$ : TSM sequence starts and Radio goes On-Air

The Link Layers all have methods of computing their DSM Exit times which then determine when the Radio goes On-Air ($\mathbf{T_{on_air}}$).

The RSIM and BLE Deep Sleep State Machines have a hardware handshake system with the Radio Power-On Sequencer, and there are separate Start Time offsets to achieve the RSIM and BLE DSM Exit times.

##### 64.2.2.5.1.1 RSIM Offset

For the RSIM Deep Sleep State Machines the POWER_OFFSET value is programmed into the RSIM DSM_PWR_OFFSET register. The amount of the Start Time offset can be calculated as:

- **POWER_OFFSET[9:0]** : This is the number of 32.768 kHz clocks (30.518 us) to use as a Start Time offset prior to the RSIM Deep Sleep Machines entering the Active State.

##### 64.2.2.5.1.2 BLE Offset

Please refer to the BLE Link Layer Controller Programming section for details on the BLE Offset.

#### 64.2.2.5.2 Settings and Calculations

The Radio Power-On Sequence Time is programmed using the RSIM DSM_PWR_OFFSET register which contains three Radio Power-On Sequence settings, please refer to the Radio Deep Sleep section for more details.

##### 64.2.2.5.2.1 Calculating the Power-On Milestones

The Radio Power-On Sequence Milestones can be calculated as follows:

1. $\mathbf{T_{power_start}}$ : Power-On Offset time = Deep Sleep Machine enters state WAIT_OSC_STABLE.

2. $\mathbf{T_{osc_start}}$ : RF_OSC_EN pin time = $\mathbf{T_{power_start}}$ + COARSE_DELAY + FINE_DELAY.
3. $\mathbf{T_{active_warning}}$ : RF_ACTIVE pin time = $\mathbf{T_{osc_start}}$ + ACTIVE_WARNING.
4. $\mathbf{T_{dsm_exit}}$ : The Link Layer exit from Deep Sleep takes a minimum of 61 us to complete.
5. $\mathbf{T_{on_air}}$ : The time it takes to go On-Air after exiting Deep Sleep depends on the Protocol and TSM timings.

#### 64.2.2.5.2.2 Minimum Power-On Time

The minimum Radio Power-On Sequence time can be calculated as follows:

If all of the DSM_PWR_OFFSET registers are set to zero:

- **COARSE_DELAY** = 0
- **FINE_DELAY** = 0
- **ACTIVE_WARNING** = 0

Then the Minimum Radio Power-On Sequence time =

- Minimum Coarse delay of 30.52 us +
- Minimum Fine delay of 30.52 us +
- Minimum Active delay of 30.52 us +
- Minimum Additional Hardware delay to complete the exit from Deep Sleep mode of 122.08 us

Which gives a minimum Power-On Sequence Time of 213.64 us.

And the Minimum Radio Power-On Offset time =

- Minimum Additional Hardware delay to start the Power-On Sequence of 61.04 us +
- Minimum Coarse delay of 30.52 us +
- Minimum Fine delay of 30.52 us +
- Minimum Active delay of 30.52 us

Which gives a minimum Power-On Offset Time of 152.6 us.

If the Minimum Power-On Offset Time is programmed, then the RF_Active pin will be asserted 61.04 us before the Deep Sleep mode exit.

If the POWER_OFFSET value is increased beyond the minimum, or other calculated value, the effect will be to increase the time between the RF_ACTIVE pin signal asserting and the Deep Sleep mode exit.

#### 64.2.2.5.3 Software Control of RF Active Warning

Software can manually control the RF_ACTIVE pin using these three methods:

1. Software RF Active bits in the RSIM : The SW_RF_ACTIVE_EN and SW_RF_ACTIVE_BIT can be used to assert a Software RF Active Warning, which will be OR'd with the three Deep Sleep Machine RF_ACTIVE warning signals and presented on the RF_ACTIVE pin.
2. RF Active Override bits in the RSIM : These can be used to either block all of the Deep Sleep Machine's from asserting the RF_ACTIVE pin, or they can be used to always assert the RF_ACTIVE pin. If the DSM RF_ACTICE signals are forced low then software has complete control of RF_ACTIVE.
3. Software can also use the SW_RF_ACTIVE_ENDS_WITH_TSM_EN bit to auto clear the RF_ACTIVE pin after the next TSM operation.

Please refer to the Wi-Fi Coexistence section for more details.

#### 64.2.2.5.4 Clearing of RF Active Warning

The default behavior is for the three Deep Sleep Machine's RF_ACTIVE warning signals to clear after the Radio Operations complete and the Link Layers go back into Deep Sleep mode.

There is an RSIM bit, RF_ACTIVE_ENDS_WITH_TSM, which instead will clear the three Deep Sleep Machines RF_ACTIVE warning signals at the end of the next TSM operation.

### 64.2.3 Radio Clocks

The Radio uses the RF Analog Reference Oscillator or an equivalently precise external clock for all Radio Operations. This RF Osc is also available for the SoC to use as it's clock source. There is also a method that allows the SoC to supply a less precise clock to the Radio that can be used to configure the Radio registers before the Radio is enabled.

#### 64.2.3.1 Clock Diagram

The Radio Clock Tree is illustrated in the following diagram.

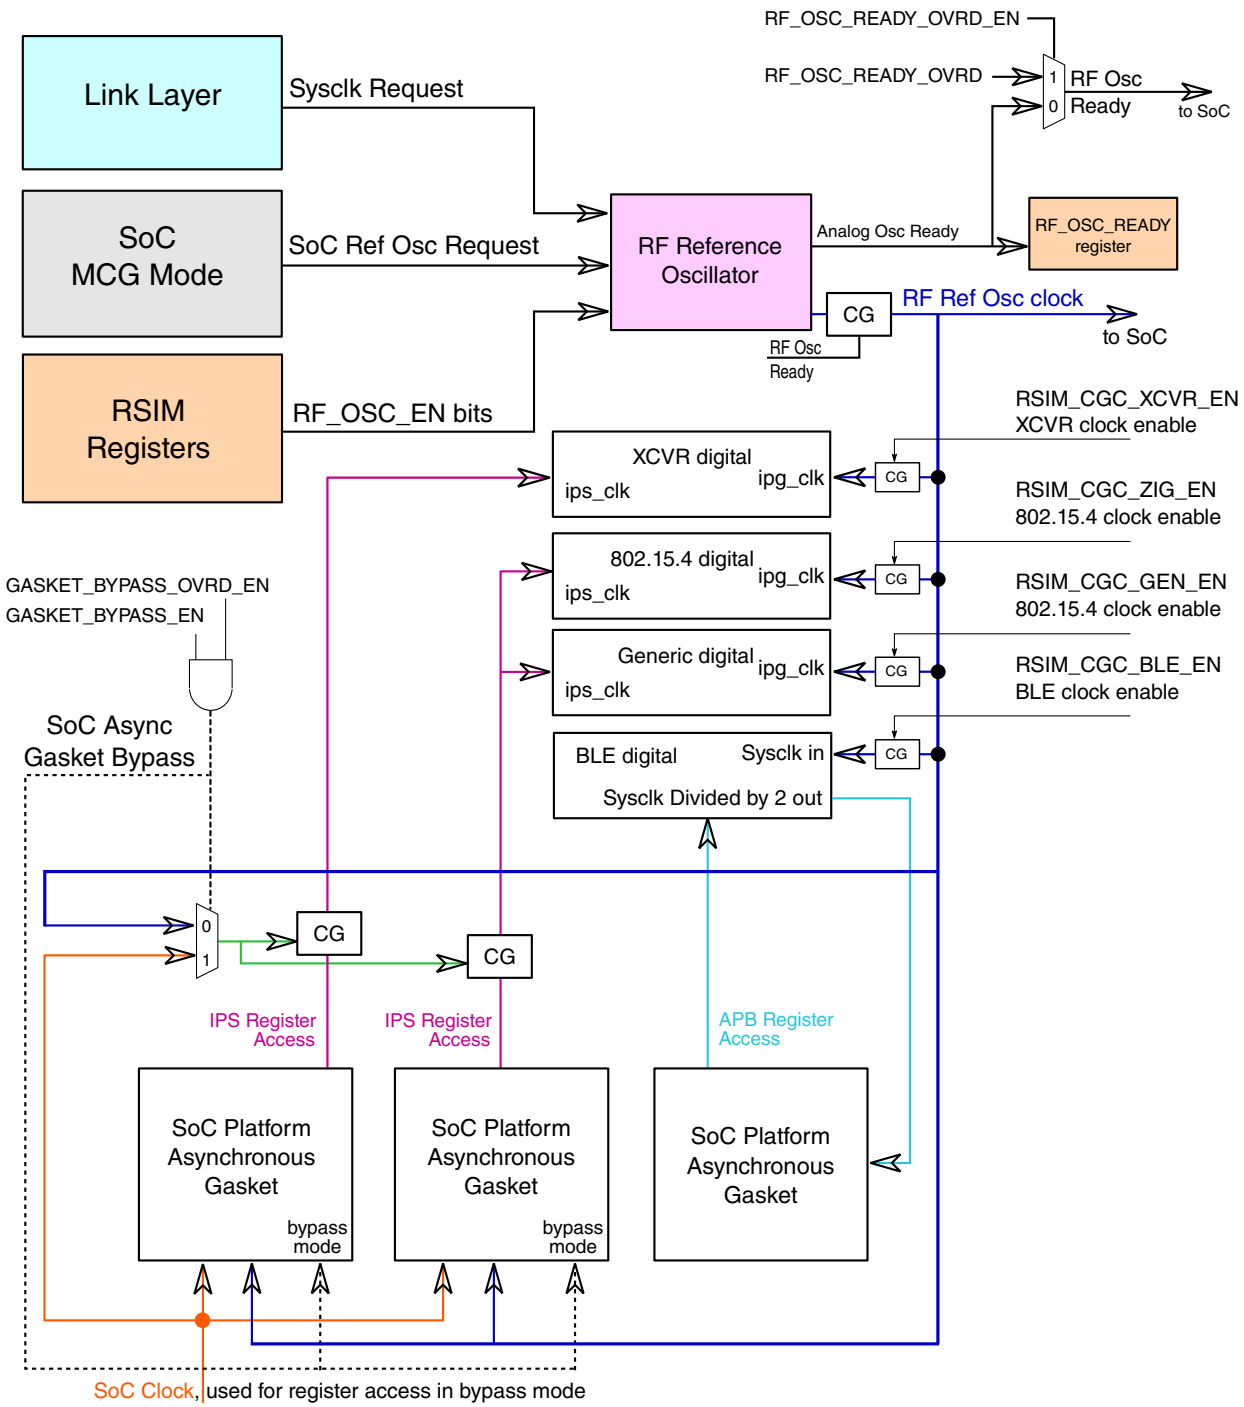

**Figure 64-6. Radio Clocking Configuration**

## 64.2.3.2 RF Osc Enable

The RF Analog Reference Oscillator must be enabled and ready before it can be used as a clock source. There are three methods of enabling the RF Osc as listed here:

1. The SoC can request the RF Osc.

2. One of the Radio Link Layers can request the RF Osc, either in RRun mode or in RLLS mode using a Deep Sleep State Machine.
3. The RF_OSC_EN bit can be set, more details in the table below.

| RF_OSC_EN | Radio Run Mode Functionality | Radio Stop Modes Functionality |
|---|---|---|
| 0 | RF Ref Osc will be Off unless it is turned On by the SoC, by a Radio link layer using RRun Mode, or by an External Pin request. | Warning: Radio will not go into Stop mode while the RF Ref Osc is being used by the SoC, or by a Radio link layer unless the Link Layer is using a Deep Sleep State Machine.<br>RF Ref Osc will be Off unless there is an external pin request. |
| 1 | The RF Ref Osc will be On.<br>Warning: The RF Ref Osc can not be enabled until the Radio has entered RRun Mode. | Radio will not go into Stop mode while RF_OSC_EN is set |

### 64.2.3.3 RF Osc Ready

The RF Analog Reference Oscillator has a programmable count time that elapses before the RF_OSC_READY signal is asserted. This count time is set using the BB_XTAL_READY_COUNT_SEL register as shown in the table below:

| BB_XTAL_READY_COUNT_SEL | Count Value | Count Time, us (32MHz Ref Osc) |
|---|---|---|
| 0 | 1024 | 32 |
| 1 | 2048 | 64 |
| 2 | 4096 | 128 |
| 3 | 8192 | 256 |

The current status of RF_OSC_READY signal from the RF Analog can be read using the RF_OSC_READY bit.

The RF_OSC_READY signal from the RF Analog can be overridden using the RF_OSC_READY_OVRD_EN and RF_OSC_READY_OVRD bits. The status bit will continue to show the RF Analog status but everywhere else will use the overridden value.

#### 64.2.3.4 RF Osc Bypass

The RF_OSC_BYPASS_EN bit engages the RF Ref Osc analog bypass circuit if the RF Ref Osc is enabled. When the RF Ref Osc is in bypass mode it passes the RF EXTAL clock as the RF Ref Osc clock. Note that the RF Ref Osc Ready signal functions normally in RF OSC Bypass mode, unless overridden with the RF_OSC_READY_OVRD_EN bit.

#### 64.2.3.5 Clock Gating Bits

To conserve power, the clocks to most Radio modules can be turned off using the RSIM_CGC_EN bits in the RSIM registers. These bits are cleared after any reset, which disables the clock to the corresponding module. Prior to initializing a module, set the corresponding RSIM_CGC_EN bit to enable the clock. Before turning off the clock, make sure to disable the module.

#### 64.2.3.6 Radio Registers Access (CAUTION)

WARNING: If the Radio Register Clocks are not configured correctly before a Memory Access the SoC Core will halt. The descriptions below and the RSIM Register descriptions are intended to help avoid such a result.

##### 64.2.3.6.1 BLE Link Layer Registers Access

The Radio Registers for the BLE Link Layer are accessed through an SoC Asynchronous Gasket in the Core Platform, and can only be accessed when the RF Ref Osc is Enabled and Ready, this is because the BLE Link Layer requires an accurate time-base clock for its time-keeping functions.

Software must use the RSIM_RUN_REQUEST bit to put the Radio in RRun Mode and then enable the RF_OSC_EN bit to enable the RF Ref Osc. After the RF Ref Osc is enabled, software can monitor the RF_OSC_READY bit to determine when the RF Ref Osc is Enabled and Ready.

WARNING: If the RF Ref Osc is not Enabled and Ready, and a BLE Link Layer Memory Access is attempted, then the SoC Asynchronous Gasket will block the SoC Core from proceeding as it waits for the Radio to send it the RF Ref Osc.

#### 64.2.3.6.2 XCVR and Link Layer Registers Access

The Radio Registers for the XCVR and the Link Layers are accessed through an SoC Asynchronous Gasket in the Core Platform, and they can be accessed with either the RF Ref Osc (Not Bypassed) or the SoC IPG clock (Bypassed).

The default behavior of this Gasket is Not Bypassed, which means the Radio registers are accessed using the RF Ref Osc clock.

When the Gasket is Not Bypassed, the Radio sends the RF Ref Osc to the asynchronous gasket which then uses that clock for SoC register accesses of the Radio registers. This requires the RF Ref Osc to be Enabled and Ready. Software must use the RSIM_RUN_REQUEST bit to put the Radio in RRun Mode and then enable the RF_OSC_EN bit to enable the RF Ref Osc. After the RF Ref Osc is enabled, software can monitor the RF_OSC_READY bit to determine when the RF Ref Osc is Enabled and Ready.

If the RF Ref Osc is not Enabled and Ready, then the IPS Gasket can be overridden to be in Bypass Mode, which forces the use of the SoC IPG clock as the register access clock.

If the RF Ref Osc IS Enabled and Ready, then the IPS Gasket can be overridden to be in Bypass Mode, but this is an ILLEGAL ACCESS if the Radio is operational, DO NOT write Radio registers with the Asynchronous Gasket Bypassed when the Radio is Operating. Test mode access is allowed but glitches may occur.

WARNING: If the RF Ref Osc is not Enabled and Ready, and a XCVR or Link Layer Memory Access is attempted, then the SoC Asynchronous Gasket will block the SoC Core from proceeding as it waits for the Radio to send it the RF Ref Osc.

#### 64.2.3.6.3 Asynchronous Gasket Bypass

The intent of Bypass Mode is to allow software to configure the Radio XCVR and Link Layer registers before the RF Ref Osc is Enabled and Ready.

The following table shows which clock is being used to access the Radio XCVR and Link Layer registers.

| Gasket Bypass Override Enable | Gasket Bypass Override | XCVR and Link Layer Register Clock |
|---|---|---|
| 1 | 0 | RF Ref Osc Clock |
| 1 | 1 | SoC IPG Clock |
| 0 | x | RF Ref Osc Clock |

More details are available in the Radio Clocks diagram, the Radio Gasket Bypass section, and in the RSIM Gasket Bypass Registers descriptions.

### 64.2.3.7 External Osc Request

The RF Analog Reference Oscillator has an External Osc mode in which the RF Osc Analog circuits can be enabled and the RF Osc can be ready and either presented externally on an SoC pin, or not.

#### 64.2.3.7.1 SoC XTAL_OUT Pin Enable

The RF Analog Driver for the SoC XTAL_OUT pin has to be enabled using the XTAL_OUT_BUF_EN bit in the RSIM ANA_TEST register.

Warning: If this bit is not set then no RF Osc signal will be presented on the SoC Pin.

#### 64.2.3.7.2 External Osc Request Register Bits

The RSIM has several bits that are used to select the External Osc mode configuration as shown in the table below:

**Table 64-3. External Osc Mode Configuration Bits**

| RSIM Register Field | Function | Setting | Description |
|---|---|---|---|
| BLOCK_EXT_OSC_PWR_REQ | Block External Requests for RF OSC from starting a Radio Power Wakeup Sequence | 0 | Configuring the RF Osc in External Osc mode causes the Radio to request Run Regulation mode. |
| | | 1 | Radio will not request Run Regulation mode when the RF Osc is configured in External Osc mode and the Radio is otherwise in a Stop mode. |
| RADIO_EXT_OSC_RF_EN_SEL | Radio External Request for RF OSC Select | 0 | SoC pin connected to EXT_OSC_RF_EN_0 is used to configure the RF Osc in External Osc mode. |
| | | 1 | SoC pin connected to EXT_OSC_RF_EN_1 is used to configure the RF Osc in External Osc mode. |
| RADIO_EXT_OSC_OVRD | Radio External Request for RF OSC Override | 0 | If the RADIO_EXT_OSC_OVRD_EN bit is set, then the RF Osc will not be configured in External Osc mode. |

*Table continues on the next page...*

**Table 64-3. External Osc Mode Configuration Bits (continued)**

| | | | |
|---|---|---|---|
| | | 1 | If the RADIO_EXT_OSC_OVRD_EN bit is set, then the RF Osc will be configured in External Osc mode. |
| RADIO_EXT_OSC_OVRD_EN | Radio External Request for RF OSC Override Enable | 0 | SoC external pin requests will control the RF Osc External Osc mode configuration. |
| | | 1 | The RADIO_EXT_OSC_OVRD bit will control the RF Osc External Osc mode configuration and any external pin request will be ignored. |

### 64.2.3.8 SoC RF Osc Pins

The SoC Pins related to the RF Osc are shown in the table below.

| Radio Pin Name | Pin Direction | SoC Pin Name | Pin Description |
|---|---|---|---|
| RF_INT_OSC_EN | I | RF_RFOSC_EN | External request to turn on the Radio's internal RF Osc. The Osc will be present on the XTAL_OUT pin if the RF Osc XTAL_OUT buffer is enabled by writing the Radio XTAL_OUT_BUF_EN bit in the RSIM ANA_TEST register. |
| RF_EXT_OSC_EN | O | RF_EXT_OSC_EN | Internal request to turn on an External Osc for use by the internal Radio, this can also be a request from the SoC if it is using the RF Osc as it's clock. |

## 64.2.4 Radio Stop Modes

The Radio hardware automatically exits and reenters Stop Mode as part of its interaction with the Deep Sleep State Machines. Software can also control the entry and exit using the register bits described in this section.

### 64.2.4.1 Radio Stop Signals

The Radio Stop mode transitions are handled by a hardware handshake with the SPM as shown in the diagram below:

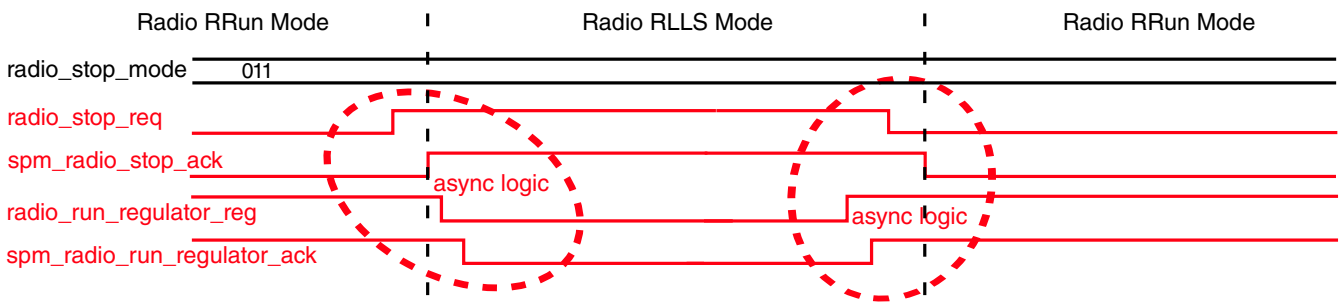

**Figure 64-7. Radio Stop Signals Diagram**

### 64.2.4.2 Radio Stop Request

The RSIM controls the Stop Request signal based upon Link Layer and software requests. Normally the Stop Request signal only changes while the Radio is powered, but it is a legal SPM mode to change the Stop Request while the Radio is powered off.

This signal can be observed and overridden as shown in the table below:

| RSIM Register Field | Function | Description |
|---|---|---|
| RADIO_STOP_REQ_STAT | Radio Stop Request Status | This is the value of the Radio Stop Request signal being sent to the SPM module, including any overrides. |
| RSIM_STOP_REQ_OVRD | Radio Stop Request Override | This bit directly controls the Radio Stop Request signal when the Radio Stop Request Override is enabled |
| RSIM_STOP_REQ_OVRD_EN | Radio Stop Request Override Enable | This bit enables the Radio Stop Request Override bit |

### 64.2.4.3 SPM Stop Acknowledge

The SPM acknowledges the Radio Stop Request after the SPM has changed the state of all the Radio Stop and Power Gating logic. This signal can be observed and overridden as shown in the table below:

| RSIM Register Field | Function | Description |
|---|---|---|

*Table continues on the next page...*

| | | |
|---|---|---|
| SPM_STOP_ACK_STAT | SPM Stop Acknowledge Status | This is the status of the Stop request Acknowledge signal received from the SPM module |
| SPM_STOP_REQ_ACK_OVRD | SPM Stop Request Acknowledge Override | This bit directly controls the SPM Stop Request Acknowledge signal when the SPM Stop Request Acknowledge Override is enabled |
| SPM_STOP_REQ_ACK_OVRD_EN | SPM Stop Request Acknowledge Override Enable | This bit enables the SPM Stop Request Acknowledge Override bit |
| RADIO_STOP_ACK_STAT | Radio Stop Acknowledge Status | This is the status of the Stop request Acknowledge signal being used by the Radio, including any override of the SPM module signal. |

### 64.2.4.4 Radio Stop Mode

The Radio software cannot change the Stop Mode value after a Stop Request has been made, typically the Stop Mode value is set to RLLS as part of the Radio configuration process.

The mode can be set, observed and overridden as shown in the table below:

| RSIM Register Field | Function | Description |
|---|---|---|
| RSIM_STOP_MODE | RSIM lowest allowed Stop Mode | This is the Stop Mode that will be requested when the RSIM asserts a Stop request to the SPM module.<br><br>000 - RSTOP (SPM supports, no planned use case)<br><br>001 - RVLPS (SPM supports, no planned use case)<br><br>011 - RLLS mode (Radio State Retention mode)<br><br>111 - RVLLS mode (This is the POR setting) |
| RADIO_STOP_MODE_OVRD | Radio Stop Mode Override | This bit directly controls the Radio Stop Mode signal when the Radio Stop Mode Override is enabled |
| RADIO_STOP_MODE_OVRD_EN | Radio Stop Mode Override Enable | This bit enables the Radio Stop Mode Override bit |
| RADIO_STOP_MODE_STAT | Radio Stop Mode Status | This is the value of the Radio Stop Mode bus that is sent to the SPM module |

### 64.2.4.5 SPM Isolation Signal

The SPM provides the Stop Mode isolation signal which is used as part of the RF Analog isolation logic. This signal can be observed and overridden as shown in the table below:

| RSIM Register Field | Function | Description |
|---|---|---|
| SPM_ISO_STAT | SPM ISO Status | This is the value of the SPM ISO signal being sent to the Radio. |
| RSIM_ISO_OVRD_EN | RSIM ISO Override Enable | This bit enables the RSIM ISO Override bit |
| RSIM_ISO_OVRD | RSIM ISO Override | This bit directly controls the Radio ISO signal when the RSIM ISO Override is enabled |
| RSIM_RADIO_ISO_POR_OVRD | RSIM ISO_POR Override | This bit directly controls the Radio ISO_POR signal when the RSIM_ISO_OVRD_EN bit is set |
| RADIO_ISO_STAT | Radio Isolation Status | This is the value of the RSIM ISO signal being sent to the Radio Isolation logic, including any overrides. |

### 64.2.4.6 RF Analog Isolation

The RSIM controls the isolation state of the RF Analog in Stop Modes, the detailed signaling description is shown in the following diagram:

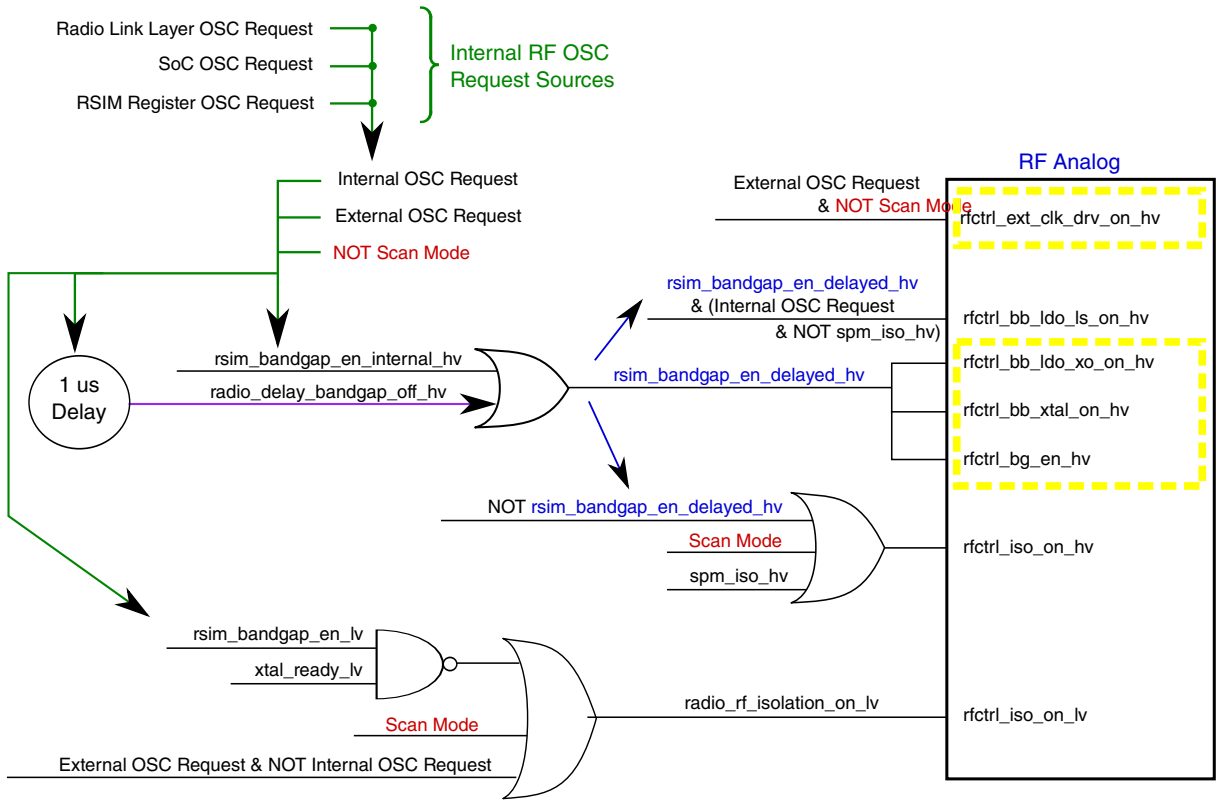

**Figure 64-8. RF Analog Isolation Diagram**

## 64.2.4.7 RAM Retention

The Radio has two internal RAM blocks that are allowed to go into a low power state when they are not being used by a link layer. If the RADIO_RAM_ACCESS_OVRD_EN and RADIO_RAM_ACCESS_OVRD bits are set, then the RAMs are kept in an active power state to allow software to access them.

WARNING: Software should not cause the RAMs to lose power if the Radio Link Layers are using the Deep Sleep State Machines and are configured to use the RAM to store data.

## 64.2.4.8 Radio Idle Mode

When the Radio is in a low power Stop Mode, such as RLLS with the SPM Run Regulator in low power mode, there is a software method that allows the RF Analog Reference Oscillator to be kept enabled in a low power state and thereby warmed up and ready for a faster transition from Stop to Run mode.

In order to configure for this Idle Mode software should write these bits before going into Stop:

- RSIM_ANA_TEST_XTAL_OUT_BUF_EN = 0, Turn off the External Pin Drive Buffer so that no Osc Clock will be present.
- RSIM_SW_CONFIG_BLOCK_EXT_OSC_PWR_REQ = 1, Radio will not request full Run Regulation mode when EXT_OSC is requested.
- RSIM_RF_OSC_CTRL_RADIO_EXT_OSC_OVRD_EN = 1, Enable the override bit.
- RSIM_RF_OSC_CTRL_RADIO_EXT_OSC_OVRD = 1, This is the software request to enable the Osc in Idle Mode.

## 64.2.5 Radio Deep Sleep

The RSIM has two Deep Sleep State Machines to support Wake on Radio and Manual Deep Sleep configurations.

Note that the BLE Link Layer has it's own Deep Sleep FSM, please refer to the BLE Link Layer chapters for additional information.

This section covers the portions of the Deep Sleep Hardware contained in the RSIM.

### 64.2.5.1 Deep Sleep Entry

The RSIM Deep Sleep State Machines will enter sleep automatically based on hardware requests from the link layer or the time as counted in the DSM_TIMER. Please refer to the Wake-On-Radio and the Manual DSM sections for more details.

### 64.2.5.2 Deep Sleep Wakeup

The RSIM Deep Sleep State Machines will automatically wakeup based upon the time as counted in the DSM_TIMER.

The DSM_TIMER is enabled using the DSM_TIMER_EN bit, and the timer can be cleared using the DSM_TIMER_CLR bit.

#### 64.2.5.2.1 Wakeup Sequence Settings

Software must configure the Deep Sleep Wakeup Sequence using these RSIM register bits. The Wakeup Sequence will be the same for all of the Radio Deep Sleep Wakeups.

The required settings and the method of calculating them are shown in the following table.

**Table 64-4. Wakeup Sequence Settings**

| RSIM Register Field | Function | Description |
|---|---|---|
| DSM_POWER_OFFSET_TIME | Deep Sleep Wakeup Power Offset Time | This register is the calculated Radio Power-On Sequence Time. |
| COARSE_DELAY | Deep Sleep Wakeup Coarse Delay Time | This is the first delay after the beginning of the Power-On sequence, the range is 0-15 and the resulting delay is 1.953 ms x COARSE_DELAY + 30.52 us, with a minimum delay of 30.52 us. |
| FINE_DELAY | Deep Sleep Wakeup Fine Delay Time | This is the second delay after the beginning of the Power-On sequence, the range is 0-63 and the resulting delay is 122.07 us x FINE_DELAY + 30.52 us, with a minimum delay of 30.52 us. This is when the RF OSC is enabled and so the Radio Analog Power must be stable at this milestone. |
| ACTIVE_WARNING | Deep Sleep Wakeup RF Active Warning Time | This is the delay after RF OSC has been enabled, the range is 0-63 and the resulting delay is 122.07 us x ACTIVE_WARNING + 30.52 us, with a minimum delay of 30.52 us. This is typically when the RF Osc should be stable. |

#### 64.2.5.2.2 BLE Link Layer Controller Programming

For BLE, the Link Layer Controller needs to be programmed to account for the RSIM DSM total wakeup time, including the Coarse, Fine, and Active Warning delay times. The BLE Link Layer Controller initiates the wakeup process by asserting **orf_sysclk_req_3v** to RSIM. At the same instant, the BLE DSM FSM transitions from DEEP_SLEEP to WAIT_OSC_STABLE state, as shown in the following diagram:

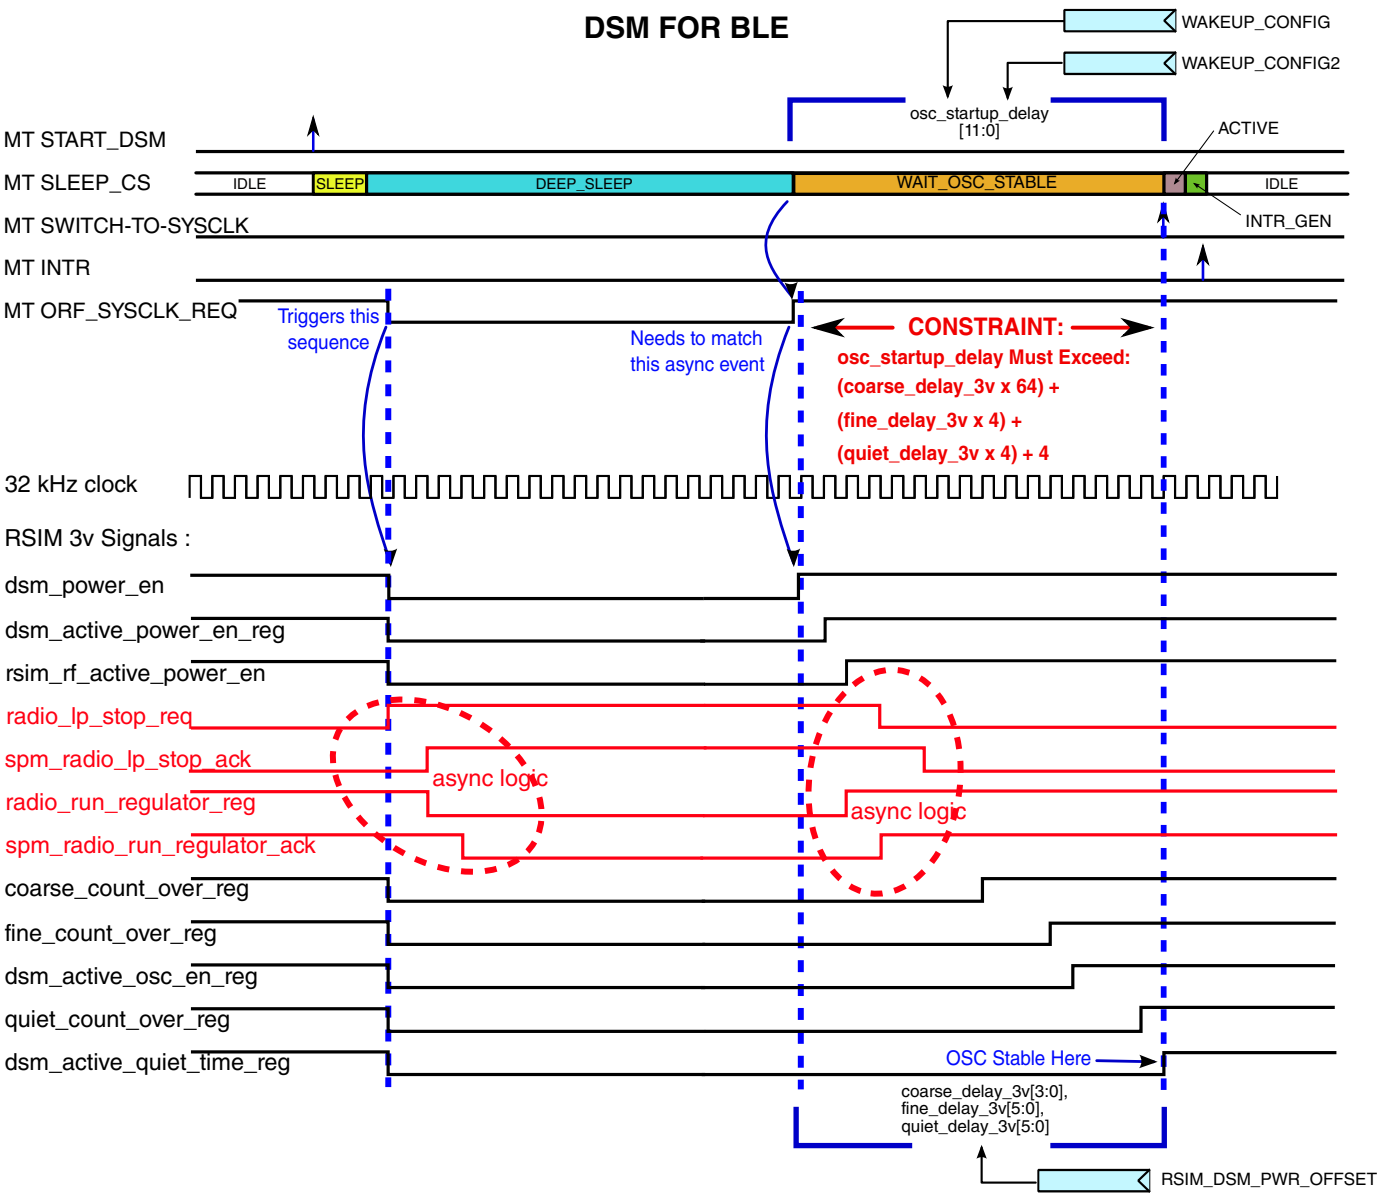

**Figure 64-9. Deep Sleep Mode For BLE**

The BLE FSM holds in WAIT_OSC_STABLE until the radio is fully powered and the RF Oscillator has stabilized. This requirement is met when the following equation is satisfied:

RSIM TOTAL WAKEUP = (COARSE * 64) + 1 + (FINE * 4) + 1 + (ACTIVE_WARNING * 4) + 1 + 2 , in units of 32.768KHz clock periods

The duration of the WAIT_OSC_STABLE state must exceed RSIM TOTAL WARMUP time, to ensure the BLE Link Layer sees a stable oscillator to resume RF operations. However, the amount by which WAIT_OSC_STABLE duration exceeds this time, must be minimized, to avoid excessive power consumption.

The duration of WAIT_OSC_STABLE is determined by 2 BLE registers:

| BLE Register | Description |
|---|---|
| WAKEUP_CONFIG[OSC_STARTUP_DELAY[4:0] | This is the Fine Setting for the BLE Radio Power-On Offset and it is the number of 16.384 kHz clocks (61.04 us) to use as a Start Time offset prior to the BLE Deep Sleep Machine entering the Active State. |
| WAKEUP_CONFIG2[OSC_STARTUP_DELAY[11:5] | This is the Coarse Setting for the BLE Radio Power-On Offset and it is the number of BT Slots (625 us) to use as a Start Time offset prior to the BLE Deep Sleep Machine entering the Active State. |

Please refer to the BLE Link Layer chapters for additional information.

Note: The BLE Radio Power-On Offset must be Longer than the Radio Power-On Sequence. The RF Osc warm-up must complete before the BLE Deep Sleep Machine enters the Active State.

Note: In order to generate a 625 us average BT Slot time from a 32.768 kHz Osc clock there is a hardware method used to occasionally increase the number of 61.04 us clocks counted while creating the 625 us clock. This results in an uncertainty of one 16 kHz clock period while calculating the Coarse Setting for the BLE Radio Power-On Offset. Since this uncertainty is always positive and always increases the actual time of the BLE Radio Power-On Offset it can be neglected for purposes of ensuring that the BLE Radio Power-On Offset is Longer than the Radio Power-On Sequence.

The sum of the intervals determined by the values programmed into these 2 registers, represents the WAIT_OSC_STABLE duration.

**Example:**

- Configure BLE Link Layer Controller for an RSIM 3/4/5 DSM Wakeup (232 clocks):
  - RSIM 3/4/5 = COARSE + FINE + ACTIVE_WARNING + 2
  - RSIM 3/4/5 = (3 x 64) + 1 + (4 x 4) + 1 + (5 x 4) + 1 + 2 = 233
  - 233 / 32768 = 7.1105957ms
  - OSC_STARTUP_DELAY >= 7.1105957ms (constraint)
  - OSC_STARTUP_DELAY_SLOTS + OSC_STARTUP_DELAY_CLKS >= 7.1105957ms (constraint)
  - (11 x 0.625ms) + (6 x [2 / 32.768]) = 7.24121ms (contraint met)
- Software Example, DUT: Config RSIM for DSM
  - `ips3.w32(`RSIM_DSM_PWR_OFFSET, (3 << `COARSE_DELAY_3V) | (4 << `FINE_DELAY_3V) | (5 << `ACTIVE_WARNING_DELAY_3V));
- Software Example, DUT: Config BLE for DSM
  - dsm_offset_to_instant = 3;
  - osc_startup_delay_slots = 11;

- osc_startup_delay_clks = 6;
- `apb.w16(`WAKEUP_CONFIG, (dsm_offset_to_instant << 10) | (osc_startup_delay_clks << 0));
- `apb.w16(`WAKEUP_CONFIG2, (osc_startup_delay_slots << 0));

### 64.2.5.3 Deep Sleep Timer

When the Deep Sleep Timer is enabled, using the DSM_TIMER_EN bit, the DSM_TIMER register represents the 24-bit internal counter that counts the 32 kHz clock cycles. The DSM_TIMER register is cleared while the DSM_TIMER_CLR bit is set.

The Deep Sleep State Machines use the DSM_TIMER value to calculate sleep and wakeup times.

### 64.2.5.4 Deep Sleep Forced Exit

While the Deep Sleep State Machines are in sleep mode software can force a wakeup using the BLE_DSM_EXIT and WOR_DSM_EXIT register bits.

The State Machines will hold in their initial idle state until the corresponding EXIT register bits are cleared.

### 64.2.5.5 Deep Sleep State Machines

The RSIM registers have fields that are used by software to configure, control, and observe the Deep Sleep State Machines, these are described in the following tables.

**Table 64-5. Wake on Radio Deep Sleep State Machine Registers**

| RSIM Register Field | Function | Description |
|---|---|---|
| WOR_FSM_STATE | WOR Deep Sleep State Machine State | This is the current State that the WOR Deep Sleep Finite State Machine is in. |
| DSM_WOR_READY | WOR Ready for Deep Sleep Mode | This is the SLEEP_READY state in the Deep Sleep Module State Machine, the state machine holds here until the sleep time is reached on the 32 kHz clock counter (Deep Sleep Timer). |
| WOR_DEEP_SLEEP_STATUS | WOR Deep Sleep Mode Status | This is the signal from the Deep Sleep Module State Machine telling the Link Layer to enter and exit Deep Sleep Mode. If this bit is set then the Link Layer is in Deep Sleep Mode. |

*Table continues on the next page...*

**Table 64-5. Wake on Radio Deep Sleep State Machine Registers (continued)**

| | | |
|---|---|---|
| DSM_WOR_FINISHED | WOR Deep Sleep Time Finished | This is the SLEEP_FINISHED state in the Deep Sleep Module State Machine, the state machine holds here until the Link Layer de-asserts the sleep_request. |
| WOR_WAKEUP_REQUEST_EN | Enable WOR Deep Sleep Module to initiate a Radio Wakeup | This bit allows the WOR Deep Sleep Module to initiate a Radio Wakeup. |
| WOR_SLEEP_REQUEST | WOR Deep Sleep Requested | From the WOR Scheduler. When the signal is asserted WOR Deep Sleep Mode is entered. |
| WOR_WAKEUP_REQ | WOR Deep Sleep Module Radio Wakeup Status | This bit shows the status of the WOR Deep Sleep Module Request for the Radio to Wakeup. If the WOR_WAKEUP_REQUEST_EN bit is set, then this signal is used by the RSIM to Wakeup the Radio if the Radio is not already awake. |
| WOR_WAKEUP_INTERRUPT_EN | WOR Deep Sleep Module Radio Wakeup Interrupt Enable | If this bit is set, then a change from a 0 to a 1 on WOR_WAKEUP_REQ will generate an interrupt which can be used by the SoC. |
| WOR_WAKEUP_REQ_INT | Interrupt Flag from an WOR Deep Sleep Module Radio Wakeup | If the WOR_WAKEUP_INTERRUPT_EN bit is set, then this flag indicates that an WOR Radio Wakeup has occurred. The flag will persist until this bit is written with a 1 to clear it. |
| WOR_DSM_DURATION | WOR Deep Sleep Time Elapsed | The RSIM calculates the duration of the WOR deep sleep time and presents it here. |

**Table 64-6. Manual Deep Sleep State Machine Registers**

| RSIM Register Field | Function | Description |
|---|---|---|
| MAN_FSM_STATE | MAN Deep Sleep State Machine State | This is the current State that the MAN Deep Sleep Finite State Machine is in. |
| DSM_MAN_READY | MAN Ready for Deep Sleep Mode | This is the SLEEP_READY state in the Deep Sleep Module State Machine, the state machine holds here until the sleep time is reached on the 32 kHz clock counter (Deep Sleep Timer). |
| MAN_DEEP_SLEEP_STATUS | MAN Deep Sleep Mode Status | This is the signal from the Deep Sleep Module State Machine telling the Link Layer to enter and exit Deep Sleep Mode. If this bit is set then the Link Layer is in Deep Sleep Mode. |
| DSM_MAN_FINISHED | MAN Deep Sleep Time Finished | This register is for debug purposes. This is the SLEEP_FINISHED state in the Deep Sleep Module State Machine, the state machine holds here until the Link Layer de-asserts the sleep_request. |
| MAN_WAKEUP_REQUEST_EN | Enable MAN Deep Sleep Module to initiate a Radio Wakeup | This bit allows the MAN Deep Sleep Module to initiate a Radio Wakeup. |

*Table continues on the next page...*

**Table 64-6. Manual Deep Sleep State Machine Registers (continued)**

| | | |
|---|---|---|
| MAN_SLEEP_REQUEST | MAN Deep Sleep Requested | From the MAN Sleep Enable register. This enables a match of MAN_SLEEP[23:0] to SLEEP_TMR[23:0]; when the match occurs Deep Sleep Mode is entered. |
| MAN_WAKEUP_REQ | MAN Deep Sleep Module Radio Wakeup Status | This bit shows the status of the MAN Deep Sleep Module Request for the Radio to Wakeup. If the MAN_WAKEUP_REQUEST_EN bit is set, then this signal is used by the RSIM to Wakeup the Radio if the Radio is not already awake. |
| MAN_WAKEUP_INTERRUPT_EN | MAN Deep Sleep Module Radio Wakeup Interrupt Enable | If this bit is set, then a change from a 0 to a 1 on MAN_WAKEUP_REQ will generate an interrupt which can be used by the SoC. |
| MAN_WAKEUP_REQ_INT | Interrupt Flag from an MAN Deep Sleep Module Radio Wakeup | If the MAN_WAKEUP_INTERRUPT_EN bit is set, then this flag indicates that an MAN Radio Wakeup has occurred. The flag will persist until this bit is written with a 1 to clear it. |
| MAN_SLEEP_TIME | MAN Deep Sleep Module Sleep Time | Software determines the future time at which it would like to enter Deep Sleep Mode by reading the DSM_TIMER, computing the number of 32 kHz clock cycles remaining until the desired DSM start-time, and writing that value into this register. The value programmed into this register should be no fewer than 4 clocks greater (in the future) than the current time as read from DSM_TIMER. |
| MAN_WAKE_TIME | MAN Deep Sleep Module Wake Time | Software determines the future time at which it would like to exit Deep Sleep Mode by reading the DSM_TIMER, computing the number of 32 kHz clock cycles remaining until the desired DSM exit time, and writing that value into this register. |

## 64.2.6 Wi-Fi Coexistence

Hardware and Software methods allow the Radio to coexist in the same space as a Wi-Fi transceiver IC, which shares the same 2.4GHz frequency band. The coexistence scheme designates the Wi-Fi transceiver as the master, and the Radio as the slave. The objective of the coexistence strategy is to prevent both the Wi-Fi and Radio from transmitting simultaneously; a configuration option exists to also prevent the Radio from receiving when the Wi-Fi transceiver owns the RF channel.

A very basic mechanism is used in cases where the Radio does not generate requests, but instead defers to the Wi-Fi transceiver to grant permission to use the medium. The Wi-Fi IC generates a signal, RF_NOT_ALLOWED. If this signal is asserted, then the Radio does not perform any communication. When this signal is de-asserted, then the Radio is free to perform communications. In case the signal RF_NOT_ALLOWED is de-asserted when the Radio has already initiated the transmission/reception of a packet, then the Radio must stop its activity immediately .

Inside the Radio, all protocols are potentially affected by the coexistence strategy. However, coexistence-driven aborting can be enabled or disabled for the different protocols, under software control.

### 64.2.6.1 Wi-Fi Coexistence Pins

The Wi-Fi Coexistence Pins are described in the following table.

| Wi-Fi Coexist Function | Pin Direction | SoC Pin Name | Pin Description |
|---|---|---|---|
| RF_ACTIVE | O | RF_ACTIVE | An output which is asserted prior to any Radio event and remains asserted for the duration of the event. |
| RF_STATUS | O | RF_STATUS | An output which indicates when the Radio is in an RX or TX event, software can also control this signal directly. |
| RF_PRIORITY | O | RF_PRIORITY | An output which indicates to the external WiFi device that the Radio event is a high priority and it needs access to the 2.4GHz antenna. |
| RF_EARLY_WARNING | O | RF_EARLY_WARNING | BLE LL generated signal which can be used to wake an external sensor to make a measurement before a BLE event |
| RF_NOT_ALLOWED | I | RF_NOT_ALLOWED | External signal which causes the internal Radio to cease radio activity. |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| RF_TX_CONF | I | RF_TX_CONF | Signal from an external Radio which indicates the availability of the 2.4GHz antenna to the internal Radio. |

### 64.2.6.2 RF Not Allowed Register Bits

Several register bits have been provided in the XCVR_CTRL registers to enable, control, and provide status for RF_NOT_ALLOWED events. These bits are described in the following table.

| Field | R/W | Description |
|---|---|---|
| RF_NOT_ALLOWED_NO_TX | RW | 1: Allow assertions on RF_NOT_ALLOWED to abort a TSM TX sequence<br>0: Don't allow such aborts on TX |
| RF_NOT_ALLOWED_NO_RX | RW | 1: Allow assertions on RF_NOT_ALLOWED to abort a TSM RX sequence<br>0: Don't allow such aborts on RX |
| RF_NOT_ALLOWED_ASSERTED | R, Write a 1 to clear | 1: An assertion on RF_NOT_ALLOWED has occurred since the last time this bit was cleared<br>0: No such assertion has occurred since the last time bit was cleared<br>**Note**: this bit will become set regardless of whether aborting on RF_NOT_ALLOWED events is enabled or not |
| RF_NOT_ALLOWED_TX_ABORT | R, Write a 1 to clear | 1: An assertion on RF_NOT_ALLOWED has aborted a TSM TX sequence since the last time this bit was cleared<br>0: No such TX abort has occurred since the last time bit was cleared |
| RF_NOT_ALLOWED_RX_ABORT | R | 1: An assertion on RF_NOT_ALLOWED has aborted a TSM RX sequence since the last time this bit was cleared<br>0: No such RX abort has occurred since the last time bit was cleared |
| RF_NOT_ALLOWED | R | Reflects the raw state of the RF_NOT_ALLOWED GPIO pin |

### 64.2.6.3 RF Active Register Bits

Several register bits have been provided in the RSIM registers to enable and control the RF_ACTIVE signaling. These bits are described in the following table.

| | | |
|---|---|---|
| ACTIVE_WARNING | Deep Sleep Wakeup RF Active Warning Time | This is the delay after RF OSC has been enabled, the range is 0-63 and the resulting delay is 122.07 us x ACTIVE_WARNING + 30.5 us. This is typically when the RF Osc should be stable. |

*Table continues on the next page...*

| | | |
|---|---|---|
| WIFI_COEXIST_1 | RF_ACTIVE Source | If this bit is set the RF_ACTIVE pin will be controlled by TSM Spare 1, otherwise it will be controlled by the RSIM RF Active Sequence along with any override by the SW_RF_ACTIVE_BIT. |
| WIFI_COEXIST_2 | RF_STATUS Source | If this bit is set the RF_STATUS pin will be controlled by TSM Spare 3, otherwise it will be controlled by TSM Spare 2. |
| WIFI_COEXIST_3 | RF_EARLY_WARNING Source | If this bit is set the RF_EARLY_WARNING pin will be controlled by TSM Spare 3, otherwise it will be controlled by the BLE Link Layer. |
| RF_ACTIVE_ENDS_WITH_TSM | RF_ACTIVE clearing mechanism | If this bit is set then the RSIM RF_ACTIVE OR source will clear when the TSM sequence ends. |
| SW_RF_ACTIVE_EN | Software RF_ACTIVE Control Enable | If this bit is set the SW_RF_ACTIVE_BIT acts as an OR source for the RF_ACTIVE pin. |
| SW_RF_ACTIVE_BIT | Software RF_ACTIVE Control Bit | If the SW_RF_ACTIVE_EN bit is set this bit acts as an OR source for the RF_ACTIVE pin. |
| SW_RF_ACTIVE_ENDS_WITH_TSM | Software RF_ACTIVE clearing mechanism | If this bit is set along with the SW_RF_ACTIVE_EN bit, then the Software RF_ACTIVE OR source will clear when the TSM sequence ends. |
| RSIM_RF_ACTIVE_OVRD | RF Active Internal Override | If the RSIM_RF_ACTIVE_OVRD_EN bit is set, then this bit controls the Internal version of RF Active instead of the Link Layers. The Internal version of RF Active whether overridden or not has a lower priority and can always be overridden by software using the SW_RF_ACTIVE_BIT or the TSM Spare 1 bit if it is selected using the WIFI_COEXIST_1 select bit. |
| RSIM_RF_ACTIVE_OVRD_EN | RF Active Internal Override Enable | This bit enables the RF Active Internal Override |
| RF_NOT_ALLOWED_OVRD | RF Not Allowed Override | If the RF_NOT_ALLOWED_OVRD_EN bit is set, then this bit controls the RF Not Allowed functionality instead of the SoC pin. |
| RF_NOT_ALLOWED_OVRD_EN | RF Not Allowed Override Enable | This bit enables the RF Not Allowed Override |

### 64.2.7 RF Early Warning

The BLE Link Layer can be programmed to provide an Early Warning signal that can assert up to 38.75 ms before related the Radio Operation begins. One use of this signal is to wakeup an external sensor so that it can collect and prepare any required data that needs to be available at the time of the Radio Operation.

Please refer to the BLE RF_ACTIVE_PERIOD register description for more details.

Note that this signal can be reconfigured as part of the Wi-Fi Coexistence Method as described in that section.

## 64.2.8 Radio Interrupts

The Radio can generate two asynchronous interrupts and one asynchronous MCU wakeup signal.

The interrupt configurations are illustrated in the diagram below and detailed in the following sections.

### 64.2.8.1 Interrupts Diagram

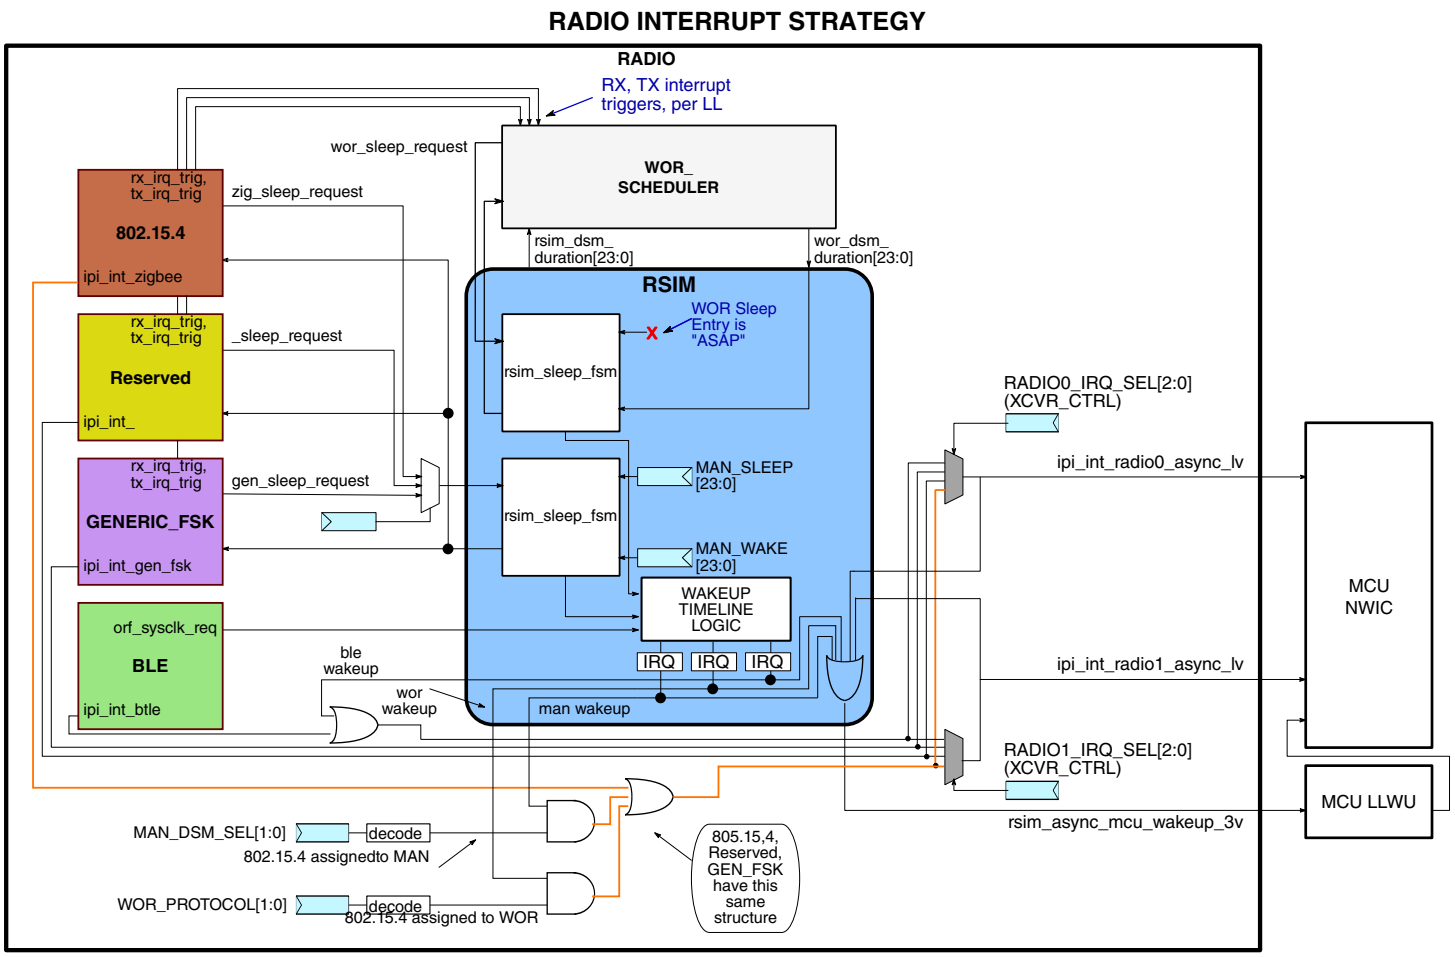

**Figure 64-10. Radio Interrupts**

### 64.2.8.2 Enabling Interrupts

There are three places that the interrupt strategy can be programmed:

1. The individual Link Layers interrupts may be configured.
2. The RSIM Deep Sleep Wakeup source may be configured.
3. The XCVR_CTRL register must be configured.

### 64.2.8.3 Deep Sleep Wakeups

Each Deep Sleep State Machine can generate a wakeup interrupt based upon this Wakeup Source selection.

The Radio Power-On Sequence can generate this wakeup interrupt at three times in the sequence, as shown in the following table:

| WAKEUP_INTERRUPT_SOURCE | Functionality |
|---|---|
| 0 | No Radio Power-On Sequence interrupt will be generated. |
| 1 | A Power-On Sequence interrupt will be generated when the RF Power Request occurs, including unblocked requests from an external source to use the RF OSC. |
| 2 | A Power-On Sequence interrupt will be generated when the RF OSC Request occurs, but not if the RF OSC request was from an external source. |
| 3 | A Power-On Sequence interrupt will be generated when the RSIM RF Active Warning occurs |

### 64.2.8.4 XCVR CTRL IRQ Select

Each of the Link Layer interrupts that can be selected here are an OR of the Link Layer interrupt, the WOR wakeup interrupt selected, or the MAN wakeup interrupt selected.

The two OR'd interrupts must be selected using the XCVR_CTRL RADIO0_IRQ_SEL and RADIO1_IRQ_SEL registers in the Transceiver as shown in the following tables:

Assign ipi_int_radio0_async_lv Interrupt (ipi_int_radio0) to a Protocol :

| RADIO0_IRQ_SEL | Functionality |
|---|---|
| 0 | Assign ipi_int_radio0_async_lv Interrupt to BLE |
| 1 | Assign ipi_int_radio0_async_lv Interrupt to 802.15.4 |
| 3 | Assign ipi_int_radio0_async_lv Interrupt to GENERIC_FSK |
| 2,4-7 | ipi_int_radio0_async_lv Interrupt unassigned |

Assign ipi_int_radio1_async_lv Interrupt (ipi_int_radio1) to a Protocol :

| RADIO1_IRQ_SEL | Functionality |
|---|---|
| 0 | Assign ipi_int_radio1_async_lv Interrupt to BLE |
| 1 | Assign ipi_int_radio1_async_lv Interrupt to 802.15.4 |
| 3 | Assign ipi_int_radio1_async_lv Interrupt to GENERIC_FSK |
| 2,4-7 | ipi_int_radio0_async_lv Interrupt unassigned |

### 64.2.8.5 MCU Wakeup

The RSIM Asynchronous MCU Wakeup signal is an OR of the enabled RADIO0_INTERRUPT, RADIO1_INTERRUPT, and the WAKEUP_INTERRUPT_SOURCE selections.

The control and observe bits for this wakeup source are shown in the following table:

| RSIM Register Field | Function | Description |
|---|---|---|
| RADIO0_INTERRUPT_EN | Radio0 Interrupt Enable | This bit enables the Radio0 interrupt source, as selected by the Radio0 IRQ Select bits, to be added to the interrupt sources that are used to generate the RSIM Asynchronous MCU Wakeup signal. |
| RADIO1_INTERRUPT_EN | Radio1 Interrupt Enable | This bit enables the Radio1 interrupt source, as selected by the Radio1 IRQ Select bits, to be added to the interrupt sources that are used to generate the RSIM Asynchronous MCU Wakeup signal. |
| BLE_RF_POWER_REQ_INT_EN | BLE RF Power Request Interrupt Enable | This bit enables an interrupt request, that is also added to the RSIM Asynchronous MCU Wakeup signal, when the WAKEUP_INTERRUPT_SOURCE selected version of the BLE RF Power Request is asserted high. |
| BLE_RF_POWER_REQ_INT | BLE RF Power Request Interrupt Flag | This bit is the BLE_RF_POWER_REQ_INT interrupt flag. |
| WOR_WAKEUP_INTERRUPT_EN | WOR Deep Sleep Module Radio Wakeup Interrupt Enable | This bit enables an interrupt request, that is also added to the RSIM Asynchronous MCU Wakeup signal, when the WAKEUP_INTERRUPT_SOURCE selected version of the WOR Wakeup Request is asserted high. |

*Table continues on the next page...*

| | | |
|---|---|---|
| WOR_WAKEUP_REQ_INT | Interrupt Flag from an WOR Deep Sleep Module Radio Wakeup | This bit is the WOR_WAKEUP_REQ_INT interrupt flag. |
| MAN_WAKEUP_INTERRUPT_EN | MAN Deep Sleep Module Radio Wakeup Interrupt Enable | This bit enables an interrupt request, that is also added to the RSIM Asynchronous MCU Wakeup signal, when the WAKEUP_INTERRUPT_SOURCE selected version of the MAN Wakeup Request is asserted high. |
| MAN_WAKEUP_REQ_INT | Interrupt Flag from an MAN Deep Sleep Module Radio Wakeup | This bit is the MAN_WAKEUP_REQ_INT interrupt flag. |

## 64.2.9 Radio Configuration

The Radio Software Configuration (SW_CONFIG) register contains the software configuration and control bits. These bits can be written by software as part of configuring the Radio and then they can be read as needed to confirm that the Radio has not been reset by either a System Reset or a Power On event.

Please read the Radio Resets section for more information about the reset signals.

The configuration bits are described in the following table:

| RSIM Register Field | Function | Description |
|---|---|---|
| RADIO_CONFIGURED_POR_RESET | Radio Configuration Bit, cleared by Radio Power On Reset | This is a bit software can write when it wants to be able to check if a Radio Power On Reset occurs. |
| RADIO_CONFIGURED_SYS_RESET | Radio Configuration Bit, cleared by Radio System Reset | This is a bit software can write when it wants to be able to check if a Radio System Reset occurs. |
| BLOCK_SOC_RESETS | Block SoC Resets of the Radio, cleared by Radio System Reset | Most SoC System or Power On Resets will be blocked and the Radio will not be affected by them when this bit is set. The Radio Power Mode logic is not blocked by this bit and will reset on any SoC Power On Reset. |
| RADIO_POR_BIT | Software Power On Reset for the Radio. This bit only clears if there is an SoC Power On Reset. | Setting this bit will reset all the radio logic that uses the Radio Power On Reset or Radio VLLS Reset signal, it will be held in reset until this bit is cleared. |
| RADIO_RESET_BIT | Software System Reset for the Radio. This bit only clears if there is an SoC Power On Reset. | Setting this bit will reset the Global Radio and RSIM logic, including all Link Layer logic. The logic will stay in reset until this bit is cleared. This bit will not reset the Power Mode logic or the Deep Sleep Mode related logic. |

*Table continues on the next page...*

| | | |
|---|---|---|
| BLOCK_EXT_OSC_PWR_REQ | Block External Requests for RF OSC from starting a Radio Power Wakeup Sequence | If this bit is set then any External request for the OSC will not start a Radio Power Wakeup Sequence, otherwise any such request does request full Run Regulation mode. |

## 64.2.10 Radio Resets

The Radio can be reset by the SoC System Reset, the SoC Power On Reset, or software can block the SoC System Reset and instead perform a Radio Resets using register bits in the RSIM. Please read the Radio Configuration section for descriptions of those bits.

### 64.2.10.1 Reset Tree Diagram

The Radio Reset Tree is illustrated in the diagram below

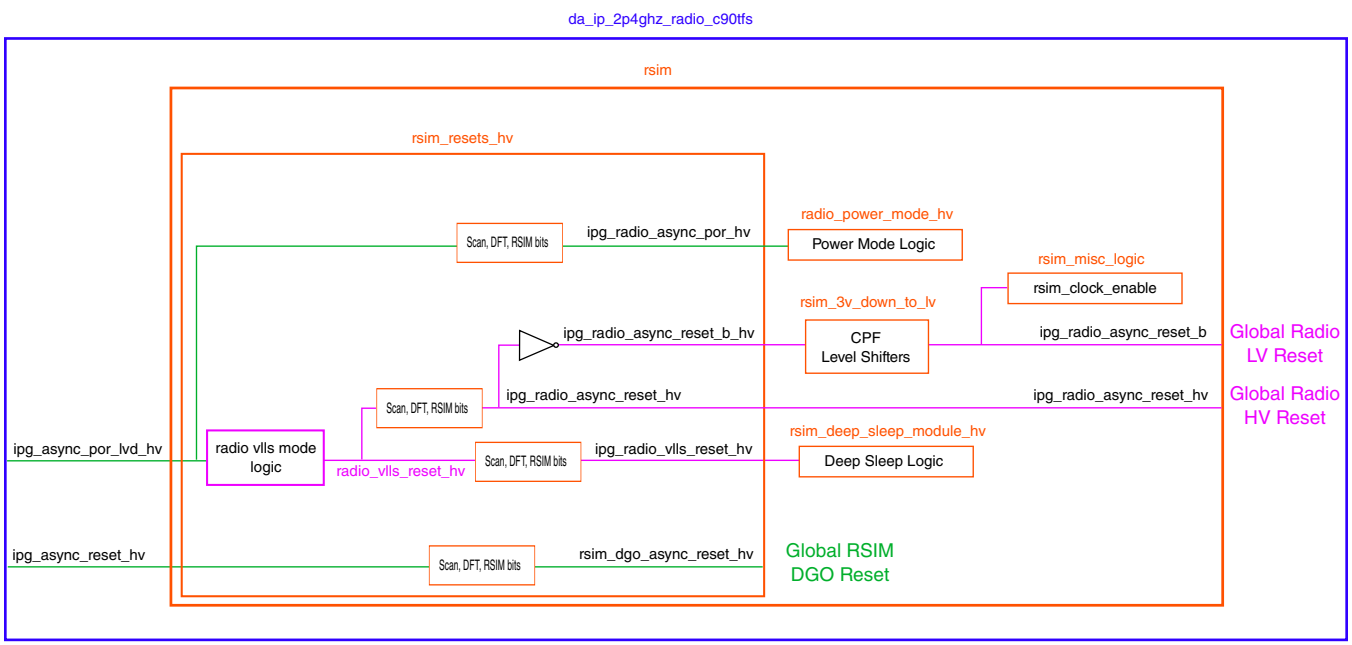

**Figure 64-11. Radio Reset Tree**

### 64.2.10.2 Blocking Resets

Software can choose to block SoC resets from reseting the Radio configuration and instead software can then monitor the SoC Resets, and also the Radio Configuration Status using the RADIO_CONFIGURED_SYS_RESET and RADIO_CONFIGURED_POR_RESET bits.

To use this method software should do the following:

- Set RSIM_SW_CONFIG_BLOCK_SOC_RESETS = 1 to start blocking SoC System Resets.
- Set RSIM_SW_CONFIG_RADIO_CONFIGURED_SYS_POR = 1 and monitor it to see if a POR has occurred, which will return all Radio settings to default.
- Monitor the SoC resets and if the Radio needs to be reset use the RSIM_SW_CONFIG_RADIO_RESET_BIT to reset the non-POR only logic.
- To return the entire Radio to the default settings use the RSIM_SW_CONFIG_RADIO_POR_BIT too.

### 64.2.10.3 Using Radio Reset Bits

In order to reset the Radio completely, software should toggle the RADIO_RESET_BIT first, and then toggle the RADIO_POR_BIT.

## 64.2.11 Radio Gasket Bypass

The SoC platform has an asynchronous gasket that allows register access for the Radio registers in all SoC clocking modes. The RADIO_GASKET_BYPASS_OVRD bit allows software to directly control the SoC platform asynchronous gasket bypass signal.

The default behavior of the SoC Asynchronous Gasket is Not Bypassed, which means the Radio registers are accessed using the RF Ref Osc clock. The Radio sends the RF Ref Osc to the asynchronous gasket which then uses that clock for SoC register accesses of the Radio registers. This requires the RF Ref Osc to be Enabled and Ready. If the RF Ref Osc is not Enabled and Ready, then the IPS Gasket can be overridden to be in Bypass Mode, which forces the use of the SoC IPG clock as the register access clock. If the RF Ref Osc Is Enabled and Ready, then the IPS Gasket can be overridden to be in Bypass Mode, but this is an ILLEGAL ACCESS if the Radio is operational, DO NOT write Radio registers with the Asynchronous Gasket Bypassed when the Radio is Operating. Test mode access is allowed but glitches may occur. The intent of Bypass Mode is to allow software to configure the Radio before the RF Ref Osc is Enabled and Ready. Note that the BLE Link Layer registers can only be accessed when the RF Ref Osc is Enabled and Ready.

Please also see the Radio Registers Access portion of the Radio Clocks section.

## 64.2.12 Radio Version ID

The RADIO_VERSION register value can be read to identify the Version of the Radio.

Note: If the Radio digital is in a low power stop mode the Version ID will read as zero.

## 64.2.13 Memory Map and Register Definition

### 64.2.13.1 RSIM register descriptions

#### 64.2.13.1.1 RSIM Memory map

RSIM base address: 4102_F000h

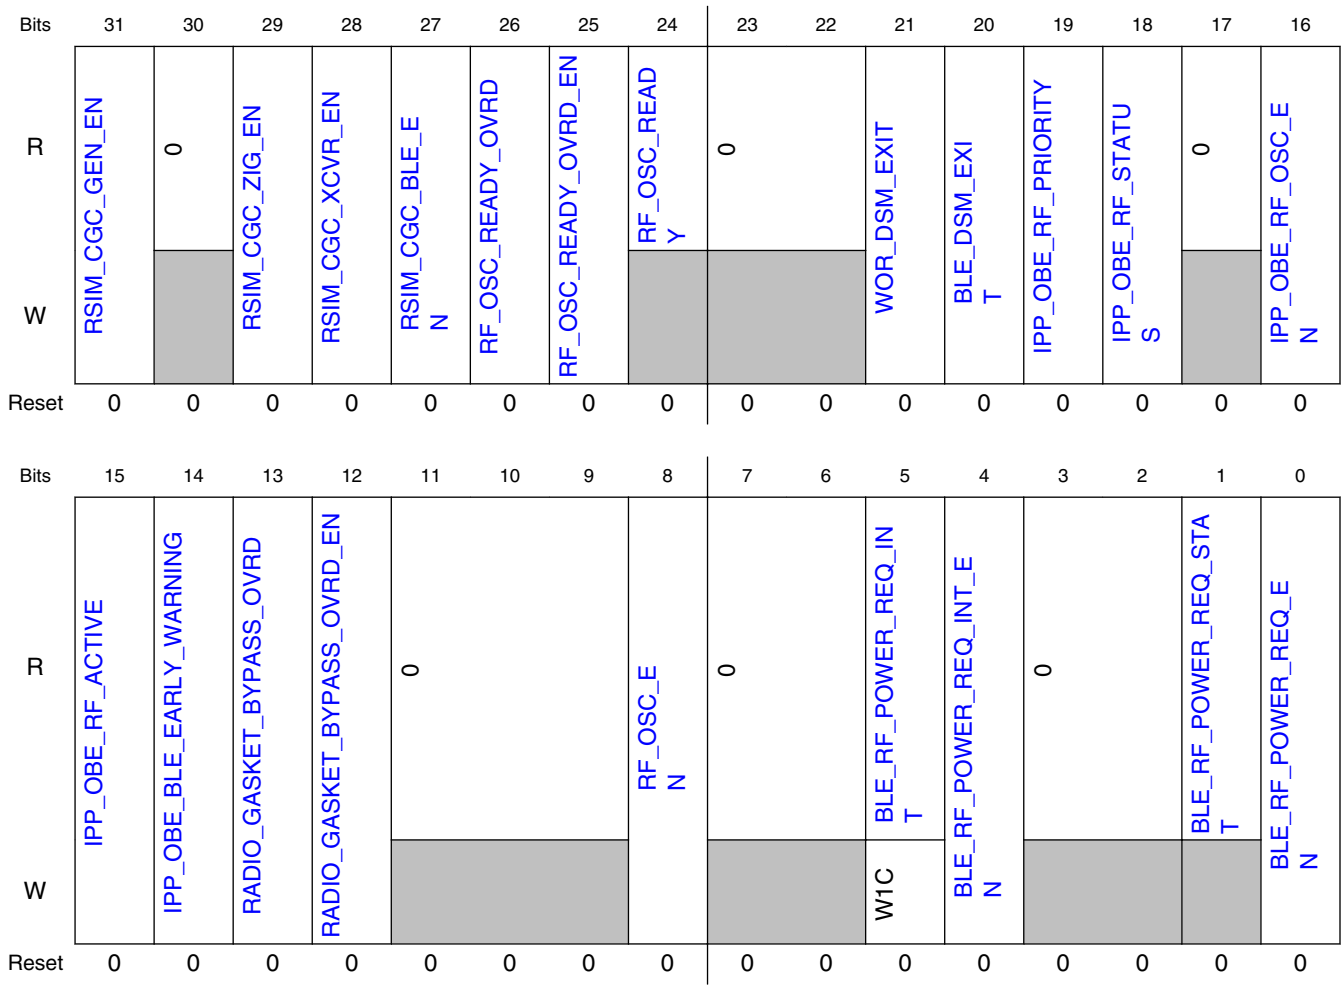
| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Radio System Control (CONTROL) | 32 | RW | 0000_0000h |
| 10h | Radio Miscellaneous (MISC) | 32 | RW | 0500_0000h |
| 14h | RSIM Power Control (POWER) | 32 | RW | 7000_0307h |
| 18h | Radio Software Configuration (SW_CONFIG) | 32 | RW | 0000_0020h |
| 100h | Deep Sleep Timer (DSM_TIMER) | 32 | RO | 0000_0000h |
| 104h | Deep Sleep Timer Control (DSM_CONTROL) | 32 | RW | 0000_0000h |
| 108h | Deep Sleep Wakeup Sequence (DSM_WAKEUP) | 32 | RW | 0000_0000h |
| 10Ch | WOR Deep Sleep Duration (WOR_DURATION) | 32 | RO | 0000_0000h |
| 110h | WOR Deep Sleep Wake Time (WOR_WAKE) | 32 | RW | 0000_0000h |
| 11Ch | MAN Deep Sleep Time (MAN_SLEEP) | 32 | RW | 0000_0000h |
| 120h | MAN Deep Sleep Wake Time (MAN_WAKE) | 32 | RW | 0000_0000h |
| 124h | Radio Oscillator Control (RF_OSC_CTRL) | 32 | RW | A020_3806h |
| 128h | Radio Analog Test Registers (ANA_TEST) | 32 | RW | 0000_0000h |
| 12Ch | Radio Analog Trim Registers (ANA_TRIM) | 32 | RW | 784B_0000h |

#### 64.2.13.1.2 Radio System Control (CONTROL)

### 64.2.13.1.2.1 Offset

| Register | Offset |
|---|---|
| CONTROL | 0h |

### 64.2.13.1.2.2 Diagram



### 64.2.13.1.2.3 Fields

| Field | Function |

| 18<br>IPP_OBE_RF_STATUS | IPP_OBE_RF_STATUS<br>This bit enables the Output Driver (OBE) on the SoC port that provides the RF Status signal as a pin interface option. |
| 17<br>— | Reserved |
| 16<br>IPP_OBE_RF_OSC_EN | IPP_OBE_RF_OSC_EN<br>This bit enables the Output Driver (OBE) on the SoC port that provides the RF Osc Enable signal as a pin interface option. |
| 15<br>IPP_OBE_RF_ACTIVE | IPP_OBE_RF_ACTIVE<br>This bit enables the Output Driver (OBE) on the SoC port that provides the RF Active signal as a pin interface option. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 14<br>IPP_OBE_BLE_EARLY_WARNING | IPP_OBE_BLE_EARLY_WARNING<br>This bit enables the Output Driver (OBE) on the SoC port that provides the BLE Early Warning signal as a pin interface option. |
| 13<br>RADIO_GASKET_BYPASS_OVRD | Radio Gasket Bypass Override<br>This bit directly controls the SoC platform asynchronous gasket bypass signal when the Gasket Bypass Override is enabled.The default behavior of the SoC Asynchronous Gasket is Not Bypassed, which means the Radio registers are accessed using the RF Ref Osc clock. The Radio sends the RF Ref Osc to the asynchronous gasket which then uses that clock for SoC register accesses of the Radio registers. This requires the RF Ref Osc to be Enabled and Ready. If the RF Ref Osc is not Enabled and Ready, then the IPS Gasket can be overridden to be in Bypass Mode, which forces the use of the SoC IPG clock as the register access clock. If the RF Ref Osc Is Enabled and Ready, then the IPS Gasket can be overridden to be in Bypass Mode, but this is an ILLEGAL ACCESS if the Radio is operational, DO NOT write Radio registers with the Asynchronous Gasket Bypassed when the Radio is Operating. Test mode access is allowed but glitches may occur. The intent of Bypass Mode is to allow software to configure the Radio before the RF Ref Osc is Enabled and Ready. Note that the BLE Link Layer registers can only be accessed when the RF Ref Osc is Enabled and Ready.<br>0b - XCVR and Link Layer Register Clock is the RF Ref Osc Clock<br>1b - XCVR and Link Layer Register Clock is the SoC IPG Clock |
| 12<br>RADIO_GASKET_BYPASS_OVRD_EN | Radio Gasket Bypass Override Enable<br>The SoC platform has an asynchronous gasket that allows register access for the Radio registers in all SoC clocking modes. This bit allows software to directly control the SoC platform asynchronous gasket bypass signal. |
| 11-9<br>— | Reserved |
| 8<br>RF_OSC_EN | RF Ref Osc Enable<br>The RF Reference Oscillator can be enabled by a Radio link layer (Including the Link Layer use of Deep Sleep Modes), by an internal SoC clock mode, by an External Pin request, or by this bit.<br>If this bit is 0, then in Radio Run Mode, the RF Ref Osc can be turned on by the SoC, or by a Radio link layer using RRun Mode (Including the Link Layer use of Deep Sleep Modes), or by an External Pin request. Warning: The RF Ref Osc can not be enabled by the SoC until the Radio has entered RRun Mode.<br>If this bit is 0, then in Radio Stop Modes, the RF Ref Osc will be off (except that the external pin request can turn the RF Osc on even if the RF Power is off). Warning: Radio will not go into Stop mode while the RF Ref Osc is being used by the SoC, or by a Radio link layer unless the Link Layer is using a Deep Sleep State Machine.<br>If this bit is 1, then the RF Ref Osc will be on in Radio Run Mode. Warning: The RF Ref Osc can not be enabled until the Radio has entered RRun Mode.<br>If this bit is 1, then the RF Ref Osc will be off in Radio Stop Modes (except that the external pin request can turn the RF Osc on even if the RF Power is off). Warning: Radio will not go into Stop mode while the RF Ref Osc is On. |
| 7-6<br>— | Reserved |
| 5<br>BLE_RF_POWER_REQ_INT | BLE RF Power Request Interrupt Flag<br>This bit is the BLE_RF_POWER_REQ_INT interrupt flag.<br>This interrupt flag is cleared by writing a 1 to it. |
| 4 | BLE RF Power Request Interrupt Enable |

*Table continues on the next page...*

| Field | Function |
|---|---|
| BLE_RF_POWER_REQ_INT_EN | This bit enables an interrupt request, that is also added to the RSIM Asynchronous MCU Wakeup signal, when the WAKEUP_INTERRUPT_SOURCE selected version of the BLE RF Power Request is asserted high. |
| 3-2<br>— | Reserved |
| 1<br>BLE_RF_POWER_REQ_STAT | BLE RF Power Request Status<br>This bit indicates the current status of the BLE link layer request to turn on the RF Power. |
| 0<br>BLE_RF_POWER_REQ_EN | BLE RF Power Request Enable<br>This bit resets on POR only.<br>If this bit is cleared (the default state), then all BLE link layer requests to turn on the RF Power will be blocked and ignored.<br>In BLE protocols the BLE link layer will always restart when exiting reset by first Requesting the RF Power, this bit blocks that behavior until software configures the Radio and enables the requests. |

## 64.2.13.1.5 Radio Software Configuration (SW_CONFIG)

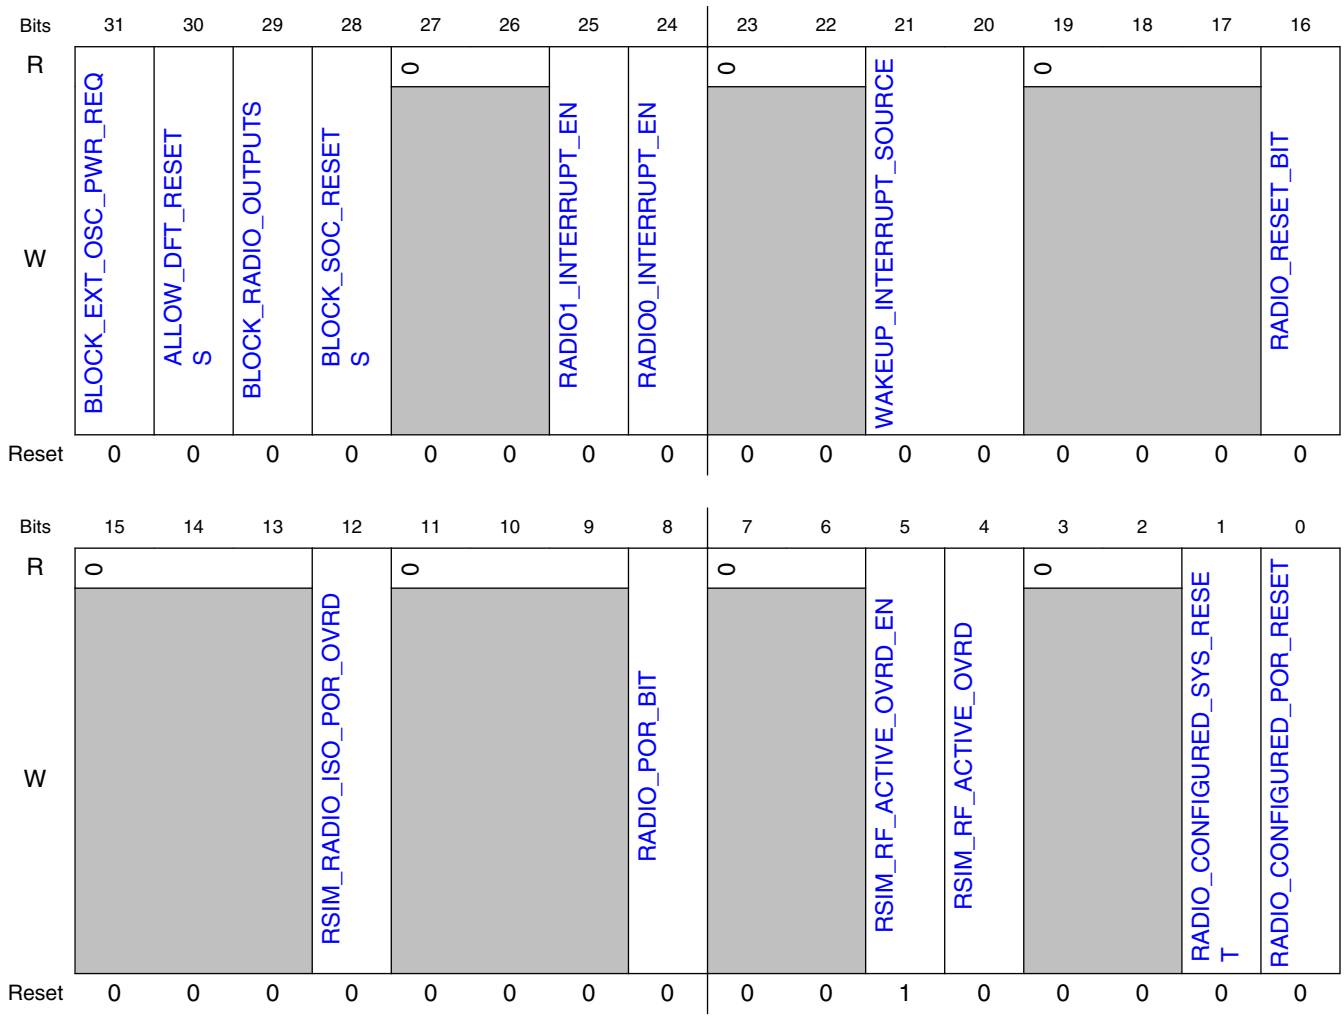
### 64.2.13.1.5.1 Offset

| Register | Offset |
|---|---|
| SW_CONFIG | 18h |

### 64.2.13.1.5.2 Function

This register contains the software configuration and control bits.

### 64.2.13.1.5.3 Diagram



### 64.2.13.1.5.4 Fields

| Field | Function |
|---|---|
| 31<br>BLOCK_EXT_OSC_PWR_REQ | Block External Requests for RF OSC from starting a Radio Power Wakeup Sequence<br>If this bit is set then any External request for the OSC will not start a Radio Power Wakeup Sequence, otherwise any such request does request full Run Regulation mode. |
| 30<br>ALLOW_DFT_RESETS | Allow the DFT Reset Pin to Reset the Radio<br>The Radio provides a port that can be connected to a test mode pin in order to provide a method of resetting the Radio independently from SoC resets. This bit enables that DFT functionality. |
| 29<br>BLOCK_RADIO_OUTPUTS | Block Radio Outputs<br>This bit resets on POR only. This bit is intended to allow the SoC to perform concurrent testing of various SoC logic while the Radio is operating independently. Any Radio output signals that go to the SoC will be blocked so as to not affect the SoC testing when this bit is set. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 28<br>BLOCK_SOC_RESETS | Block SoC Resets of the Radio, cleared by Radio System Reset<br>Most SoC System or Power On Resets will be blocked and the Radio will not be affected by them when this bit is set.<br>The Radio Power Mode logic is not blocked by this bit and will reset on any SoC Power On Reset. |
| 27-26<br>— | Reserved |
| 25<br>RADIO1_INTERRUPT_EN | Radio1 Interrupt Enable<br>This bit enables the Radio1 interrupt source, as selected by the Radio1 IRQ Select bits, to be added to the interrupt sources that are used to generate the RSIM Asynchronous MCU Wakeup signal (typically connected to the MCU LLWU). |
| 24<br>RADIO0_INTERRUPT_EN | Radio0 Interrupt Enable<br>This bit enables the Radio0 interrupt source, as selected by the Radio0 IRQ Select bits, to be added to the interrupt sources that are used to generate the RSIM Asynchronous MCU Wakeup signal (typically connected to the MCU LLWU). |
| 23-22<br>— | Reserved |
| 21-20<br>WAKEUP_INTERRUPT_SOURCE | RSIM Wakeup Interrupt Source Selector<br>The Radio Power-On Sequence can generate an interrupt at three times in the sequence, these bits make that selection.<br>00b - No Radio Power-On Sequence interrupt will be generated.<br>01b - A Power-On Sequence interrupt will be generated when the RF Power Request occurs, including unblocked requests from an external source to use the RF OSC.<br>10b - A Power-On Sequence interrupt will be generated when the RF OSC Request occurs, but not if the RF OSC request was from an external source.<br>11b - A Power-On Sequence interrupt will be generated when the RSIM RF Active Warning occurs |
| 19-17<br>— | Reserved |
| 16<br>RADIO_RESET_BIT | Software System Reset for the Radio<br>This bit only clears if there is an SoC Power On Reset.<br>Setting this bit will reset the Global Radio and RSIM logic, including all Link Layer logic.<br>The logic will stay in reset until this bit is cleared.<br>This bit will not reset the Power Mode logic or the Deep Sleep Mode related logic. |
| 15-13<br>— | Reserved |
| 12<br>RSIM_RADIO_ISO_POR_OVRD | RSIM ISO_POR Override<br>This bit directly controls the Radio ISO_POR signal when the RSIM_ISO_OVRD_EN bit is set. |
| 11-9<br>— | Reserved |
| 8<br>RADIO_POR_BIT | Software Power On Reset for the Radio<br>This bit only clears if there is an SoC Power On Reset.<br>Setting this bit will reset all the radio logic that uses the Radio Power On Reset or Radio VLLS Reset signal, it will be held in reset until this bit is cleared. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 7-6<br>— | Reserved |
| 5<br>RSIM_RF_ACTIVE_OVRD_EN | RF Active Internal Override Enable<br>This bit enables the RF Active Internal Override bit. |
| 4<br>RSIM_RF_ACTIVE_OVRD | RF Active Internal Override<br>If the RSIM_RF_ACTIVE_OVRD_EN bit is set, then this bit controls the Internal version of RF Active instead of the Link Layers. The Internal version of RF Active whether overridden or not has a lower priority and can always be overridden by software using the SW_RF_ACTIVE_BIT or the TSM Spare 1 bit if it is selected using the WIFI_COEXIST_1 select bit. |
| 3-2<br>— | Reserved |
| 1<br>RADIO_CONFIGURED_SYS_RESET | Radio Configuration Bit, cleared by Radio System Reset<br>This is a bit software can write when it wants to be able to check if a Radio System Reset occurs. |
| 0<br>RADIO_CONFIGURED_POR_RESET | Radio Configuration Bit, cleared by Radio Power On Reset<br>This is a bit software can write when it wants to be able to check if a Radio Power On Reset occurs. |

# 64.3 Transceiver Digital

## 64.3.1 Transmitter Digital Module

### 64.3.1.1 About the Transmitter Digital

The Transmitter Digital processes the Transmission Data from the RF Protocol Link Layers and presents the processed data to the PLL Frequency Synthesizer as the Baseband Frequency Word.

## 64.3.1.1.1 Block diagram

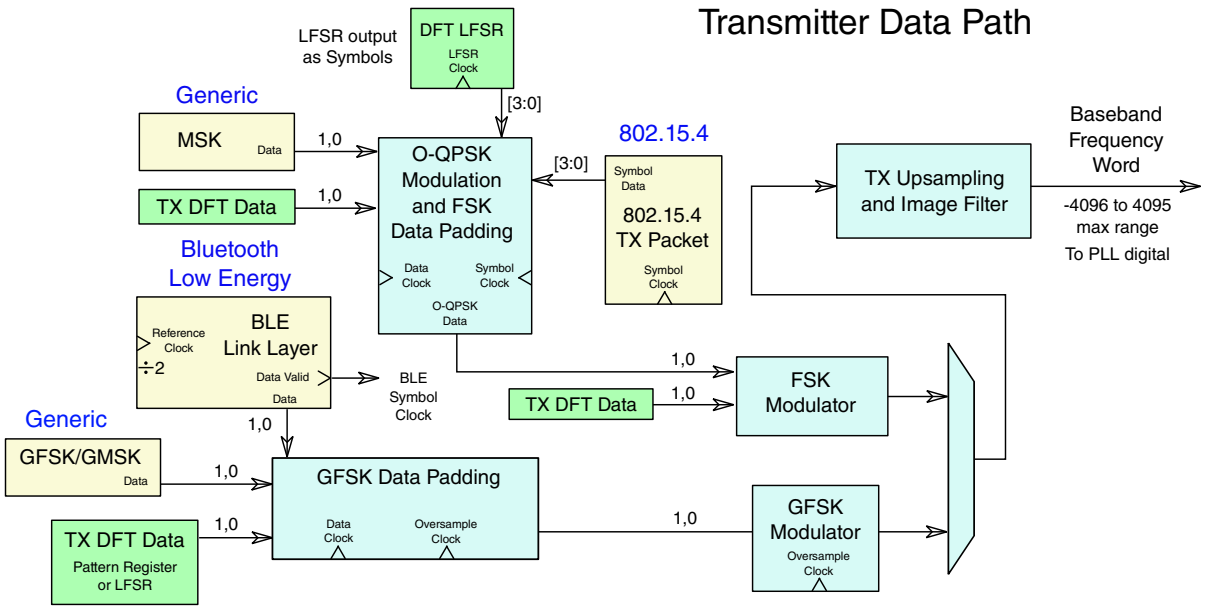

**Figure 64-12. Transmitter Digital**

## 64.3.1.1.2 Modulation Types

| Modulation Type[1] | Data/Chip Rate (kbps)[2] | BT Product[3] | Modulation Index[4] | Symbol Time (us) | Max Frequency Deviation (kHz) |

| | 250 | NA | 0.5 | 4 | 62.5 |
| **Generic FSK** | 2000 | NA | 0.5 | 0.5 | 500 |
| | 1000 | NA | 0.5 | 1 | 250 |
| | 500 | NA | 0.5 | 2 | 125 |
| | 250 | NA | 0.5 | 4 | 62.5 |

1. Modulation Type is set using the PROTOCOL bits in the XCVR_CTRL register.
2. Data Rate is set using the BITRATE bits in the GENFSK register.
3. Bandwidth Time Product is changed by reprogramming the GFSK Gaussian Filter coefficients.
4. Modulation Index is set using the GFSK_MI register bits.
5. IEEE 802.15.4 uses O-QPSK modulation at a symbol rate of 62.5 ksps, which is spread to a chip rate of 2 Mbps.

#### 64.3.1.1.3 Data Rates

For other Radio protocols, the Transit Data Rate is set by the BITRATE bits in the GENFSK register.

The supported data rates are shown in the table below.

**Table 64-7. Transmitter Data Rates**

| GENFSK BITRATE[1:0] Register | TX Data Rate |
|---|---|
| 0 | 1000 kbit/sec |
| 1 | 500 kbit/sec |
| 2 | 250 kbit/sec |
| 3 | 2000 kbit/sec |

#### 64.3.1.1.4 Over-Sampling

The TX Digital uses an Oversample Clock to process the transmission data.

The GFSK, GMSK, and MSK Oversample Ratios are summarized below.

**Table 64-8. Oversample Ratios for GFSK, GMSK, and MSK Modulations**

| TX Data Rate (kb/s) | Ref Clk Freq (MHz) | OSR Ref Clk Divider | OSR Clk Rate (MHz) | Data Oversample Rate |
|---|---|---|---|---|
| 2000 | 32 | 2 | 16 | 8 |
| 1000 | 32 | 4 | 8 | 8 |
| 500 | 32 | 8 | 4 | 8 |
| 250 | 32 | 16 | 2 | 8 |
| 2000 | 26 | 1 | 26 | 13 |
| 1000 | 26 | 2 | 13 | 13 |
| 500 | 26 | 4 | 6.5 | 13 |
| 250 | 26 | 8 | 3.25 | 13 |

#### 64.3.1.1.5 Frequency Word Adjust

The Transmitter has a frequency adjustment register, FREQ_WORD_ADJ, which is used as a signed 9-bit number that is added to the TX Digital output before it is presented to the PLL as the baseband frequency word. This allows the baseband frequency word to be adjusted, or skewed, by a range of -512 to +511.

This frequency adjustment is applied to the final modulation word from any source (GFSK, FSK, DFT) and there is no protection from a math overflow. So the baseband frequency word range of -4096 to 4095 must be considered when adding this frequency word adjustment.

### 64.3.1.2 Data Pre-Processing

Before the Transmission Data is processed by the GFSK or FSK Modulators, it can be inverted, and it can also have additional preamble-like data pre-pended.

#### 64.3.1.2.1 Data Polarity

The Transmission Data that is received by the TX Digital module is mapped to a positive frequency deviation if the data is a 1, and is mapped to a negative frequency deviation if the data is a 0

This mapping can be reversed by setting the TX_CAPTURE_POL register bit.

#### 64.3.1.2.2 Data Padding

Transmission Data Padding is done to avoid abrupt steps in On-Air frequency modulation and thereby minimize spectral transients during the transition from a low Power Amplifier setting to a high Power Amplifier setting prior to protocol data packet transmission.

The abrupt step in modulation is avoided by pre-pending symbols of preamble-like modulation onto the front end of the actual preamble transmission. The Power Amplifier ramp-up is done while modulating these additional symbols, and then the modulating power ramp-up smoothly transitions into the packet transmission at the Target Power level.

Data padding is supported for all of the Radio Protocols packet preambles. For example, the BLE preamble is an alternating 1-0-1-0-1-0-1-0 or 0-1-0-1-0-1-0-1 pattern, depending on the first bit of the packet that follows. Data padding pre-pends the same 1 or 0 pattern as required to match the preamble case.

The data padding pattern is programmed into two 8-bit register fields to allow for two padding choices as seen in the BLE example shown above. If 16 bits of padding is selected, the 8-bit register fields are used twice for each case.

The DATA_PADDING_EN bits in the XCVR_TSM_CTRL register enable data padding as follows:

**Table 64-9. Data Padding Selection**

| DATA_PADDING_EN[1:0] | Result |
|---|---|
| 00 | No Data Padding |
| 01 | 8 bits or symbols of padding |
| 10 | 16 bits or symbols of padding |
| 11 | Reserved |

#### 64.3.1.2.3 Power Amplifier Ramping

The XCVR_TSM provides the TX Digital module with the ramp-up timing needed to adjust the data padding to match the time when the start of the protocol data packet transmission needs to go On-Air.

During ramp-down of the Power Amplifier the TX Digital holds the TX Modulation Data at the final value until power reaches the minimum level.

Please refer to the section Power Amplifier Ramping in the Transceiver Sequence Manager chapter for more details on the Power Ramping topic.

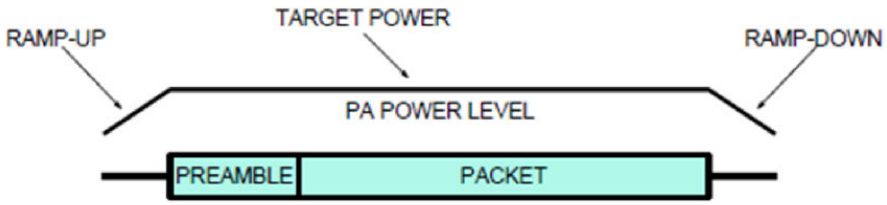

**Figure 64-13. Power Amplifier Ramping**

## 64.3.1.3 GFSK Modulator

### 64.3.1.3.1 Gaussian Filter

GFSK Modulation is implemented using a Gaussian filter and a lookup table to implement the various reference frequencies, data rates, and modulation index values.

The Gaussian filter is a symmetric 16-tap FIR filter with 11-bit quantized coefficients and supports reference frequencies of 32 and 26 MHz at oversampling ratios of 8 and 13 respectively. There are 2 sets of pre-programmed filter coefficients available as shown in the table below.

**Table 64-10. Gaussian Filter Coefficients**

| Filter OSR | 8 | 13 |
|---|---|---|
| Tap Number(s) | 32 MHz Ref | 26 MHz Ref |
| 1 | 1 | 23 |
| 2 | 4 | 41 |
| 3 | 13 | 68 |
| 4 | 41 | 103 |
| 5 | 99 | 144 |
| 6 | 192 | 186 |
| 7 | 300 | 220 |
| 8 | 374 | 239 |
| 9 | 374 | 239 |
| 10 | 300 | 220 |
| 11 | 192 | 186 |
| 12 | 99 | 144 |
| 13 | 41 | 103 |
| 14 | 13 | 68 |
| 15 | 4 | 41 |
| 16 | 1 | 23 |
| Coefficient Sum | 2048 | 2048 |

The pre-programmed filter coefficients can be manually overridden using the GFSK_FLD bit to disable the GFSK Filter Lookup Table. In this case the filter coefficients will be taken from the TX GFSK Filter Coefficients register.

#### 64.3.1.3.2 Multiplier

The GFSK Modulator has a multiplier in hardware that uses a lookup table to choose the correct value to multiply the output of the Gaussian filter by in order to get the correct frequency deviation range.

The lookup table value chosen is dependent upon the Reference Clock frequency, the Transmitter Data Rate, and the Modulation Index.

The GFSK Multiplier Lookup Table value can be overridden by setting the GFSK_MLD register bit and programming the GFSK_MULTIPLY_TABLE_MANUAL register to contain a valid integer, using bits [15:4], and a valid fraction, using bits [3:0].

#### 64.3.1.3.3 Modulation Scaling

The GFSK modulator supports nominal modulation indices of 0.32, 0.5, 0.7 and 1.0. Transmit modulation scaling adds the capability to scale the GFSK modulated output up or down by a factor 1/32, 1/16 or 1/8. The scaling coefficients have been chosen so that the scaling can be realized without a multiplication.

The TX modulation scaling is equivalent to having some programmability on the nominal modulation index, which can be useful to alter the modulation bandwidth and/or effective frequency deviation of the TX modulation signal.

Transmit modulation scaling is applied to the Gaussian Filter output.

**Table 64-11. Transmit Modulation Scaling Choices**

| GFSK_MOD_INDEX_SCALING[2:0] | Modulation Scaling | Scaling of nominal modulation Index (%) |
|---|---|---|
| 0 | 1 | 0 |
| 1 | 1 + 1/32 | +3.125 |
| 2 | 1 + 1/16 | +6.25 |
| 3 | 1 + 1/8 | +12.5 |
| 4 | 1 - 1/32 | -3.125 |
| 5 | 1 - 1/16 | -6.25 |
| 6 | 1 - 1/8 | -12.5 |

#### 64.3.1.3.4 On-Air Frequency Deviation

By default, the GFSK Modulator presents the modulation word to the PLL starting with the Negative Frequency Deviation, this results in the PLL going On-Air at the Carrier Frequency minus the frequency deviation.

The GFSK Modulator can instead be configured to begin modulating at Zero Frequency Deviation, allowing the PLL to go On-Air at the Carrier Frequency. This configuration is used if the ZERO_FDEV bit in the TX Digital Control register is set.

### 64.3.1.4 FSK Modulator

#### 64.3.1.4.1 FSK Modulation Word

For 802.15.4 FSK Modulation, the FSK modulation word presented to the PLL is a direct mapping of a data 1 to the signed value of the FSK_MODULATION_SCALE_1 register, and of a data 0 to the signed value of the FSK_MODULATION_SCALE_0 register.

For Generic MSK and Generic FSK, the FSK modulation word presented to the PLL is also scaled based on the BITRATE bits in the GENFSK register as shown in the table below.

This scaling can be disabled by setting the FSK_BITRATE_SCALE_DISABLE bit in the FSK_SCALE register.

**Table 64-12. FSK Modulation Scaling**

| GENFSK BITRATE[1:0] Register | FSK Modulation Data Rate | FSK Modulation Scaling |
|---|---|---|
| 0 | 1000 kbit/sec | Divide by 2 |
| 1 | 500 kbit/sec | Divide by 4 |
| 2 | 250 kbit/sec | Divide by 8 |
| 3 | 2000 kbit/sec | No Scaling |

Note that a frequency inversion is allowed by inverting the values in the FSK_MODULATION_SCALE registers.

The default FSK Modulation mapping translates the chips/bits to a frequency modulation of +Frequency Deviation/PLL Minimum Modulation Step for a data 1, and -Frequency Deviation/PLL Minimum Modulation Step for a data 0.

For a 32 MHz reference clock with a PLL Minimum Modulation Step Size of 244.14 Hz, the default FSK Modulation mapping translates to a +/- 500 kHz peak Frequency Deviation, which is a PLL Baseband Frequency Word of +2047/-2047.

#### 64.3.1.4.1.1 Half-Sine Pulse Shaping

The half-sine pulse shaping results from the inherent VCO reaction to the digital FSK modulation and the resulting modulation is as specified in IEEE 802.15.4 section 10.2.5, Figure 71, shown below.

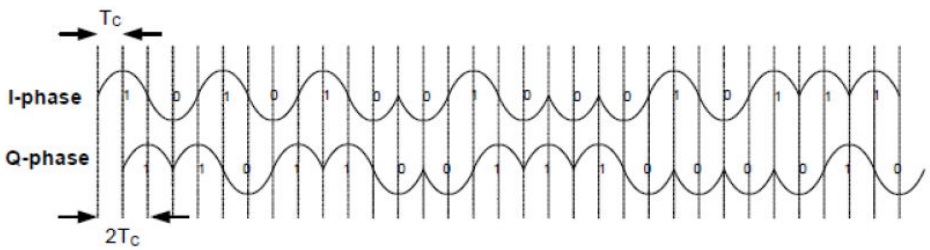

Figure 71—Sample baseband chip sequences with pulse shaping

**Figure 64-14. Half-Sine Pulse Shaping**

### 64.3.1.4.2 MSK Modes

Minimum-shift keying (MSK) is a type of continuous-phase frequency-shift keying with a frequency separation of one-half the bit rate. MSK modulation construction is quite similar to O-QPSK; MSK is encoded with bits alternating between quadrature components, with the Q component delayed by half the symbol period.

However, instead of square pulses as used by ordinary O-QPSK, MSK encodes each bit as a half sinusoid, which is similar to IEEE 802.15.4 O-QPSK. This results in a constant-modulus signal (constant envelope signal), which reduces problems caused by non-linear distortion.

In MSK the difference between the higher and lower frequency is identical to half the bit rate. Consequently, the waveforms used to represent a 0 and a 1 bit differ by exactly half a carrier period.

Thus, the maximum frequency deviation is $\delta = 0.25$ fm where fm is the maximum modulating frequency. As a result, the modulation index M is 0.5. This is the smallest FSK modulation index that can be chosen such that the waveforms for 0 and 1 are orthogonal.

As an example, 1 Mbps MSK would result in a frequency deviation of +/-250 kHz.

MSK data comes to the O-QPSK Modulator at the chip/data rate (no symbol to chip mapping is done), and the O-QPSK conversion is done on the data in the same manner as it is in IEEE 802.15.4-2011 section 10.2.5, as shown above.

### 64.3.1.5 Data Post-Processing

After the Transmission Data is processed by the GFSK or FSK Modulators, it can be post-processed to remove TX modulation images.

#### 64.3.1.5.1 Sample/Hold Images

Power efficient constant envelope transmit modulation is done at a multiple of the symbol clock (Over-Sample Rate), which is chosen as a fraction of the RF Osc reference clock frequency. The transmit modulation signal is then converted to the reference clock rate, at which it is presented to the PLL as the modulation word. This sample/hold (or zero-order hold, ZOH) operation results in TX modulation images that repeat at the fractional reference clock rate at used.

These modulation images are automatically filtered by the sinc ZOH transfer function and the integration (i.e., 1/s) operation of the VCO. These inherent filtering operations result in these modulation images not violating any of the transmit modulation frequency mask. However, to provide additional spectral margin to support using an external power amplifier to boost the transmit power, an image suppression set of FIR filters has been included in the transmit path to suppress the transmit sample/hold images by at least an additional 20 dB.

The transmit image filters are enabled by default in GFSK and GMSK modes and not enabled in IEEE 802.15.4 and MSK modulation modes, but their usage can be overridden using the TX_IMAGE_FILTER_OVRD_EN bit.

#### 64.3.1.5.2 Image Filters

The Transmitter uses up to three image filters, by default they are enabled based upon the modulation type and data rate as shown below:

**Table 64-13. Default Transmit Image Filter Usage**

| Modulation Type; Data Rate | TX Image Filter 2 | TX Image Filter 1 | TX Image Filter 0 |
|---|---|---|---|
| OQPSK/FSK/MSK Modes; All data rates | 0 | 0 | 0 |
| GFSK/GMSK; 1000 kbps | 0 | 0 | 1 |
| GFSK/GMSK; 500 kbps | 0 | 1 | 1 |
| GFSK/GMSK; 250 kbps | 1 | 1 | 1 |

### 64.3.1.5.3 Image Filters Frequency Response

The frequency response of the TX image suppression filters and the reduction in the level of TX images for the 1 Mbps GMSK (BLE) with the FIR filter are demonstrated in the plots below.

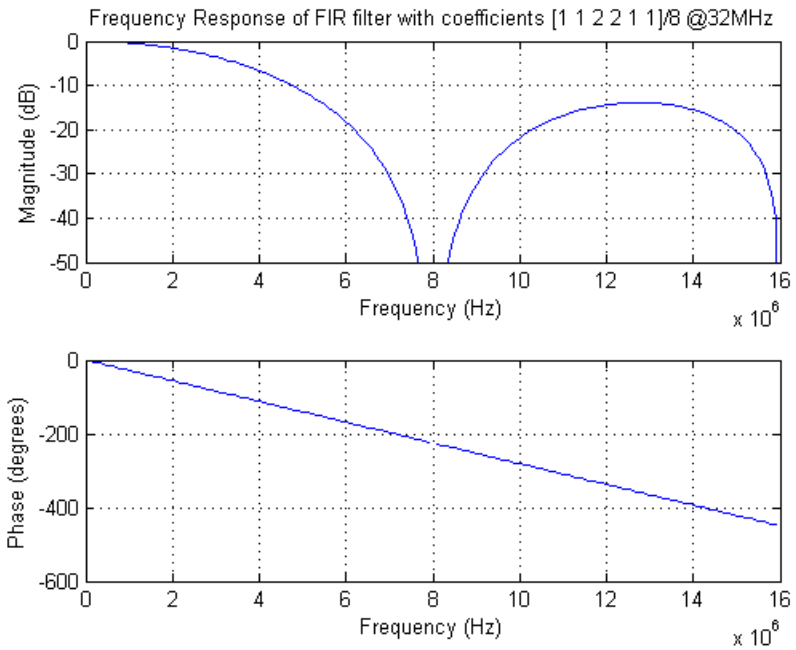

**Figure 64-15. Frequency response of the 6-Tap FIR Transmit Image Suppression filter**

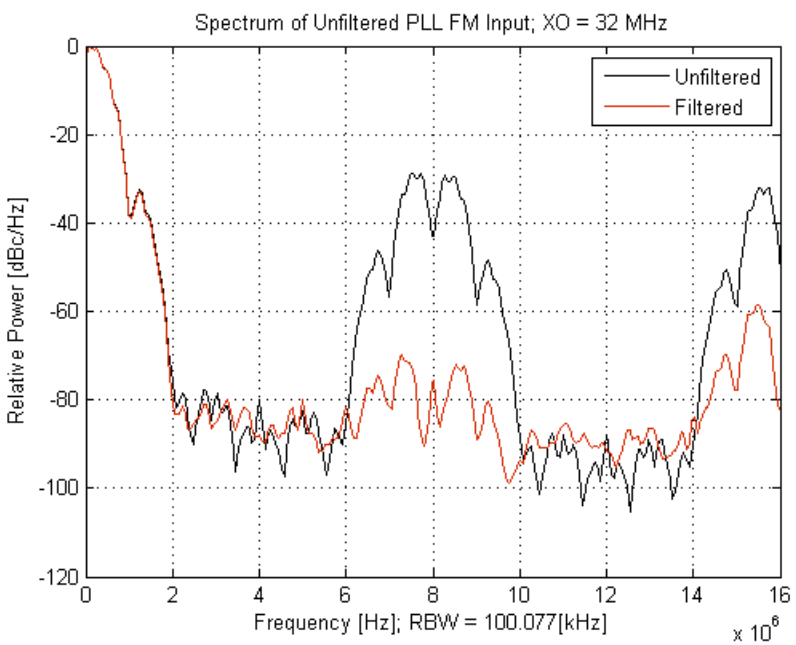

**Figure 64-16. Comparison of Transmit Modulation Images at the PLL Input for BLE**

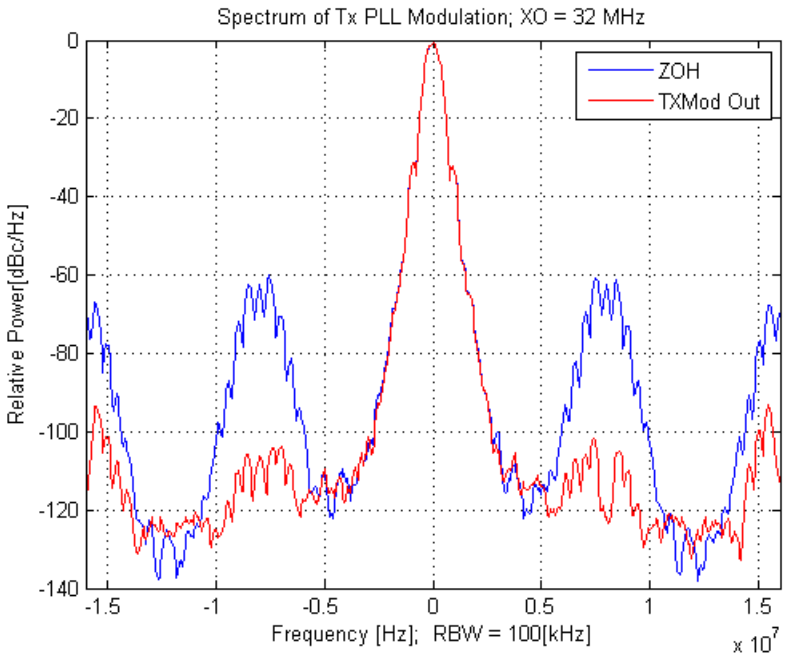

**Figure 64-17. Comparison of Transmit Modulation Images at the PLL Output for BLE (1 Mbps GMSK)**

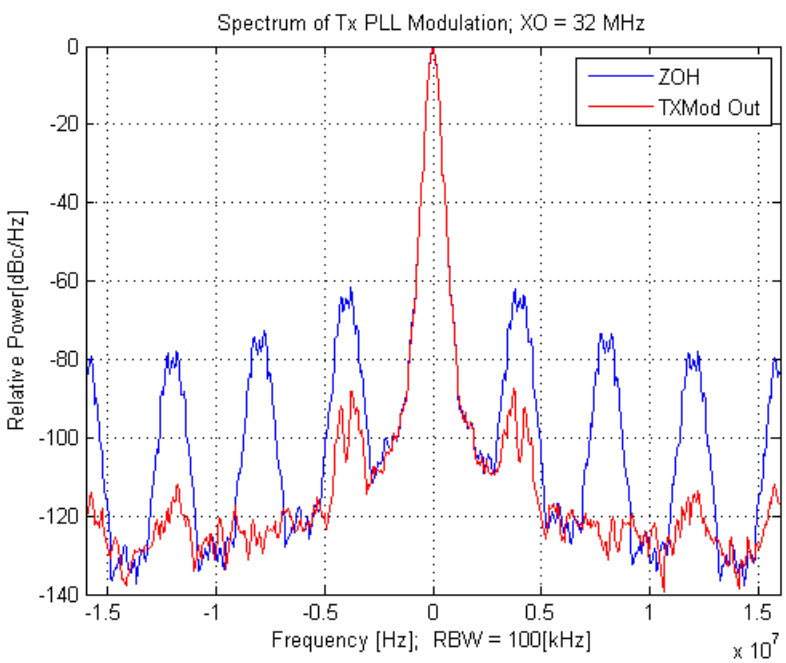

**Figure 64-18. Comparison of Transmit Modulation Images at the PLL Output for 500 kbps GMSK**

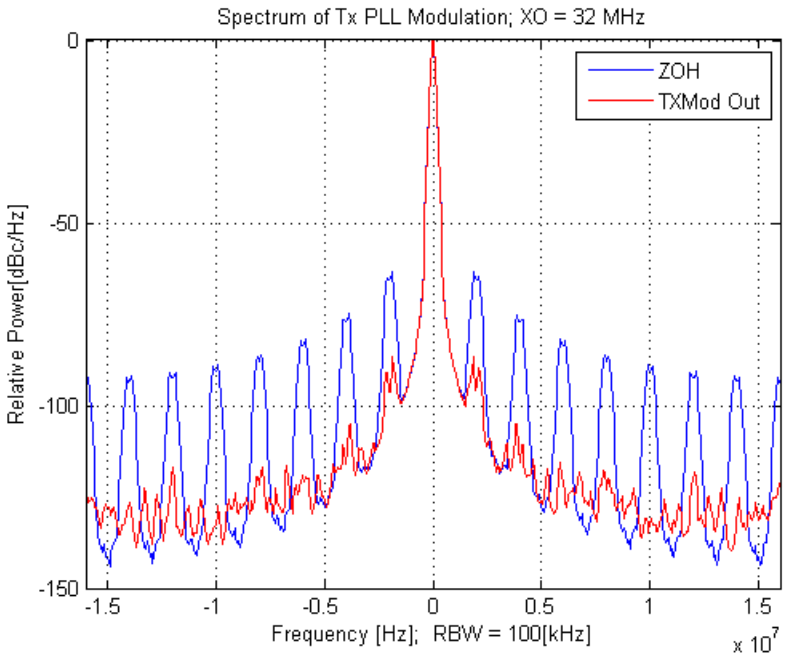

**Figure 64-19. Comparison of Transmit Modulation Images at the PLL Output for 250 kbps GMSK**

## 64.3.1.6 Memory Map and Register Definition

The Transmitter Digital memory map and detailed descriptions of all its registers are as follows.

### 64.3.1.6.1 XCVR_TX_DIG register descriptions

#### 64.3.1.6.1.1 XCVR_TX_DIG_ADDR Memory map

XCVR_TX_DIG base address: 4103_0200h

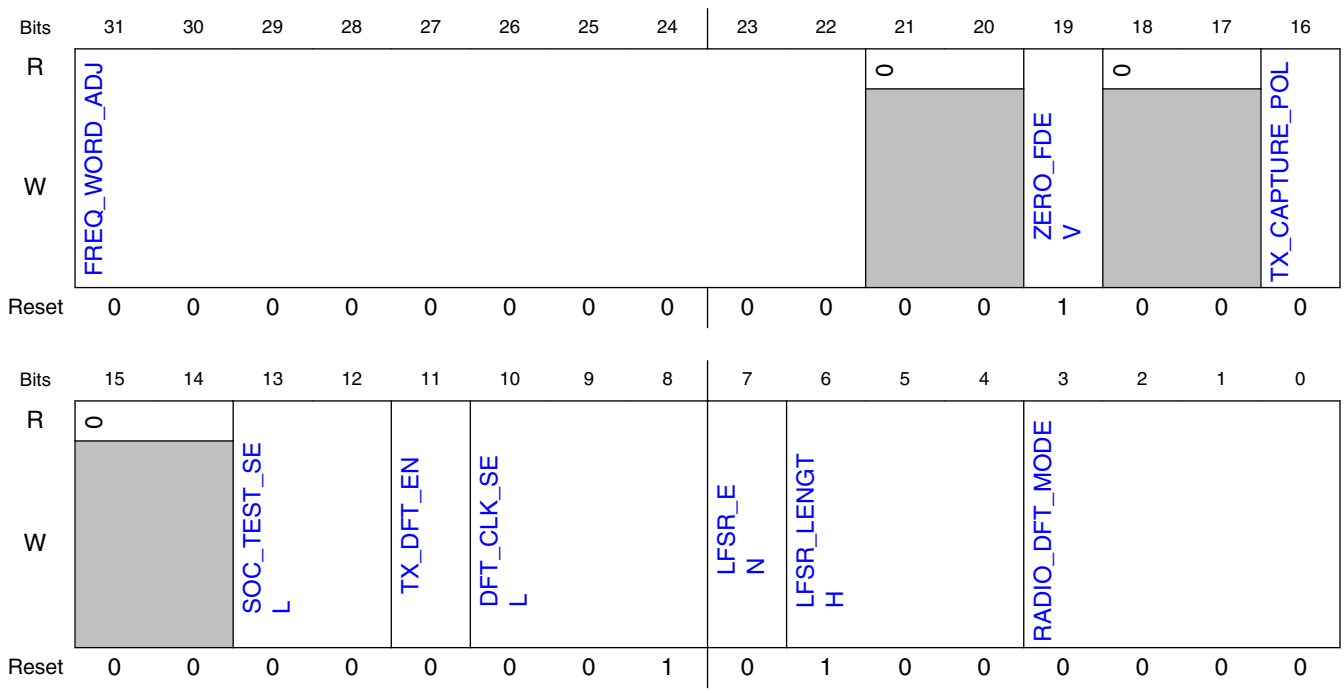
| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | TX Digital Control (CTRL) | 32 | RW | 0008_0140h |
| 4h | TX Data Padding (DATA_PADDING) | 32 | RW | 7FFF_55AAh |
| 8h | TX GFSK Modulator Control (GFSK_CTRL) | 32 | RW | 0001_4000h |
| Ch | TX GFSK Filter Coefficients 2 (GFSK_COEFF2) | 32 | RW | C063_0401h |
| 10h | TX GFSK Filter Coefficients 1 (GFSK_COEFF1) | 32 | RW | BB29_960Dh |
| 14h | TX FSK Modulation Levels (FSK_SCALE) | 32 | RW | 0800_1800h |
| 18h | TX DFT Modulation Pattern (DFT_PATTERN) | 32 | RW | 0000_0000h |

## 64.3.1.6.1.2 TX Digital Control (CTRL)

### *64.3.1.6.1.2.1 Offset*

| Register | Offset |
|---|---|
| CTRL | 0h |

### *64.3.1.6.1.2.2 Diagram*



### *64.3.1.6.1.2.3 Fields*

| Field | Function |
|---|---|
| 31-22<br>FREQ_WORD_ADJ | Frequency Word Adjustment<br>This register is a signed 9 bit number that is added to the TX Digital output before it is presented to the PLL as the baseband frequency word. This allows the baseband frequency word to be adjusted, or skewed, by a range of -512 to +511.<br>This frequency adjustment is applied to the final modulation word from any source (GFSK, FSK, DFT) and there is no protection from a math overflow. So the baseband frequency word range of -4096 to 4095 must be considered when adding this frequency word adjustment. |
| 21-20<br>— | Reserved |
| 19 | On-Air at Zero FDev |

*Table continues on the next page...*

| Field | Function |
|---|---|
| ZERO_FDEV | If this bit is set, then in Gaussian Modulation modes the modulation will start at the Carrier Frequency instead of at the negative modulation value. |
| 18-17<br>— | Reserved |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | The formula used for the Peak Modulation is { Symbol Rate / (2 x 1/Modulation Index) }<br>00b - 0.32<br>01b - 0.50<br>10b - 0.70<br>11b - 1.00 |
| 15-0<br>GFSK_MULTIPLY_TABLE_MANUAL | Manual GFSK Multiply Lookup Table Value<br>The GFSK Modulator Multiplier uses a lookup table to select the multiplicand representing the { Frequency Deviation divided by the Low Port Sigma Delta LSB resolution in Hz } for the Modulation requested based on the Modulation Index, the Symbol Rate, and the Reference Clock Frequency.<br>The lookup table value is overridden by this register if GFSK_MLD is set, and these bits should then contain a number that represents { FDev/SD_LSB integer[11:0] + FDev/SD_LSB fraction[3:0] } |

## 64.3.1.6.1.5 TX GFSK Filter Coefficients 2 (GFSK_COEFF2)

### *64.3.1.6.1.5.1 Offset*

| Register | Offset |
|---|---|
| GFSK_COEFF2 | Ch |

### *64.3.1.6.1.5.2 Function*

The two registers TX_GFSK_COEFF1 and TX_GFSK_COEFF2 form a 64-bit little endian register that is memory mapped internally as shown to override the GFSK Filter Coefficients.

In 64-bit they combine as {TX_GFSK_COEFF2[31:0],TX_GFSK_COEFF1[31:0]}

The resulting 64-bit value is the GFSK Manual Filter Coefficient [63:0]

### *64.3.1.6.1.5.3 Diagram*

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 64.3.2 PLL Frequency Synthesizer

### 64.3.2.1 Introduction

#### 64.3.2.1.1 About the PLL Frequency Synthesizer

The PLL Frequency Synthesizer is a Digital Module that -

1. Selects the Radio Carrier Frequency
2. Coarse Tunes the VCO and Calibrates the High Port DAC
3. Controls the PLL Loop Divider value to lock the VCO at the Carrier Frequency

4. Applies the Baseband Frequency Word as High Port Modulation (HPM) to the VCO High Port DAC
5. Applies the Baseband Frequency Word as Low Port Modulation (LPM) to the PLL Loop Divider
6. Monitors the PLL lock status and flags unlocked conditions
7. Provides DFT features for evaluating the PLL Frequency Synthesizer during factory validation and testing

### 64.3.2.1.2 Block diagram

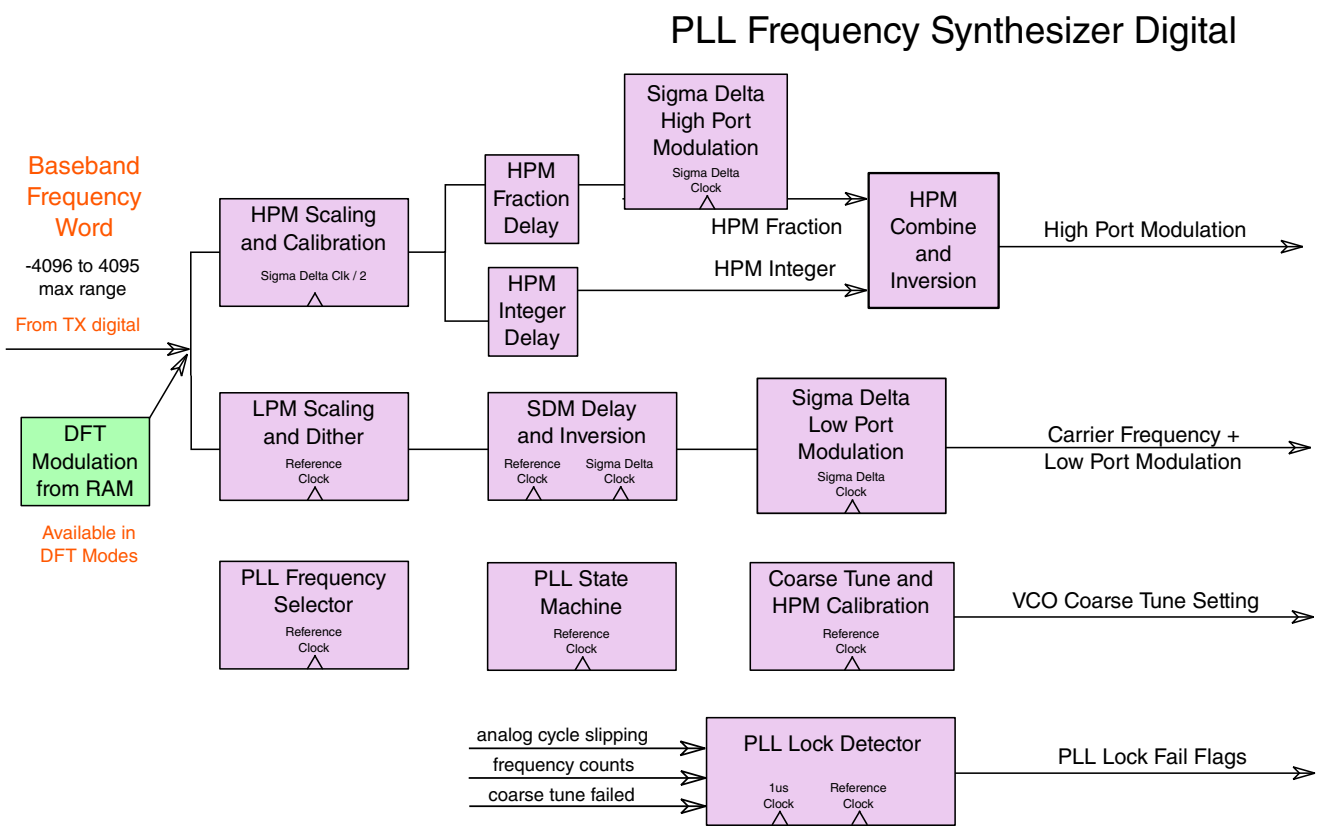

**Figure 64-20. PLL Frequency Synthesizer**

### 64.3.2.1.3 Baseband Frequency Word

The Transmitter Digital presents the PLL Frequency Synthesizer with a signed 13-bit Baseband Frequency word to modulate onto the RF Carrier Frequency. The Baseband Frequency Word range is -4096 to 4095, which provides a modulation range of +/- 1000 kHz when using a 32 MHz reference frequency with a PLL Minimum Frequency Step Size of 244.14 Hz.

#### 64.3.2.1.3.1 Manual Frequency Word

The Baseband Frequency word can be overridden by software if the MOD_DISABLE bit is set. In this case the PLL Digital will use the MODULATION_WORD_MANUAL register as the source of the modulation.

Note that due to the speeds at which the High Port and Low Port react to changes in the modulation word, and the speed at which software is able to effect such changes, for all practical purposes this can only support low frequency modulation.

## 64.3.2.2 Carrier Frequency Tuning

### 64.3.2.2.1 Carrier Frequency Control

#### 64.3.2.2.1.1 Radio Frequency Selection

The PLL Carrier Frequency is selected in these ways, depending on the Hop Configuration selected :

| HOP_TBL_CFG | PLL Carrier Frequency Selection |
|---|---|
| 0 or 1 | Channel Mode<br>The channel number, from the link layer or the Hop Frequency Word, is used by the Radio Frequency Selector to tune to a channel on the 1 MHz raster. |
| 2 | Frequency Offset Mode<br>The link layer channel number, from the Hop Frequency Word, is used by the Radio Frequency Selector to tune to a channel on the 1 MHz raster. A signed 9-bit Frequency Offset from the Hop Frequency Word is added to the channel selected. This provides approximately a +/- 1 MHz adjustment to the 1 MHz raster channels. The step size of the adjustment is 3.906 kHz for a 32 MHz clock and 3.174 kHz for a 26 MHz clock. |
| 3 | Direct Carrier Frequency Selection<br>An Integer is selected and the Hop Frequency Word is applied directly as a signed 15-bit value for the Numerator. This provides tuning with approximately a 2 kHz frequency resolution that covers the full 2400 - 2480 MHz range with a 32 MHz clock, and covers a range of 2400 - 2470 MHz with a 26 MHz clock. |
| 4,5,6,7 | Reserved |

The Radio mapping of the 128 RF channels on the 1 MHz raster, spanning the range from 2.360 GHz to 2.487 GHz, is shown in the figure below along with the Hop Frequency Word options.

There is also an option to allow an override of the Protocol Channel Frequency Mapping in order to allow any Protocol to choose to use any of the available Channel Frequency Mapping tables.

Note that there is also a full manual mode where the Integer and Fraction can be selected by software and thereby choose any RF Carrier Frequency in increments of the PLL SDM LSB (as long as the requested frequency is within the VCO specified range)

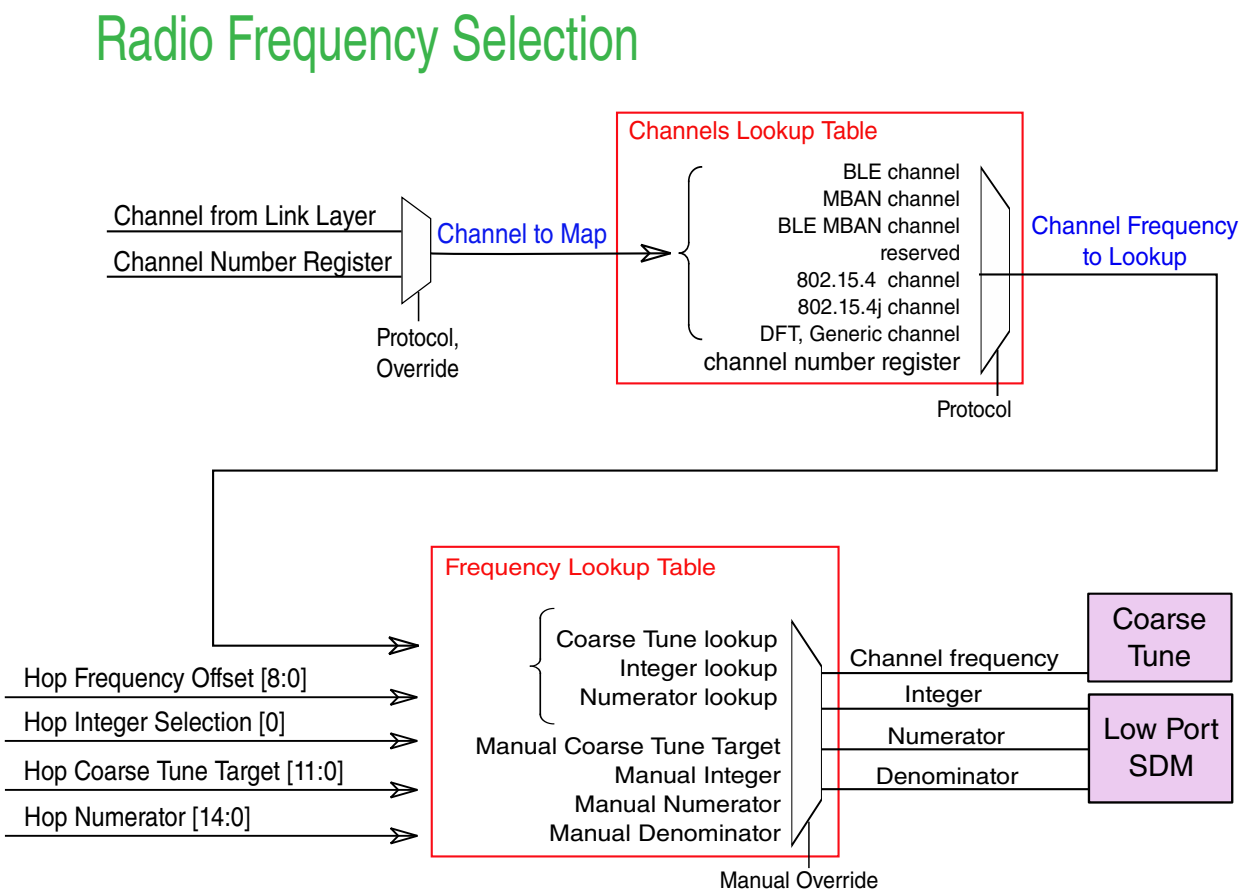

**Figure 64-21. Radio Frequency Selection**

### 64.3.2.2.1.2 RF Channels Supported

The channel frequencies for each protocol are shown in the tables below.

**Table 64-14. Radio Protocols (0 to 5) Channel Frequencies**

| Radio Protocols Supported, Channel Frequency in MHz | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| BLE | | MBAN | | BLE/MBAN | | Reserved | | | | 802.15.4 | | 802.15.4j MBAN | |

#### 64.3.2.2.1.3 Channel Selector

During typical Radio usage, the channel selection is done automatically by the Link Layer.

Channel selection can be overridden using the PLL_CHAN_MAP register bits BOC (BLE protocols 0 and 2) and ZOC (802.15.4 protocols 4 and 5). If these are set then the CHANNEL_NUM register selects the Radio Channel Number instead of the Link Layer.

#### 64.3.2.2.1.4 Manual Carrier Frequency

The internal frequency mapping can be bypassed and software can directly control the Low Port Sigma Delta inputs to select any channel frequency in the VCO's range (in increments of the Low Port Minimum Frequency Step Size).

The Radio Channel Frequency override is manually selected by setting the SDM_MAP_DISABLE bit along with the LPM_INTG, LPM_NUM, and LPM_DENOM register values.

Any modulation from the TX Digital will be added to this manual frequency selection.

The Manual carrier frequency selected can be calculated using the formula below:

Radio Carrier Frequency = ((Reference Clock Frequency x 2) x (LPM_INTG + (LPM_NUM / LPM_DENOM))

WARNING : The fraction (LPM_NUM / LPM_DENOM) must be in the range of -0.55 to +0.55 for valid Sigma Delta Modulator operation.

#### 64.3.2.2.2 Hop Frequency Word

The Hop Frequency Word is used to provide the PLL with Channel Selection, Frequency Offset, Integer Selection, and Direct Numerator Control of the Low Port Sigma Delta Modulator.

The figure below shows an overview of how the Hop Table interfaces to the PLL.

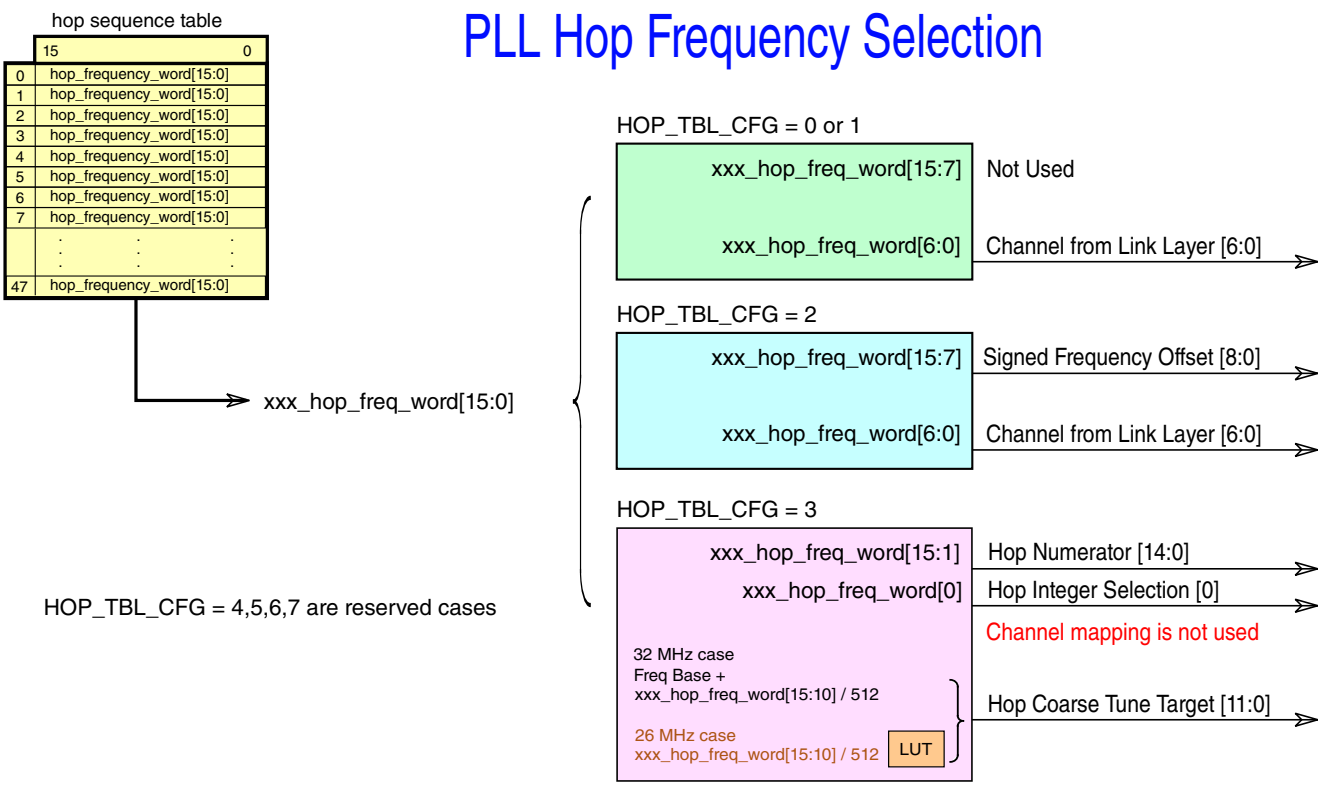

**Figure 64-22. PLL Hop Frequency Selection**

For much of the Radio usage the mapping of the 128 RF channels on a 1 MHz raster is sufficient. However, there are additional cases where Carrier Frequency Tuning at a finer resolution is desired and the Hop Frequency Word contains the information needed to get these finer resolutions.

The table below shows some of these desired Channel Spacings.

| Modulation Type | Data Rate | Sensitivity Estimate (dBm) | Frequency Deviation (kHz) | 99.5% Signal BW (kHz) | Typical Channel Spacing (kHz) | Notes | Desired Offsets from 1 MHz Channel Map |
|---|---|---|---|---|---|---|---|
| GFSK BT=0.5, h=0.5 | 1000 | -96 | 250 | 1105 | 2000 | Bluetooth-LE | 1000 |

**Figure 64-23. PLL Typical Channel Frequency Spacings**

#### 64.3.2.2.2.1 Frequency Offset Mode

In order to support the desired Channel Spacings, a Frequency Offset Mode is provided that allows the Carrier Frequency to be offset from the selected channel in approximately 4 kHz steps. The tables below shows the resulting Frequency Error for some of the channel spacings.

The Hop Frequency Word contains a 1 MHz channel number and a 9-bit signed offset value. The offset is left shifted and then applied to the Numerator from the channel lookup table to create the Numerator applied to the Low Port SDM.

The Frequency Offset Range is approximately +/- 1 MHz

The Coarse Tune Target is not effected in this mode.

| Integer | Min Fraction | Max Fraction | SDM Denominator | Min Numerator | Max Numerator | Min Frequency | Max Frequency | Frequency Range |
|---|---|---|---|---|---|---|---|---|
| 38 | -0.5 | 0.5 | 1,048,576 | -16,320 | 16,320 | 2,431,003,906 | 2,432,996,094 | 1,992,188 |

**Figure 64-25. PLL Hop Frequency Offset Mode, 26 MHz**

### 64.3.2.2.2.2 Direct Carrier Frequency Mode

For a finer Carrier Frequency resolution, the Direct Carrier Frequency mode is provided which allows approximately a 2 kHz step size. This method allows for complete coverage of the 2400 - 2480 MHz range while using a 32 MHz reference clock, and a range of 2400 - 2470 MHz while using a 26 MHz reference clock. The Frequency Errors from a 2 kHz raster are shown in the tables below.

The Hop Frequency Word contains the Integer choice and a 15-bit signed value to be left shifted and then applied as the Numerator to the Low Port SDM.

The Frequency Offset Range is +/- 32 MHz for a 32 MHz clock, and +/- 26 MHz for a 26 MHz clock.

In this mode the Coarse Tune Target is specially calculated as follows :

- For 32 MHz clock operations, the signed 15-bit Hop Frequency Word is divided by 512 and added to the selected Frequency Base.
  - Frequency Base for integer 38 is 2432, for integer 39 it is 2496
- For 26 MHz clock operations, the signed 15-bit Hop Frequency Word is divided by 512 and then a Look Up Table is used to select the best Coarse Tune Target.

| Integer | Min Fraction | Max Fraction | SDM Denominator | Min Numerator | Max Numerator | Min Frequency | Max Frequency | Frequency Range |
|---|---|---|---|---|---|---|---|---|

**Figure 64-27. PLL Hop Direct Carrier Frequency Selection, 26 MHz**

## 64.3.2.3 VCO Calibration

### 64.3.2.3.1 Coarse Tune

The VCO Coarse Tune is carried out by a Successive Approximation Register method that computes the best coarse tune setting for the VCO in successive steps from MSB to LSB.

This SAR method uses a Frequency Meter count value that is successively compared to expected counts to determine the best coarse tune setting for the VCO.

The coarse tune setting can be overridden for test and validation purposes, and the individual frequency counts used at each successive step for the coarse tune setting are available for viewing in DTEST mode and also as register values in the PLL register space.

#### 64.3.2.3.2 High Port DAC Calibration

The objective of the HPM DAC Calibration is to determine the DAC Step Size and estimate the ratio of this DAC unit step to the Low Port Minimum Frequency Step Size.

Once the step size of the High Port DAC is known, a scaling factor is applied to correctly map the baseband frequency word to the High Port modulation.

The length of the calibration time is set using the HPM_CAL_TIME register and the size of the DAC array used is selected using the HPM_CAL_ARRAY_SIZE register.

The register HPM_COUNT_ADJUST[3:0] provides a (-8/+7) range of adjustment to the HPM Calibration Count Difference for the HPM Calibration lookup table to allow for any count error bias that may be present. This adjusted Count Difference is used with a Lookup Table to choose the HPM Calibration Factor

##### 64.3.2.3.2.1 HPM CAL Factor

The HPM_CAL_FACTOR register shows the value that is currently being used by High Port Modulation Multiplier. This value is from the most recent High Port calibration unless it is being overridden using the HP_CAL_DISABLE and HPM_CAL_FACTOR_MANUAL registers.

### 64.3.2.4 High Port Modulation

The High Port Modulator multiplies the HPM Calibration Factor and the PLL Baseband Frequency Word to get the High Port Modulation Word.

The High Port Modulation Word is represented by both an Integer and a Fractional portion. The Fraction is processed by the High Port Sigma Delta Modulator and the result is combined with the Integer and used to control the VCO High Port DAC.

#### 64.3.2.4.1 High Port DAC

The High Port Digital to Analog Converter is designed to take the High Port Modulation Word and convert it to a control voltage that is applied as modulation to the VCO High Port.

#### 64.3.2.4.1.1 HPM DAC Settings

The HPM DAC settings during calibration and normal operation are shown in the table below.

Warning : TX operation with On-Air modulation ranges greater than +/- 250 kHz (+/- 500 kHz at the VCO) require that the VCO Kvm be adjusted using the SY_VCO_KVM[2:0] register.

**Table 64-16. Nominal HPM DAC parameters in various modes**

| Radio TX Mode | | DAC max swing (mV) | DAC output common mode (mV) | DAC swing during operation | Vcm (mV) / HPM_VCM | OPAMP gain setting (R2/R1) / HPM_FDB_RES | Common mode at varactor (mV) | Swing at Varactor input (mV) | Kvm (MHz/Kv) | Deviation at VCO (KHz)[1] |
|---|---|---|---|---|---|---|---|---|---|---|
| 802.15.4/ 2000kHz | HPM calibration | +/-82 | 82 | +/-82 | 288 / 3'b001 | 2/ 2'b01 | 700 | +/-164 | 20 | +/-3280 |
| | TX operation | +/-82 | 82 | +/-51.2 | 391 / 3'b000 | 1/ 2'b00 | 700 | +/51.2 | 20 | +/-1024 |
| BLE/ 1000kHz | HPM calibration | +/-82 | 82 | +/-82 | 288 / 3'b001 | 2 / 2'b01 | 700 | +/-164 | 10 | +/-1640 |
| | TX operation | +/-82 | 82 | +/-51.2 | 391 / 3'b000 | 1/ 2'b00 | 700 | +/51.2 | 10 | +/-512 |
| 500kHz | HPM calibration | +/-82 | 82 | +/-82 | 288 / 3'b001 | 2/ 2'b01 | 700 | +/-164 | 10 | +/-1640 |
| | TX operation | +/-82 | 82 | +/-25.6 | 391 / 3'b000 | 1/ 2'b00 | 700 | +/25.6 | 10 | +/-256 |
| 250kHz | HPM calibration | +/-82 | 82 | +/-82 | 288 / 3'b001 | 2/ 2'b01 | 700 | +/-164 | 10 | +/-1640 |
| | TX operation | +/-82 | 82 | +/-12.8 | 391 / 3'b000 | 1/ 2'b00 | 700 | +/12.8 | 10 | +/-128 |

1. On-Air modulation frequency is a divide by 2 of the VCO frequency.

#### 64.3.2.4.1.2 HPM DAC Bump

The HPM DAC Calibration is normally done at 2X the On-Air Modulation Range, this is accomplished by writing the PLL HPM Analog Bump Control (PLL_HPM_BUMP) register bits:

- HPM_VCM_CAL, value applied during HPM DAC Calibration
- HPM_FDB_RES_CAL, value applied during HPM DAC Calibration
- HPM_VCM_TX, value applied during Radio Transmissions
- HPM_FDB_RES_TX, value applied during Radio Transmissions

If the registers are written in such a way that the DAC range is not doubled, then the HPM_CAL_NOT_BUMPED bit must be set to change the math in the HPM Calibration.

#### 64.3.2.4.1.3 HPM DAC 1 MHz Range

TX operation with On-Air modulation ranges greater than +/- 250 kHz (+/- 500 kHz at the VCO) require that the VCO Kvm be adjusted using the SY_VCO_KVM[2:0] register.

This VCO Kvm setting should be made prior to HPM DAC calibration.

### 64.3.2.4.2 High Port Sigma Delta

The High Port fractional modulation is implemented using a 2nd-order MASH Sigma Delta Modulator (SDM), which converts the 6-bit fractional portion of the high port modulation word to a 3-state thermometric code {-1,0,+1}. The resulting code is then added to the integer portion of the high port modulation word and the final result is applied to the HPM DAC.

#### 64.3.2.4.2.1 HPM SDM Dither

In addition to the nominal SDM functionality, the HPM SDM design includes a zero-mean dithering to mitigate idle tones that can occur when modulating a string of ones or zeros.

The Dither is implemented using a Linear-Feedback Shift Register (LFSR) which provides a 1-bit pseudo-randomization that adds or subtracts 1-bit to the 6-bit fractional portion before it is processed by the Sigma Delta Modulator.

The length of the LFSR can be selected using the HPM_LFSR_SIZE register, and the scale can be changed using the HPM_DTH_SCL bit. The Dither can also be disabled by clearing the HPM_DTH_EN bit.

### 64.3.2.4.3 High Port Delay, Disable, Invert

The HPM Integer and Fraction portions each have an array of programmable delays available to allow the HPM modulations to be matched to each other and to the LPM modulation and the delay through the PLL Loop Divider and onto the VCO feedback loop.

The HPM delay steps are in increments of the PLL Sigma Delta Clock divided by 2, and the LPM SDM delay steps are in increments of the PLL Sigma Delta Clock. All three delay step settings are in the range of {0 to 15}.

There are several inversion bits that can be used if needed:

- HPM_CAL_INVERT, Invert the High Port Modulator during Calibration
- HPM_MOD_IN_INVERT, Invert the input word to the High Port Modulator

- HPM_INTEGER_INVERT, Invert the High Port Modulation Integer portion
- HPM_SDM_OUT_INVERT, Invert the HPM SDM Fractional Output

High Port Modulation can be disabled by setting the HPM_MOD_DISABLE bit, in this case the HPM_MOD_MANUAL register value is applied to the VCO High Port.

### 64.3.2.5 Low Port Modulation

The Low Port Modulator uses a 3rd order Sigma-Delta to produce a fractional division (Fractional-N Frequency Synthesis) to control the PLL Loop Divider and tune the VCO to the Radio Carrier Frequency.

The Low Port Baseband Frequency Word is added as modulation to the Sigma-Delta input.

#### 64.3.2.5.1 Low Port Resolution

The table below shows the PLL Minimum Frequency Step Sizes for Modulation and Carrier Frequency tuning.

Note that the minimum step size for carrier frequency tuning is a divide by 512 of the modulation step sizes.

**Table 64-17. PLL Minimum Frequency Step Size**

| Ref Clk Freq (MHz) | 32 | 26 |
|---|---|---|
| PLL Minimum Modulation Step (Hz) | 244.14 | 198.36 |
| PLL Minimum Carrier Frequency Step (Hz) | 0.9537 | 0.7749 |

#### 64.3.2.5.2 Low Port Sigma-Delta

The Integer, Numerator, and Denominator are presented at the input to the Sigma-Delta Modulator.

A 3-level quantized Sigma-Delta output signal {-1, 0, +1} is generated and combined with the Integer divide value to produce the Modulus Divide Ratio for the PLL Loop Divider. The resulting RF Frequency can be calculated using the formula below:

RF Frequency = ((Reference Clock Frequency x 2) x (LPM_INTG + (LPM_NUM / LPM_DENOM))

WARNING : The fraction (LPM_NUM / LPM_DENOM) must be in the range of -0.55 to +0.55 for valid Sigma Delta Modulator operation.

#### 64.3.2.5.2.1 LPM SDM Dither

While in Transmit mode the input to the SDM is naturally dithered by the Low Port modulation, which keeps the SDM from generating a pseudo-periodic output. However, in Receive mode, the SDM can potentially generate idle tones (dominant frequency modes at its output) when the input to the SDM is a constant. And in either Transmit or Receive mode the LPM SDM can generate idle tones if the Fraction is near zero.

To mitigate these impairments, the Numerator input to the SDM is dithered whenever the Numerator is in the near zero range { -64 to 63 }, or whenever the Radio is in Receive Mode.

This dither operation can also be overridden using the LPM_D_OVRD and LPM_D_CTRL bits.

### 64.3.2.5.3 Low Port Delay, Disable, Invert

The Low Port Modulator has an array of programmable delays available to allow the HPM modulation to be matched to the LPM modulation and the delay through the PLL Loop Divider and onto the VCO feedback loop.

The Low Port Modulation can be delayed at the PLL Loop Divider by delaying the input to the LPM SDM (LPM_SDM_DELAY).

There is an option to invert the Numerator (LPM_SDM_INV) before it is applied to the SDM in order to invert the sigma-delta modulation to the PLL.

The Low Port Modulation of the Loop Divider can be disabled by setting the LPM_DISABLE bit. When the modulation is disabled the LPM SDM will continue to tune the VCO to the Radio Carrier Frequency.

## 64.3.2.6 Lock Detector

The PLL Lock Detector has three methods to measure the stability of the PLL and check that it is tuned to the selected Radio Frequency.

The real-time results of the PLL Lock Detect module can be read as register bits, and flags are set and can be cleared to provide software long-term access to any PLL unlock events.

The TSM can be configured to choose any or all of the PLL Lock Detect module methods to generate an Abort and avoid violating any FCC On-Air or other radio requirements. This abort option is also a power saving feature and avoids continuing a radio operation that will be unsuccessful.

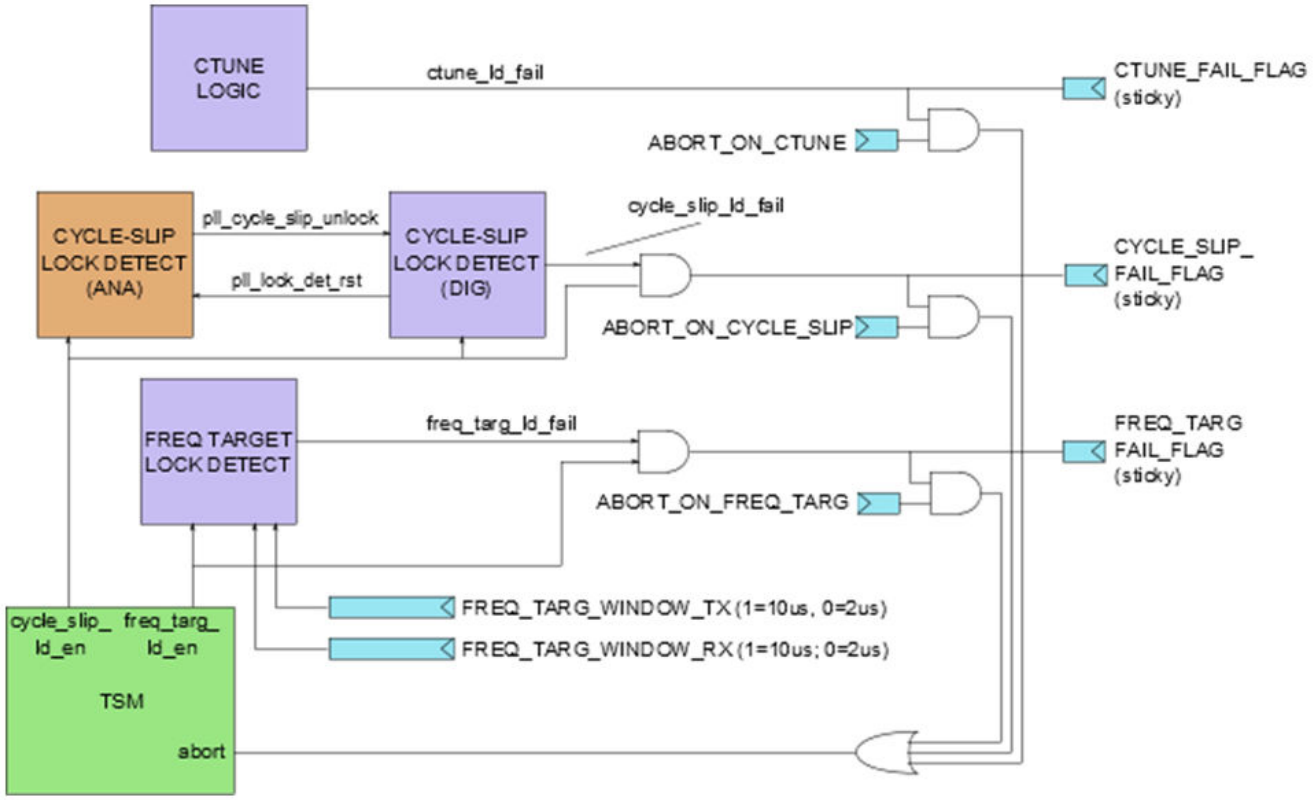

**Figure 64-28. PLL Lock Detect Block Diagram**

### 64.3.2.6.1 Coarse Tune Fail

During every Radio start-up sequence the PLL does a Coarse Tune Calibration to select a VCO setting that will allow the PLL to correctly tune and lock the VCO when the PLL/VCO loop is closed.

During the coarse tune calibration a count is maintained that indicates how close the coarse tune is to the targeted Radio Frequency, if this count is outside of the threshold selected by the Coarse Tune Lock Detect Fail Level register (CTUNE_LDF_LEV), then the Coarse Tune Failure Flag bit (CTFF) will be set and it can be used to abort the TSM sequence.

The CTFF bit is cleared by writing a 1 to it.

The CT_FAIL bit always shows the real time status of the latest Coarse Tune Calibration. If the absolute count difference was out of the range selected by CTUNE_LDF_LEV, then this bit will be set.

#### 64.3.2.6.2 Fine Tune Fail

At the end of every Radio start-up sequence the PLL turns on the PLL Frequency Meter for a time that is requested by the Frequency Target Window time select register bits, separately selected for RX (FTW_RX) and TX (FTW_TX).

These bits select either a 4us or an 8us count period and if the frequency counter is outside of the threshold selected by the Frequency Target Fail Threshold registers, FTF_RX_THRSH and FTF_TX_THRSH, then the Frequency Target Fail Flag bit (FTFF) will be set and it can be used to abort the TSM sequence.

The FTFF bit is cleared by writing a 1 to it

The FT_FAIL bit always shows the real time status of the latest Fine Tune Frequency Measurement. If the absolute count difference was out of the range selected by Frequency Target Fail Threshold registers, then this bit will be set.

#### 64.3.2.6.3 Cycle Slip Fail

During any radio sequence, the PLL can turn on an analog cycle slip detection circuit that measures the phase difference between the VCO and the reference clock. If the phase is not properly aligned the circuit will send a signal to the PLL Lock Detect digital circuit.

The PLL Lock Detect digital circuit evaluates the number and timing of the analog cycle slip events and can generate a Cycle Slip Fail Flag (CSFF).

There is a programmable state machine that controls the monitoring of Cycle Slip Events as shown in the figure below. The CS_FAIL bit always shows the real time status of the cycle slip state machine.

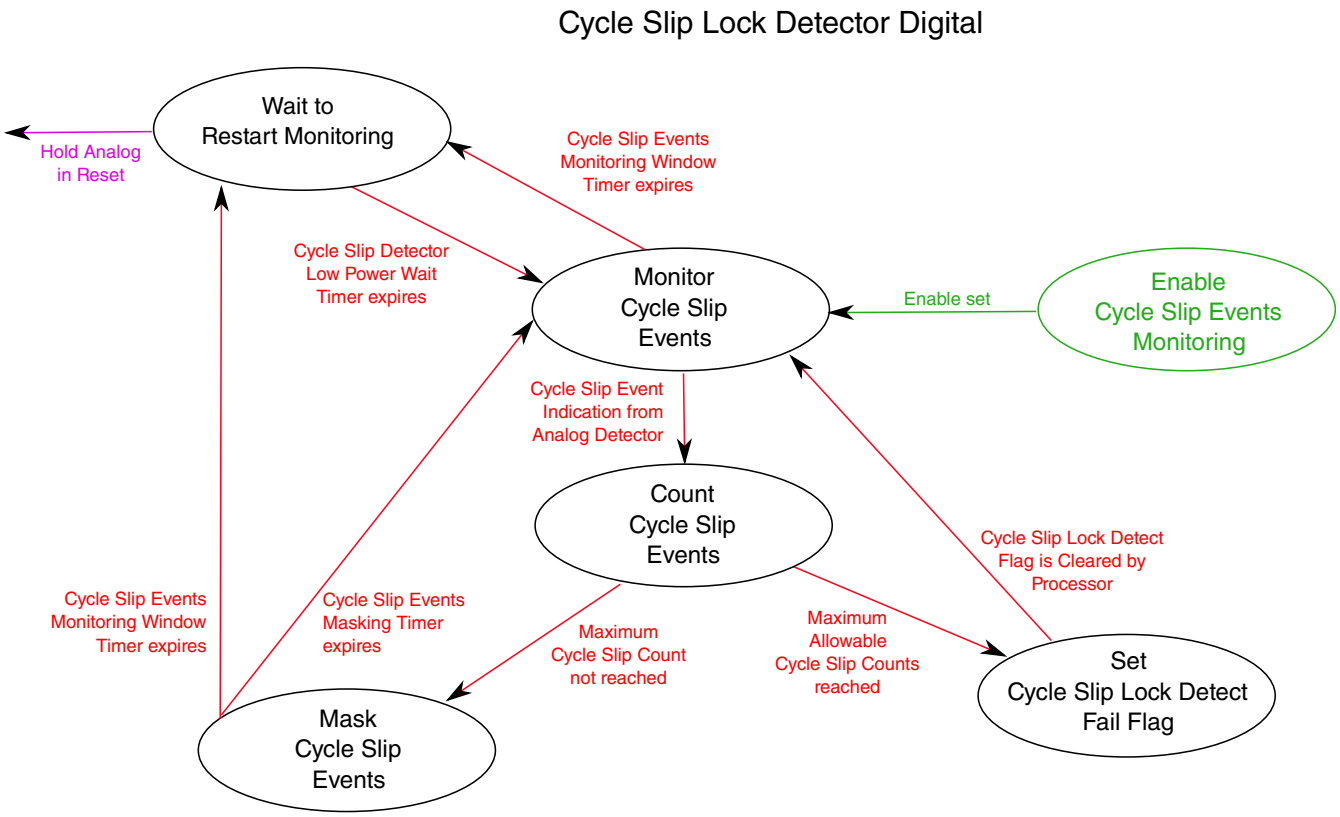

**Figure 64-29. PLL Lock Detect State Machine**

The following table below shows an example calculation of the time needed for the Cycle Slip Lock Detector to fail as a function of the number of cycle slip events and the VCO frequency error.

| Crystal frequency | 32 | MHz | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Reference Time Period | 31.25 | ns | | | | | | | |
| | | | | 3 | 4 | 5 | 8 | 10 | 15 |
| Frequency Error (kHz) | Loop Divider Time Period(ns) | Num cycles in 32MHz Time Period | Cycle-Slip Time (us) | Time for 3 cycle-slips (us) | Time for 4 cycle-slips (us) | Time for 5 cycle-slips (us) | Time for 8 cycle-slips (us) | Time for 10 cycle-slips (us) | Time for 15 cycle-slips (us) |
| -5000 | 37.04 | 5.400 | **0.169** | 0.506 | 1.519 | 4.556 | 13.669 | 41.006 | 123.019 |
| -2000 | 33.33 | 15.000 | **0.469** | 1.406 | 4.219 | 12.656 | 37.969 | 113.906 | 341.719 |

| 20000 | 19.23 | 2.600 | **0.081** | 0.244 | 0.731 | 2.194 | 6.581 | 19.744 | 59.231 |
| 50000 | 12.20 | 1.640 | **0.051** | 0.154 | 0.461 | 1.384 | 4.151 | 12.454 | 37.361 |

**Figure 64-30. Cycle Slip Monitoring Window as a function of frequency error and number of cycle slip events**

A PLL Cycle Slip Fail example is shown in the figure below.

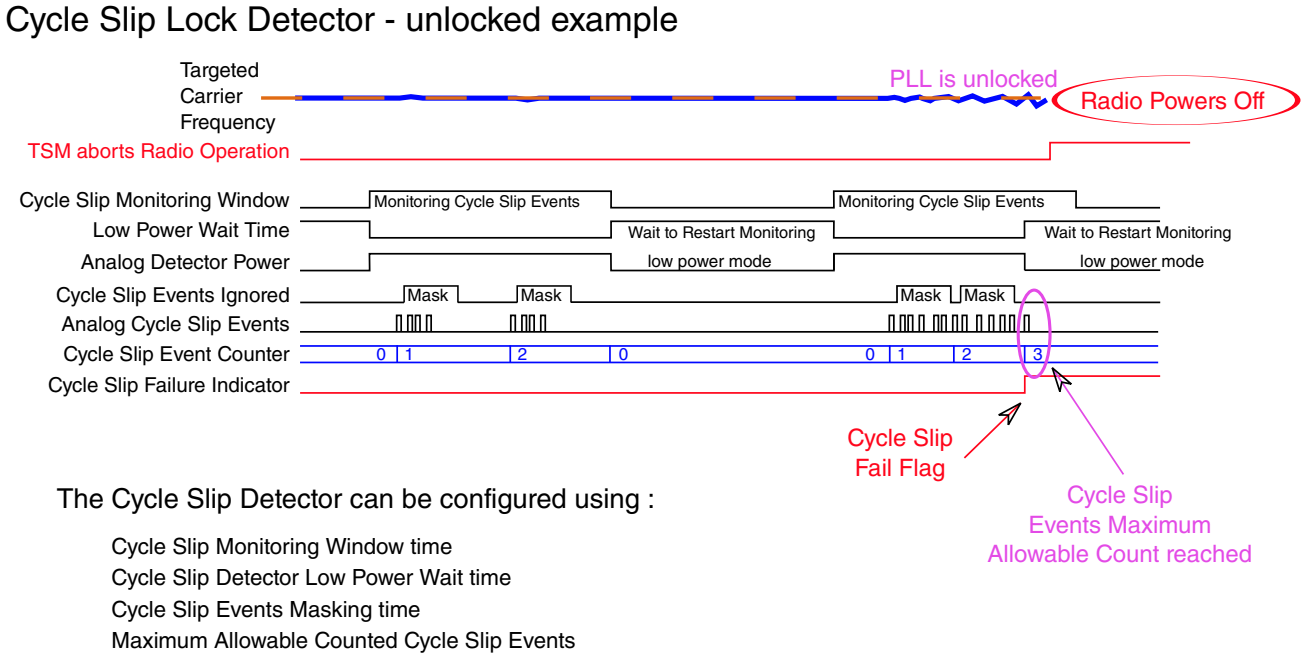

**Figure 64-31. PLL Unlock Example**

### 64.3.2.6.3.1 Cycle Slip Events Monitor Window

The Cycle Slip Events Monitoring Window Timer selects the time in microseconds that the Cycle Slip Lock Detector will monitor Cycle Slip Events.

If the Cycle Slip Events Monitoring Window Timer expires before the Cycle Slip Events Count is reached, then the Events Counter will be reset and the Events Counting sequence can restart after the Cycle Slip Detector Low Power Wait Time if the Cycle Slip Recycle bit is set.

The following selections are to be supported for the Cycle Slip Events Monitoring Window Time:

**Table 64-18. Cycle Slip Events Monitoring Window Times**

| CS_FW[2:0], Cycle Slip Monitor Time | Monitor Time (us) |
|---|---|
| 0 | 8 |
| 1 | 16 |
| 2 | 24 |
| 3 | 32 |
| 4 | 64 |

*Table continues on the next page...*

**Table 64-18. Cycle Slip Events Monitoring Window Times (continued)**

| | |
|---|---|
| 5 | 96 |
| 6 | 128 |
| 7 | 256 |

### 64.3.2.6.3.2 Cycle Slip Detector Low Power Wait Timer

The Cycle Slip Detector Low Power Wait Timer is a method for saving power by turning off the analog cycle slip detector circuit for a programmable period of time. If the Cycle Slip Recycle bit is set when the Cycle Slip Events Monitoring Window Timer expires, then the Events Counter will be reset and the Events Counting sequence will restart after the Cycle Slip Detector Low Power Wait Time expires.

The following selections are to be supported for the Low Power Wait Time:

**Table 64-19. Cycle Slip Detector Low Power Wait Times**

| CS_WT[2:0], Cycle Slip Wait Time | Wait Time (us) |
|---|---|
| 0 | 128 |
| 1 | 256 |
| 2 | 384 |
| 3 | 512 |
| 4 | 640 |
| 5 | 768 |
| 6 | 896 |
| 7 | 1024 |

### 64.3.2.6.3.3 Cycle Slip Events Masking Timer

The Cycle Slip Events Masking Timer selects the number of nanoseconds that the Cycle Slip Lock Detector will wait before counting the next Cycle Slip Event. This allows time for the PLL to try to regain lock on the VCO.

The following selections are to be supported for the Cycle Slip Events Masking time after an analog cycle slip event:

**Table 64-20. Cycle Slip Events Masking Times**

| CS_FT[4:0], Cycle Slips Masking Time | Wait Time (ns), 26 MHz | Wait Time (ns), 32 MHz |
|---|---|---|
| 0 | 38 | 31 |

*Table continues on the next page...*

**Table 64-20. Cycle Slip Events Masking Times (continued)**

| | | |
|---|---|---|
| 1 | 77 | 63 |
| 2 | 115 | 94 |
| 3 | 154 | 125 |
| 4 | 192 | 156 |
| 5 | 231 | 188 |
| 6 | 269 | 219 |
| 7 | 308 | 250 |
| 8 | 346 | 281 |

| 27 | 1077 | 875 |
| 28 | 1115 | 906 |
| 29 | 1154 | 938 |
| 30 | 1192 | 969 |
| 31 | 1231 | 1000 |

#### 64.3.2.6.3.4 Cycle Slip Events Count

The Cycle Slip Events Count (CS_FCNT) determines the number of Cycle Slip Events that will cause a Cycle Slip Fail Flag to be set.

The range of Cycle Slip Events Counted that will cause a Fail Flag shall be from 1 to 15.

## 64.3.2.7 Memory Map and Register Definition

The PLL Digital memory map and detailed descriptions of all its registers are as follows.

### 64.3.2.7.1 XCVR_PLL_DIG register descriptions

#### 64.3.2.7.1.1 XCVR_PLL_DIG_ADDR Memory map

XCVR_PLL_DIG base address: 4103_0224h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | PLL HPM Analog Bump Control (HPM_BUMP) | 32 | RW | 0000_1010h |
| 4h | PLL Modulation Control (MOD_CTRL) | 32 | RW | 0000_0000h |
| 8h | PLL Channel Mapping (CHAN_MAP) | 32 | RW | 0000_0200h |
| Ch | PLL Lock Detect Control (LOCK_DETECT) | 32 | RW | 0060_6800h |
| 10h | PLL High Port Modulator Control (HPM_CTRL) | 32 | RW | 9084_0000h |
| 20h | PLL High Port Sigma Delta Results (HPM_SDM_RES) | 32 | RW | 0100_0000h |
| 24h | PLL Low Port Modulator Control (LPM_CTRL) | 32 | RW | 0202_0000h |
| 28h | PLL Low Port Sigma Delta Control 1 (LPM_SDM_CTRL1) | 32 | RW | 0026_0026h |
| 2Ch | PLL Low Port Sigma Delta Control 2 (LPM_SDM_CTRL2) | 32 | RW | 0008_0000h |
| 30h | PLL Low Port Sigma Delta Control 3 (LPM_SDM_CTRL3) | 32 | RW | 0010_0000h |

## 64.3.3 Receiver Digital Module

### 64.3.3.1 Introduction

The RX DIG module for Radio 3.0 implements the receive digital signal processing functions common to BTLE, 802.15.4, and Generic Link Layer modes. Generally this includes conditioning the input samples from the ADC and produces a data output for the PHY and an RSSI/LQI for the Link Layers.

#### 64.3.3.1.1 Features

The rx_dig module includes the following features:

- Decimation Filter
- I/Q Mismatch Correction
- DC Offset Calibration, Estimation and Correction
- Channel Filter
- Sample Rate Converter
- DC Residual Correction
- AGC & RSSI
- Normalizer
- RC Calibration
- AuxPLL Frequency Calibration

#### 64.3.3.1.2 Modes and operations

The rx_dig module supports BTLE, 802.15.4, and Generic Link Layer modes of operation through use of programmable values such as the oversampling rate, channel filter coefficients, etc. Another configuration is possible to simply pass the values received from the ADC.

The table below shows the data rates supported by RX DIG. Note that the ADC is clocked at twice the reference clock frequency, so ADC clock of 64Mhz corresponds to a 32MHz reference clock, and an ADC clock of 52MHz corresponds to a 26MHz reference clock.

**Table 64-21. RX Digital Modes and Rates**

| ADC clock (MHz) | Decimator OSR | Decimation Filter Output Rate(MHz) | SRC conversion factor | SRC Output Rate (MHz) | Use-Case |
|---|---|---|---|---|---|
| 64 | 8 | 8 | bypass | 8 | Generic FSK at 2Mbps |
| | 16 | 4 | bypass | 4 | IEEE 802.15.4, BTLE, or Generic FSK at 1 Mbps |
| | 32 | 2 | bypass | 2 | Generic FSK at 500 kbps |
| | 64 | 1 | bypass | 1 | Generic FSK at 250 kbps; |
| | | | | | |
| 52 | 6 | 8.67 | ZOH; 12/13 | 8 | Generic FSK at 2Mbps |
| | 8 | 6.5 | FOH; 8/13 | 4 | BTLE, or Generic FSK at 1Mbps |
| | 12 | 4.33 | ZOH; 12/13 | 4 | BTLE, or Generic FSK at 1Mbps (alternate) |
| | 16 | 3.25 | FOH; 8/13 | 2 | Generic FSK at 500 kbps |
| | 24 | 2.167 | ZOH; 12/13 | 2 | Generic FSK at 500 kbps (alternate) |
| | 48 | 1.625 | FOH; 8/13 | 1 | Generic FSK at 250 kbps |
| | 64 | 1.083 | ZOH; 12/13 | 1 | Generic FSK at 250 kbps (alternate) |

#### 64.3.3.1.3 Block diagram

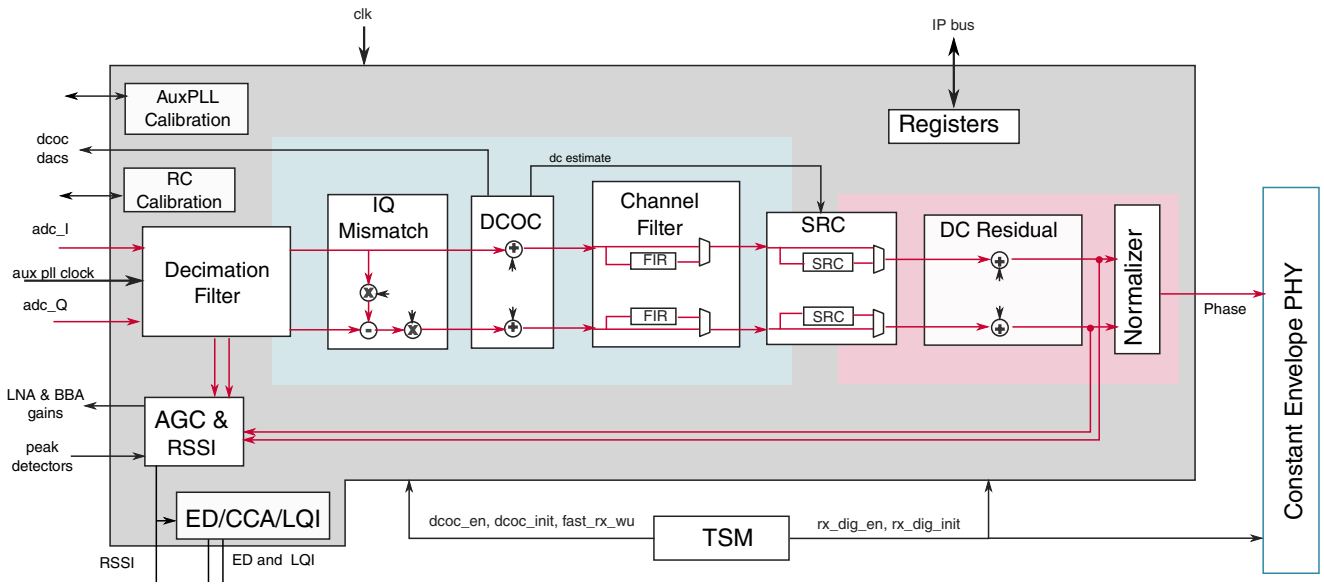

**Figure 64-32. RX DIG Block diagram**

### 64.3.3.2 Functional description

The following sections describe functional details of the RX_DIG module.

The RX_DIG module has two overall funtions. Samples from the ADC are computed to usable formats for the demodulator. Additionally, the module conditions the received sample in various ways, including sending feedback to the analog circuitry.

#### 64.3.3.2.1 Decimation Filter

The decimation filter is a 4th order Cascaded Integrator Comb (CIC) filter. Its frequency response comprises a 4th order sinc filter that supports oversampling ratios (OSR) of 4, 6, 8, 12, 16, 24 , 32, 48, and 64. There are two decimation filters: one for the I channel and one for the Q channel. The decimators consume the sigma-delta modulated output from the ADCs at the Aux PLL frequency clock rate (2x reference clock rate) and output samples at the decimation rate in the reference clock domain which used by the rest of the logic in RX DIG. Refer to Table 64-21 for information on the supported decimation rates.

A block diagram of the decimation filter is shown below.

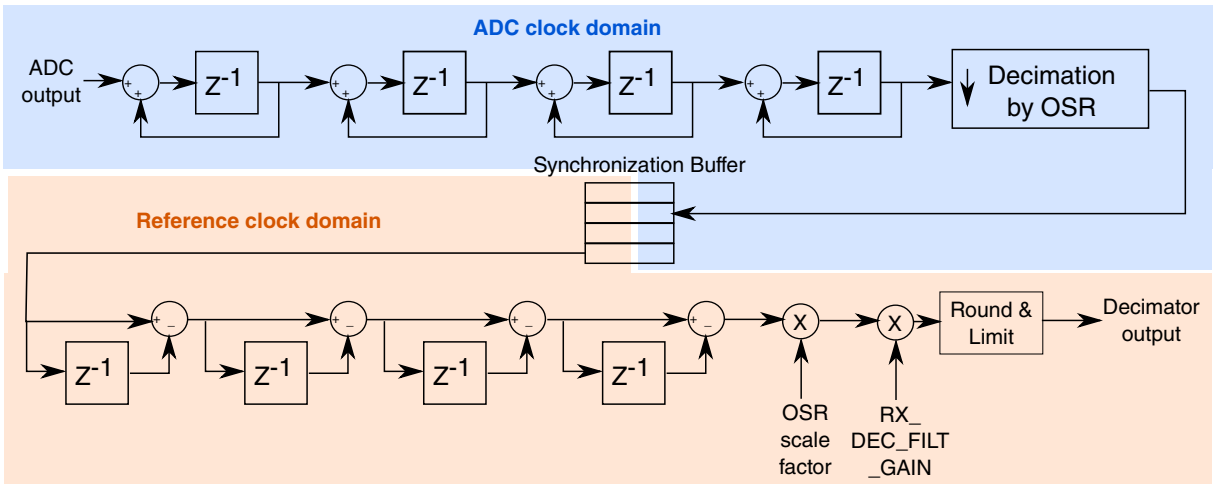

**Figure 64-33. Decimation Filter Block Diagram**

The decimator output scaling is dependant on the OSR scale factor (fixed in hardware, depends on the programmed OSR) and the programmable RX_DEC_FILT_GAIN. The RX_DEC_FILT_GAIN is intended to be programmed based on the maximum signal level at the ADC input, the ADC gain (1code/1.7V), and the OSR scale factor so that the maximum signal range (+2047/-2048) can be realized in the decimator output. An example of RX_DEC_FILT_GAIN programming is shown in the table below for the case where the maximum input signal level to the ADC is 1.0V. The "Maximum Decimator Output" column is computed as

```
Maximum Decimator Ouput = 1.0V * (1code/1.7V) * OSR^4  * OSR_scale_factor *
RX_DEC_FILT_GAIN / 2
```

**Table 64-22. Decimation Filter Gain Table Example, ADC input 1.0V**

| OSR | Gain at output of 4th order CIC (OSR^4) | OSR scale factor | RX_DEC_FILT_GAIN | Maximum Decimator Output |
|---|---|---|---|---|
| 4 | 256 | $2^{4}$ | 1+1/2+1/8+1/16=1.6875 | 2033 |
| 6 | 1296 | $2^{2}$ | 1+1/4+1/16+1/32=1.3438 | 2049 (saturated to +2047/-2048) |
| 8 | 4096 | $2^{0}$ | 1+1/2+1/8+1/16=1.6875 | 2033 |
| 12 | 20736 | $2^{-2}$ | 1+1/4+1/16+1/32=1.3438 | 2049 (saturated to +2047/-2048) |
| 16 | 65536 | $2^{-4}$ | 1+1/2+1/8+1/16=1.6875 | 2033 |
| 24 | 331776 | $2^{-6}$ | 1+1/4+1/16+1/32=1.3438 | 2049 (saturated to +2047/-2048) |
| 32 | 1048576 | $2^{-8}$ | 1+1/2+1/8+1/16=1.6875 | 2033 |
| 48 | 5308416 | $2^{-10}$ | 1+1/4+1/16+1/32=1.3438 | 2049 (saturated to +2047/-2048) |
| 64 | 16777216 | $2^{-12}$ | 1+1/2+1/8+1/16=1.6875 | 2033 |

The decimator is controlled via several programmable bitfields, and there are also a few status bits , as noted below:

- The OSR is programmed using RX_DEC_FILT_OSR
- The RX_DEC_FILT_LP bit can be used to reduce the power consumption of the decimator. When this bit is set, a decimate-by-2 operation is performed on the ADC samples (by simply averaging the ADC output over a window of 2 samples), and the CIC is then operated at 1/2 of the rate programmed via RX_DEC_FILT_OSR.
- The decimation output is scaled based on the OSR and a programmable fractional gain (RX_DEC_FILT_GAIN), as described above. After decimation, the samples are output at the appropriate lower rate in 12-bit signed format.
- The decimator outputs RX_DEC_FILT_SAT_I and RX_DEC_FILT_SAT_Q flags to indicate if the decimator output has saturated during an RX burst
- The single-bit ADC samples can be sampled on either the posedge (default, RX_ADC_NEGEDGE=0) or negedge (RX_ADC_NEGEDGE=1) of the adc_clk.
- The single-bit ADC samples can be mapped as 1'b1->+1, 1'b0->-1 (default, RX_ADC_POL=0) or as 1'b0->+1, 1'b1->-1 (RX_ADC_POL=1).
- The decimator includes a sample buffer to handle the synchronization between the ADC output (adc_clk) clock domain and decimator output (clk) clock domains.
  - The decimator outputs a flag (RX_DEC_FILT_HAZARD) to indicate if a hazard condition has been detected (write and read pointers match) .
  - By default, synchronization hazard correction logic is enabeld (RX_DEC_FILT_HZD_CORR_DIS=0) . In this case, if a hazard condition is detected, the buffer pointers will be adjusted to overcome the hazard condition, though there will be a few corrupted samples at the decimator output. Conversely, if a hazard condition is detected and correction is disabled, the buffer pointers will not be adjusted, and it is possible that the decimator output could be corrupted for a much longer period.

For an ADC clocked at a 64 MHz reference clock, an OSR of 8 is used for BTLE at 2Mbps and an OSR of 16 is used for BLE at 1Mbps, and for IEEE 802.15.4 mode. The frequency response of the decimation filter for these two cases is shown in the figures below.

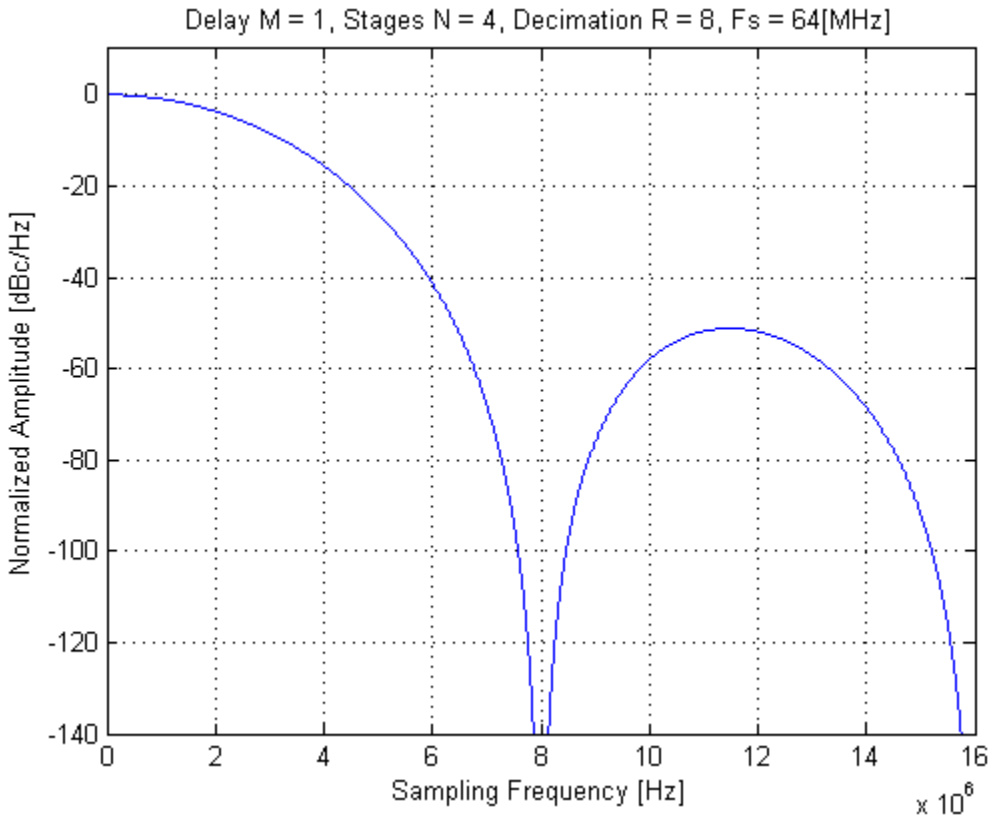

**Figure 64-34. 4th order CIC (OSR=8) Decimation Filter Frequency Response**

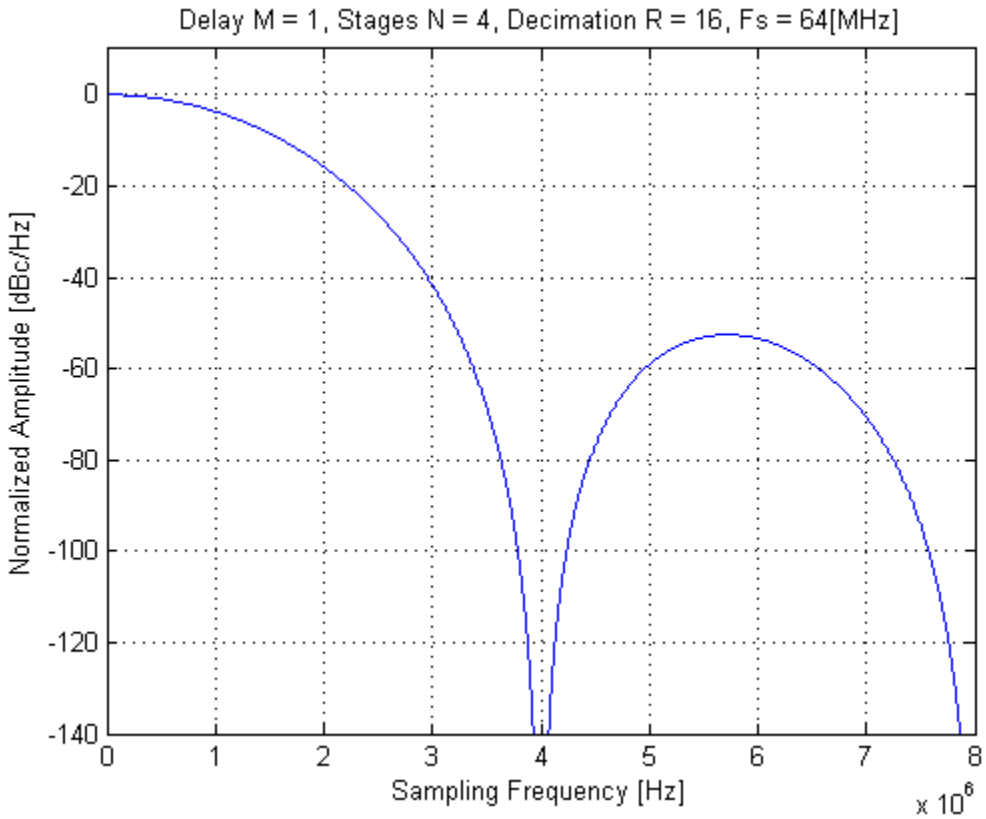

**Figure 64-35. 4th order CIC (OSR=16) Decimation Filter Frequency Response**

The decimator block provides a separate output for wide-band RSSI measurement that is used by the AGC algorithm and CCA1/CCA3/ED/LQI. This output is at 8MHz (32MHz reference clock) or 8.667MHz (26MHz reference clock). As the objective of the wide-band RSSI measurement is to compute a dBVrms value of the ADC output stream with minimal delay, a 2nd order CIC configuration is used. This 2nd order CIC shares the first two CIC integrators with the main datapath, but uses 2 dedicated difference stages.

The decimator for wide-band RSSI measurements is controlled via several programmable bitfields, and there are also a few status bits , as noted below:

- The decimation ratio is determined by XCVR_CTRL[REF_CLK_FREQ]. For a 32MHz reference clock, the decimation ratio is 8 so the decimator output is 8MHz; for a 26MHz reference clock, the decimation ratio is 6 so the decimation output rate is 8.667MHz
- After decimation, the samples are output at the appropriate lower rate in 10-bit signed format. The decimation output is scaled based on the OSR so that the maximum signal level is +/-576 codes.
- The decimator includes a buffer to handle the synchronization between the ADC output (adc_clk) clock domain and decimator output (clk) clock domains.

- The wideband RSSI decimator outputs a flag (RX_RSSI_FILT_HAZARD) to indicate if a hazard condition has been been detected (write and read pointers match)
- By default, synchronization hazard correction logic is enabeld (RX_DEC_FILT_HZD_CORR_DIS=0) . In this case, if a hazard condition is detected, the buffer pointers will be adjusted to overcome the hazard condition, though there will be a few corrupted samples at the decimator output. Conversely, if a hazard condition is detected and correction is disabled, the buffer pointers will not be adjusted, and it is possible that the decimator output could be corrupted for a much longer period.

#### 64.3.3.2.2 AGC & RSSI

The AGC & RSSI module has two main functions. It estimates the energy of an incoming signal (RSSI) and it executes the Automatic Gain Control (AGC) by varying the front-end analog gain. These two functions are designed into the same block and the AGC operation relies, at times, on the estimates provided by the RSSI estimator.

##### 64.3.3.2.2.1 RSSI estimator

The role of the RSSI (Received Signal Strength Indication) estimator is to measure the energy of an incoming signal. The estimator:

- provides a wideband ADC signal level measurement for AGC operation using a decimated version of the ADC output (*RSSI_adc*);
- provides an inband received energy estimate using the "Gain adjustment" block in Figure 64-39;
- targets RSSI accuracy with tunable gains and coefficients.

RSSI accuracy is better than +/- 3dB for input signals in the range of -50dBm to 0dBm. This is the intended operating range for the AGC system. RSSI accuracy is better than +/- 6dB for all input signals below -50dBm.

RSSI estimation is performed using the binary samples output by the ADC. After this operation the signal is filtered using a second order CIC and rate reduction (to 8 MHz if 32 MHz crystal is used or to 8.66MHz for a crystal frequency of 26 MHz). The signal magnitude is then estimated with an L1-norm approach as follows:

$$\textbf{\textit{Magnitude}}(i) = max(|I_i|,|Q_i|) + {}^{3}/_{8} * min(|I_i|,|Q_i|)$$

The estimated magnitude is then passed through a smoothing, low-pass single-tap IIR filter with the transfer function (update factor is α in Figure 64-39):

$$y[n] = (1-\alpha)*y[n-1] + \alpha*x[n]$$

In order to reduce the filter settling duration, when *cca1_ed_trig* is asserted, the α IIR output is seeded with the first value of the estimated magnitude. Configuration of this filter is described in Table 64-25, parameter *rssi_iir_weight*. Then a down-sampler is used to reduce the sampling rate (8 MHz or 8.66 MHz) to a lower rate. A down-sampling cycle is as follows: *N* samples are accumulated, then the results is divided by *N*, division result is output (at a rate *N* times smaller than the input signal) and the internal accumulator is reset to 0.

Following the smoothing filter and down-sampler, the RSSI estimator converts the approximated magnitude to dB. This conversion is achieved using a look-up table ("lin2dB" block) that approximates:

$$RSSI_adc = 20*log_{10}(^{approx.\ magnitude}/_{ADC\ full\ scale})$$

The computed value *RSSI_adc* is intended to be used by the AGC mechanism.

*RSSI_adc* estimate is converted to an estimate for the signal strength at the antenna, in the "Gain Adjustment" block, using parameters as follows:

$$RSSI = RSSI_adc - lnm_gain - bbf_gain + rssi_adj+13$$

where *rssi_adj* is described in Table 64-25 and represents a constant value which allows taking into account different adjustments needed. The adjustment which accounts for scaled dBVrms to dBm conversion is considered using the constant 13. *lnm_gain* and *bbf_gain* values have resolution of a quarter dB.

The rest of the blocks in Figure 64-39 are used for CCA1, CCA3 and ED. In order to obtain these measurements an averager is used ("RSSI Averager") which essentially is another down-sampler with a factor *M*. This block functions in the same manner as the *N* order down-sampler. In the wideband mode context, the block "RSSI Averager" and the sub-sequent blocks are enabled only if a CCA/ED measurement is in progress or if the test mode is enabled.

#### 64.3.3.2.2.2 AGC

The Automatic Gain Control (AGC) system is designed to ensure that the received signal does not become distorted because of clipping in the analog receive chain, while attempting to maintain an optimal signal level for demodulation. There are two locations where gain may be adjusted: analog BBA, and analog LNA. The AGC system

manipulates these gains to maintain a targeted ADC input signal level. The targeted ADC signal level is chosen as a compromise between receiver linearity, blocker headroom requirements and the goal to maximize the digital signal SNR that is provided to the protocol-specific PHY demodulators.

Additionally, the AGC system may be manually controlled by setting the USER_BBA_GAIN_EN and USER_LNA_GAIN_EN bits. If these bits are set, the gains selected in BBA_USER_GAIN and LNA_USER_GAIN will be applied.

The key components of the AGC system are: peak detectors in the analog front end, gain control, RSSI estimation, and a state machine. Additionally, the AGC system has appropriate interation with the DCOC block to maintain a coherent state of the gains.

If the manual control of the gains is not enabled, and the AGC system is enbled, the system will automatically control the gains based on peak detector states and/or RSSI measurements.

The AGC sytem operated with a state machine that is depicted in Figure 64-36 and has the following significant modes:

- **IDLE**: No actions are taken. The system waits for either rx_init (for normal receive operation) or cal_init (for DC calibration).
- **DC Calibration**: When cal_init is observed while in IDLE, the AGC enters the DC Calibration state. According to values programmed in DCOC_CAL_GAIN, gains will be applied for DC CAL 1, 2, 3 phases and the DCOC block can take measurements of the DC level with those gains applied. During DC Calibraion, the AGC system takes no other action.
- **FAST AGC**: When rx_init is observed while in IDLE, the system advances to FAST AGC. Maximum gain is applied immediately. While in FAST AGC, the high level peak detectors are observed to see if clipping is occurring in the analog. If a high peak detector becomes set, a gain adjustment is applied based on the settings AGC_DOWN_LNA_STEP_SZ, AGC_DOWN_BBA_STEP_SZ, and AGC_GAIN_TBL. Depending on which of the two peak detectors is set, the corresponding step is taken in the gain table. When a change is made, a timer prevents further changes until the gain change has had time to settle. This time is defined by the settings LNA_GAIN_SETTLE_TIME and BBA_GAIN_SETTLE_TIME. This time is also utilized to reset the state of the peak detectors. FAST AGC can be exited by reaching the minimum possible gain setting, or if the fast_expire timer expires. This time is configured with the AGC_FAST_EXPIRE setting.
- **SLOW AGC**: The SLOW AGC state allows for observation of RSSI, while still monitoring the peak detectors. Alternatively, RSSI can be ignored and the low peak detectors can be used to take upward gain steps. These steps are smaller than the steps taken in FAST AGC. Before entering SLOW AGC, there is a PRESLOW state

where RSSI_adc is quickly checked. If there is not enough ADC headroom (as determined by PRESLOW_DOWN_THRESH), a small downward gain step is taken before proceding to SLOW AGC. If there is too much ADC headroom (as determined by PRESLOW_UP_THRESH), a small upward gain step is taken before proceeding to SLOW AGC. Similar to FAST AGC, SLOW AGC will allow for a gain settling time whenever an adjustment is made. SLOW AGC can be exited because of several condtions. If a high peak detector indicates clipping, the system immediately moves to the FAST AGC state. If a drastic change in measured RSSI occurs, the system will similarly transition to the FAST AGC state. Finally, if the slow_expire timer (ipr_agc_fast_expire when in slow mode) reaches the pre-determined time, the system will move to HOLD AGC.

- **HOLD**: The AGC HOLD state will not take any actions unless a high peak detector is set, a large RSSI change is experienced, or the hold_expire timer expires. These conditions cause transitions into approriate states to take action. The expiration of the hold_timer moves the system back to SLOW AGC, where monitoring of the RSSI can be done and gain increases can happen, if appropriate.

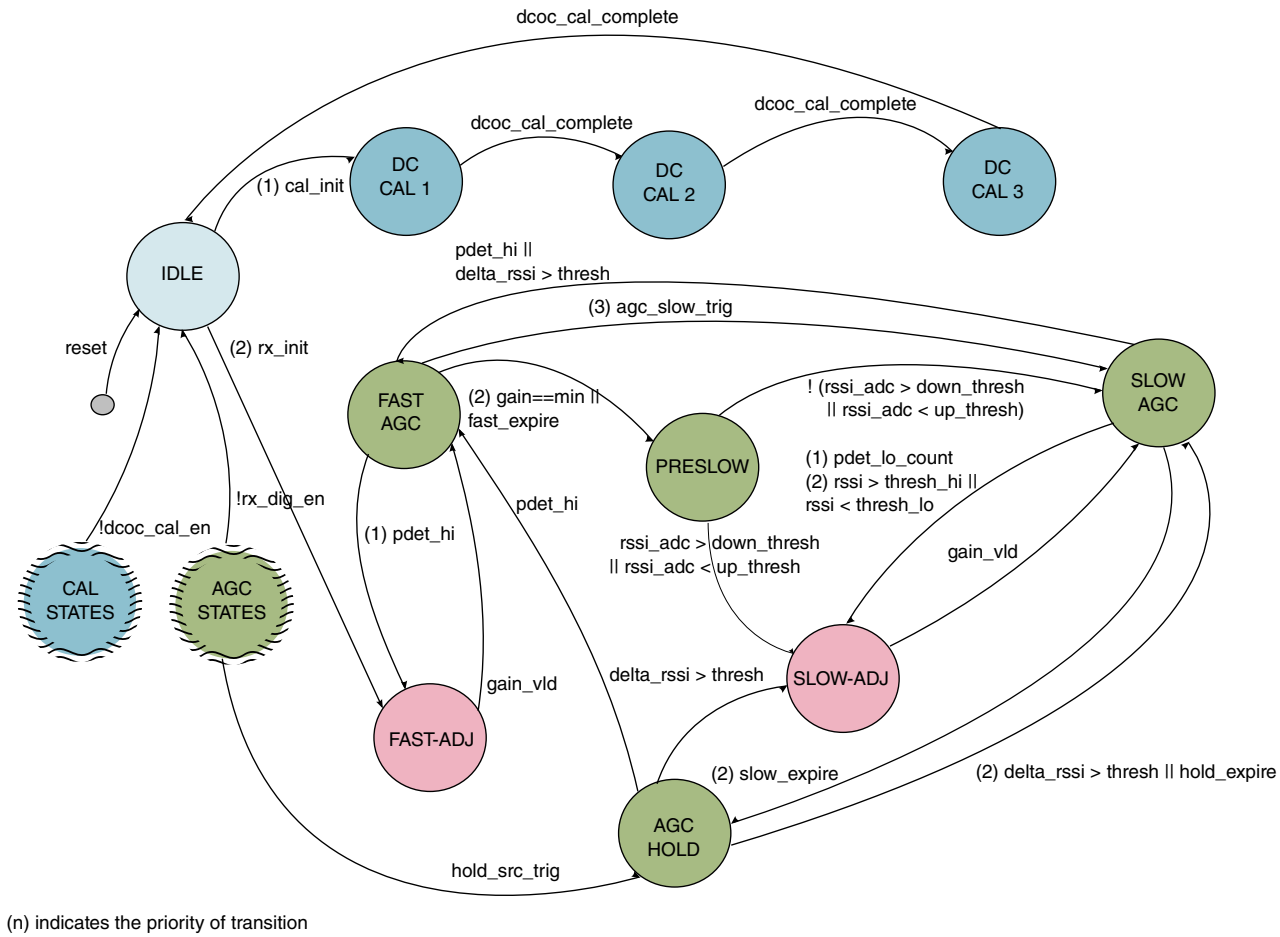

**Figure 64-36. AGC State Machine**

As previously mentioned, gain steps are performed by striding through the user programmed gain table. There are 27 entries in the table, and each entry contains an index for LNA gain and an index for BBA gain. The mapping of these indicies to codes and nominal gains is described in Table 64-23 and Table 64-24. Entry 0 is interpreted as the lowest possible gain setting, and entry 26 the highest.

**Table 64-23. LNA Gains**

| lna_gain (AGC_GAIN_TBL) | LNA Gain (dB) | lna_gain code |
|---|---|---|
| 0 | -8.6 | 01 |

### 64.3.3.2.3 RSSI, Energy Detection, CCA1 and LQI module

There are two modules that achieve RSSI, Energy Detection, CCA, and LQI: rx_agc_rssi_est and rx_cca_ed_lqi.

See the AGC section for additional RSSI details.

The RSSI module is responsible with the generation of estimates used for AGC and RSSI or required by the upper layers of the protocols stack. Two modes are defined:

- **Wideband mode**, which uses as input the samples from the output of the ADC decimator (signals *dec_8m_out_i[10:0]* and *dec_8m_out_q[10:0]*). In this mode the incoming samples have sampling frequency of either 8 MHz (if 32 MHz crystal is used) or 8.66 MHz(if 26 MHz crystal is used).
- **Narrowband mode**, which uses as input the samples from the output of the min-max residual DC offset compensator (signals *narrow_band_out_i[11:0* and *narrow_band_out_q[11:0]*). In this mode, the incoming samples have sampling frequency of either 2, 4 or 8 MHz depending on PHY configuration.

The cca_ed_lqi module uses rssi outputs from the rssi_est module.

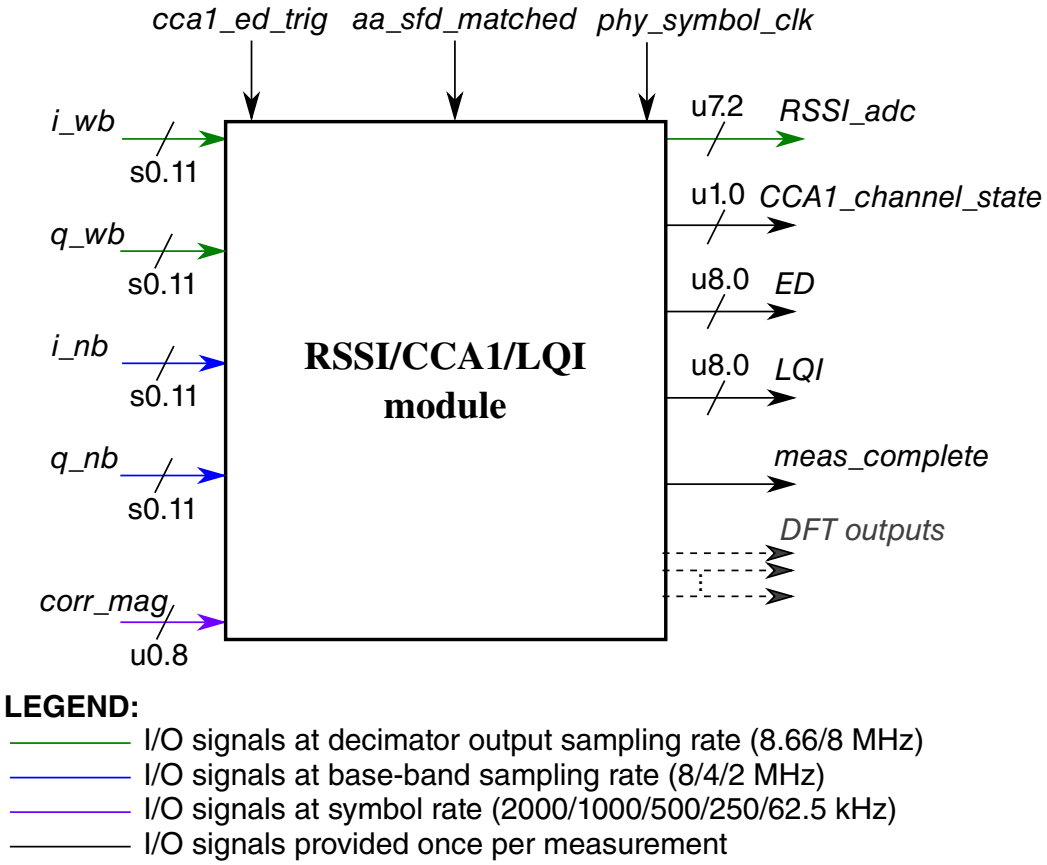

**Figure 64-37. Top level view of the block diagram**

Following table is showing the valid configurations and the valid outputs thereto.

**Table 64-26. Valid configurations and corresponding outputs**

| *cca1_ed_trig* | *sfd_aa_match* | State | Valid outputs |
|---|---|---|---|
| 0 | 0 | RSSI | *RSSI_adc* |
| 1 | 0 | CCA1/ED measurement | *RSSI_adc*<br>*zb_cca1_channel_state*<br>*zb_cca3_channel_state*<br>*ED* |
| 0 | 1 | LQI measurement | *LQI* |
| 1 | 1 | LQI measurement | *LQI* |

Following figure describes the state machine of the module.

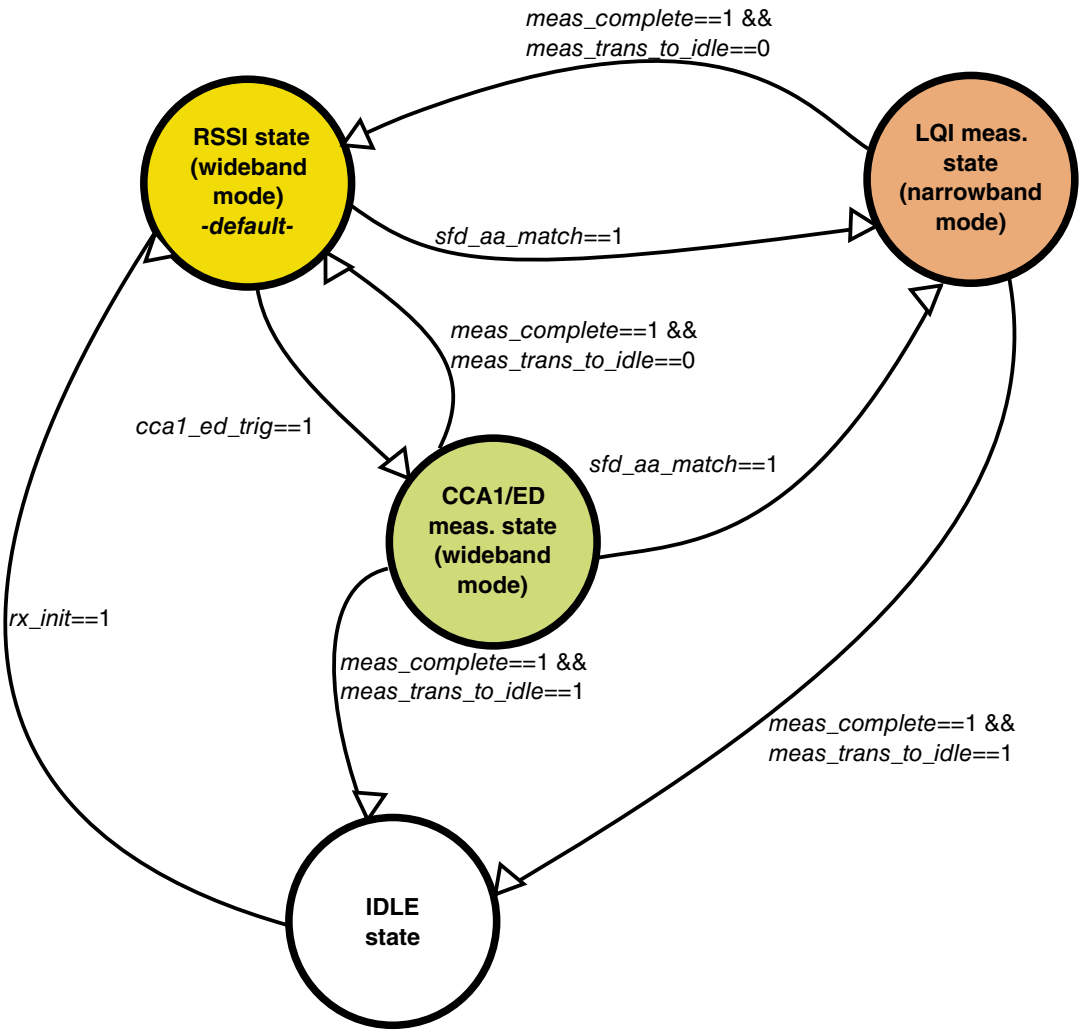

**Figure 64-38. Module state machine**

### 64.3.3.2.3.1 Wideband mode

The instantiation of the block diagram corresponding to wideband mode is illustrated in Figure 64-39. Blocks drawn using dashed lines are shared between the wideband and narrowband modes. Following functions are intended in the wideband mode (as described in Table 64-26):

- Estimation of RSSI at the output of the ADC decimator (*RSSI_adc*) used for AGC and of received inband RSSI;
- Energy detection (*ED*), required by the upper layers, which is an 8 bits value achieved through measuring the energy of the channel;
- Clear Channel Assessment Mode 1 (*zb_cca1_channel_state*), required by the upper layers, which is a flag indicating whether the channel is busy or idle.

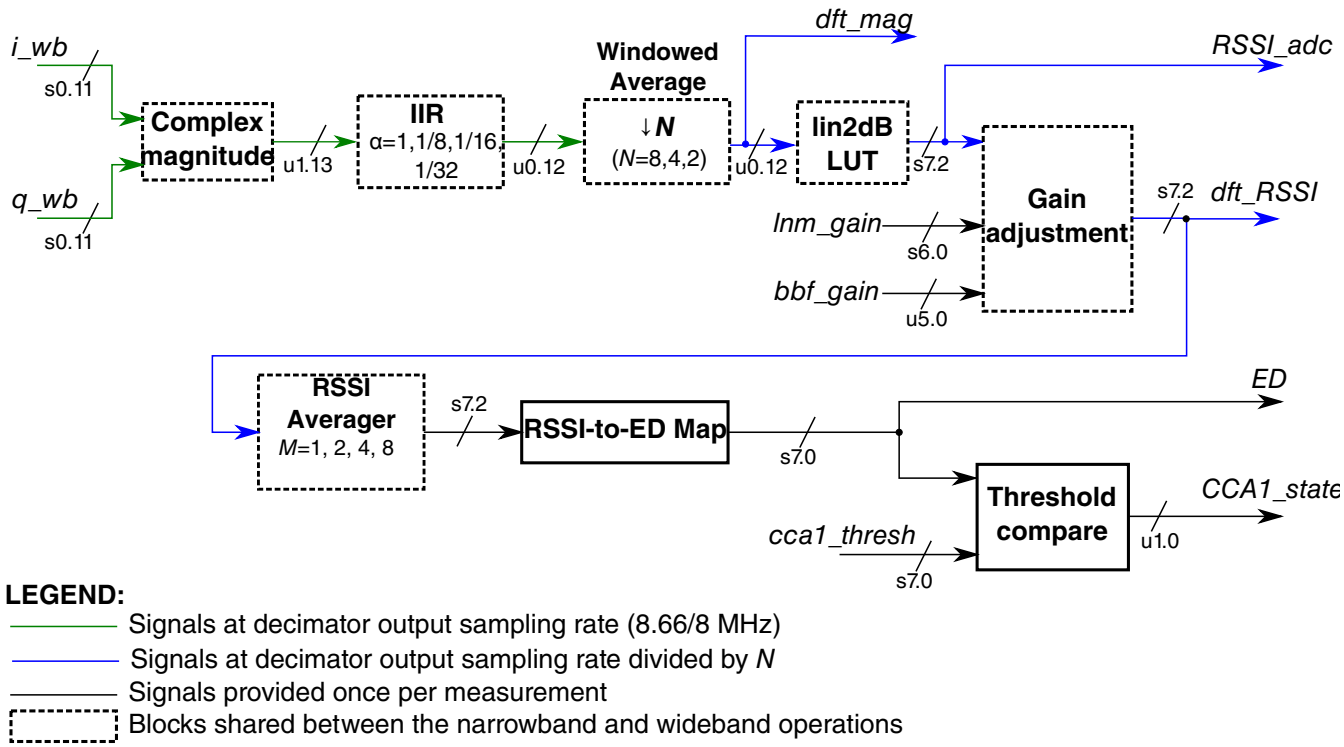

**Figure 64-39. Block diagram instantiated for wideband mode**

#### *64.3.3.2.3.1.1 ED and CCA1*

Module transitions to CCA1/ED measurement state and ED and CCA1 operations start based on a command signal *cca1_ed_trig* (configuration described in Table 64-26). When this signal is asserted, signal *meas_complete* is forced to low state.

When a *cca1_ed_trig* command is asserted, "RSSI averager" is enabled after a programmable delay in order to take into consideration the settling time of the IIRs (programmable delay is configured via parameter *rssi_noise_avg_delay*). After a result is produced by the "RSSI averager" block (i.e. after *M*N* samples have been input to the RSSI/CCA/ED/LQI module since "RSSI averager" has been enabled) in Figure 64-39 signal *meas_complete* is asserted. This signal is intended to let know the external modules consuming the outputs that ED, CCA1 and CCA3 values are ready. In a non-test mode, the module returns to RSSI state after asserting *meas_complete* signal, if parameter *meas_trans_to_idle* is 0 or it transitions to IDLE state if parameter *meas_trans_to_idle* is 1 (see Table 64-25). The measured values of ED, CCA1 and CCA3 are stored until the next deassertion of signal *meas_complete*.

However, the module may be configured to remain in CCA1/ED measurement state for an arbitrary period of time in a test scenario.

**Table 64-27. Typical CCA/ED measurement window values and corresponding configuration**

| Crystal frequency [MHz] | ADC decimator output sampling frequency [MHz] | *N* | *M* | Approximative duration [µs] |
|---|---|---|---|---|
| 32 | 8 | 16 | 64 | 128 |
| 26 | 8.66 | 16 | 70 | 128 |
| 32 | 8 | 8 | 128 | 128 |
| 26 | 8.66 | 8 | 139 | 128 |
| 32 | 8 | 8 | 64 | 64 |
| 26 | 8.66 | 8 | 70 | 64 |
| 32 | 8 | 4 | 64 | 32 |
| 26 | 8.66 | 4 | 70 | 32 |

Based on computed value *RSSI* an energy detection value *ED* is computed, expressed in dBm. This value is obtained by rounding the output of the "RSSI Averager" block to 8 signed bits by using block "RSSI-to-ED Map" in Figure 64-39.

Assessment of the channel's state is by comparing value *ED* with threshold *cca1_thresh*. If the threshold is exceeded at the end of the measurement then *zb_cca1_channel_state* is put to '1'. Otherwise it is put to '0'.

The CCA3 estimation *zb_cca3_channel_state* is realized by combining *zb_cca1_channel_state* and *zb_cca2_channel_state* . This is handled outside RX_DIG.

#### 64.3.3.2.3.2 Narrowband mode

The instantiation of the block diagram corresponding to narrowband mode is illustrated in Figure 64-40. Blocks drawn using dashed lines are shared between the wideband and narrowband modes. Following functions are intended for this mode (as described in Table 64-26):

- Link Quality Indication determination (*LQI*), required by the upper layers. LQI is an 8 bits value obtained by combining inband RSSI (corresponding to channel filtered samples), SNR (signal-to-noise ratio) and correlation magnitudes;

LQI is computed in three steps:

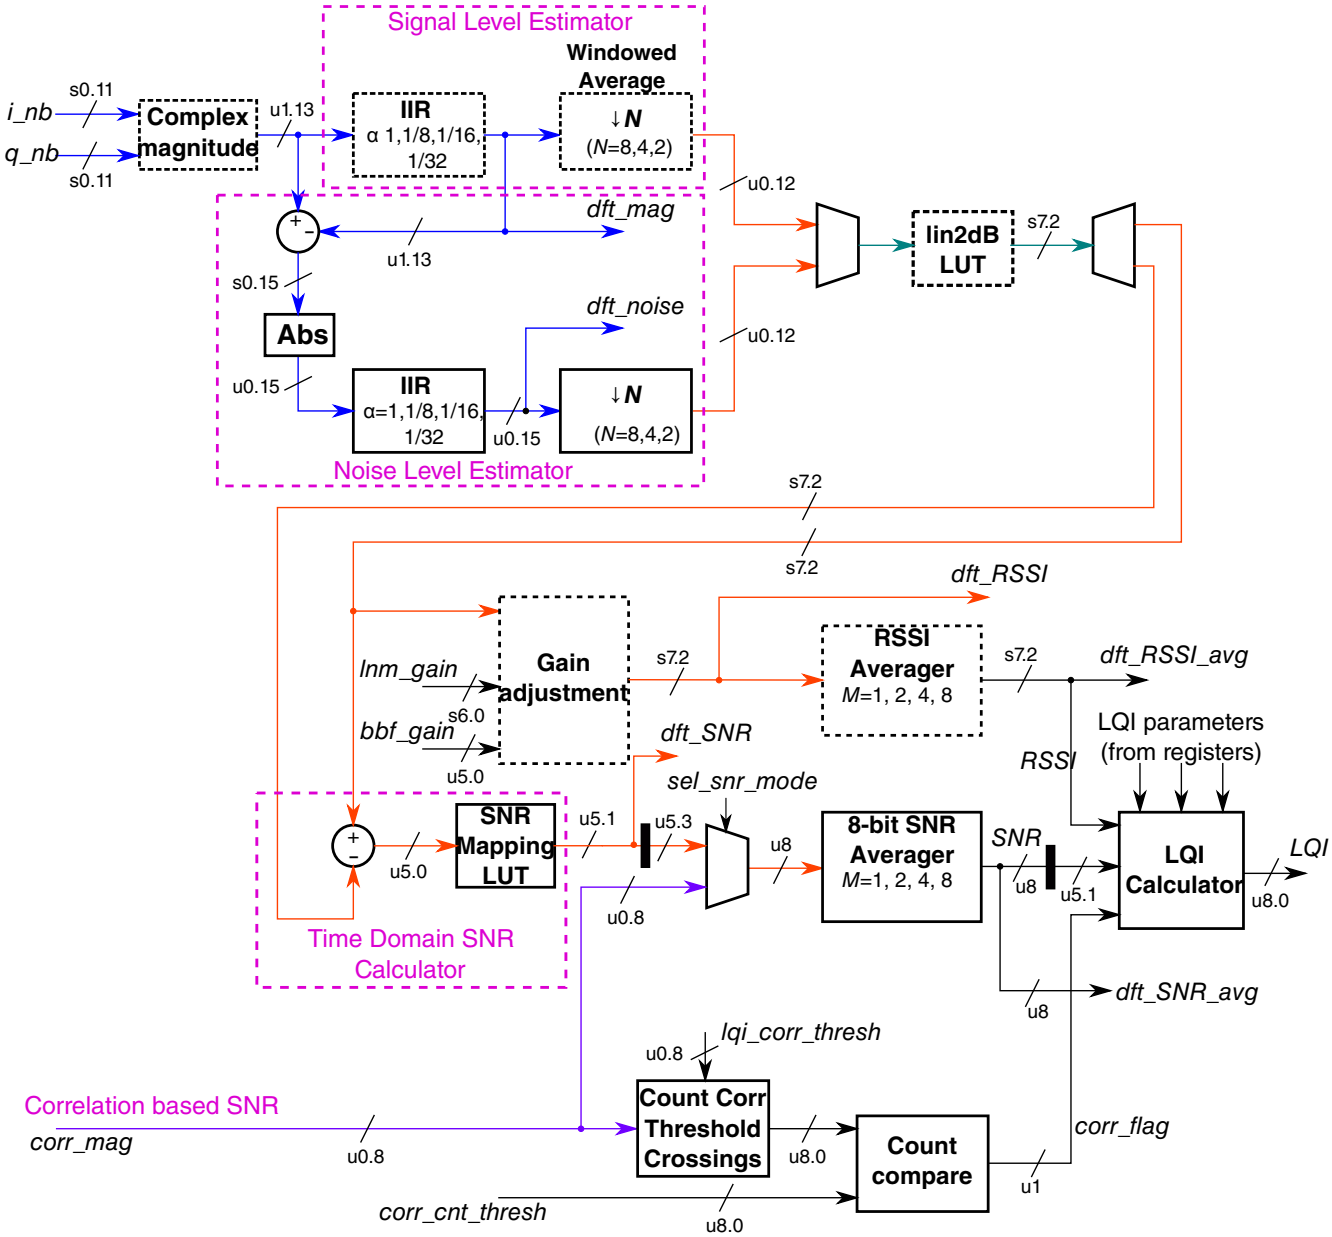
- RSSI (using narrow band I/Q samples) and SNR estimation;
- Correlation flag determination, used to determine whether receiver is at the sensitivity boundary or not;
- LQI calculation which represents a linear combination of RSSI, SNR and correlation flag.

An LQI measurement is triggered by the assertion of *aa_sfd_matched* signal. Following this event, the module transitions to LQI measurement state. When *aa_sfd_matched* is asserted the signal *meas_complete* is deasserted (i.e. forced to low state). The blocks "RSSI averager" and "Noise averager" are enabled after a programmable delay in order to take into consideration the settling time of the IIRs (programmable delay is configured via parameter *rssi_noise_avg_delay*). Values *N* and *M* (configured through parameters *mag_downsamp_factor* and *rssi_noise_avg_factor* respectively), and the base-band sampling frequency *Fs*, directly determine the LQI measurement window duration. At the end of this window *meas_complete* is asserted and measured value *LQI* is provided, after a result is produced by the "RSSI averager" block (i.e. after *M*N* samples have been input to the RSSI/CCA/ED/LQI module since "RSSI averager" has been enabled in Figure 64-39). This signal is intended to let know the external modules consuming the outputs that LQI value is ready. The measured value of LQI is stored until the next deassertion of signal *meas_complete*. In a non-test mode, the module returns to RSSI state after asserting *meas_complete* signal, if parameter *meas_trans_to_idle* is 0 or it transitions to IDLE state if parameter *meas_trans_to_idle* is 1 (see Table 64-25).

However, the module may be configured to remain in LQI measurement state for an arbitrary period of time in a test scenario.

**Table 64-28. Examples of configuration of LQI block**

| Protocol | *N* | *M* | *Fs* [MHz] | Window duration [µs] |
|---|---|---|---|---|
| IEEE 802.15.4 | 4 | 128 | 4 | 128 |
| BLE | 8 | 32 | 8 | 32 |
| BLE | 8 | 64 | 8 | 64 |
| FSK-500kbps | 4 | 64 | 2 | 128 |
| FSK- 250kbps | 4 | 64 | 2 | 128 |



**LEGEND:**

- Signals at base-band sampling rate $F_S$ (8/4/2 MHz)
- Signals at $F_S/N$
- Signals at $2*(F_S/N)$
- Signals at symbol rate (2000/1000/500/250/62.5 kHz)
- Signals provided once per measurement
- Blocks shared between the narrowband and wideband operations

**Figure 64-40. Block diagram instantiated for narrowband mode**

#### 64.3.3.2.3.2.1 RSSI and SNR estimation

RSSI is estimated in a similar manner as described in RSSI estimator. The downsampling with *N* block is basically an accumulator. At the end of *N* accumulated values, it divides the result by *N*, outputs the result and resets the internal accumulator to 0. In the same manner function the blocks "RSSI Averager" and "SNR Averager" in Figure 64-40.

In order to estimate the SNR, a noise standard deviation estimation is needed. Noise is estimated after taking the absolute value of the subtraction of smoothed magnitude from the magnitude samples. After IIR and downsampling by *N* of magnitude and noise, conversion from linear domain to dBm is needed. In order to save die-size, "lin2dB" block is shared between the two processing paths by using a synchronous pair MUX/DEMUX. The sampling rate at the input of the "lin2dB" block is doubled due to muxing.

The signal magnitude and noise processing paths are outputting estimates of magnitude and noise respectively, expressed in dBm. The SNR is estimated by subtracting noise from signal. However, an estimation error is present due to the fact that signal and noise are estimated by averaging L1 magnitude samples and not energy values. In order to compensate for this error a non-linear SNR mapping look-up table (block "SNR Mapping LUT") is used in order to map measured SNR to more accurate SNR values. LUT values are specified in Table 64-29. These values have 0.5 dB resolution.

**Table 64-29. SNR mapping LUT**

| Input value (format (u,5,0)) | Output value (format (u, 5,1)) | Input value (format (u,5,0)) | Output value (format (u, 5,1)) |
|---|---|---|---|
| {0,1,2,...,8} | 0 | 17 | 12 |
| 9 | 1 | 18 | 13.5 |
| 10 | 3 | 19 | 15 |
| 11 | 4.5 | 20 | 16 |
| 12 | 6 | 21 | 17.5 |
| 13 | 7.5 | 22 | 19.5 |
| 14 | 8.5 | 23 | 21.5 |
| 15 | 10 | 24 | 25 |
| 16 | 11 | {25,26,27,..,31} | 26.5 |

The estimated SNR is adjustable by addition to the estimated value of the value of the parameter *snr_adjustment_factor* (signed integer) in Table 64-25.

After estimating RSSI and SNR the two quantities are passed through the "RSSI Averager" and "SNR Averager" blocks respectively.

#### 64.3.3.2.3.2.2 Correlation flag determination

During the LQI measurement window, a counter is used to count how many times the correlation products, provided at symbol rate, exceed the correlation threshold *lqi_corr_thresh*. The count is compared with threshold *corr_cnt_thresh*. *corr_cnt_thresh* takes values between 0 and the maximum number of symbols which can be received within the measurement window.

**Table 64-30. Examples of maximum number of symbols in the measurement window**

| Protocol | Symbol rate [kHz] | Window duration [µs] | Maximum *corr_cnt_thresh* |
|---|---|---|---|
| IEEE 802.15.4 | 62.5 | 128 | 8 |
| BLE | 1000 | 32 | 32 |
| FSK-500kbps | 500 | 64 | 32 |

The output of the comparator, *corr_flag*, will take value 0 if *corr_cnt_thresh* is exceeded and 1 otherwise.

#### 64.3.3.2.3.2.3 LQI calculator

Based on narrow band *RSSI* (expressed in dBm), *SNR* (dB) and *corr_flag*, *LQI_raw* is computed as described in following formula:

$$LQI_raw = (RSSI\text{-}Sensitivity)*w_{RSSI} + SNR*w_{SNR} - corr_flag*w_{CorrFlag}+LQI_{bias}$$

Configuration of parameters *Sensitivity*, $w_{RSSI}$, $w_{SNR}$ and $LQI_{bias}$ is described in Table 64-25. $w_{CorrFlag}$ is a constant and takes value 200.

After computing *LQI_raw*, the obtained value is saturated to interval [0,255] and then quantized using 8 integer bits. Thus *LQI* is determined.

### 64.3.3.2.4 I/Q Mismatch Correction

The I/Q mismatch block corrects for I/Q gain and phase mismatch. It can correct up to +/- 9 degrees of phase mismatch and +/- 4 dB of gain mismatch. After correction, phase mismatch is reduced to less than 0.5 degree and gain mismatch less than 0.3 dB.

During factory calibration, the I/Q phase adjustment coefficient (iqmc_phase_adj) and the I/Q gain adjustment coefficient (iqmc_gain_adj) are determined. Calibration is enabled by setting the iqmc_cal_en bit. The following values should be used for calibration: iqmc_num_iter=0x80, and rx_dec_filt_osr=2 (OSR of 16). The IQMC_CAL register should be set to its default value 0x0000_0400. A CW input with a 250 kHz (+/-75 kHz) offset and -2 dBm (+/- 6 dBm) level at the ADC I channel input is required

for calibration, though the calibration should also work with lower signal levels down to -18 dBm. With the standard number of iterations (iqmc_num_iter=0x80), calibration takes approximately 2 ms. After calibration is completed the IQMC_CAL register is updated and the iqmc_cal_en bit is cleared automatically. The gain calibration and phase calibration loops are shown in the figures below.

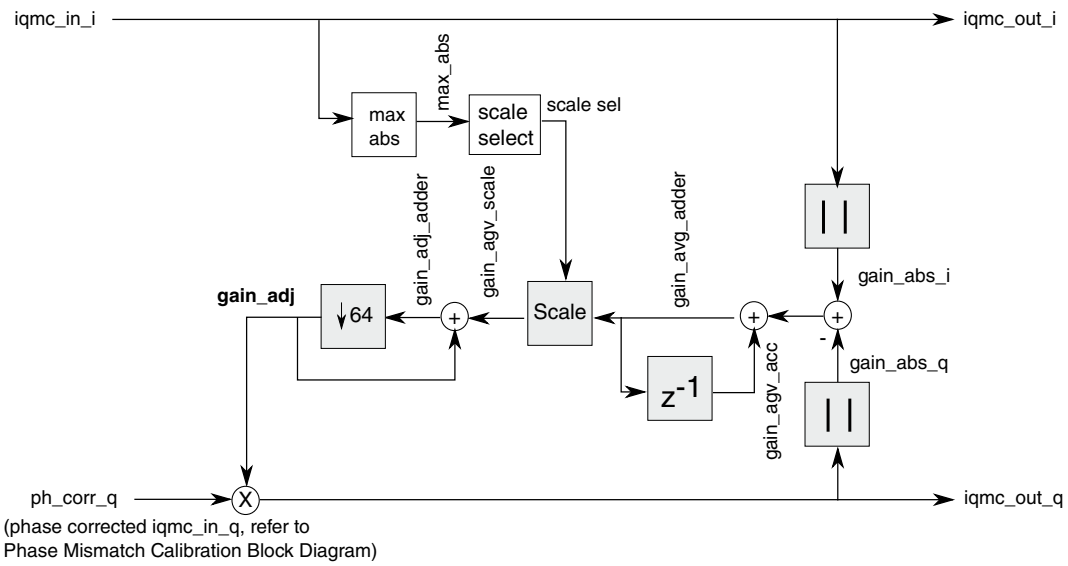


**Figure 64-41. I/Q Gain Mismatch Calibration Block Diagram**

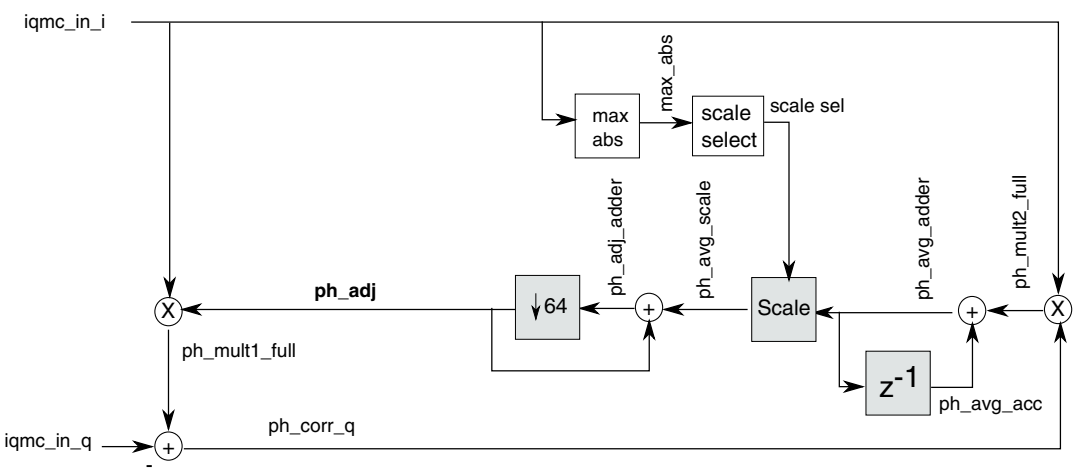

**Figure 64-42. I/Q Phase Mismatch Calibration Block Diagram**

When the receiver is enabled for packet reception, the calibration loops are disabled and the corrections are static. For gain correction, the Q channel is scaled by the gain adjustment coefficient. For phase correction, the I channel is scaled by the phase

adjustment coefficient and subtracted from the Q channel. The gain and phase correction values are stored in programming model registers and may be stored in flash to eliminate the need to run I/Q mismatch calibration after each reset.

There is also a separate gain adjusment coefficient (iqmc_dc_gain_adj) which is used only during DCOC calibration; that is, during the period after the TSM dcoc_en is asserted but before the TSM rx_dig_en is asserted. The applied phase adjustment coefficient is 0 during this time. There is no hardware calibration support to determine iqmc_dc_gain_adj.

The gain and phase corrections are illustrated in the figure below.

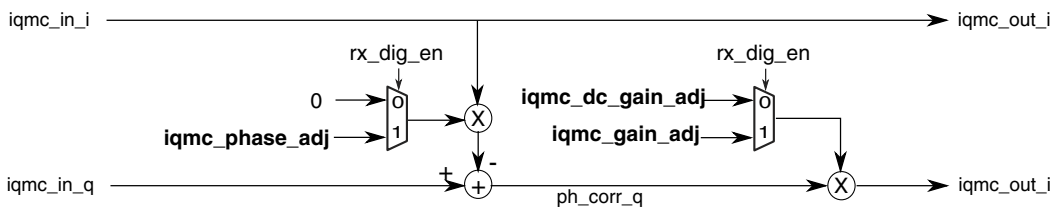

**Figure 64-43. I/Q Mismatch Correction Block Diagram**

### 64.3.3.2.5 DC Offset Correction

DC offsets in a direct conversion receiver can originate in RF (e.g., LO leakage, IP2, etc.), baseband (e.g., operational amplifier offsets, mismatches, etc.) and interfaces (due to DC level mismatches between various RF/analog circuits).

The DC (or origin) offset estimation and correction loop comprises of two distinct DC estimators. One of the estimators is used during wake-up calibration of DC offsets, while a second adaptive estimator is used during normal receiver operation. Both DC estimates are computed on the Rx I/Q data after the decimation stage. In the receiver, there are three distinct DC offset correction points, which are at the TZA output, BBA output (after first BBA active filter stage) and in the digital domain after the decimation filter. The DC estimation and correction systems operate as follows:

- A DC offset calibration is carried out at receiver warm-up to compute independent I/Q DC offsets at three distinct RX gain points.
- A DC correction is then estimated for all the entries in the AGC gain table using the 3 calibration estimates. Note that only TZA and BBA DC corrections are stored in the AGC gain lookup table.
- During AGC, the system applies a DC offset correction corresponding to the {LNA, BBA} gain combination that is applied.
- DC tracking estimates are reset upon a gain change and the algorithm is seeded with the calibrated DC estimates corresponding to the active gain setting

- Once AGC gain is settled, DC offset tracking estimation continues for a programmed amount of time
- After a pre-programmed interval expires, the tracked DC offset is sampled and a DC offset correction is estimated and applied
- Based on configuration, the DC offset tracking update can be applied once or iterated upon a programmable number of times.

A block diagram of the RX digital DCOC is shown in the figure below.

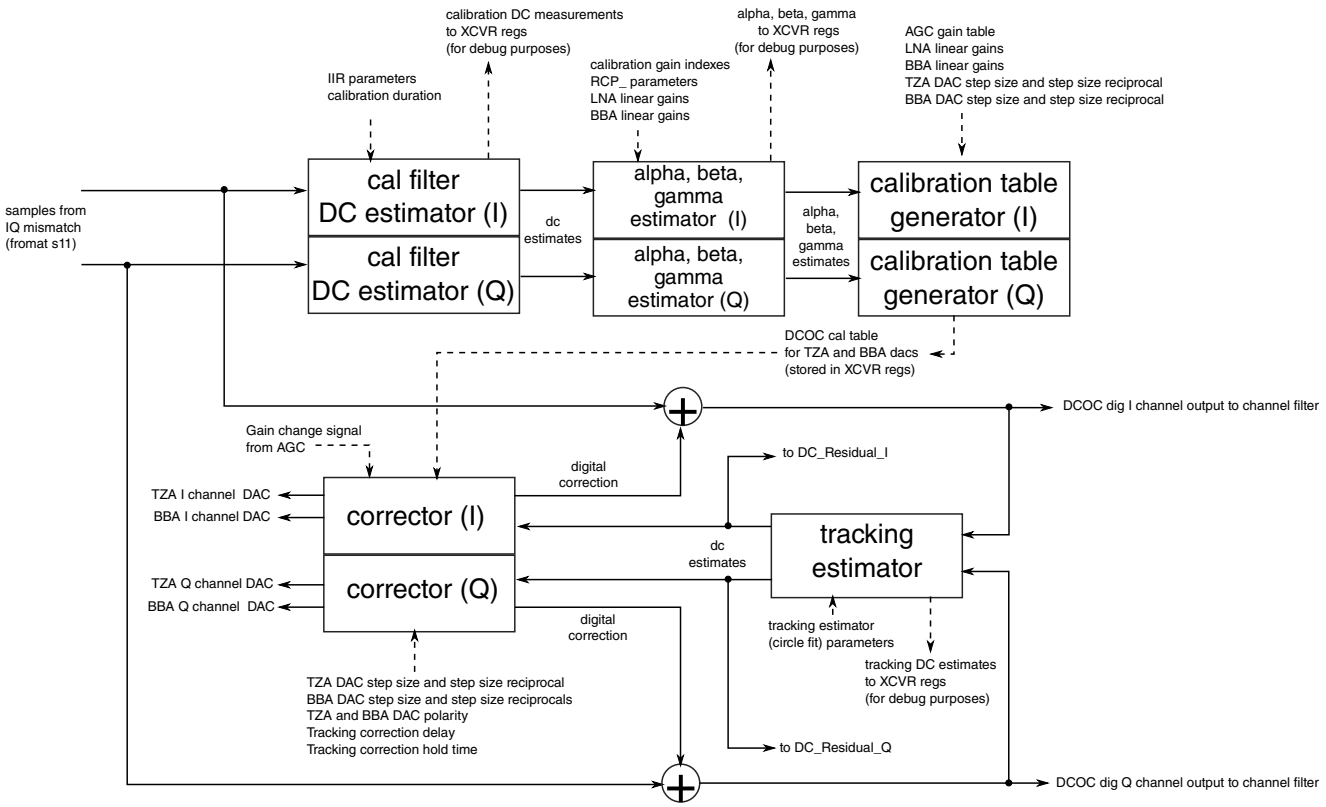

**Figure 64-44. RX_DIG DCOC Block Diagram**

### 64.3.3.2.5.1 Operating Modes

The DCOC supports several programmable bits to control the DCOC behavior. The combinations of these control bits which are supported are described in the table below.

**Table 64-31. DCOC Operating Modes**

| Mode | RX_ DCOC_EN | RX_DCOC _CAL_EN | CORRECT _EN | CORRECT _SRC | TRK_ FROM_0 | TRK_EST _OVR | MAN |
|---|---|---|---|---|---|---|---|
| Calibrate and Correct with Tracking | 1 | 1 | 1 | 1 | 0 or 1 | 0 or 1 | 0 |

*Table continues on the next page...*

**Table 64-31. DCOC Operating Modes (continued)**

| Mode | RX_ DCOC_EN | RX_DCOC _CAL_EN | CORRECT _EN | CORRECT _SRC | TRK_ FROM_0 | TRK_EST _OVR | MAN |
|---|---|---|---|---|---|---|---|
| Calibrate and Correct without Tracking | 1 | 1 | 1 | 0 | X | 0 or 1 | 0 |
| Correct with Tracking (no calibration) | 1 | 0 | 1 | 1 | 0 or 1 | 0 or 1 | 0 |
| Correct without Tracking (no calibration) | 1 | 0 | 1 | 0 | X | 0 or 1 | 0 |
| Debug: Calibration only (no correction, no tracking). | 1 | 1 | 0 | X | X | 0 or 1 | 0 |
| Debug: Manual mode (manual DAC values and DCOC_DIG_MAN corrections applied). No calibration, no correction | X | 0 | X | X | X | X | 1 |
| Debug: Manual mode (manual DAC values and DCOC_DIG_MAN corrections applied) with tracking estimator enabled. No calibration, no correction | 1 | 0 | 0 | X | 0 or 1 | 1 | 1 |
| DCOC disabled. Manual DAC values applied. No calibration, no correction | 0 | 0 | X | X | X | X | 0 |

#### 64.3.3.2.5.2 DCOC State Diagram

The main states of the DCOC are described in the bullet list and figure below.

- WAIT (IDLE)
- CALIBRATION. State where DCOC is performing calibration measurements, estimating alpha/beta/gamma, and starts writing the DCOC OFFSET table
- APPLY_IDX_CAPT. This state is also associated with calibration. DCOC transitions to this state from CALIBRATION when the table index matches the AGC's starting index. The DCOC values matching this index are applied to the DCOC DACs, and DCOC then finishes writing the rest of the DCOC OFFSET table
- NO_CAL_INIT. State where no calibration is performed, but correction is enabled. In this state, the DCOC will output the DCOC DAC values from the DCOC OFFSET table corresponding to the AGC's starting index.
- CORRECT. State where the AGC is enabled and DCOC changes the DCOC DAC values when AGC gain changes by reading from the DCOC OFFSET table.
- CORRECT_AND_TRACK. Similar to CORRECT state, but the DCOC tracking estimator is also activated, to further refine the DCOC DAC values after an AGC gain change, and also to apply a digital correction to the DCOC output.

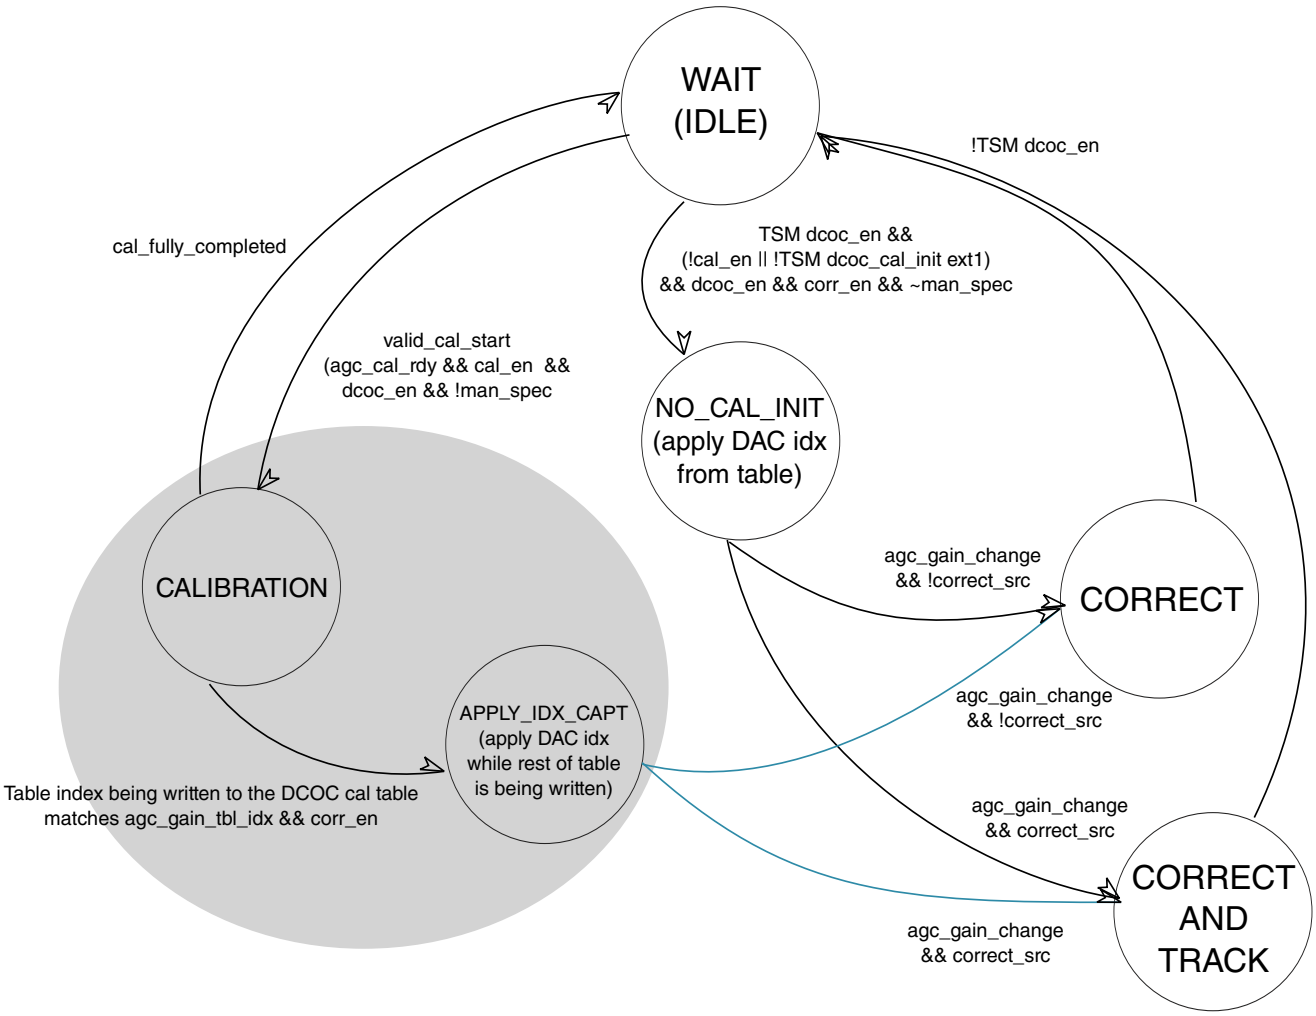

**Figure 64-45. DCOC State Diagram**

### 64.3.3.2.5.3 DC Offset Calibration

If the RX_DIG_CTRL[RX_DCOC_EN] and RX_DIG_CTRL[RX_DCOC_CAL_EN] bits are set, the direct conversion receiver will perform a DC offset calibration for I/Q receive data paths at every RX warm-up. The calibration will compute a table of DC correction values (DCOC_OFFSET_n registers) for each of the 27 AGC gain table entries.

The calibration starts when the TSM DCOC_INIT signal pulses high then low.The total calibration time includes the time for each of three DC estimates (DCOC_CAL_DURATION) and overhead to compute the DCOC_OFFSET_n table :

```
calibration time (in µs) = 3*DCOC_CTRL_0[DCOC_CAL_DURATION] + (4*27 + 15)/
reference_clock_frequency
```

A value of DCOC_CAL_DURATION=19 and a reference clock frequency of 32MHz results in a calibration time of 60.8us. The system will operate correctly as long as the calibration completes before the 1us TSM RX_INIT pulse completes.

The figure below illustrates the DC Offset Calibration timing. To allow as much time as possible for the DACs to settle before the AGC is enabled, the DCOC will initialize the DACs as soon as it calculates the DCOC table entry corresponding to the initial AGC table index. Normally, the AGC table index begins at 26 (as shown in the figure below), so the DCOC always calculates and writes the DCOC calibration table from index 26 to index 0.

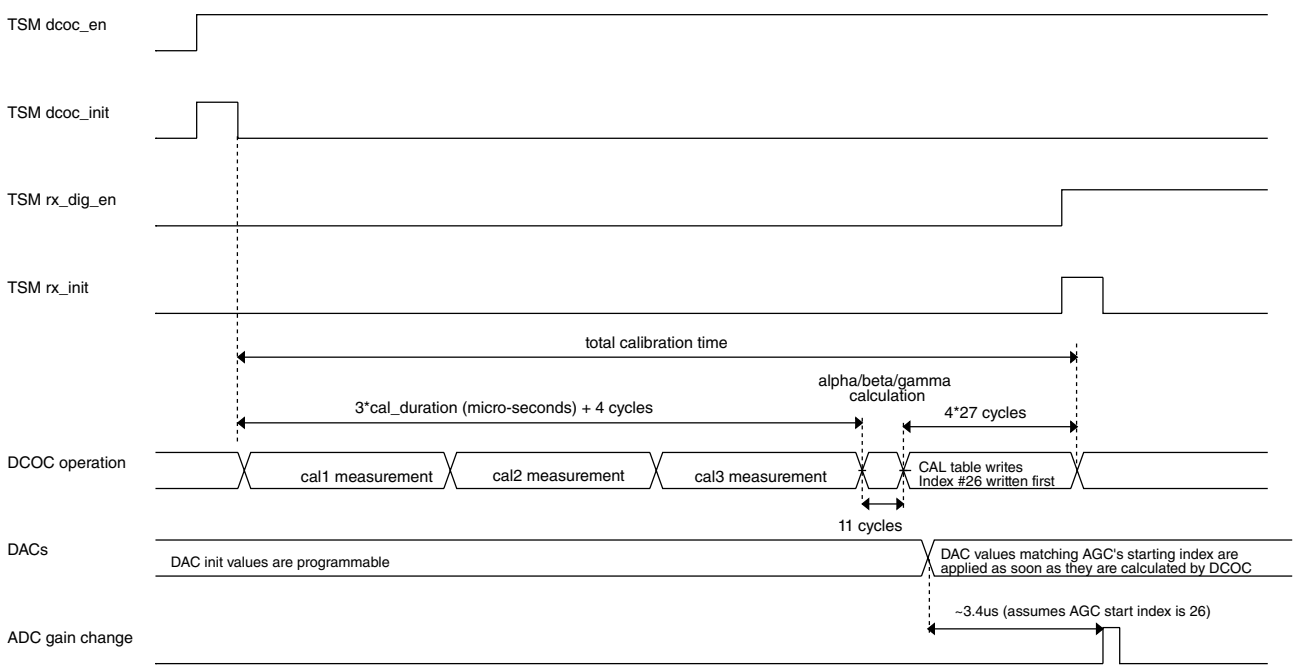

**Figure 64-46. DCOC Calibration Timing Diagram**

#### *64.3.3.2.5.3.1 DC Offset Estimation during Calibration Phase*

During the calibration phase, the DCOC makes DC offset estimates at three distinct RX LNA/BBA gain points. The three gain points are programmed in the DCOC_CAL_GAIN register, and are described more in the next section. The duration of the DC offset estimate for each of the 3 gain points is programmable up to 31us as defined by DCOC_CTRL_0[DCOC_CAL_DURATION].

DC offset estimation during calibration is carried out by using a cascade of 3 single-tap IIR filters of the type

$$y_k[n] = (1-\alpha_k)\,y_k[n-1] + \alpha_k x_k[n]$$

where $\alpha_i$ are programmable co-efficients assuming values shown below as programmed in the DCOC_CAL_IIR register:

- $\alpha_1$: {1, 1/4, 1/8, 1/16}
- $\alpha_2$: {1, 1/4, 1/8, 1/16}
- $\alpha_3$: {1/4, 1/8, 1/16, 1/32}

**Figure 64-47. DC Offset Estimation using a filter bank during calibration**

Using a cascade of 3 IIR filters as shown with $\alpha_1$=1/16; $\alpha_2$=1/16; $\alpha_3$=1/16, the transfer function of the cascaded filter is a narrowband filter with a 3dB bandwidth of approximately 170kHz and a settling time of < 18µs.

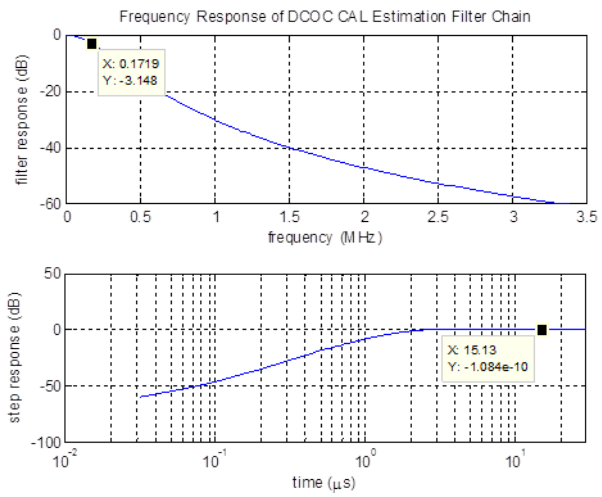

**Figure 64-48. Magnitude and Step response of DC Offset Calibration Estimator**

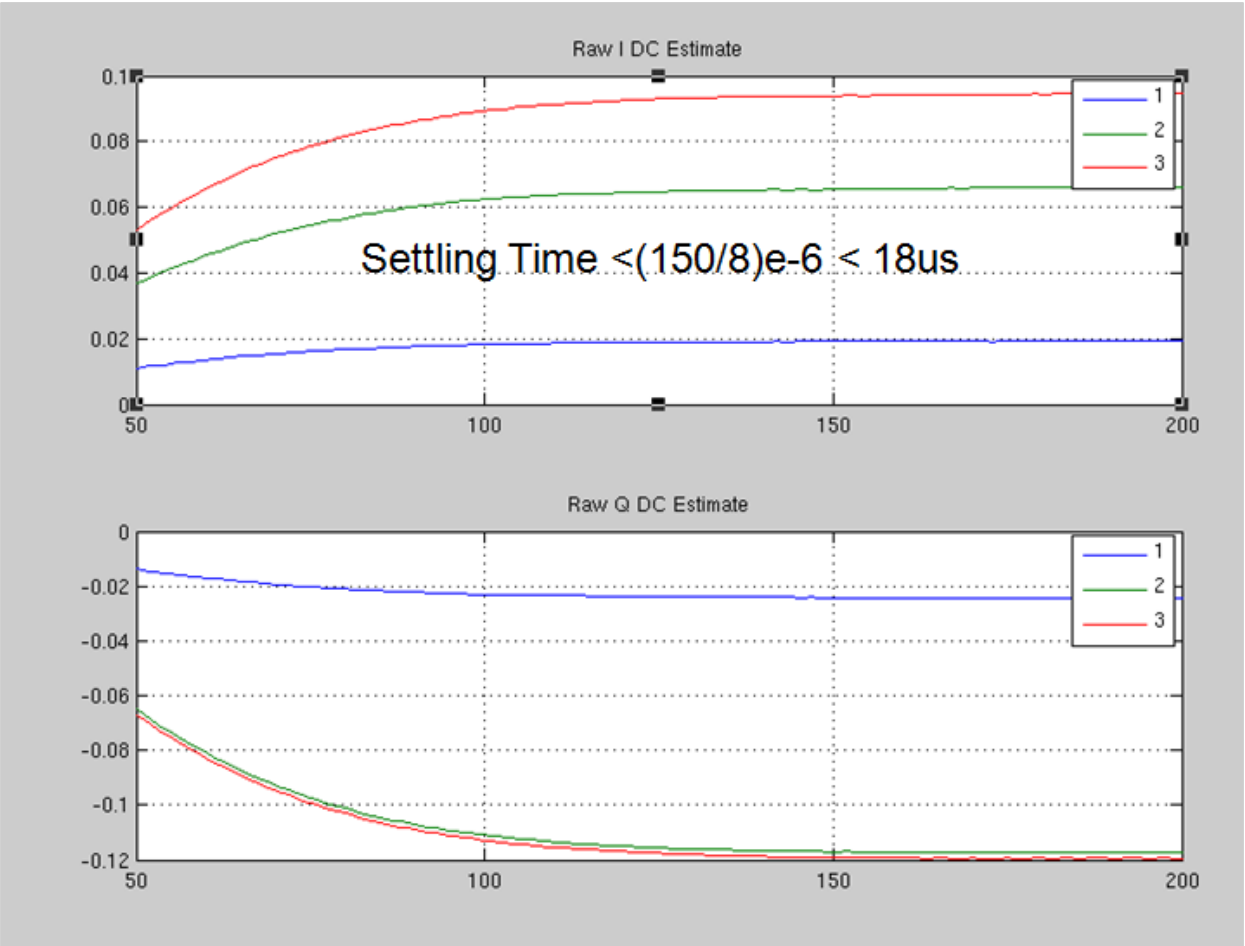

**Figure 64-49. 3-step {I,Q} DC estimation during calibration**

For debug, the DC offset estimates for the three gain points can be read after calibration from the DCOC_CAL1, DCOC_CAL2, and DCOC_CAL3 registers.

The DCOC operates on the decimated output of the ADC. As BTLE and 802.15.4 have different oversample rates, different IIR filter settings are expected to be used assuming a settling time of 20us is desired. Recommended sets of IIR1/2/3 parameters are shown below.

- Decimation rate 8: $\alpha_1 = 1/8$, $\alpha_2 = 1/16$, $\alpha_3 = 1/16$
- Decimation rate 16: $\alpha_1 = 1/4$, $\alpha_2 = 1/8$, $\alpha_3 = 1/8$

#### *64.3.3.2.5.3.2 DC Estimation at 3 operation gain points of the receiver*

The ZIF receiver performs a 3 point DC Offset calibration. The calculations shown below are shown for one branch of Rx (I or Q) only. In hardware the calculations are carried out independently for both I and Q branches and stored independently in the AGC/DCOC lookup table

The DC offset calibration scheme approximates the DC offset behavior of the system observed at three distinct gain settings by calculating the DC offset for the three gain points, and decomposing the correction into 3 DC components, which are

- α - An RF component (such as LO feed through), which scales with both LNA and BBA gains
- β - A TZA DC offset which scales with BBA gains
- γ - represents an un-scaled DC offset at the ADC input

These DC components are illustrated in the figure below.

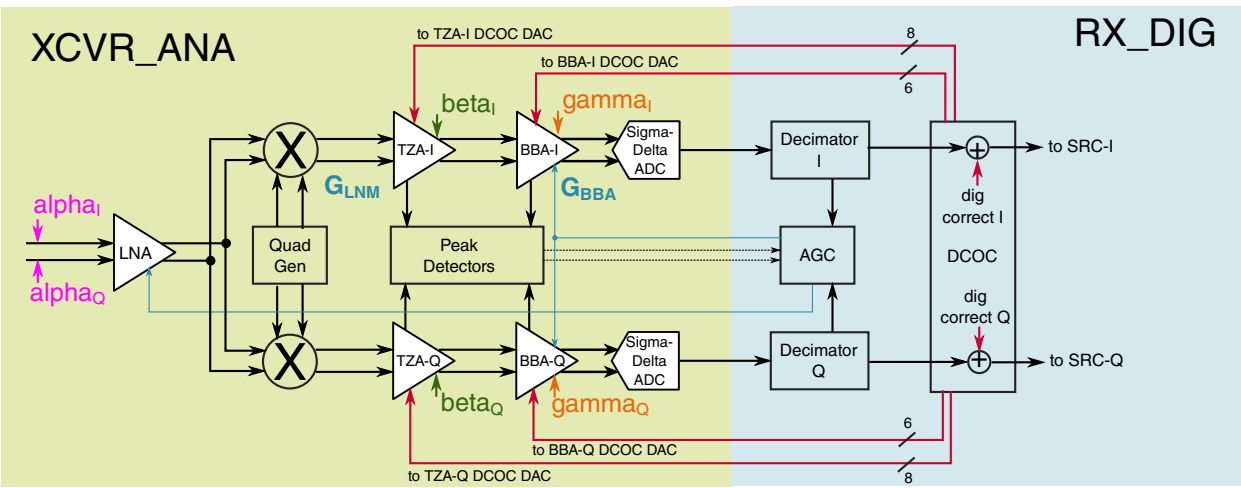

**Figure 64-50. Receiver model showing three contributors of DC offset**

The DC offset correction after calibration is applied at 2 points in the receiver, which are at

- the TZA output using an 8-bit DAC with LSB = 1.2V/2^7*(22.9kΩ/34kΩ) = 6.31mV
- the BBA output using a 6-bit DACs with LSB = 1.2V/2^5*(63.44kΩ/120kΩ) = 19.83mV

Calibration is performed open-loop. During calibration, the DCOC normally measures the DC values while the DACs are set to apply an offset of 0V. However, other DAC values can be used during calibration by using the TZA_DCOC_INIT_Q/I and BBA_DCOC_INIT_Q/I bitfields.

**NOTE**

The equations below are for the case when the TZA_DCOC_INIT_Q/I and BBA_DCOC_INIT_Q/I use their default reset values (which represent DAC values of 0). The α-hat/β-hat/γ-hat calculations in the RTL also support the scenario where non-default values are used; in that case, the α-

hat/β-hat/γ-hat are calculated such they should yield the same estimates as if DAC values of 0 were used.

The equations below provide the calculations from 3 distinct DC offset measurements to the estimation of the three decomposed DC offset components.

At any given time, the total DC offsets observed at ADC input would follow the formula

$RxDCOC_pre_ADC \cong (\alpha * G_L + \beta) * G_B + \gamma$

where

- $G_L$ – Voltage gain of the LNA stage (in linear domain)
- $G_B$ – Voltage gain of the BBA stage (in linear domain)

The ADC has an effective gain of 1code/1.7V. In the decimator, there is a decimation-rate-dependent gain factor, and also a programmable gain factor as described in Decimation Filter. Let ADC_gain represent the combined gain through the ADC and decimator in terms of codes/mV:

```
ADC_gain = 1/1700mV * (OSR^4) * (OSR_scale_factor) * RX_DEC_FILT_GAIN / 2
```

For example, if OSR is 8 (OSR_scale_factor is therefore 2^0 as shown in Table 64-22) and RX_DEC_FILT_GAIN is programmed for a gain of 1.6875, ADC_gain is 2.033codes/mV.

Note that the ADC_gain factor is a component of the value programmed for the BBA_DCOC_STEP, BBA_DCOC_STEP_RECIP, DCOC_TZA_STEP_GAIN, and DCOC_TZA_STEP_RECIP bitfields.

**NOTE**

The DCOC calibration actually performs slighty better when the ADC_gain factor shown above is multiplied by a scaling factor of ~0.96; this is due to the fixed point arithmetic implementation of the calibration algorithm. The scaling factor effectively causes the calibration algorithm to compute slightly larger TDAC and BDAC values (see below) than it would otherwise calculate.

The total DC offset observed at the RxDCOC is

$RxDCOC_post_ADC \cong ADC_gain * ((\alpha * G_L + \beta) * G_B + \gamma)$

The DC offset calibration is carried at three distinct {LNA, BBA} gain settings, as summarized below.

**Table 64-32. DC offset calibration at selected {LNA,BBA} gain settings**

| DCOC_CAL | LNA linear gain (V/V) | BBA linear gain (V/V) | DC offset Measured at ADC input |
|---|---|---|---|
| **DCOC[1]** | $G_{L_LO}$ | $G_{B_LO}$ | ADC_gain *((α * $G_{L_LO}$ + β )*$G_{B_LO}$ + γ ) |
| **DCOC[2]** | $G_{L_HI}$ | $G_{B_LO}$ | ADC_gain *((α * $G_{L_HI}$ + β )*$G_{B_LO}$ + γ ) |
| **DCOC[3]** | $G_{L_LO}$ | $G_{B_HI}$ | ADC_gain *((α * $G_{L_LO}$ + β )*$G_{B_HI}$ + γ ) |

The three gain point settings are defined by programming the DCOC_CAL_GAIN register. Here is an example:

**Table 64-33. Example DCOC_CAL_GAIN programming**

| DCOC_CAL | DCOC LNA CAL GAIN index | DCOC BBA CAL GAIN index |
|---|---|---|
| **DCOC[1]** | 3 (corresponds to $G_{L_LO}$ of 15dB) | 5 (corresponds to $G_{B_LO}$ of 15dB) |
| **DCOC[2]** | 6 (corresponds to $G_{L_HI}$ of 33dB) | 5 (corresponds to $G_{B_LO}$ of 15dB) |
| **DCOC[3]** | 3 (corresponds to $G_{L_LO}$ of 15dB) | 10 (corresponds to $G_{B_HI}$ of 30dB) |

Calculations of estimates for α , β and γ are carried out post ADC, i.e., ADC_gain is used implicitly in calculations.

Using [1] & [2]

$$\alpha\text{-hat} = \alpha * ADC_gain = (DCOC[2] - DCOC[1]) * [1.0((G_{L_HI} - G_{L_LO>}) * G_{B_LO})] \quad [4]$$

Using eq. [1] & eq. [3]

$$DCOC_tmp = (\alpha\text{-hat} * G_{L_LO} + \beta\text{-hat}) * ADC_gain$$
$$= (DCOC[3] - DCOC[1]) * [1.0/(G_{B_HI} - G_{B_LO})] \quad [5]$$

Normally, the TZA_DCOC_INIT bitfield is left at its default value of 0x80 in which case the TZA DCOC DAC applies an offset of 0V. In this case, using eq. [4] & eq. [5]

$$\beta\text{-hat} = \beta * ADC_gain = [5] - [4] * G_{L_LO} \quad [6]$$

To account for scenarios where TZA_DCOC_INIT is not 0x80, equation [6] can be generalized as shown below to subtract the contribution from the TZA DCOC DAC. In equation [6a], "tza_dac_sign" is +1 if DCOC_CTRL_0[TZA_CORR_POL] is clear, and -1 if it is set.

$$\beta\text{-hat} = \beta * ADC_gain = [5] - [4] * G_{L_LO} - (TZA_DCOC_INIT - 0x80) * TZA_dcoc_step_norm * tza_dac_sign \quad [6a]$$

Likewise, the BBA_DCOC_INIT bitfield is normally left at its default value of 0x20 in which case the BBA DCOC DAC applies an offset of 0V. In this case using eq. [5] & eq. [3]

$$\gamma\text{-hat} = \gamma * ADC_gain = [3] - [5] * G_{B_HI} \quad [7]$$

To account for where scenarios where BBA_DCOC_INIT is not 0x20, equation [7] can be generalized as shown below to subtract the contribution from the BBA DCOC DAC. In equation [7a], "bba_dac_sign" is +1 if DCOC_CTRL_0[BBA_CORR_POL] is clear, and -1 if it is set.

$$\gamma\text{-hat} = \gamma * ADC_gain = [3] - [5] * G_{B_HI} - (BBA_DCOC_INIT - 0x20) * BBA_dcoc_step * bba_dac_sign \quad [7a]$$

After calibration, α-hat, β-hat, and γ-hat can be read from the DCOC_CAL_ALPHA, DCOC_CAL_BETA, and DCOC_CAL_GAMMA registers, respectively for debug purposes.

To perform the α-hat/β-hat/γ-hat calculations, the DCOC also uses the following register bitfields:

- DCOC_CAL_RCP[ALPHA_CALC_RECIP]. This is the $1.0/((G_{L_HI}- G_{L_LO>})*G_{B_LO})$ factor from equation [4] above.
- DCOC_CAL_RCP[DCOC_TMP_CALC_RECIP]. This is the $1.0/(G_{B_HI}- G_{B_LO})$ factor from equation [5] above.
- LNA_GAIN_LIN_VAL_x (LNA_GAIN_LIN_VAL_x_y registers). The $G_{L_LO}$ and $G_{L_HI}$ gains are found from the appropriate index into this table.
- BBA_RES_TUNE_LIN_VAL_x (BBA_RES_TUNE_LIN_VAL_x_y registers). The $G_{B_LO}$ and $G_{B_HI}$ gains are found from the appropriate index into this table.
- DCOC_CTRL_0[TZA_CORR_POL] bit determines the polarity of the TZA DCOC DAC value applied during calibration.
- DCOC_CTRL_0[BBA_CORR_POL] bit determines the polarity of the BBA DCOC INIT DAC value applied during calibration.

#### *64.3.3.2.5.3.3 Calculation of DC Offset Table*

Once the estimates for α , β and γ , that is, α-hat, β-hat and γ-hat are computed, the calibrated DC offset correction values for the 27 entries in the AGC gain table (AGC_GAIN_TBL_xx_yy registers) can be calculated and stored (in the DCOC_OFFSET_n registers).

If DCOC_CTRL_0[DCOC_CAL_CHECK_EN] is set, the α-hat and β-hat estimates are checked against the thresholds in the DCOC_CAL_FAIL_TH and DCOC_CAL_PASS_TH registers as a condition of updating the DCOC_OFFSET_n registers:

- If the absolute value of all of the α-hat and β-hat estimates are less than the "pass" thresholds, the DCOC_OFFSET_n tables are updated.

- If the absolute value of any of the α-hat and β-hat estimates are greater than the "fail" thresholds, the DCOC_OFFSET_n tables are not updated.
- If neither a "pass" nor a "fail" condition is detected, the DCOC_OFFSET_n tables are only updated if a "pass" condition has not occurred since the last reset

In the cases where the DCOC_OFFSET_n table is not updated, the DCOC will use whatever values were previously written into the table to perform corrections during the burst.

The calculations are independently carried out for both the I/Q branches of the transceiver but only one branch is shown below. The computations are as follows for all k=26, 25, ... 0 entries of the AGC_GAIN_TBL, and where $TDAC_k$ and $BDAC_k$ represent the TZA and BBA DAC values:

```
DCOC_TZA_TOTAL = α-hat * G_Lk + β-hat
TDAC_k = round(DCOC_TZA_TOTAL*[1.0/TZA_dcoc_step_norm])
DCOC_TZA_RESIDUAL = DCOC_TZA_TOTAL - TDAC_k * TZA_dcoc_step_norm
DCOC_BBA_TOTAL = DCOC_TZA_residual *G_Bk + γ-hat
BDAC_k = round(DCOC_BBA_TOTAL*[1.0/BBA_dcoc_step])
```

| Information derived from the programmable AGC_GAIN_TBL_xx_yy registers | | Computed and stored in the DCOC_OFFSET_n registers | | | |
|---|---|---|---|---|---|
| **LNA linear gain (V/V)** | **BBA linear gain (V/V)** | **TZA-I DAC code** | **BBA-I DAC Code** | **TZA-Q DAC code** | **BBA-Q DAC Code** |
| $G_{L26}$ | $G_{B26}$ | $TDAC_{I26}$ | $BDAC_{I26}$ | $TDAC_{Q26}$ | $BDAC_{Q26}$ |
| … | … | … | … | … | … |
| $G_{L0}$ | $G_{B0}$ | $TDAC_{I0}$ | $BDAC_{I0}$ | $TDAC_{Q0}$ | $BDAC_{Q0}$ |

Note that the values stored in the DCOC_OFFSET_n table represent the DC offset at the DAC. Normally the DCOC will then apply the negative of this DC offset to the DAC when it applies the correction, but this depends on the DCOC_CTRL_0[TZA_CORR_POL] and DCOC_CTRL_0[BBA_CORR_POL] bits. Also, note that the DAC code values themselves (which are reflected in the DCOC_STAT register) include a bias offset of 0x80 for the TZA DACs and 0x20 for the BBA DACs.

To compute the TDAC and BDAC values for the DCOC_OFFSET_n registers, the DCOC uses the following register bitfields:

- DCOC_BBA_STEP[BBA_DCOC_STEP_RECIP]. This is the 1.0/BBA_dcoc_step referred to above.
- DCOC_TZA_STEP_0[DCOC_TZA_STEP_RCP]. This is the 1.0/ TZA_dcoc_step_norm referred to above.
- DCOC_TZA_STEP_0[DCOC_TZA_STEP]. This is the TZA_dcoc_step_norm referred to above.

- LNA_GAIN_LIN_VAL_x (LNA_GAIN_LIN_VAL_x_y registers). This is used for the $G_{Lk}$ referred to above
- BBA_RES_TUNE_LIN_VAL_x (BBA_RES_TUNE_LIN_VAL_x_y registers). This is used for the $G_{Bk}$ referred to above
- RF_TZA[RX_TZA_SPARE]. The RX_TZA_SPARE[2] bit specifies the allowed range of values for the TZA DCOC DAC.
- DCOC_CTRL_0[DCOC_CAL_CHECK_EN]. Determines whether calibration check logic is enabled or not. If it is, then the pass and fail threshold registers are used:
  - DCOC_CAL_PASS_TH[DCOC_CAL_ALPHA_P_TH]. Alpha pass threshold
  - DCOC_CAL_PASS_TH[DCOC_CAL_BETA_P_TH]. Beta pass threshold
  - DCOC_CAL_FAIL_TH[DCOC_CAL_ALPHA_F_TH]. Alpha fail threshold
  - DCOC_CAL_FAIL_TH[DCOC_CAL_BETA_F_TH]. Beta fail threshold

#### *64.3.3.2.5.3.4 Use of DC offset Table After Calibration*

After calibration, when the TSM RX_DIG_EN is asserted, if the DCOC_CTRL_0[DCOC_CORRECT_EN] bit is 1, the DCOC will apply the value stored in the DCOC_OFFSET_n table on each AGC gain change. As indicated previously, the value stored in the DCOC_OFFSET_n register represents the DAC vaue of the DC offset.

If the DCOC_CTRL_0[TZA_CORR_POL] bit is clear (normal polarity), the DCOC will subtract the TDAC value from the TZA DAC zero bias value of 0x80. If the TZA_CORR_POL bit is set, the DCOC will add the TDAC value to the TZA DAC zero bias value.

If the DCOC_CTRL_0[BBA_CORR_POL] bit is clear (normal polarity), the DCOC will subtract the BDAC value from the BBA DAC zero bias value of 0x20. If the BBA_CORR_POL bit is set, the DCOC will add the BDAC value to the BBA DAC zero bias value.

The DCOC also allows software to write to the DCOC_OFFSET_n table. In this case, the RX_DIG_CTRL[RX_DCOC_CAL_EN] bit should be cleared so that the DCOC will not overwrite the DCOC_OFFSET_n table, but DCOC_CTRL_0[DCOC_CORRECT_EN] bit should still be set.

### 64.3.3.2.5.4 DC Offset Tracking

The DCOC also supports a closed-loop DC tracking estimator which can be used with or without DC Offset calibration. The tracking estimator applies a DAC correction and also applies a digital correction to the downsampled output of the ADC.

The tracker is used if the DCOC_CTRL_0[DCOC_CORRECT_SRC] bit is programmed to 1 (RX_DIG_CTRL[RX_DCOC_EN] and DCOC_CTRL_0[DCOC_CORRECT_EN] should also be programmed to 1). The tracking estimator operation is as follows:

- On every AGC gain change, the DCOC will apply the DC offset correction to the DACs from the DCOC_OFFSET_n table, and resets the digital correction to zero.
- If the AGC gain table index is larger than or equal to DCOC_CTRL_1[DCOC_TRK_MIN_AGC_IDX], then...
  - After the AGC gain settles (refer to AGC_CTRL_1[LNA_GAIN_SETTLE_TIME] and AGC_CTRL_2[BBA_GAIN_SETTLE_TIME] bitfields) , the tracker's estimate is reset to either 0 or the current I/Q sample, depending on programming of the DCOC_CTRL_0[TRACK_FROM_ZERO] bit.
  - The DCOC will periodically adjust the DACs and digital correction at intervals defined by the DCOC_CTRL_0[DCOC_CORR_DLY] bitfield until a timeout defined by the DCOC_CTRL_0[DCOC_CORR_HOLD_TIME] bitfield is reached.
  - The tracking estimator supports two set of parameters so that estimator can be gearshifted from a high bandwidth to a narrow bandwidth configuration after a number of update corrections defined by DCOC_CTRL_1[DCOC_TRK_EST_GS_CNT].
  - If the DCOC_CTRL_0[DCOC_MIDPWR_TRK_DIS] bit is set, the tracking corrections are disabled if either the TZA or BBA lo peak detector asserts. This is implemented by resetting the counters associated with DCOC_CORR_DLY and DCOC_HOLD_TIME, so if the lo peak deters stop asserting, then tracking corrections woud be resumed. The counter associated with DCOC_TRK_EST_GS_CNT is not affected by the DCOC_MIDPWR_TRK_DIS bit.
- If DCOC_CTRL_1[DCOC_TRK_MIN_AGC_IDX_CFG] is set and the AGC gain table index is smaller than DCOC_CTRL_1[DCOC_TRK_MIN_AGC_IDX], then...
  - After the AGC gain settles (refer to AGC_CTRL_1[LNA_GAIN_SETTLE_TIME] and AGC_CTRL_2[BBA_GAIN_SETTLE_TIME] bitfields) , the tracker's estimate is reset to either 0 or the current I/Q sample, depending on programming of the DCOC_CTRL_0[TRACK_FROM_ZERO] bit.
  - The DCOC will periodically adjust the DACs and digital correction at intervals defined by the DCOC_CTRL_2[DCOC_CORR_DLY_ALT] bitfield until a timeout defined by the DCOC_CTRL_2[DCOC_CORR_HOLD_TIME_ALT] bitfield is reached.
  - The tracking estimator supports two set of parameters so that estimator can be gearshifted from a high bandwidth to a narrow bandwidth configuration after a number of update corrections defined by DCOC_CTRL_1[DCOC_TRK_EST_GS_CNT].
  - If the DCOC_CTRL_0[DCOC_MIDPWR_TRK_DIS] bit is set, the tracking corrections are disabled if either the TZA or BBA lo peak detector asserts. This

is implemented by resetting the counters associated with DCOC_CORR_DLY and DCOC_HOLD_TIME, so if the lo peak deters stop asserting, then tracking corrections woud be resumed. The counter associated with DCOC_TRK_EST_GS_CNT is not affected by the DCOC_MIDPWR_TRK_DIS bit.

- If DCOC_CTRL_1[DCOC_TRK_MIN_AGC_IDX_CFG] is clear and the AGC gain table index is smaller than DCOC_CTRL_1[DCOC_TRK_MIN_AGC_IDX], then tracking is not activated for this gain setting.

The figure below illustrates the timing behavior during DC offset tracking correction after an AGC gain change. If the DCOC_CTRL_0[DCOC_CORRECT_SRC] bit were programmed to 0 instead of 1, only the DCOC DAC change at agc_gain_chng pulse would occur and the digital correction applies to the signal through the DCOC would remain at 0. The figure shows an example where DCOC_TRK_EST_GS_CNT=2, so the tracking estimator changes its parameters after 2 update correction periods.

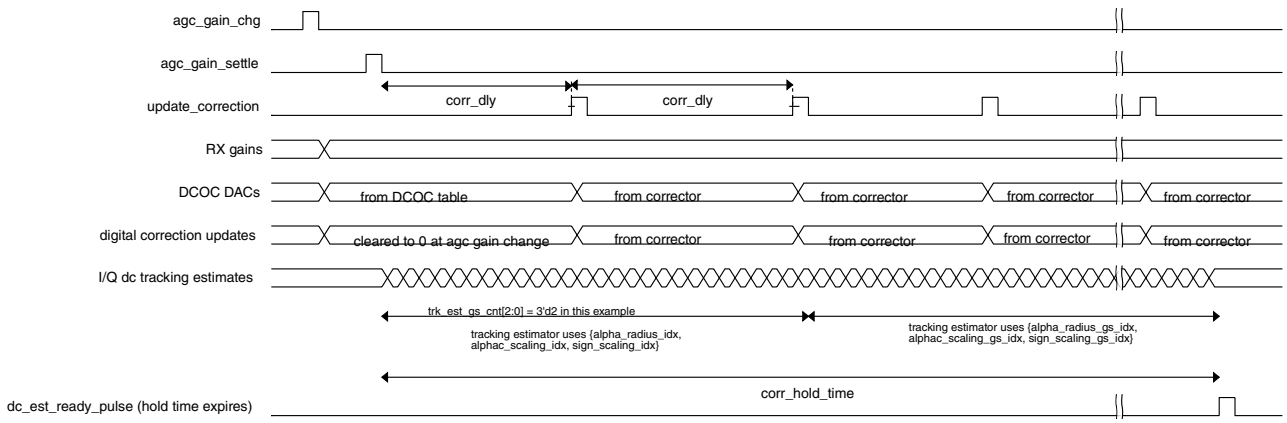

**Figure 64-51. DC Offset Tracking Correction Timing**

#### *64.3.3.2.5.4.1 DC Offset Estimation during Tracking Phase*

There are two distinct DC offset estimators: the one use during calibration described previously, and one used for DC tracking during normal receiver operation.

DC Offset estimation during normal receiver operation requires estimation of DC signal in the presence of a constant envelope modulation signal. A circle-fit type of algorithm is used for DC estimation in the presence of desired as well as interfering signals.

The circle-fit algorithm relies on the programmable bitfields shown in the list below. Note that there are two sets of alpha_radius, alphac_scale, and sign_scale parameters, which allows the algorithm to gearshift from a high-bandwidth configuration

{alpha_radius_idx, alphac_scale_idx, sign_scale_idx} to a low-bandwidth configuration {alpha_radius_gs_idx, alphac_scale_gs_idx, sign_scale_gs_idx} after the number of update corrections defined by DCOC_TRK_EST_GS_CNT.

- DCOC_CTRL_1[DCOC_ALPHA_RADIUS_IDX] and DCOC_CTRL_1[DCOC_ALPHA_RADIUS_GS_IDX]. Step size for radius, assumes values of {1, 1/2, 1/4, 1/8, 1/16, 1/32, or 1/64}. In pseudo-code below, this is referred to as "alpha_radius".
- DCOC_CTRL_1[DCOC_ALPHAC_SCALE_IDX] and DCOC_CTRL_1[DCOC_ALPHAC_SCALE_GS_IDX]. Step size for I/Q center, assumes values of {1/2, 1/4, 1/8, 1/16, 1/32 or 1/64}. In pseudo-code below, this value times the "alpha_radius" value is referred to as "alpha_center"
- DCOC_CTRL_1[DCOC_SIGN_SCALE_IDX] and DCOC_CTRL_1[DCOC_SIGN_SCALE_GS_IDX]. sign_scaling. Scaling factor for sign() based correction of the I/Q center, assumes values of {1/8, 1/16, 1/32, or 1/64}. In psuedo-code below, this is referred to as "sign_scaling".
- DCOC_CTRL_1[DCOC_TRK_EST_GS_CNT]. If this is 0, then the algorithm only uses the {alpha_radius_idx, alphac_scale_idx, sign_scale_idx} parameters above. Otherwise, the algorithm begins with the {alpha_radius_idx, alphac_scale_idx, sign_scale_idx} parameters after each AGC gain change, but then switches to the 2nd parameter set {alpha_radius_gs_idx, alphac_scale_gs_idx, sign_scale_gs_idx} after DCOC_TRK_EST_GS_CNT number of update correction periods.
- DCOC_CTRL_0[TRACK_FROM_ZERO]. This control bit determines the initial value used by the tracking estimator on each AGC gain change. If TRACK_FROM_ZERO=1, the tracking estimate starts from I/Qcenter=0; if TRACK_FROM_ZERO=0, the tracking estimator starts from I/Qcenter using the current I/Q sample. TRACK_FROM_ZERO=1 can be used in conjunction with calibration, whereas TRACK_FROM_ZERO=0 can be used with or without calibration and also works well at a wider range of RSSI levesl.

Pseudo-code for the circle-fit algorithm in the tracking estimator is as follows:

```
epsilon_I = I - Icenter;
epsilon_Q = Q - Qcenter;
i_abs = abs(epsilon_I);
q_abs = abs(epsilon_Q);
delta_radius = max(i_abs,q_abs)+min(i_abs,q_abs)*3/8;
delta_Icenter = I - Radius*sign(epsilon_I)*sign_scaling;
delta_Qcenter = Q - Radius*sign(epsilon_Q)*sign_scaling;
Icenter = alpha_center*delta_Icenter + (1 - alpha_center)*Icenter;
Qcenter = alpha_center*delta_Qcenter + (1 - alpha_center)*Qcenter;
Radius = alpha_radius*delta_radius + (1 - alpha_radius)*Radius;
```

For debug, the tracker's DC estimate (Icenter, Qcenter) can be read from the DCOC_DC_EST register.

The DC correction applied by the tracking algorithm makes use of the following register bitfields:

- DCOC_BBA_STEP[BBA_DCOC_STEP].
- DCOC_BBA_STEP[BBA_DCOC_STEP_RECIP].
- DCOC_TZA_STEPn[TZA_DCOC_STEP], where n=0..10.
- DCOC_TZA_STEPn[TZA_DCOC_STEP_RECIP], where n=0..10.
- DCOC_CTRL_0[TZA_CORR_POL]
- DCOC_CTRL_0[BBA_CORR_POL]
- RF_TZA[RX_TZA_SPARE]. The RX_TZA_SPARE[2] bit specifies the allowed range of values for the TZA DCOC DAC.

Normally, the tracking estimator is only enabled when it is needed by the corrector. However, by setting the DCOC_CTRL_0[TRK_EST_OVR] bit, the tracking estimator can be enabled continuously while the DCOC is active.

#### 64.3.3.2.5.5 DC Offset Manual Mode

For debug purposes, the DCOC supports a manual mode. This mode is enabled when the DCOC_CTRL_0[DCOC_MAN] bit is set, which overrides all other DCOC programmable control bits. In this mode, the DCOC DAC values are applied from DCOC_DAC_INIT[TZA_DCOC_INIT_Q], DCOC_DAC_INIT[TZA_DCOC_INIT_I], DCOC_DAC_INIT[BBA_DCOC_INIT_Q], and DCOC_DAC_INIT[BBA_DCOC_INIT_Q], and the digital correction is applied from DCOC_DIG_MAN[DIG_DCOC_INIT_Q] and DCOC_DIG_MAN[DIG_DCOC_INIT_I].

### 64.3.3.2.6 Channel Filter

The channel filter is a programmable, 24 tap symmetric FIR filter with 6-bit to 10-bit coefficients. The channel filter can also be configured to operate as a 16 tap filter by setting RX_DIG_CTRL[RX_CH_FILT_LEN], in which case only coefficients 4-11 are used. It operates at the decimated sample rate on the output from the DCOC. The coefficient values are programmable and should be configured for the mode of operation (BTLE, 802.15.4, Generic LL). The filter output is scaled by 1/256; the sum of the 12 coefficients programmed is expected to be <=256 in order to avoid saturation. A few example coefficient filter sets are given in the table below.

**Table 64-34. Channel Filter Coefficients**

| Link Layer | XO MHz | COEF 0 | COEF 1 | COEF 2 | COEF 3 | COEF 4 | COEF 5 | COEF 6 | COEF 7 | COEF 8 | COEF 9 | COEF 10 | COEF 11 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 802.15.4 | 32 | -2 | 0 | 8 | 2 | -19 | -10 | 34 | 31 | -56 | -87 | 71 | 282 |
| BLE | 32 | -2 | -5 | -3 | 7 | 19 | 14 | -16 | -51 | -49 | 16 | 122 | 204 |
| BLE[1] | 26 | -2 | -2 | 2 | 12 | 15 | 1 | -28 | -50 | -33 | 31 | 122 | 187 |

1. BLE at 26MHz configuration: OSR 12, SRC configured for ZOH 12/13 mode

#### 64.3.3.2.7 Sample Rate Conversion (SRC) Filter

The sample rate conversion block is used for a fractional clock rate conversion of the sampled decimated signal, when 26MHz reference clock is used. In this mode, the ADC is clocked at 2xFref or 52 MHz. For the 2.4GHz targeted modulations, the PHY data rate is always 4x the symbol rate (of 2Mbps, 1Mbps, 500kbps or 250kbps) for (G)FSK modes and 4x the 2Mchips/sec rate for IEEE 802.15.4. These desired frequencies are not related to the ADC clock rate by an integer factor, which necessitates the need for a fractional sample rate conversion that is performed by SRC. For a complete list of the fractional conversion modes refer to Table 64-21. The SRC is enabled by setting RX_DIG_CTRL[RX_SRC_EN] to 1, and the conversion factor is selected by RX_DIG_CTRL[RX_SRC_RATE] as described below.

##### 64.3.3.2.7.1 Sample Rate Conversion by a factor of 8/13

If RX_DIG_CTRL[RX_SRC_RATE] = 0, the SRC block is configured to perform a data rate conversion by a factor of 8/13, i.e., for every 13 input samples, the SRC block generates 8 output samples at a reduced data rate. A linearly interpolated first order hold (FOH) resampler is used for implementation as it provides significant better anti-aliasing as compared to a zero order hold (ZOH).

##### 64.3.3.2.7.2 Sample Rate Conversion by a factor of 12/13

If RX_DIG_CTRL[RX_SRC_RATE] = 1, the SRC block is configuration a zero-order hold sample rate conversion is used. This mode is realized by skipping one out of every 13 input samples.

#### 64.3.3.2.8 DC Residual Correction

This block is used to compensate for the DC offset which is still present after AGC and DCOC calibration/tracking has completed. It estimates the DC offset by measuring the minimum and maximum value and then applies an additive correction factor to the I and Q channels. This block does not change the value of the DCOC DACs.

The DC offset is compensated independently on I and Q channels. The correction loop determines the minimum and maximum values over a specified window of samples (*Nwin*) which are then averaged and used (with an update parameter *Alpha*) to create the DC estimate. This DC estimate is then subtracted from the input samples. The applied DC estimate continues to be updated every *NWIN* samples until *IT_FREEZE* of these windows have elapsed, at which time the DC estimate is frozen.

Multiple modes of operations can be identified for residual DC offset compensation block. They are presented in table below.

**Table 64-35. Residual DC offset compensation operational modes**

| Mode | Description | DC_RESID_EN | EXT_DC_EN | IT_FREEZE | DLY | NWIN, ALPHA |
|---|---|---|---|---|---|---|
| **Bypass** | The DC residual is disabled. The input I and Q samples to the DC Residual block are passed directly to the DC Redisdual output without any modifications.<br>. | 0 | - | - | - | - |
| **Mode 1** | In this mode, DC residual has the role of calculating and applying a DC offset without use of an initial estimate from the DCOC.<br>The DC residual processing is restarted at every AGC gain change<br>This mode is suitable for use when an AGC gain change occurs which is not followed by DCOC tracking. | 1 | 0 | >1 | >0 | program as needed |
| **Mode 2** | In this mode, DC residual has the role of refining the DC offset estimate provided by the DCOC at the end of the DCOC tracking after the last DCOC DAC update.<br>The DC residual processing is restarted whenever DCOC's tracking hold timer expires.<br>This mode is suitable after AGC gain change followed by DCOC tracking. | 1 | 1 | >1 | - | program as needed |
| **Mode 3** | In this mode, DC residual has the role of applying a correction based on the DC offset estimate provided by the DCOC at the end of the DCOC tracking after the last DCOC DAC update.<br>The DC residual processing is restarted whenever DCOC's tracking hold timer expires.<br>This mode is suitable after AGC gain change and DCOC tracking when no further refining is desired. | 1 | 1 | 1 | - | - |

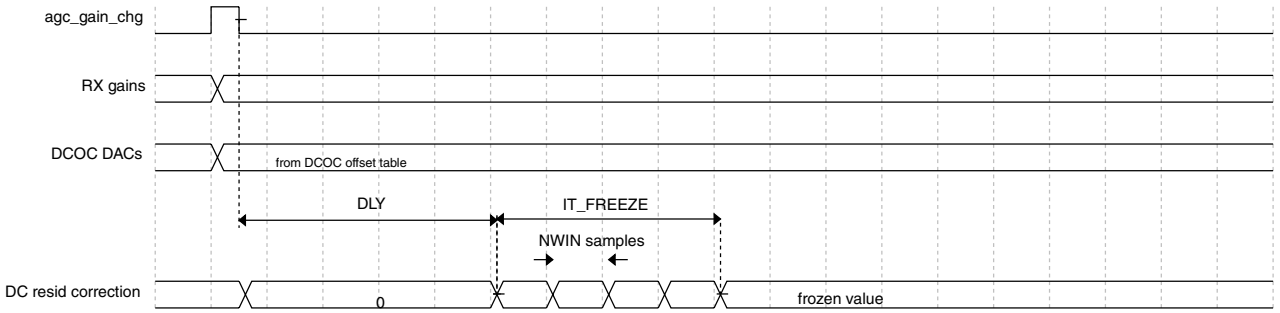

**Figure 64-52. DC residual mode 1 timing**

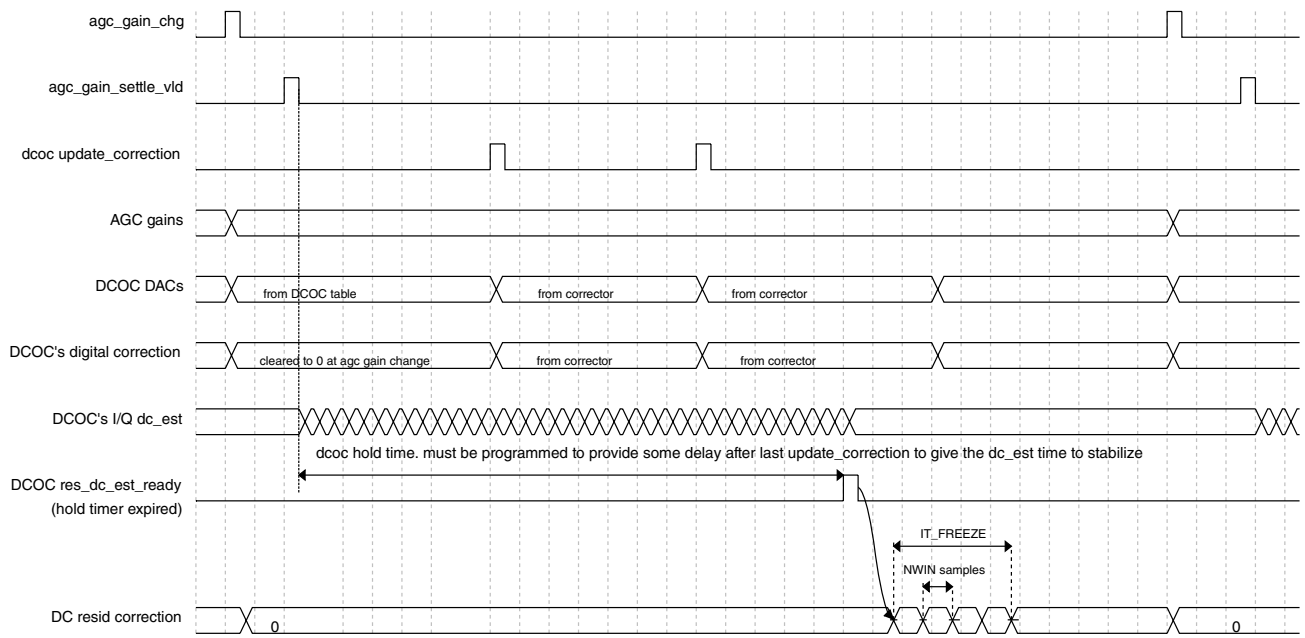

**Figure 64-53. DC residual mode 2 timing**

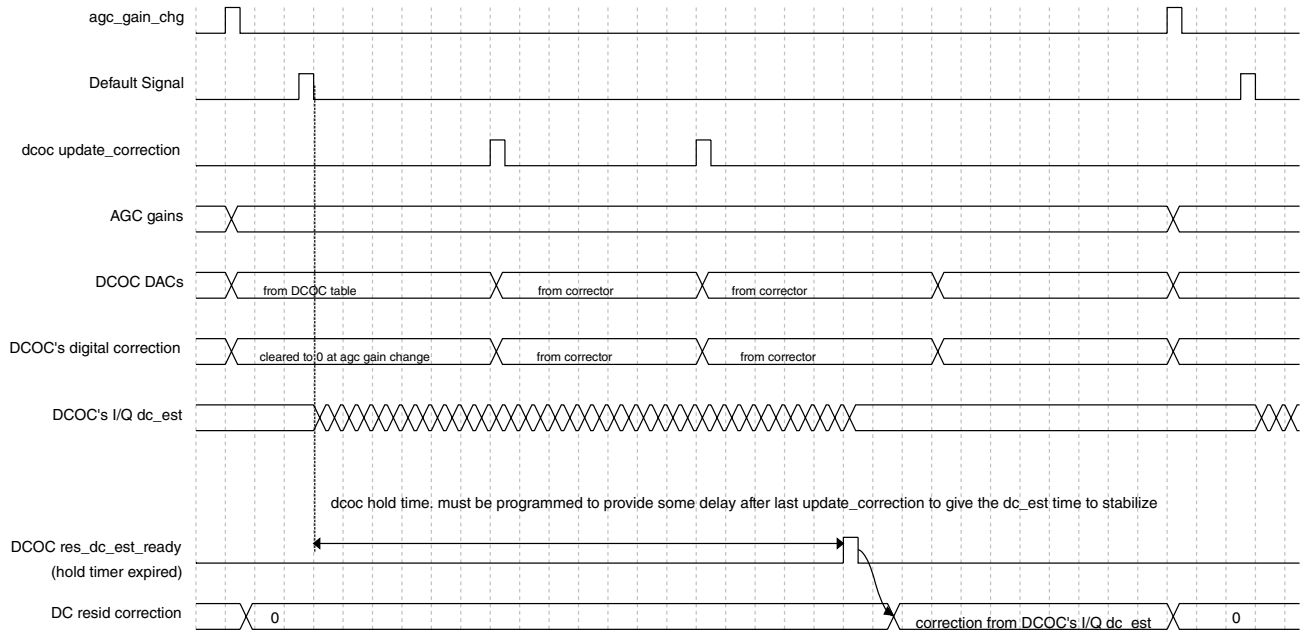

**Figure 64-54. DC residual mode 3 timing**

The behavior of the Resdual DC block is also dependent on the AGC index and the values programmed for DC_RESID's MIN_AGC_IDX and the DCOC's DCOC_CTRL_1[DCOC_TRK_MIN_AGC_IDX]. This behavior is defined in the table below, which assumes DC_RESID_EN=1.

**Table 64-36. Residual DC offset compensation operation dependency on AGC table index**

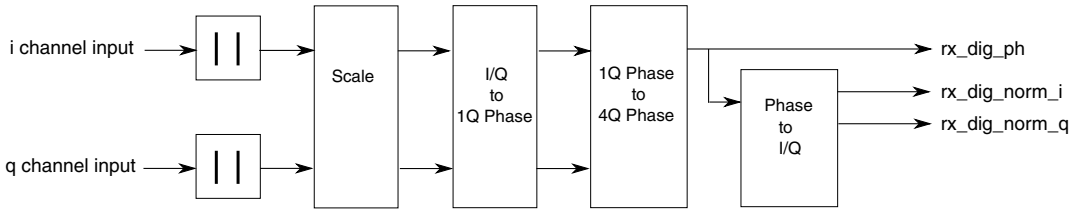
| EXT_DC_EN | MIN_AGC_IDX | DCOC_TRK_MIN_AGC_IDX | Behavior |
|---|---|---|---|
| - | AGC_IDX < MIN_AGC_IDX | - | DC residual is disabled |
| 0 | AGC_IDX >= MIN_AGC_IDX | - | DC residual operates in Mode 1 (it does not use an initial estimate from the DCOC) |
| 1 | | AGC_IDX >= DCOC_TRK_MIN_AGC_IDX | DC residual operates in Mode 2 or 3 (It uses the estimate from the DCOC) |
| | | AGC_IDX < DCOC_TRK_MIN_AGC_IDX | DC residual operates in Mode 1. it does not use the estimate from the DCOC, since the DCOC's tracker is disabled for this AGC gain index |

## 64.3.3.2.9 Normalizer

The normalizer block converts the 12-bit I/Q input signal into a normalized 5-bit I/Q output and a 5-bit phase output as shown in the block diagram below.

**NOTE**

The normalizer's 5-bit I/Q output is currently not used.



Normalizer Block Diagram

**Figure 64-55. Normalizer Block Diagram**

The absolute value of each component of the I/Q input is taken and shifted by a common factor to yield the largest 5-bit values which have a zero MSB for both I and Q. This is followed by rounding that yields I and Q values between 0 and 16 decimal. The scaled I/Q values are used as inputs to a one quadrant phase lookup table. The one quadrant table output is converted to a 4 quadrant 5-bit phase value based on the input sign bits. The 5-bit I/Q output is generated by another lookup table. The normalizer has a maximum quantization error of 8.9 degrees and a RMS error of 3.5 degrees for a random input.

Since the normalizer's phase output can be unreliable at very low signal levels, the normalizer includes a feature which, if enabled by setting RX_DIG_CTRL[RX_NORM_SUPP_EN], suppresses the rx_dig_ph output (sets it to 0) if none of the least last 6 I or Q input samples had an absolute value above a programmable threshold. The threshold is configured via RX_DIG_CTRL[RX_NORM_SUPP_TH].

### 64.3.3.2.10 AuxPLL Frequency Calibration

The AuxPLL Frequency Calibration module finds the best calibration code associated with the AuxPLL. Calibration is initiated using a TSM control signal, and it is expected that this calibration will be performed on each RX warmup. Features of the module include the following:

- Supports two different calibration run window lengths: 64 reference clock cycles, and 128 reference clock cycles. For a 32Mhz reference clock, the overall calibration time is <17us for a run window of 64 reference clock cycles, and <31us for a run window of 128 reference clock cycles.
- Calibration logic can be disabled and a manual calibration value can be applied
- The clk cycle at which the fcal_count[9:0] input from the analog is sampled is programmable.

The module uses a binary search to find the best 7bit calibration code (auxpll_fco_dac_cal_adjust[6:0]). At the end of each calibration stage, the auxpll_fcal_count[9:0] value output from the analog (which counts the number of positive and negative edges of the auxpll clock during the run window) is sampled and compared against the expected count (256 for a run window length of 64 clk cycles, 512 for a run window length of 128 clk cycles), and a decision is made whether the appropriate auxpll_vco_dac_cal_adjust[6:0] bit should be set or cleared. The decision logic is programmable:

- AUXPLL_FCAL_CTRL[FCAL_COMP_INV]=1'b0 (default behavior): if the fcal_count is larger than or equal to the expected count, the cal_adjust bit remains set.
- AUXPLL_FCAL_CTRL[FCAL_COMP_INV]=1'b1: if the fcal_count is less than or equal to the expected count, the cal_adjust bit remains set.

After each of the seven calibration cycles, the current count error is compared to the best (smallest absolute) count error found so far, and after the binary search is complete, the module outputs the calibration code associated with the smallest absolute count error which was found.

Debug features include the following:

- Count value for each of the several calibration stages are saved to registers
- The best absolute count error found during calibration is saved to a register
- Calibration logic can be disabled and a manual calibration value can be applied

The figure below shows the beginning of the AuxPLL calibration timing. For a run window length of 64 clk cycles (which is the configuration expected to be used) each of the 7 calibration stages requires ~76clks, with total calibration time of ~532 clks, which is <17us at 32MHz. Only the 1st (and the beinning of the 2nd) of the 7 calibration stages are shown in the figure.

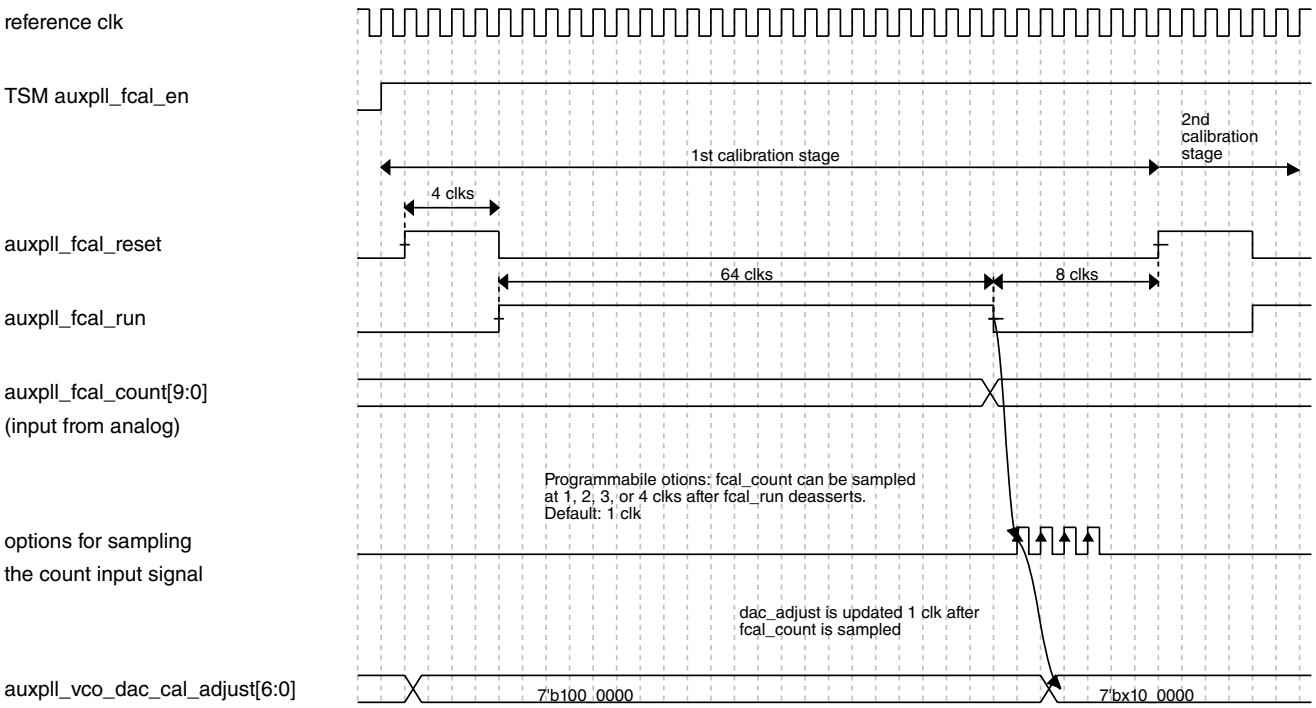


**Figure 64-56. RX AuxPLL FCAL timing**

## 64.3.3.2.11 RX RC Calibration

The RX RC Calibration module finds the best 5bit calibration code for the RC calibration circuit in the analog. From the resulting RC calibration code, separate 5bit codes are derived for each of the following analog circuits: TZA, BBA, BBA2, and ADC. The calibration sequence is initiated by a TSM control signal, and it is expected that this calibration will be performed on each RX warmup.

Features of the module include the following:

- The run window length for each of the five calibration stages is fixed at 4us. The total calibration time is 1us + 5*(4us + 10clks + ipr_rccal_smpl_dly[1:0] clks) - 1 clk.
  - For a 32MHz clk, this is <=23us for all values of ipr_rccal_smpl_dly[1:0]
  - For a 26MHz, this is <=23us for ipr_rccal_smpl_dly[1:0] = 2'b0, and <=24us for other values.
- The four (TZA, BBA, BBA2, and ADC) calibration codes are derived from the RC calibration code by adding signed 4bit programmable offsets. Each of TZA, BBA, BBA2 and ADC have their own programmable offset with saturation detection.
- The comparator output (rccal_comp_out in figure below) from the analog can be programmably inverted.

- The clk cycle at which the comp_out input from the analog is sampled is programmable.
- The output for each of the individual calibration codes (TZA, BBA, BBA2, and ADC) can be applied manually from a register

The module uses a binary search to find the best 5bit calibration code (rccal_code[4:0]). At the end of each calibration stage, the comp_out value output from the analog is sampled, optionally inverted, and used to determine whether the appropriate rccal_code[4:0] bit should be set or cleared.

The figure below illustrates the RC calibration timing. There is a 1us initialization after the calibration circuit is enabled, and then each of the 5 calibration stages requires 5us, for a total of 26us for the entire calibration sequence. Only the inialization 1us and the 1st calibration stage are shown in the figure. The rccal_comp_out signal level at end the end of the calibration stage is used to determine whether the appropriate bit of rccal_code[4:0] will be set or cleared.

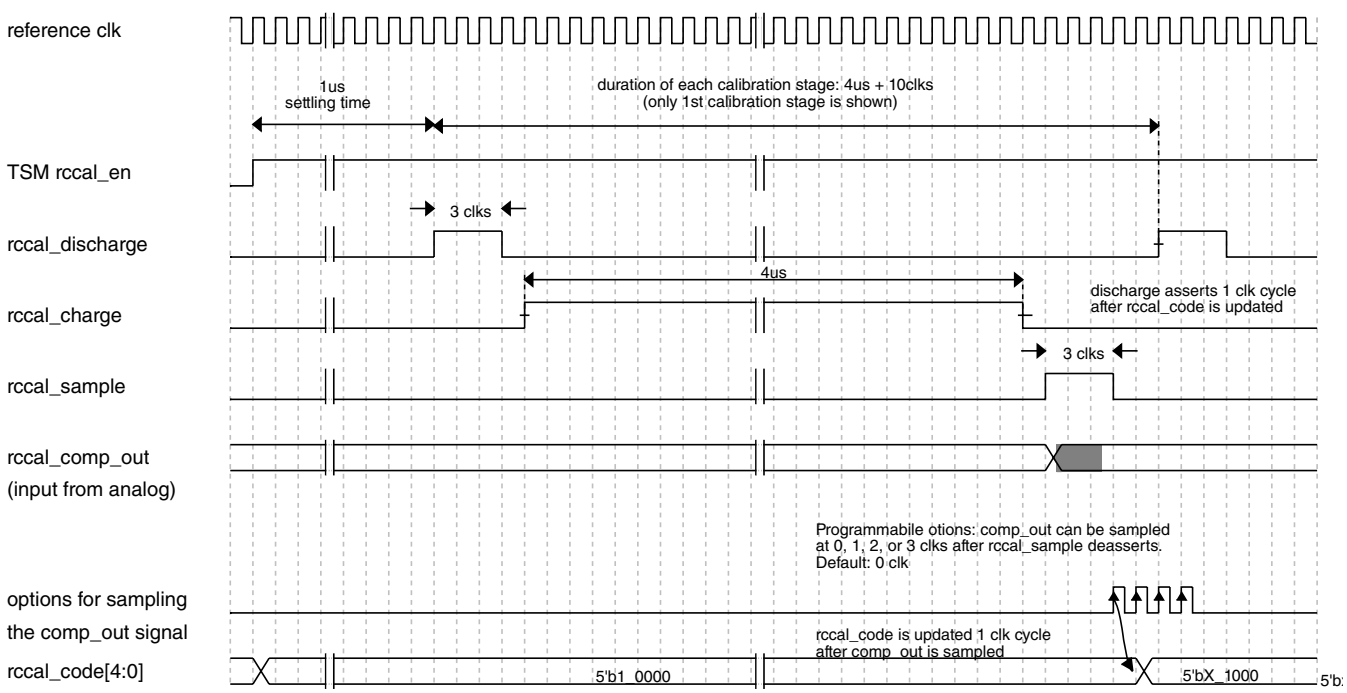

**Figure 64-57. RX RCCAL timing**

## 64.3.3.3 Memory Map and register definition

The rx_dig memory map and description of the rx_dig registers is included in the following register section.

## 64.3.3.3.1 XCVR_RX_DIG register descriptions

### 64.3.3.3.1.1 XCVR_RX_DIG_ADDR Memory map

XCVR_RX_DIG base address: 4103_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | RX Digital Control (RX_DIG_CTRL) | 32 | RW | 0000_0000h |

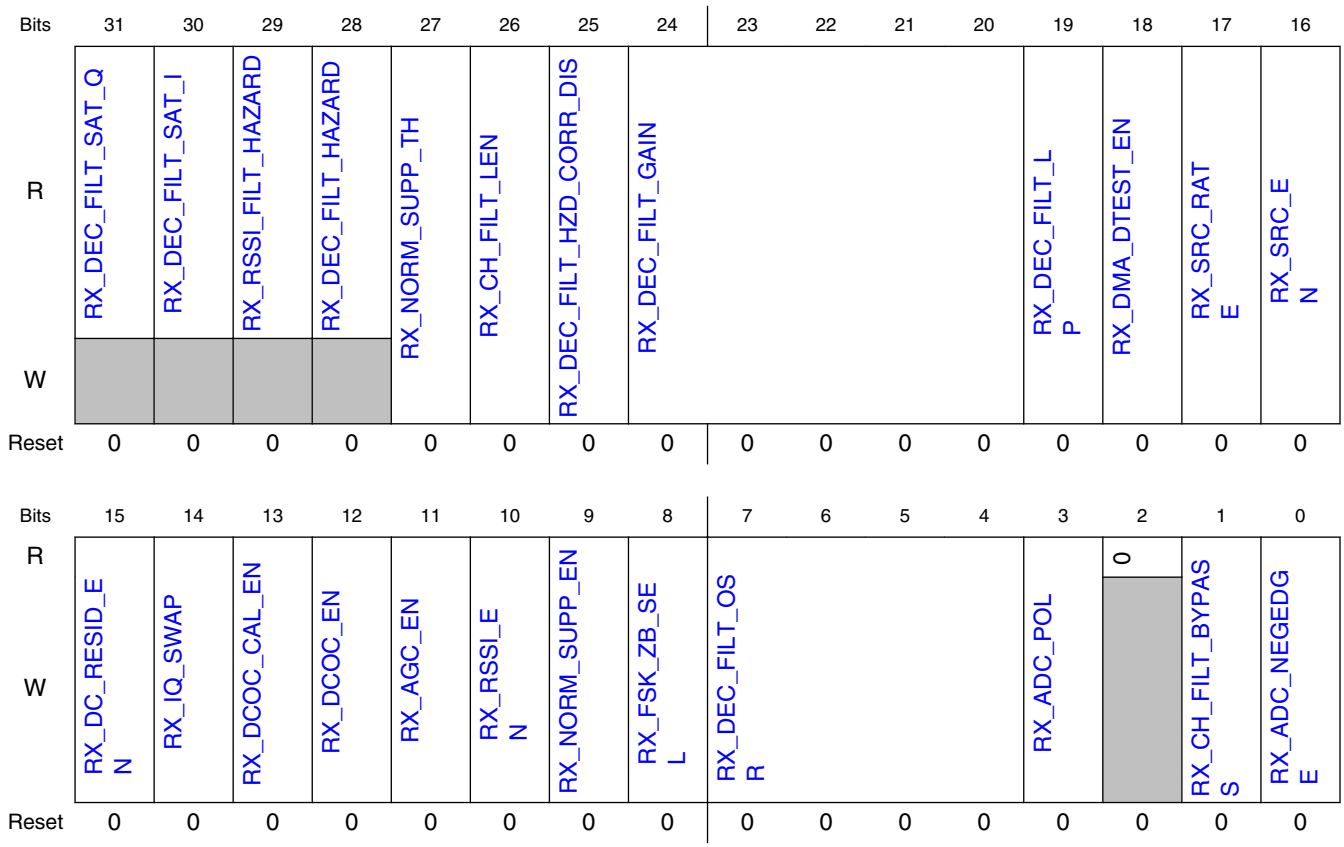
### 64.3.3.3.1.2.2 Diagram



### 64.3.3.3.1.2.3 Fields

| Field | Function |
|---|---|
| 31<br>RX_DEC_FILT_SAT_Q | Decimator output, saturation detected for Q channel<br>This bit will be set if a saturation condition is detected in the decimator filter Q channel. This bit is cleared by tsm_rx_dcoc_init and rx_init.<br>0b - A saturation condition has not occurred.<br>1b - A saturation condition has occurred. |
| 30<br>RX_DEC_FILT_SAT_I | Decimator output, saturation detected for I channel<br>This bit will be set if a saturation condition is detected in the decimator filter I channel. This bit is cleared by tsm_rx_dcoc_init and rx_init.<br>0b - A saturation condition has not occurred.<br>1b - A saturation condition has occurred. |
| 29<br>RX_RSSI_FILT_HAZARD | Decimator output for RSSI, hazard condition detected<br>This bit will be set if a hazard condition is detected in either the I or Q decimator filter related to the wideband RSSI measurement. This does not indicate that a data corruption has occurred, only that the conditions associated with data corruption were detected. This bit is cleared by rx_init.<br>0b - A hazard condition has not been detected<br>1b - A hazard condition has been detected |
| 28 | Decimator output, hazard condition detected |

*Table continues on the next page...*

| Field | Function |
|---|---|
| RX_DEC_FILT_HAZARD | This bit will be set if a hazard condition is detected in either the I or Q decimator filter. This does not indicate that a data corruption has occurred, only that the conditions associated with data corruption were detected. This bit is cleared by rx_init.<br>0b - A hazard condition has not been detected<br>1b - A hazard condition has been detected |
| 27<br>RX_NORM_SUPP_TH | Normalizer Suppression Threshold<br>Configures the threshold for suppressing the normalizer's phase output when RX_NORM_SUPP_EN is set.<br>0b - Normalizer suppression threshold is 12'd7.<br>1b - Normalizer suppression threshold is 12'd15. |
| 26<br>RX_CH_FILT_LEN | RX Channel Filter Length<br>0b - Channel filter length is 24.<br>1b - Channel filter length is 16. Only RX_CHF_COEF_4 - RX_CHF_COEF_11 are used in this mode. |
| 25<br>RX_DEC_FILT_HZD_CORR_DIS | Decimator filter hazard correction disable<br>The decimator uses an asynchronous FIFO between the data coming out of the ADC (in the ADC clock domain) and the decimator output (in the ref osc clock domain, with the rest of the radio digital logic). The hazard detection logic checks for a hazard condition when the ADC clock domain logic may be about to write into the same FIFO location where the ref osc clock domain logic is about to read. If hazard correction is not disabled, the FIFO pointers will be adjusted on detection of a hazard condition.<br>0b - Hazard correction is enabled<br>1b - Hazard correction is disabled |
| 24-20<br>RX_DEC_FILT_GAIN | Decimation Filter Fractional Gain<br>Defines the fractional gain which is applied at the decimator output. The format is u0.5. The gain applied is 1 + RX_DEC_FILT_GAIN/32, so e.g. if RX_DEC_FILT_GAIN is 5'b10110=5'd22, the gain is 1+22/32=1.6875. The nominal gain through the ADC is 2048codes/1.7V; the combined gain through the ADC and decimator would therefore be 2048codes/1.7e3mV*1.6875=2.03codes/mV for the example RX_DEC_FILT_GAIN=5'b10110. |
| 19<br>RX_DEC_FILT_LP | RX Decimator Low Power<br>This bit can be set to reduce the power in the decimator.<br>0b - Decimator operates in normal mode.<br>1b - Decimator operates in low power mode. |
| 18<br>RX_DMA_DTEST_EN | RX DMA and DTEST enable<br>This bit should be set to ensure that all of the rx_dig outputs related to DMA or DTEST are enabled. In mission mode this bit is intended to be cleared to reduce switching power. |
| 17<br>RX_SRC_RATE | RX Sample Rate Converter Rate Selections<br>0b - SRC is configured for a First Order Hold rate of 8/13.<br>1b - SRC is configured for a Zero Order Hold rate of 12/13. |
| 16<br>RX_SRC_EN | RX Sample Rate Converter Enable<br>0b - SRC is disabled.<br>1b - SRC is enabled. |
| 15<br>RX_DC_RESID_EN | DC Residual Enable<br>Enables DC Residual block<br>0b - DC Residual block is disabled.<br>1b - DC Residual block is enabled. |
| 14<br>RX_IQ_SWAP | RX IQ Swap<br>Enable swap of I/Q channels (does not affect ADC raw mode).<br>0b - IQ swap is disabled.<br>1b - IQ swap is enabled. |

*Table continues on the next page...*

## 64.3.4 Bit Streaming Mode

### 64.3.4.1 Introduction

The 2.4GHz Radio features a Bit Streaming Mode for BLE. When activated, this feature allows all received BLE packet data, to be serialized and shifted out to external hardware for further processing.

#### 64.3.4.1.1 Overview

Bit Streaming Mode (BSM) allows all received BLE packet data, to be serialized and shifted out to external hardware for further processing. A simple development system can be crafted to consume the BSM outputs and generate packet trace data for all BLE traffic

appearing on a network, within range of the receiving device. This enables network-level monitoring and debugging. BSM-for-BLE uses a simple, synchronous 3-wire interface, consisting of BSM_CLK, BSM_DATA, and BSM_FRAME outputs. Packet data is shifted out serially, at the BLE bit rate (1MHz). Signalling is provided on BSM_FRAME to indicate the start of reception. BSM_DATA and BSM_FRAME are synchronous to BSM_CLK. BSM_DATA and BSM_FRAME are valid at rising BSM_CLK, and are intended to be captured on that edge. A single control bit activates or deactivates BSM. Aside from controlling this bit, BSM requires no software support from the host processor. The SoC's BSM outputs are multiplexed with GPIO, so that the pins are available for general purpose use when BSM is disabled. BSM does not interfere with BLE packet processing in any way; it is merely a passive monitoring and debugging tool. BSM, when engaged, will not measurably increase current consumption, since the BSM module operates at a 1MHz clock rate. Only received packets are made available to BSM; packets transmitted by the device do not appear on the BSM interface.

This BSM implementation features some new automation not included in previous BSM versions. Access Address checking is now done in hardware, not software. No protocol engine (link layer) is engaged, so software communicates directly with the transceiver (PHY), reducing initialization overhead. And there are no "blind spots" due to link layer SCAN_INTERVAL timeouts. Packets can be received at any time under direct software control.

#### 64.3.4.1.2 Features

- Enables monitoring and debugging of all network traffic within range of the device
- Simple, synchronous 3-wire interface facilitates external hardware development
- Low power consumption
- Non-intrusive design
- Minimal software support required
- Hardware Access Address Correlation
- No Link Layer Overhead

### 64.3.4.1.3 Block Diagram

### 64.3.4.2 External Signal Descriptions

| Name | Direction | Size | Description |
|---|---|---|---|
| BSM_DATA | output | 1 | Serial BLE packet bit stream, LSB-first. Valid on rising edge of BSM_CLK |
| BSM_FRAME | output | 1 | Framing signal to indicate the start of reception. Active high |
| BSM_CLK | output | 1 | 1MHz bit-rate clock. BSM_DATA and BSM_FRAME are synchronized to BSM_CLK. |

| Name | Direction | Size | Descriptiom |
|---|---|---|---|
| | | | External device should capture BSM_FRAME and BSM_DATA on rising edge of BSM_CLK |

### 64.3.4.3 Memory Map and Register Definition

BSM-for-BLE is enabled by a single register bit. The bit is BSM_EN_BLE. This bit resides in the FSK_CFG register of XCVR address space. Several other programmable configuration parameters pertaining to BSM mode are listed in the table below.

| Register | Address | Field | Bit(s) | Desciption |
|---|---|---|---|---|
| FSK_CFG | XCVR_BASE + 0x408 | BSM_EN_BLE | [3] | 1: enable BSM (bit streaming mode) for BLE<br>0:disable BSM<br><br>When enabled, the 3 BSM outputs (BSM_DATA, BSM_FRAME, and BSM_BLK) appear on the BSM interface pins of the SoC. At the SoC level, these are alternate, muxed-GPIO pins, so the appropriate port programming is required. |
| NTW_ADR_BSM | XCVR_BASE + 0x410 | NTW_ADR_BSM[31:0] | [31:0] | PHY will search for this Access Address when BSM_EN_BLE=1 |
| FSK_CFG | XCVR_BASE + 0x408 | BLE_NTW_ADR_THR[2:0] | [22:20] | PHY will tolerate this many bit errors in its search for NTW_ADR_BSM |
| TSM_CTRL | XCVR_BASE + 0x2C0 | FORCE_RX_EN | [3] | Software will set FORCE_RX_EN=1 to launch an RX sequence in search of a packet with an Access Address equal to NTW_ADR_BSM. Software will clear FORCE_RX_EN=0 after the last bit of the packet has been received and processed by the application. Clearing this bit ends the RX sequence. |

### 64.3.4.4 Functional Description

The BSM implementation configures the device to enter receive mode and search the airwaves for BLE packets bearing an Access Address matching the one programmed by the application. In this mode, the application communicates directly with the Multi-standard PHY, and no link layers are engaged. Once configured and enabled for searching, BLE packets with an Access Address match will appear at the BSM pins of the device. An Access Address match will result in the device asserting BSM_FRAME=1. At this point, the device will begin shifting out the packet bits serially, LSB first, starting with the packet header (preamble and Access Address will *not* appear on the BSM pins). The BSM pins are a synchronous interface to an external MCU. BSM_FRAME and BSM_DATA bits change on the falling edge of BSM_CLK. The external device must capture BSM_FRAME and BSM_DATA on the rising edge. The application is responsible for all packet processing after the AA match (BSM_FRAME=1), including header parsing and CRC checking. The application terminates the receive operation once the last bit of the packet has been received and processed by the application. The number of bit errors tolerated by the PHY in its correlation of Access Address is programmable, with a default setting of 1 bit error tolerated. The BSM hardware on the device has no knowlege of Bluetooth Low Energy states, so it is up to the application to track BLE state (e.g., Advertising, Initiating), and configure the Access Address accordingly.

The following steps can be used to receive a BLE packet in BSM mode:

1. Configure the RX digital for BLE protocol
2. Configure the PHY for BLE protocol
3. Set FSK_CFG[BSM_EN_BLE]=1 to enable BSM feature
4. Program the desired Access Address into the NTW_ADR_BSM register
5. Program the desired maximum number of tolerated bit errors into FSK_CFG[BTLE_NTW_ADR_THR]
6. Set TSM_CTRL[FORCE_RX_EN]=1 to initiate the RX sequence
7. Monitor the BSM interface for BSM_FRAME=1 (Access Address match)
8. After BSM_FRAME=1, use each rising edge of BSM_CLK to capture the next bit of BSM_DATA
9. Shift in and parse the incoming packet on the fly, using the header to determine packet length
10. After the last bit of CRC, terminate the RX sequence by clearing TSM_CTRL[FORCE_RX_EN]=0.

The following diagram depicts the occurrence of a BLE packet which matches the programmed Access Address at the BSM interface:

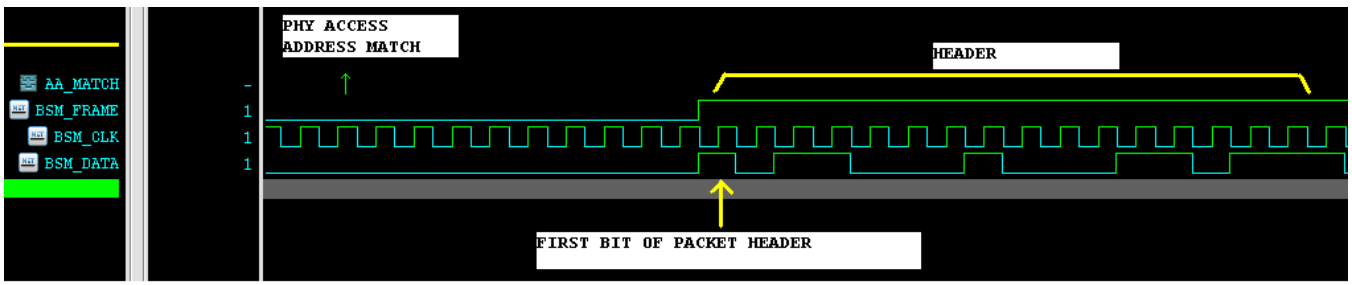

**Figure 64-59. BSM Timing Diagram**

The following sequence of events is depicted in the diagram

1. AA match occurs internally in the PHY
2. A delay of several microseconds after internal PHY AA match (transparent to application)
3. BSM_FRAME is asserted
4. At the next rising edge of BSM_CLK, first bit of packet header (LSB) is valid
5. Subsequent header bits are shifted out LSB-first on BSM_DATA, valid at each rising edge of BSM_CLK
6. Payload and CRC bits follow the header

The FSK_STAT register (XCVR_BASE + 0x414) contains several fields which may assist software monitoring the BSM interface:

| Field | Bit(s) | Desciption |
|---|---|---|
| PREAMBLE_FOUND | [0] | PHY has detected a BLE preamble. This should not be relied on by the application but it may be useful for debug. In the hardware, preamble detection is a prerequisite for Access Address correlation. |
| AA_MATCHED | [1] | PHY has detected an Access Address match. After a delay of several microseconds, BSM_FRAME will be asserted and packet data bit shifting will commence. |
| AA_MATCH[0] | [4] | Indicates that the Access Address match occurred on the PHY's Network Address 0 input. This will always be the case for BLE. |

Software could elect to poll the AA_MATCHED bit, to determine when to start monitoring the BSM_FRAME, since this bit will transition high several microseconds before BSM_FRAME=1. A procedure for polling AA_MATCHED as a prerequisite to the monitoring of the BSM interface pins, is as follows:

1. Ascertain the length of the RX Warmup by reading the third byte of the END_OF_SEQ register in XCVR space
2. Set variable **end_of_rx_wu** to this value: **end_of_seq** = (r32(END_OF_SEQ) & 0xFF0000) >> 16
3. Set TSM_CTRL[FORCE_RX_EN]=1 to initiate the RX sequence. (AA_MATCHED may still be asserted here from the previous packet reception)
4. Poll XCVR_STATUS register in XCVR space to determine when RX Warmup is complete. Set variable **tsm_count** to the LS byte of XCVR_STATUS
5. while (**tsm_count** < **end_of_rx_wu**) {**tsm_count** = (r32(XCVR_STATUS) & 0xFF);}
6. When the while() loop exits, the RX Warmup is complete. BSM_FRAME will assert soon
7. Begin monitoring the BSM pins for incoming BLE packet

## 64.3.5 Transceiver Sequence Manager

### 64.3.5.1 Introduction

The TSM is a fully-programmable, multi-protocol transceiver sequence manager, which supports Bluetooth Low Energy, 802.15.4, and other 2.4GHz transceivers.

#### 64.3.5.1.1 Overview

The Transceiver Sequence Manager controls the warmup and warmdown processes for all radio sequences. The TSM provides for a TX sequence, and an RX sequence. For both TX and RX, a warmup and a warmdown sequence is supported. The length of each sequence is programmable, from 1 – 254us. The resolution of the TSM is 1us. Controls for all analog and digital transceiver blocks are provided. The TSM has 67 outputs with which to control the warmup and warmdown processes. Each TSM output enables, or otherwise provides control for, a transceiver-related block. Each TSM output (or group of outputs) has 4 8-bit registers, with which to control the point at which the output asserts during the warmup (1 register for TX, 1 for RX), and the point at which it deasserts (1 register for TX, 1 for RX). Some TSM outputs, which are known in advance to require identical timing, are “ganged together”, to reduce area and required programming. For

DFT, and non-mission-mode validation, each TSM output can be put under direct software control, using register overrides. Any sequence can be optionally aborted by software, or by a PLL unlock condition. And, any sequence can be temporarily halted, by setting an optional, programmable breakpoint.

#### 64.3.5.1.2 Features

The TSM includes the following features:

- TX warmup and warmdown sequence and RX warmup and warmdown sequence sequence for every controllable output.
- Programmable sequence length from 1 to 254 microseconds for each sequence in 1 microsecond increments.
- 67 total outputs.
- Multi-protocol
- PA Target Power Selection
- PA Ramping
- Ability to place TSM outputs under software control for test and non-mission mode validation.
- Ability to abort sequences upon PLL unlock condition.
- Fast Warmup Capability for TX and RX
- LPPS Support
- Programmable breakpoint capability to halt any sequence temporarily.

### 64.3.5.1.3 Block diagram

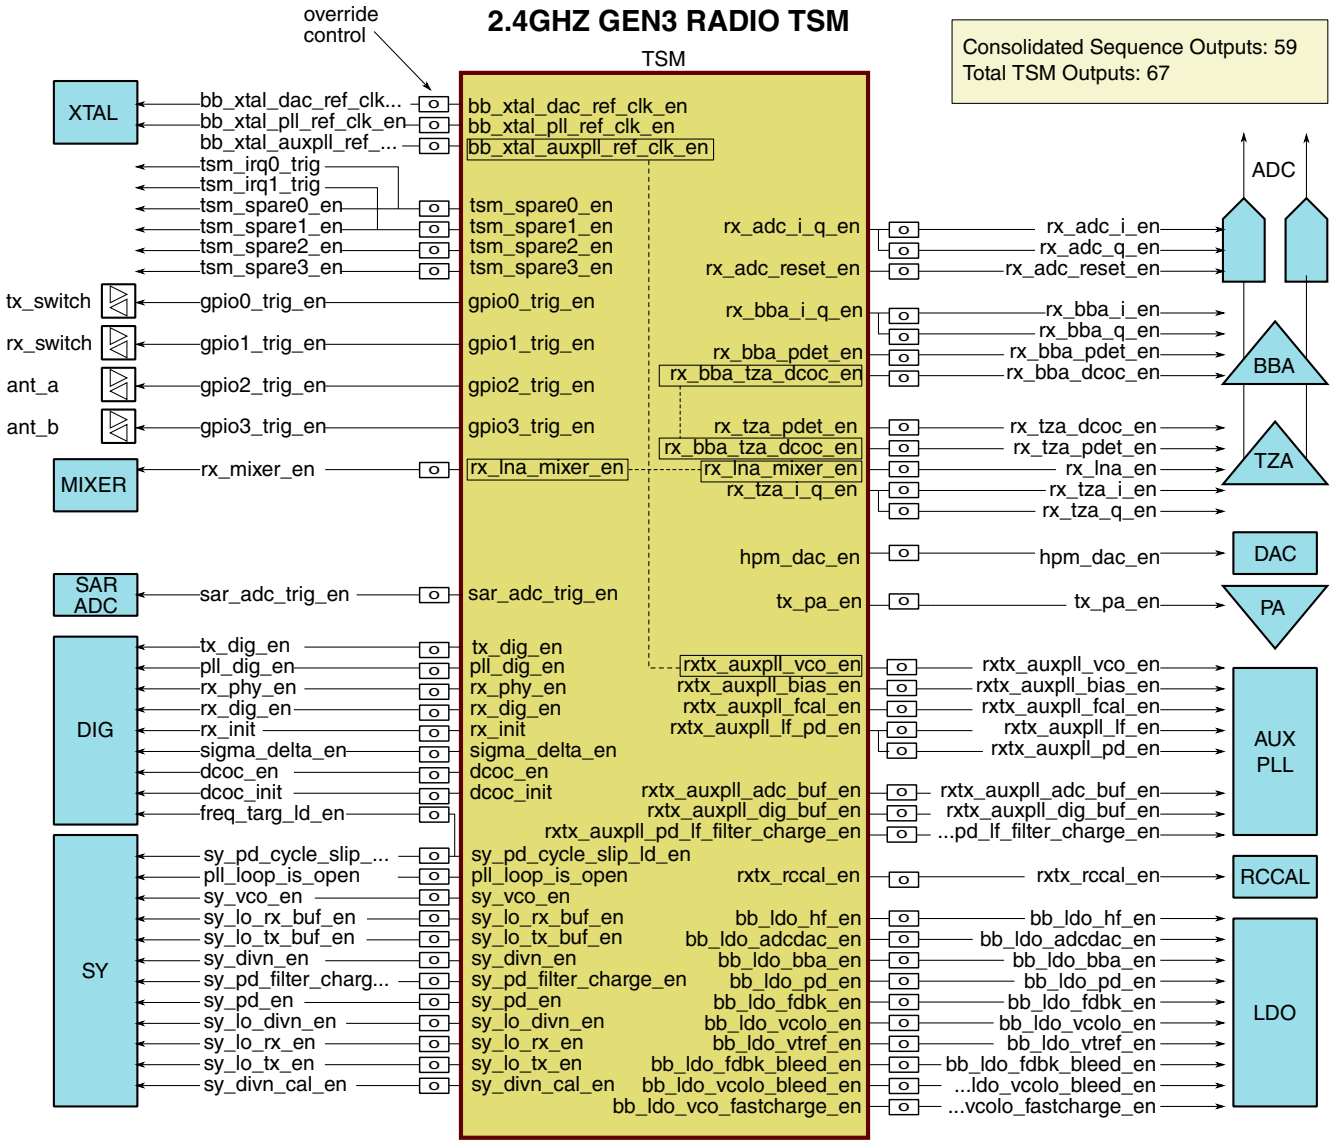

**Figure 64-60. Block diagram**

## 64.3.5.2 Functional description

### 64.3.5.2.1 Sequence Counter

The TSM supports 1 TX and 1 RX sequence. Each sequence consists of 3 phases:

1. WARMUP phase
2. ON phase
3. WARMDOWN phase

The central element of the TSM is an 8-bit counter. The counter is held at 0 during the idle state. From idle state, any sequence can be launched, by an initiating event. (See Section Sequence Initiation). At an initiating event, the TSM counter counts up from 0 to a programmed stop point during the WARMUP phase, determined by the END_OF_TX_WU or END_OF_RX_WU register, depending on whether the sequence is TX or RX. At the end-of-warmup “stop point”, the TSM counter holds its count, and the TSM sequence enters the ON phase. The TSM counter will remain in the ON phase, and hold its count, until the initiating event deasserts, or an abort occurs (See Section Sequence Termination). When either of these conditions occurs during the ON phase, the TSM will resume counting from the point it was holding during the ON phase, and the sequence will enter the WARMDOWN phase. The counter will continue counting until a programmed stop point is reached. This stop point is determined by the END_OF_TX_WD or END_OF_RX_WD register, depending on whether the sequence is TX or RX. Once this point is reached, the sequence returns to idle, and the TSM counter returns to 0.

The 4 8-bit registers which control the duration of the WARMUP phase (END_OF_TX_WU[7:0] and END_OF_RX_WU[7:0]), and the duration of the WARMDOWN phase (END_OF_TX_WD[7:0] and END_OF_RX_WD[7:0]), reside in the END_OF_SEQ register.

All TSM-controlled outputs are active-high. Any TSM-controlled output can be asserted once during a sequence (either TX or RX sequence), and then deasserted once. Or, the output can be held in a deasserted state for the duration of the sequence. The precise timing for the assertion and deassertion of each TSM-controlled output, for both TX and RX sequences, is determined by 4 8-bit registers assigned to that output (see Section TSM-Controlled Outputs). The TSM resolution is 1us. This is the update rate for the TSM counter, and sets the granularity with which warmup and warmdown processes can be controlled.

#### 64.3.5.2.2 TSM-Controlled Outputs

The TSM has 67 timing-controlled outputs, for enabling and control of the various transceiver blocks. The outputs are shown in the following diagram.

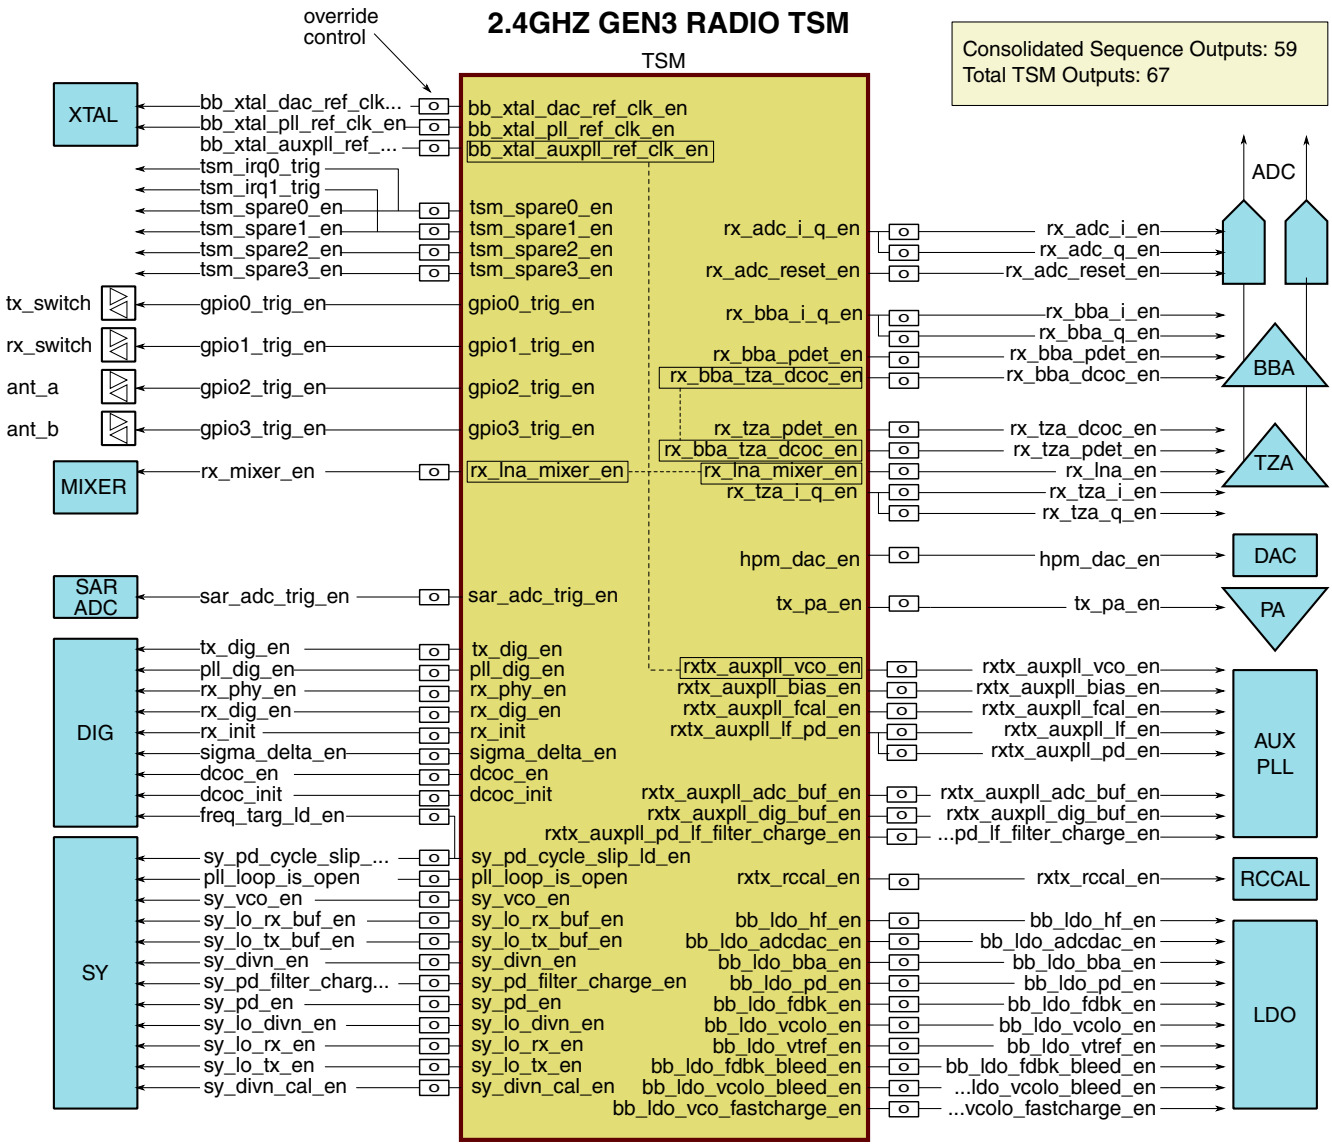

**Figure 64-61. 2.4GHZ RADIO TSM**

In some cases, some of the 67 outputs are grouped together, for outputs which need identical timing. For example, rx_bba_i_en and rx_bba_q_en. These groupings save area, because only 1 set of timing registers is needed to control timing for the entire group. Groupings also reduce the amount of required TSM programming. In all cases, even for grouped outputs, each output has an individual override control, to allow software to take command of any of the 67 TSM-controlled outputs at any time. As a consequence of the groupings, there are only 59 sets of timing registers, to control the 67 outputs. The table below, lists the 67 TSM-controlled outputs, and for the grouped outputs, indicates the signal which controls the timing for the entire group.

For example, TSM-controlled ouputs rx_bba_i_en, and rx_bba_q_en, are both members of the same group. The timing registers to program the timing on these outputs (RX_BBA_I_Q_TX_HI, RX_BBA_I_Q_TX_LO, RX_BBA_I_Q_RX_HI, RX_BBA_I_Q_RX_LO), control the timing for both members of the group. Each member of the group, however, has in independent software override.

During the WARMUP and WARMDOWN phases of any sequence, any TSM-controlled output can be programmed to assert once and then deassert once, by programming the timing registers associated with the output. Each output has 4 8-bit timing registers associated with it. The name of the register matches the name of the output:

*OUTPUTNAME*_TX_HI[7:0]
*OUTPUTNAME*_TX_LO[7:0]

*OUTPUTNAME*_RX_HI[7:0]
*OUTPUTNAME*_RX_LO[7:0]

In the case of grouped outputs, the timing registers associated with the signal controlling the group, control timing for the entire group.

During the WARMUP phase of a TX sequence, as the 8-bit TSM counter increments, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_TX_HI[7:0], but is less than the programmed value of *OUTPUTNAME*_TX_LO[7:0], the corresponding TSM output will transition high. During the WARMUP or WARMDOWN phase of the TX sequence, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_TX_LO[7:0], the TSM output will transition low. If the programmed value of *OUTPUTNAME*_TX_HI[7:0], is greater than the length of the TX sequence (set by register END_OF_TX_WD[7:0]), then that signal will never transition high during the TX sequence. A convenient way of ensuring a signal does not assert during a TX sequence, is to set its *OUTPUTNAME*_TX_HI[7:0]=255.

During the WARMUP phase of a RX sequence, as the 8-bit TSM counter increments, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_RX_HI[7:0], but is less than the programmed value of *OUTPUTNAME*_RX_LO[7:0], the corresponding TSM output will transition high. During the WARMUP or WARMDOWN phase of the RX sequence, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_RX_LO[7:0], the TSM output will transition low. If the programmed value of *OUTPUTNAME*_RX_HI[7:0], is greater than the length of the RX sequence (set by register END_OF_RX_WD[7:0]), then that signal will never transition high during the RX sequence. A convenient way of assuring a signal does not assert during a RX sequence, is to set its *OUTPUTNAME*_RX_HI[7:0]=255.

The following diagram depicts the TSM counter, and the control logic used to assert and deassert the TSM-controlled outputs. For clarity, logic for only 2 of the 67 outputs is shown.

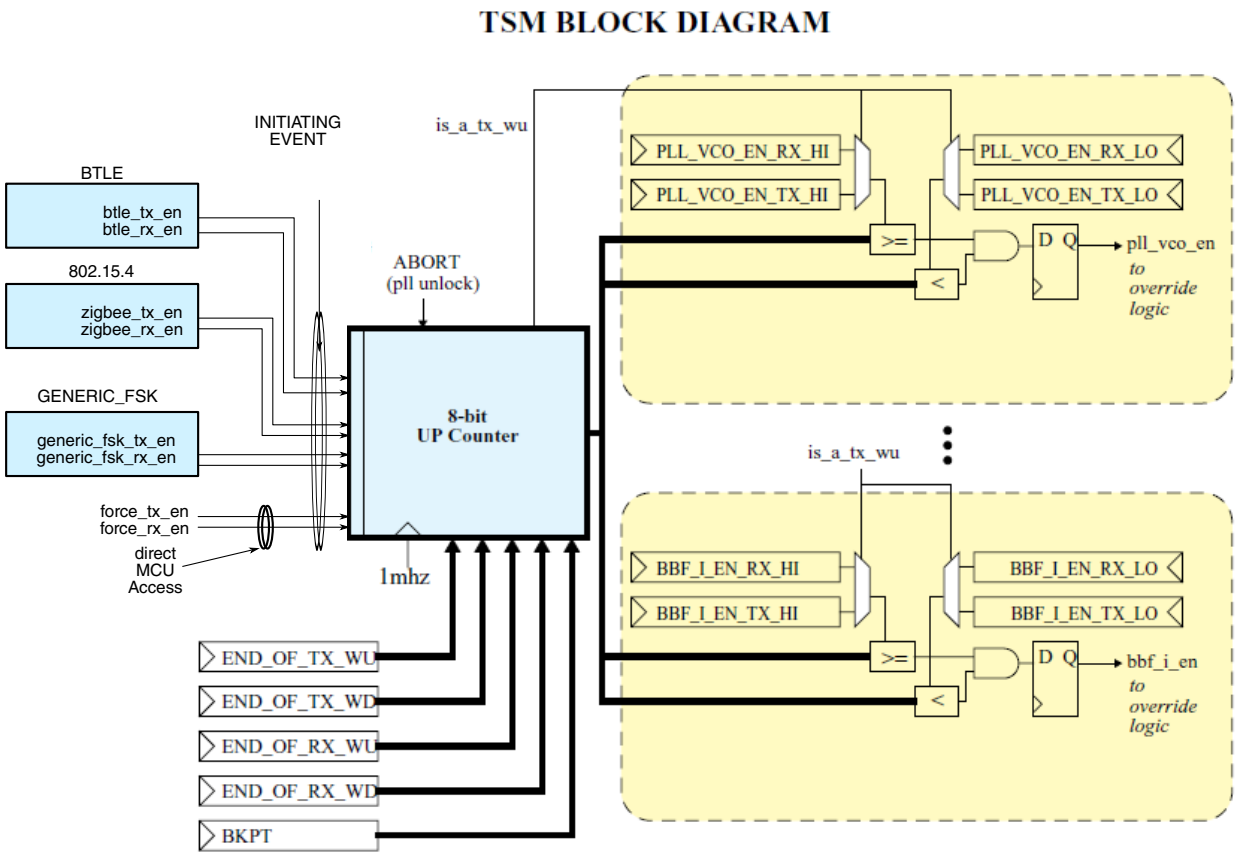

**Figure 64-62. 2.4GHZ RADIO TSM BLOCK DIAGRAM**

### 64.3.5.2.3 Timing Registers

There are 59 sets of timing registers for the TSM, one set for each TSM-controlled output (or, for the signal controlling the group for the “grouped” outputs). Each register set consists of 4 registers: one to control the assertion time of the output for TX sequences, one to control the assertion time for RX sequence, one to control the deassertion time for TX sequences, and one to control the deassertion time for RX sequences. For TSM-controlled outputs that are grouped, one set of timing registers controls the timing for all members of the group. For each of these 59 sets, the following table lists the register name (TSM_TIMING00 – TSM_TIMING58), and 4 timing register names associated with each.

| REGISTER NAME | BITS [31:24] | BITS [23:16] | BITS [15:8] | BITS [7:0] |
|---|---|---|---|---|
| TSM_TIMING00 | BB_LDO_HF_EN_RX_LO[7:0] | BB_LDO_HF_EN_RX_HI[7:0] | BB_LDO_HF_EN_TX_LO[7:0] | BB_LDO_HF_EN_TX_HI[7:0] |

Some of the TSM outputs have relevance for TX sequences only. For those, timing registers are only provided for TX assertion and deassertion times. For such outputs, the RX timing registers are shown as “n/a” in the table above. The RX timings for such outputs are essentially hardwired to 255, meaning there will be no signal assertion during RX sequences.

Some of the TSM outputs have relevance for RX sequences only. For those, timing registers are only provided for RX assertion and deassertion times. For such outputs, the TX timing registers are shown as “n/a” in the table above. The TX timings for such outputs are essentially hardwired to 255, meaning there will be no signal assertion during TX sequences.

#### 64.3.5.2.4 Sequence Initiation

The SoC will include one or more protocol engines. Any of the protocol engines, can launch a TSM sequence. Each protocol engine will have an initiating signal for a TX sequence, and another for an RX sequence. In lieu of a protocol engine, the SoC host can launch a TSM sequence directly. The following table lists the initiating sources supported by the TSM, and the name of the sequence launching signal (TSM input):

| Initiating Source | Initiating Signal Names |
|---|---|
| BTLE | btle_tx_en, btle_rx_en |
| 802.15.4 | zigbee_tx_en, zigbee_rx_en |
| Generic FSK | generic_tx_en, generic_rx_en |
| MCU/Host | force_tx_en, force_rx_en |

For direct software control, the MCU/Host can initiate a TX sequence warmup directly, by setting the FORCE_TX_EN bit, and later initiate a TX sequence warmdown by clearing the bit. The MCU/Host can initiate a RX sequence warmup directly, by setting the FORCE_RX_EN bit, and later initiate a RX sequence warmdown by clearing the bit. These bits reside in the TSM_CTRL register.

From idle state, the asserting of any initiating event (*source*_tx_en or *source*_rx_en), will begin the TSM WARMUP phase and begin incrementing the TSM counter from 0. The initiating source needs to hold the initiating signal asserted (high) through the course of the WARMUP, and then for the duration of the desired ON phase. Deasserting the initiating signal transitions the TSM to the WARMDOWN phase (see Section Sequence Termination).

From idle state, a TX-initiating event (assertion of any TSM *source*_tx_en input) will launch a TX sequence. The TSM output **tx_mode** will go high to indicate a TX sequence is underway. Also, from idle state, an RX-initiating event (assertion of any TSM *source*_rx_en input) will launch an RX sequence. The TSM output **rx_mode** will go high to indicate a RX sequence is underway.

Only 1 initiating source can be allowed to assert at any given time. Under no circumstances should a TX and RX initiating source be asserted simultaneously.

Once a TSM sequence has been launched, the WARMUP phase is entered and TSM counter incrementing will commence. Up-counting will continue until one of the following conditions is met:

1. Deassertion of the initiating event. TSM will transition to WARMDOWN phase
2. Abort. TSM will transition to WARMDOWN phase
3. tsm_count=END_OF_*SEQ*_WU, where *SEQ*=TX or RX. TSM will transition to ON phase
4. Breakpoint. TSM stay in its current phase and hold its count

A transition from WARMUP to ON phase means TSM will hold its count at END_OF_*SEQ*_WU, where *SEQ*=TX or RX.

A transition from ON to WARMDOWN phase means TSM will cease its hold, and resume counting at END_OF_*SEQ*_WU+1, where *SEQ* = TX or RX. (See Section Sequence Termination).

A transition from WARMUP to WARMDOWN phase means the tsm_count will jump to END_OF_*SEQ*_WU+1 (where *SEQ* = TX or RX), and resume counting from there. (see Section Sequence Termination).

The 4 8-bit registers which control the duration of the WARMUP phase (END_OF_TX_WU[7:0] and END_OF_RX_WU[7:0]), and the duration of the WARMDOWN phase (END_OF_TX_WD[7:0] and END_OF_RX_WD[7:0]), reside in the END_OF_SEQ register.

#### 64.3.5.2.5 Sequence Termination

A sequence may be terminated during the WARMUP or ON phase. A sequence will be terminated when one of the following conditions is met:

1. Deassertion of the initiating event. TSM will transition to WARMDOWN phase
2. Abort. TSM will transition to WARMDOWN phase

Deassertion of the initiating event (*source*_tx_en or *source*_rx_en), will cause a transition to WARMDOWN phase, at which point the TSM counter will resume counting from END_OF_*SEQ*_WU+1 (where *SEQ*=TX or RX).

An abort is caused by a PLL unlock event. An unlock abort will cause a transition to WARMDOWN phase, at which point the TSM counter will resume counting from END_OF_*SEQ*_WU+1 (where *SEQ* = TX or RX). See Section TSM Aborting.

During the WARMDOWN phase, whether caused by a deassertion of the initiating event, or a PLL unlock, subsequent aborts (PLL unlock events) will not be recognized by the TSM.

#### 64.3.5.2.6 Overrides

Each of the 67 TSM-controlled outputs has independent override control, except for the 4 GPIO triggers, and the SAR_ADC_TRIG output. In addition, two special TSM outputs, tx_mode and rx_mode, also have their own override controls, for a total of 67 – 5 + 2 = 64 overrides.

Two register bits are assigned to each output, to implement the override function. The bits are named:

*OUTPUTNAME*_OVRD_EN
*OUTPUTNAME*_OVRD

Setting the *OUTPUTNAME*_OVRD_EN=1, allows the *OUTPUTNAME*_OVRD bit to directly control the state of the output. Clearing *OUTPUTNAME*_OVRD_EN=0 returns control of the output to the TSM.

The 64 override bit-pairs, reside in the TSM_OVRD0, TSM_OVRD1, TSM_OVRD2, and TSM_OVRD3 registers.

Overrides have no effect on TSM operation, TSM counting, sequence initiation, or sequence termination. Overrides may be engaged at any time, during any TSM phase, including during idle state.

#### 64.3.5.2.7 Breakpoint

Breakpoint can be used to temporarily suspend a TSM sequence. A breakpoint can be set during the WARMUP or WARMDOWN phase of any TSM sequence. An 8-bit BKPT[7:0] register field resides in the TSM_CTRL register. During a TSM sequence, when the TSM counter matches the BKPT register value, counting stops and the counter holds in its current state. Aborts (PLL unlocks) will be ignored while holding at a breakpoint. Deassertion of the initiating event will also be ignored during the breakpoint. The breakpoint can be lifted by modifying the BKPT[7:0] register. Once the breakpoint is lifted, the TSM proceeds in the phase it was in prior to the breakpoint match, and the TSM counter begins incrementing again from the point at which the breakpoint occurred. Aborts (PLL unlocks) and deassertion of the initiaing event, will then be recognized and handled as per the description in the “Sequence Termination” section. The default value for BKPT[7:0] is 255, which is greater than the length of any allowed sequence, so a breakpoint will not trigger during a sequence, unless a lower value is programmed.

#### 64.3.5.2.8 TSM Aborting

The TSM can be enabled to abort any sequence on a PLL unlock condition. There are 3 mechanisms available for detecting PLL unlock. These are:

1. Coarse Tune Unlock
2. Frequency Target Unlock
3. Cycle Slip Unlock

Any of these mechanisms, or any combination of them, can be enabled to cause a TSM abort. Each of these mechanisms has a “_FAIL_FLAG” flag in the PLL_LOCK_DETECT register. On an unlock detection by any of these mechanisms, the corresponding “_FAIL_FLAG” flag (sticky bit) will become set, regardless of whether the mechanism is enabled to abort the TSM sequence. The “_FAIL_FLAG” flags are type “write-1-to-clear”.

An overview of the 3 PLL unlock mechanism is shown below

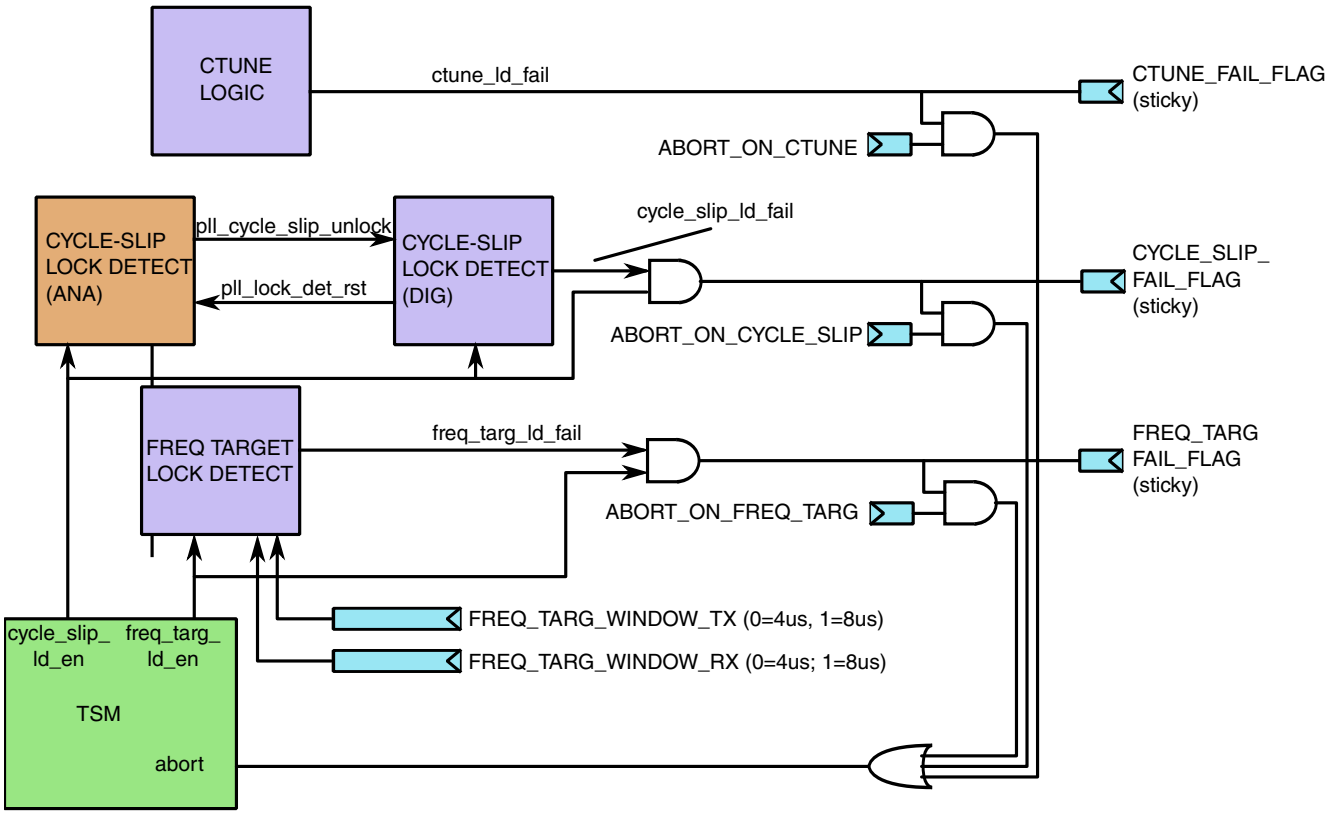

**Figure 64-63. PLL UNLOCK MONITORING AND ABORT LOGIC**

Each of the 3 PLL unlock mechanisms has an “ABORT_ON_” bit, to enable or disable that mechanism from aborting any TSM sequence. Any combination of “ABORT_ON_” bits can be configured.

In addition, the TSM directly controls the timing for 2 of the 3 unlock detect mechanisms: the Cycle Slip Lock Detect and the Frequency Target Lock Detect. (The timing for Coarse Tune Lock Detect mechanism is indirectly controlled by TSM via the pll_dig_en output; the PLL digital state machine is triggered by this signal and directly controls Coarse Tune). Enabling a lock detection mechanism via TSM programming allows an unlock condition to set the respective “_FAIL_FLAG” flag bit; To allow an unlock condition to cause an abort requires the respective “ABORT_ON_” bit to be set.

For each PLL unlock detect mechanism, the table below summarizes the TSM controlling signal for the mechanism, the timing register associated with that signal, and the default timing for the assertion of the controlling signal for both TX and RX sequences.

| Lock Detect Mechanism | TSM Controlling Signal | Associated TSM Timing Register | Controlling Signal Assertion Time(TX) | Controlling Signal Assertion Time(RX) |
|---|---|---|---|---|
| Coarse Tune | pll_dig_en (indirect) | TSM_TIMING34 | 7us | 7us |
| Freq. Target | freq_targ_ld_en | TSM_TIMING14 | 99us | 49us |
| Cycle Slip | pll_cycle_slip_ld_en | TSM_TIMING14 | 99us | 49us |

For each PLL unlock detect mechanism, the table below indicates the TSM controlling signal, the name of the "_FAIL_FLAG" flag bit, and the name of the "ABORT_ON_" enable bit to allow TSM aborting:

| Lock Detect Mechanism | TSM Controlling Signal | Lock Detect Fail Flag (PLL_LOCK_DETECT register) | Abort Enable Bit (TSM_CTRL register) |
|---|---|---|---|
| Coarse Tune | pll_dig_en (indirect) | CTUNE_FAIL_FLAG | ABORT_ON_CTUNE |
| Freq. Target | freq_targ_ld_en | FREQ_TARG_FAIL_FLAG | ABORT_ON_FREQ_TARG |
| Cycle Slip | pll_cycle_slip_ld_en | CYCLE_SLIP_FAIL_FLAG | ABORT_ON_CYCLE_SLIP |

All "_FAIL_FLAG" flag bits all reside in the PLL_LOCK_DETECT register; All "ABORT_ON_" bits reside in the TSM_CTRL register.

In addition to the controls listed above associated with each unlock source, there are 2 controls to allow TSM aborting to be disabled based on sequence type (TX or RX), instead of unlock source. When TX_ABORT_DIS is set to 1, TX sequences cannot be aborted, regardless of the state of the "ABORT_ON_" bits or any unlock condition. Likewise, when RX_ABORT_DIS is set to 1, RX sequences cannot be aborted, regardless of the state of the "ABORT_ON_" bits or any unlock condition. The TX_ABORT_DIS and RX_ABORT_DIS bits reside in the TSM_CTRL register. The TX_ABORT_DIS and RX_ABORT_DIS bits have no effect on the setting of the "_FAIL_FLAG" bits on any unlock condition; the TX_ABORT_DIS and RX_ABORT_DIS only affect aborting.

### 64.3.5.2.9 Special Handling for 802.15.4

Any of the 3 unlock detect mechanisms can be used to abort a 802.15.4 autosequence. However the method for aborting a 802.15.4 autosequence is different than a non-802.15.4 abort. For 802.15.4, the unlock condition does not abort the sequence directly. There is a higher-level 802.15.4 Sequence Manager (ZSM), which handles unlock aborts. For 802.15.4, the unlock condition is blocked from aborting the TSM as shown in the following diagram

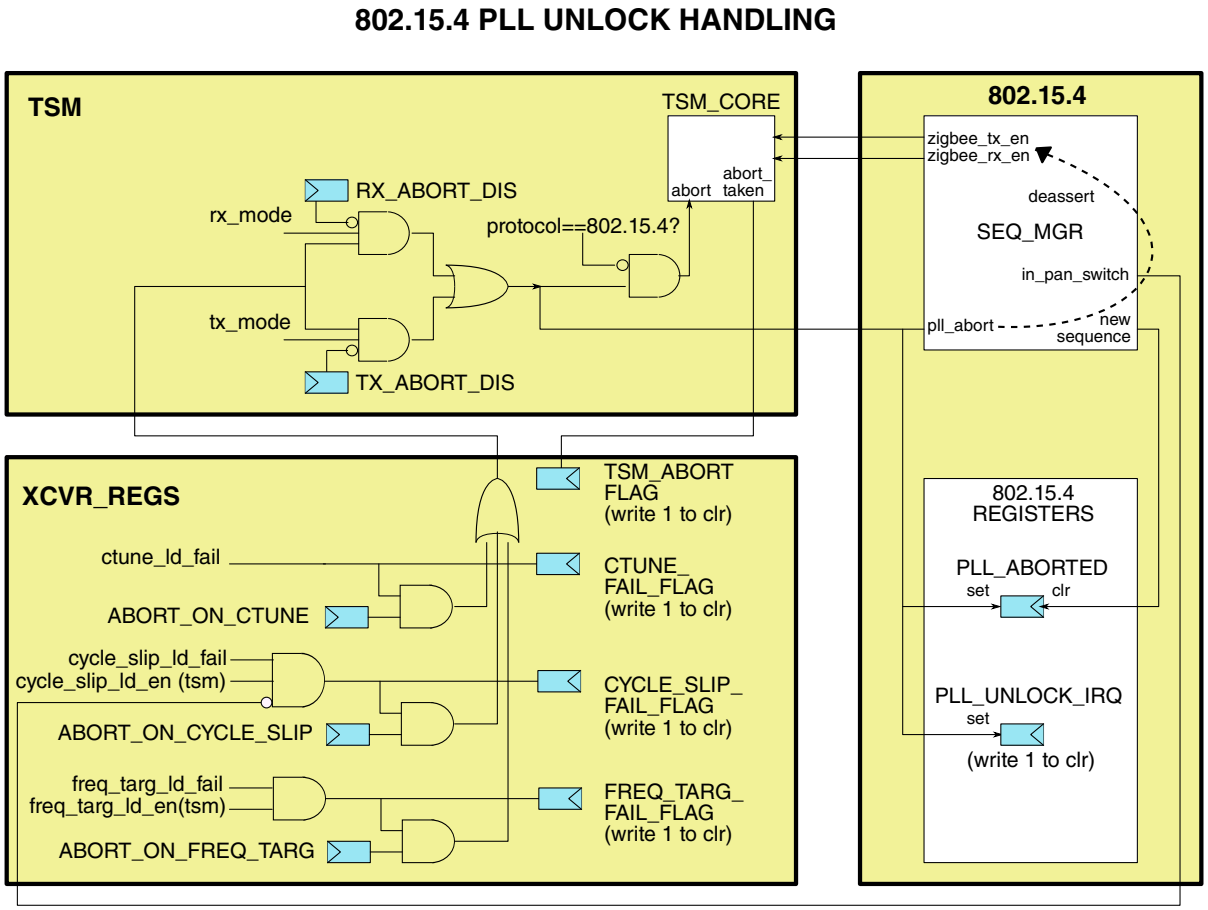

**Figure 64-64. 802.15.4 PLL UNLOCK HANDLING**

The combined-abort signal is blocked from reaching the TSM, and instead is routed to the ZSM. This is due to the fact that the ZSM already includes abort-handling logic, which is being re-used from previous NXP 802.15.4 transceivers. Keeping the unlock handling intact, facilitates the porting of software from one NXP 802.15.4 product to the next.

For 802.15.4, the logic which determines which ZSM states allow aborting, is designed into the ZSM state machine. Not all states require an abort-on-unlock. When an unlock event occurs during a ZSM state that requires an abort, the ZSM will deassert its initiating signal to TSM (zigbee_tx_en or zigbee_rx_en), which results in a de facto abort, similar to a TSM-generated abort. For a ZSM abort, the PLL_UNLOCK_IRQ bit will become set, as will the PLL_ABORTED bit. The PLL_UNLOCK_IRQ bit is of type write-1-to-clear, and resides in the IRQSTS1 register of 802.15.4 space. The PLL_ABORTED bit is a read-only bit, and resides in the ABORT_STS register of 802.15.4 space; it will self-clear at the start of the next autosequence.

For 802.15.4, the TX_ABORT_DIS and RX_ABORT_DIS control bits are still available, and allow/disallow aborting during the TX portions of any autosequence (TX_ABORT_DIS), or the RX portions of any autosequences (RX_ABORT_DIS). The

802.15.4 autosequences are concatenations of TX and RX operations, under the control of the ZSM. The ZSM engages the TSM when needed, to perform a TX or RX warmup or warmdown, by asserting or deasserting zigbee_tx_en or zigbee_rx_en.

See the 802.15.4 Chapter, Section Sequence Manager, sub-section ZSM/TSM Interaction.

As mentioned previously, for 802.15.4 the PLL_UNLOCK_IRQ will become set to indicate a PLL unlock event has caused an 802.15.4 autosequence to be aborted. When 802.15.4 is not in use, another bit is provided to indicate a non-802.15.4 unlock abort (a TSM abort) has occurred. This bit is TSM_ABORT_FLAG. This bit is of type write-1-to-clear, and resides in the PLL_LOCK_DETECT register of transceiver space. This bit will not be set for an 802.15.4 abort (use PLL_UNLOCK_FLAG or PLL_ABORTED instead).

#### 64.3.5.2.10 Special Handling for GENERIC_FSK

The GENERIC_FSK Link Layer Controller already has built-in handling for PLL unlock conditions, and an interrupt status bit to notify on such an event. The combined-abort signal is blocked from reaching the TSM, and instead is routed to the GENERIC_FSK Command Decoder. The Command Decoder state machine handles the unlock event by deasserting the TX or RX command signal to the TSM (e.g., generic_fsk_tx_en), causing a TSM warmdown to occur. The Generic controller will also set the PLL_UNLOCK_IRQ interrupt status bit in its address space. The diagram below shows the GENERIC_FSK Link Layer handling of the PLL unlock event.

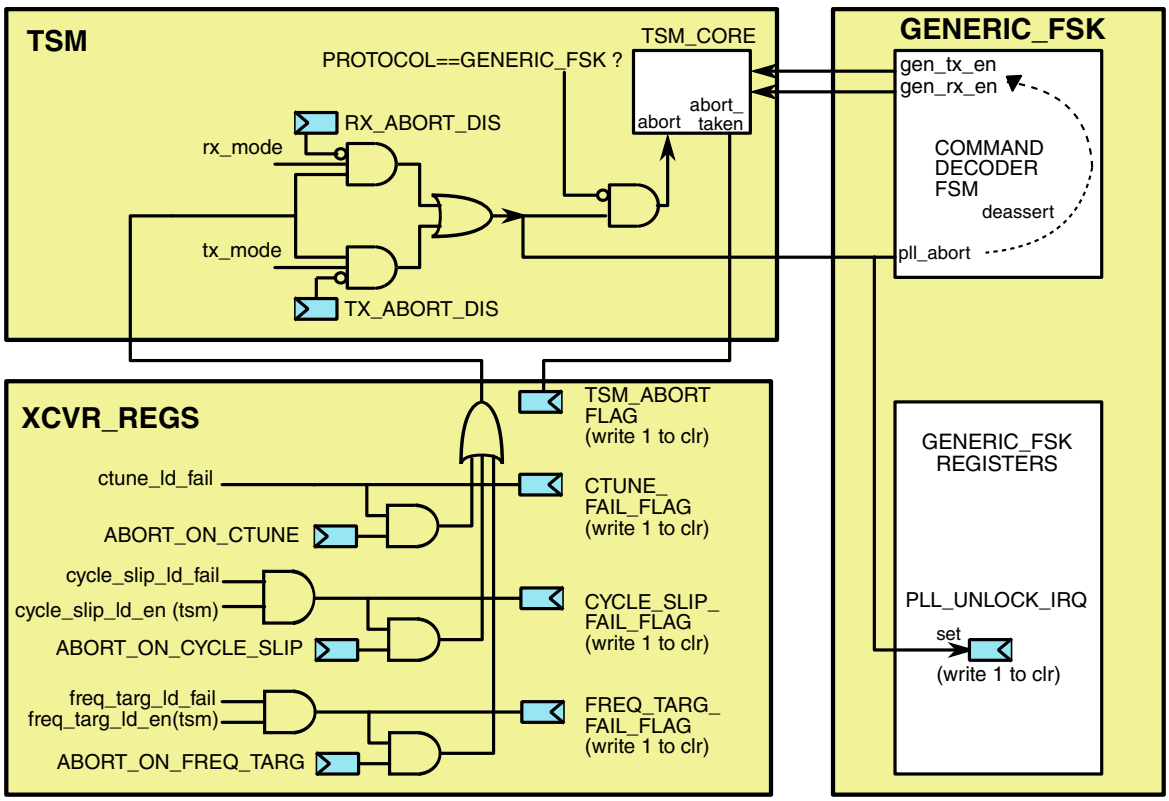

**Figure 64-65. GENERIC_FSK PLL UNLOCK HANDLING**

For GENERIC_FSK, the TX_ABORT_DIS and RX_ABORT_DIS control bits are still available, and selectively allow/disallow aborting during the TX sequences (TX_ABORT_DIS), or the RX sequences (RX_ABORT_DIS).

### 64.3.5.2.11 PA Target Power

The TSM controls the power level that is sent to the PA. Target power level is the power level that is used during packet transmission. Nominally, power level is constant over the course of the packet.

During a packet transmission sequence, prior to the start of preamble, while the PA is being turned on, power level must be ramped up gradually, to prevent unwanted spectral effects. After the packet is complete, and the PA is being turned off, power level must be ramped down slowly for the same reason.

The TSM controls power level to the PA during these 3 phases, as shown below:

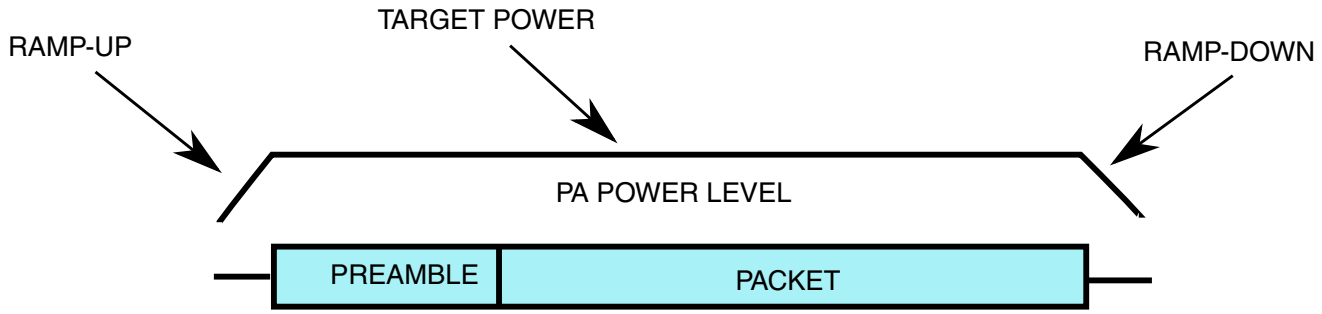

**Figure 64-66. PA Target Power**

Target power, the steady-state power level that is used to transmit the packet, can be selected from one of the following sources:

1. PA_POWER[5:0] register in XCVR address space
2. BTLE Link Layer (2 distinct power levels supported, for Advertising- and Data-channel Packets)
3. 802.15.4 Link Layer (PA_PWR[5:0] register in 802.15.4 address space)
4. GENERIC_FSK Link Layer (TX_POWER[5:0] register in GENERIC_FSK address space)

The following diagram depicts target power selection.

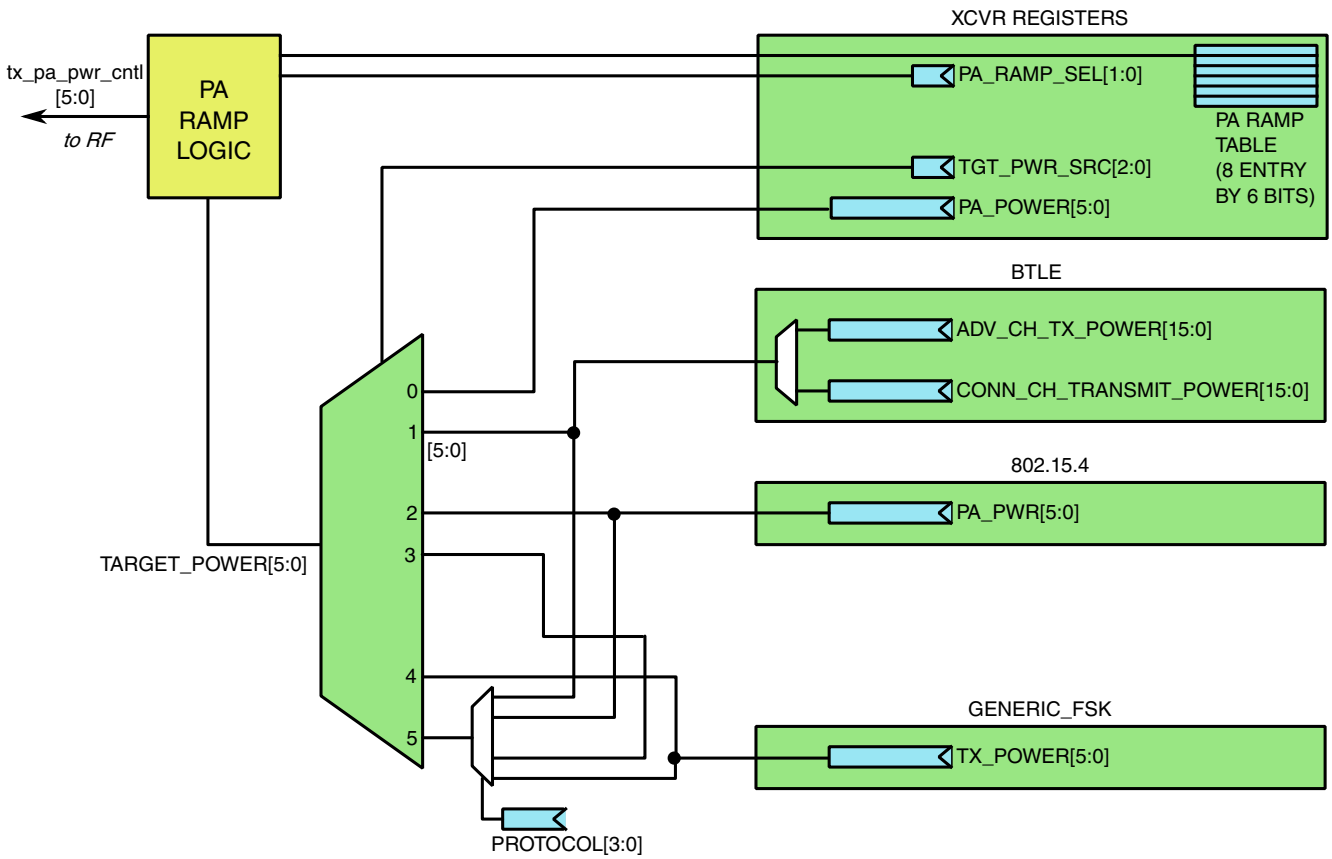

**Figure 64-67. PA Target Power Selection**

The XCVR register TGT_PWR_SRC[2:0], controls target power selection, according to the following table.

| TGT_PWR_SRC[2:0] | TARGET POWER SOURCE |
|---|---|
| 000 | PA_POWER[5:0] register (XCVR space) |
| 001 | BTLE Link Layer |
| 010 | 802.15.4 Link Layer (PA_PWR[5:0] register in 802.15.4 space) |
| 011 | Reserved |
| 100 | GENERIC_FSK Link Layer (TX_POWER[5:0] register in GENERIC space) |
| 101 | Reserved |
| 110 | Reserved |
| 111 | PROTOCOL[3:0] bits select target power source |

These bits reside in the XCVR_CTRL register in XCVR address space.

See Section “BTLE Radio Operation” for a description of how the BTLE Link Layer controls target power.

The TSM provides power control information to the PA as a 6-bit output: tx_pa_pwr_ctrl[5:0].

### 64.3.5.2.12 PA Ramping

PA ramping is included in the TSM, to prevent abrupt transitions in PA (power amplifier) power, that could cause unwanted spectral transients. During a TX sequence, PA ramping gradually ramps up PA power, between a programmable minimum, and the TX target power. The trajectory of the ramp is programmable, and ramping takes place over the course of 1, 2, or 4µs (programmable).

During a TX sequence, PA ramping, if enabled, is triggered by a low-to-high transition on the TSM output **tx_pa_en**, which is also the enable for the PA (tx buffer). At assertion of **tx_pa_en** during the TX sequence with ramping enabled, the TSM will enable the PA, with a minimum power level determined by the register PA_RAMP0[5:0]. After that, power level will increment according to a 16-deep pre-programmed register table (PA_RAMP Table). Incrementing will occur at a programmable rate. At each ramp step, PA power level will be taken from the next entry in the PA_RAMP Table, from 0-15. After the 16th and final ramp step, PA power level will be the selected target power. The target power will remain in effect for the duration of the packet transmission, i.e., the "ON" phase of the TSM seqeuence.

The ramp trajectory is determined by the contents of the PA_RAMP Table. The PA_RAMP table contains register fields PA_RAMP0[5:0] … PA_RAMP15[5:0]. These register fields can be found in the PA_RAMP_TBL0, PA_RAMP_TBL1, PA_RAMP_TBL2, and PA_RAMP_TBL3 registers in XCVR address space. The default contents of the PA_RAMP table are as shown:

| PA_RAMP Table Entry | POWER CONTROL VALUE (DEFAULT) |
|---|---|
| PA_RAMP0[5:0] | 0x01 |
| PA_RAMP1[5:0] | 0x02 |
| PA_RAMP2[5:0] | 0x04 |
| PA_RAMP3[5:0] | 0x06 |
| PA_RAMP4[5:0] | 0x08 |
| PA_RAMP5[5:0] | 0x0C |
| PA_RAMP6[5:0] | 0x10 |
| PA_RAMP7[5:0] | 0x14 |
| PA_RAMP8[5:0] | 0x18 |
| PA_RAMP9[5:0] | 0x1C |
| PA_RAMP10[5:0] | 0x22 |
| PA_RAMP11[5:0] | 0x28 |

*Table continues on the next page...*

| PA_RAMP Table Entry | POWER CONTROL VALUE (DEFAULT) |
|---|---|
| PA_RAMP12[5:0] | 0x2C |
| PA_RAMP13[5:0] | 0x30 |
| PA_RAMP14[5:0] | 0x36 |
| PA_RAMP15[5:0] | 0x3C |

At each step of the ramp-up, the selected entry of the PA_RAMP Table is compared against target_power. The lesser of the two becomes the output power for that ramp step. This allows the same PA_RAMP table to be used for various target_power levels, without re-programming the table.

The ramp rate is controlled by the PA_RAMP_SEL[1:0] field of the TSM_CTRL register in XCVR address space. For each setting, the table below describes the total ramp duration, and the duration of each ramp step.

| PA_RAMP_SEL[1:0] | TOTAL RAMP DURATION (32MHZ) | DURATION PER RAMP STEP (32MHZ) | TOTAL RAMP DURATION (26MHZ) | DURATION PER RAMP STEP (26MHZ) |
|---|---|---|---|---|
| 00 | No ramp | No ramp | No ramp | No ramp |
| 01 | 1.0µs | 2 Reference Clocks (0.0625µs) | 1.23µs | 2 Reference Clocks (0.077µs) |
| 10 | 2.0µs | 4 Reference Clocks (0.125µs) | 2.46µs | 4 Reference Clocks (0.154µs) |
| 11 | 4.0µs | 8 Reference Clocks (0.25µs) | 4.92µs | 8 Reference Clocks (0.308µs) |

When PA_RAMP_SEL[1:0] is set to 0, there is no ramping, and tx_pwr_ctrl[5:0] tracks the selected Target Power at all times (see Section PA Target Power).

When PA_RAMP_SEL[1:0] is set to 1, a 1µs ramp is generated, as shown:

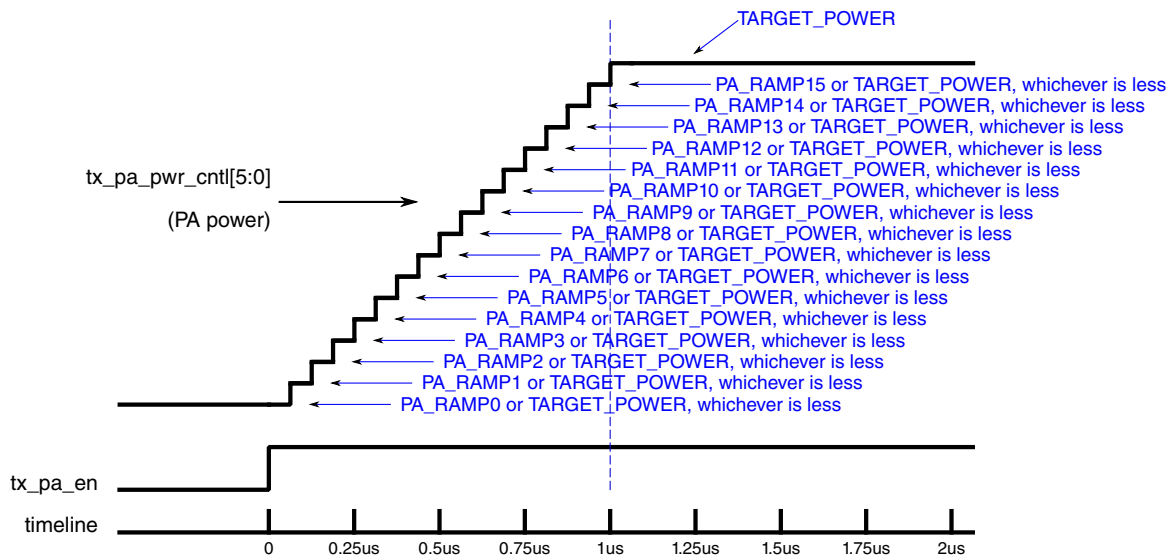

**Figure 64-68. 1µS PA RAMP UP (32MHZ TIMING)**

When PA_RAMP_SEL[1:0] is set to 2, a 2µs ramp is generated, as shown:

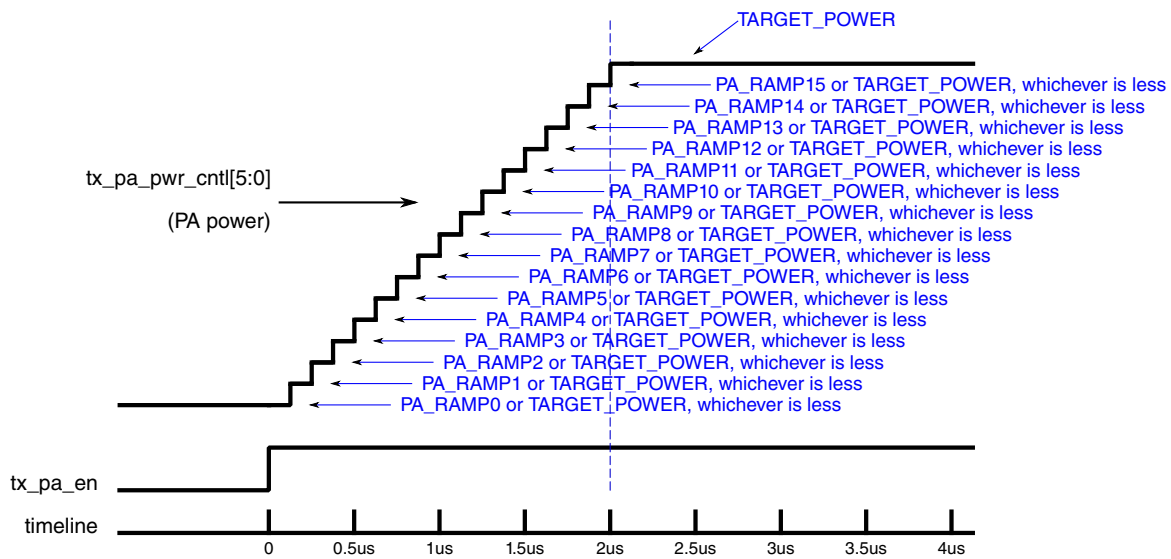

**Figure 64-69. 2µS PA RAMP UP (32MHZ TIMING)**

When PA_RAMP_SEL[1:0] is set to 3, a 4µs ramp is generated, as shown:

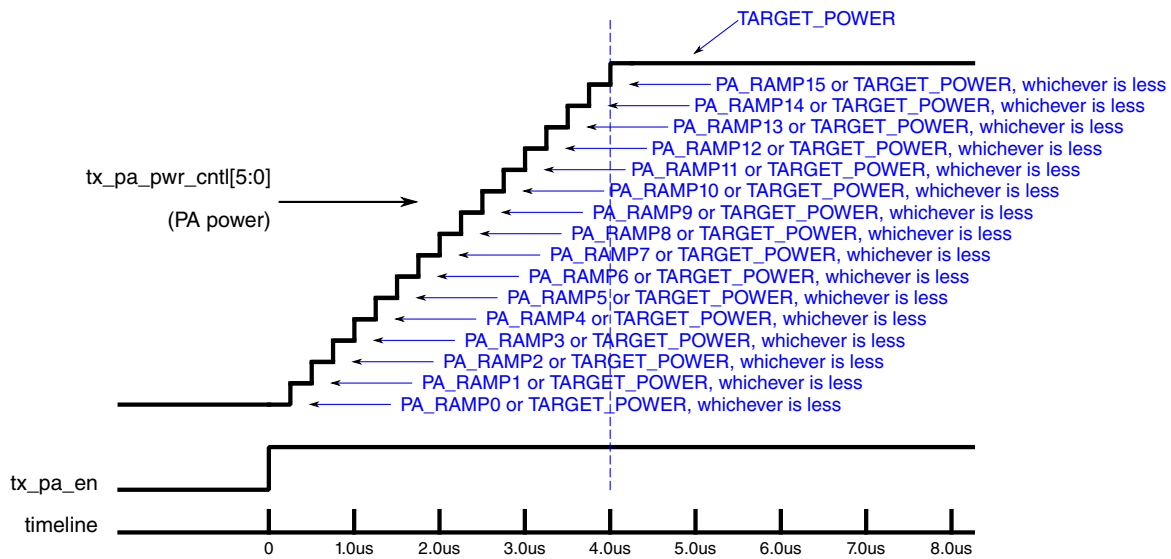

**Figure 64-70. 4µS PA RAMP UP (32MHZ TIMING)**

PA ramp-down is the mirror image of ramp-up. Ramp-down is triggered by the deassertion of the sequence-initiating event (e.g., btle_tx_en, zigbee_tx_en, or force_tx_en). At deassertion of the initiating event, output power will continue to hold at target_power for a programmable duration, controlled by the register TSM_CTRL[RAMP_DN_DLY]. This 4-bit register accommodates filter, and other, delay in the TX path before beginning the ramp down. RAMP_DN_DLY[3:0] is in units of µs. The default for RAMP_DN_DLY is 4. The effect of RAMP_DN_DLY, can be viewed as extending the "ON" phase of the TSM by a programmable number of microseconds. After RAMP_DN_DELAY expires, output power will step through the PA_RAMP Table in reverse order, starting at PA_RAMP15, and ending at PA_RAMP0. At each step of the ramp-down, the selected entry of the PA_RAMP Table is compared against target_power. The lesser of the two becomes the output power. The PA_RAMP_SEL[1:0] register controls the ramp-down rate in the same manner that it controls the ramp-up rate. After the last step of the ramp-down (PA_RAMP0 level), **tx_pa_en** deasserts to disable the PA.

The following diagram shows an example of PA ramp down. In this example, PA_RAMP_SEL=2 (2µs), and RAMP_DN_DLY=3 (3µs):

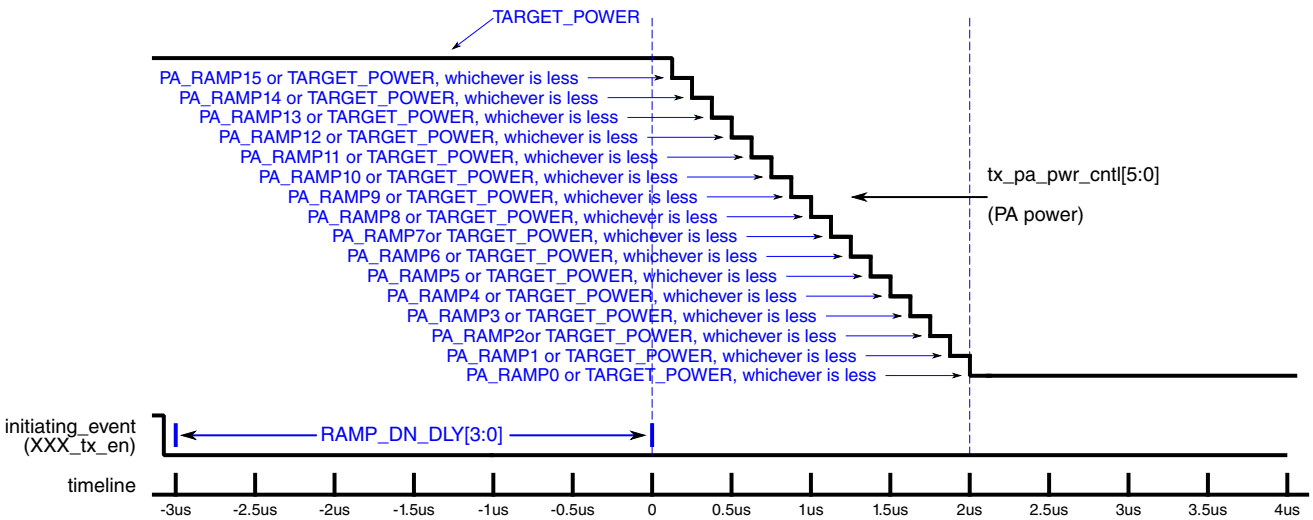

**Figure 64-71. PA RAMP DOWN (32MHZ TIMING)**

### 64.3.5.2.13 Fast Antenna Diversity (FAD)

#### FAD INTRODUCTION

The Fast Antenna Diversity (FAD) mode, when enabled, will allow the optimal choice between two antennae to be selected during the preamble search. The 2.4GHz Gen3 radio provides 2 alternatives for FAD:

1. FAD for 802.15.4
2. FAD for FSK

The 2 FAD options are described in the sections that follow.

#### 1. FAD for 802.15.4

See Chapter *Multi-standard PHY*, Section *FAD process in IEEE 802.15.4* for a full description of this FAD option.

The output of the 802.15.4 FAD algorithm, is a 1-bit signal, antx_out_zig, which indicates the selected antenna. This output is provided to the FAD Common Pin Interface logic.

#### 2. FAD for FSK

See Chapter *Multi-standard PHY*, Section *FAD process in FSK* for a full description of this FAD option.

The output of the FSK FAD algorithm, is a 1-bit signal, antx_out_fsk, which indicates the selected antenna. This output is provided to the FAD Common Pin Interface logic.

## FAD COMMON PIN INTERFACE

The FAD Common Pin Interface consists of 4 pins: ANT_A, ANT_B, TX_SWITCH, and RX_SWITCH. All pins are outputs from the device. The switch outputs convey timing information to the external module directly interfacing to the antennae, and they also can be used to control an external LNA or PA, via use of a Front End Module, or FEM. The FAD Common Pin Interface offers multiple configurations that allow for a wide range of FEM control schemes. Each of the 4 FAD-related outputs can be configured to be in FAD or TSM mode; in FAD mode, ANT_A and ANT_B are controlled by the selected FAD algorithm through signal antx_out_zig (802.15.4) or antx_out_fsk (FSK); in TSM mode, ANT_A and ANT_B are pure timing outputs with programmable timing configurable in the TSM. The 4-bit register FAD_CTRL[FAD_NOT_GPIO] determines whether each FAD-related output is in FAD or TSM mode:

**NOTE**

When FAD is enabled (FAD_EN=1), programming of the appropriate TSM_TIMING registers for TX_SWITCH and RX_SWITCH is *mandatory*, regardless of which FAD-pin Control Mode is selected, and even if the TX_SWITCH and RX_SWITCH pins are not used by the external module.

In FAD mode (FAD_NOT_GPIO[0]=1), ANT_A is controlled by the FAD algorithm, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In FAD mode (FAD_NOT_GPIO[1]=1), ANT_B is controlled by the FAD algorithm, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In FAD mode (FAD_NOT_GPIO[2]=1), TX_SWITCH output is derived from TSM output **gpio2_trig_en**, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}. Program TSM_TIMING49 register to obtain the desired timing on the TX_SWITCH pin.

In FAD mode (FAD_NOT_GPIO[3]=1), RX_SWITCH output is derived from TSM output **gpio3_trig_en**, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}. Program TSM_TIMING50 register to obtain the desired timing on the RX_SWITCH pin.

In TSM mode, ANT_A and ANT_B become pure TSM timing-controlled outputs, similar to TX_SWITCH and RX_SWITCH, and with independently-controlled timing and capable of providing signalling in TX mode, RX mode, or both; for pins in TSM mode, the ANTX_CTRLMODE, ANTX_EN, and ANTX_POL register settings have no effect.

In TSM mode (FAD_NOT_GPIO[0]=0), ANT_A output is a pure timing signal, derived from TSM output **gpio0_trig_en**. Thus, program TSM_TIMING47 register to obtain the desired timing on the ANT_A pin.

In TSM mode (FAD_NOT_GPIO[1]=0), ANT_B output is a pure timing signal, derived from TSM output **gpio1_trig_en**. Thus, program TSM_TIMING48 register to obtain the desired timing on the ANT_B pin.

In TSM mode (FAD_NOT_GPIO[2]=0), TX_SWITCH output is derived from TSM output **gpio2_trig_en**. Program TSM_TIMING49 register to obtain the desired timing on the TX_SWITCH pin.

In TSM mode (FAD_NOT_GPIO[3]=0), RX_SWITCH output is derived from TSM output **gpio3_trig_en**. Program TSM_TIMING50 register to obtain the desired timing on the RX_SWITCH pin.

The control register XCVR_CTRL[DEMOD_SEL] determines which FAD algorithm drives the FAD Common Pin Interface: 0b10 = 802.15.4 FAD, 0b01 = FSK FAD.

The state of the antenna selection can be ascertained at any time by reading the FAD_CTRL[ANTX] bit: 0 = ANT_A, 1 = ANT_B.

Antenna selection can be placed under direct software control: Setting the FAD_CTRL[ANTX_OVRD_EN]=1 allows FAD_CTRL[ANTX_OVRD] to substitute for the algorithm-driven antenna selection; in this case, ANTX_OVRD=0 asserts ANT_A, and ANTX_OVRD=1 asserts ANT_B. Note that the algorithm-driven state of the antenna is not lost while ANTX_OVRD_EN=1. The override is temporary, for as long as the override enable is set, and control over antenna state reverts to the selected FAD algorithm (antx_out_zig or antx_out_fsk) when ANTX_OVRD_EN is cleared to 0. The FAD_CTRL register resides in XCVR space.

The following diagram illustrates the FAD pinout, register controls, and FAD/TSM-mode multiplexing.

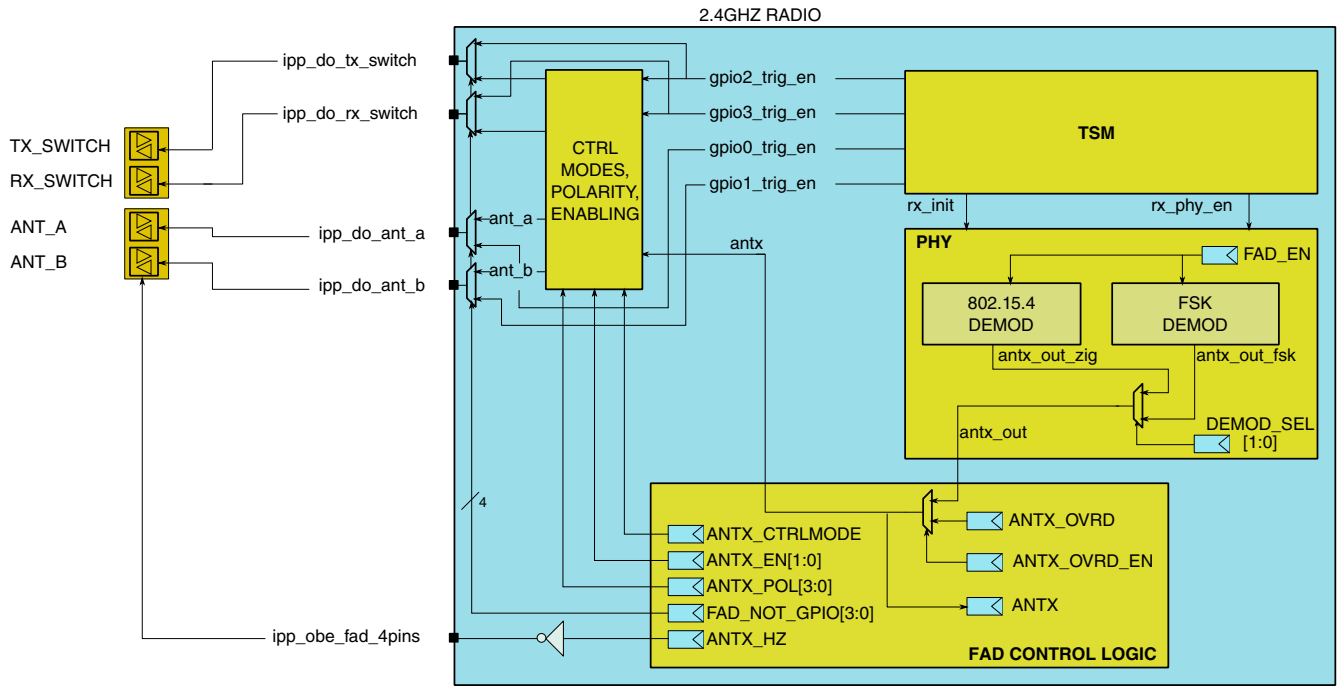

**Figure 64-72. FAD Common Pin Interface**

## FAD REGISTERS

The following table describes the programmable registers which control FAD:

**Table 64-37. FAD Registers**

| Field | R/W | Description |
|---|---|---|
| ANTX_CTRLMODE | rw | **FAD control mode-** selects the single or dual mode<br>**0 : single mode.**<br>ANT_A = antx_out<br>TXSWITCH = gpio2_trig_en<br>RXSWITCH= (gpio2_trig_en OR gpio3_trig_en)<br>**1:dual mode:**<br>ANTA = antx_out AND (gpio2_trig_en OR gpio3_trig_en)<br>ANTB = NOT(antx_out) AND (gpio2_trig_en OR gpio3_trig_en)<br>TX_SWITCH = gpio2_trig_en<br>RX_SWITCH = gpio3_trig_en |
| ANTX_EN[1:0] | rw | **FAD Pin Enable-**<br>00: all disabled<br>01:only RX_SWITCH/TX_SWITCH enabled |

*Table continues on the next page...*

## Table 64-37. FAD Registers (continued)

| Field | R/W | Description |
|---|---|---|
| | | 10:only ANT_A/ANT_B enabled<br><br>11: all enabled |
| ANTX_POL[3:0] | rw | **Antenna controls mode-** Control the polarity of the FAD pins:<br><br>ANTX_pol<0>=1 : invert the ANT_A output<br><br>ANTX_pol<1>=1 : invert the ANT_B output<br><br>ANTX_pol<2>=1 : invert the TX_SWITCH output<br><br>ANTX_pol<3>=1 : invert the RX_SWITCH output |
| ANTX_HZ | rw | **FAD controls high impedance**- Set ANTA,ANTB,RXSWITCH and TXSWITCH in high impedance |
| FAD_NOT_GPIO[3:0] | rw | **xxx1**: The ANT_A pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL}<br><br>**xxx0**: The ANT_A pad is controlled directly by the TSM output gpio0_trig_en<br><br>**xx1x**: The ANT_B pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL}<br><br>**xx0x**: The ANT_B pad is controlled directly by the TSM output gpio1_trig_en<br><br>**x1xx**: The TX_SWITCH pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL}<br><br>**x0xx**: The TX_SWITCH pad is controlled directly by the TSM output gpio2_trig_en<br><br>**1xxx**: The RX_SWITCH pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL}<br><br>**0xxx**: The RX_SWITCH pad is controlled directly by the TSM output gpio3_trig_en |
| ANTX | ro | **Antenna Selection State-**<br><br>This read-only register reflects the current state of the antenna selection: 0 = ANT_A, 1 = ANT_B. |
| DEMOD_SEL[1:0] | rw | **These bits select the demodulator used during reception. Also select which FAD engine is used to select the antenna-**<br><br>• 0b00: No demodulator selected<br>• 0b01: Use NXP Constant Envelope demodulator, and the FSK FAD engine<br>• 0b10: Use Legacy 802.15.4 demodulator, and the 802.15.4 FAD engine<br>• 0b11: Reserved |
| ANTX_OVRD_EN | rw | **FAD ANTX Override Enable-** |

*Table continues on the next page...*

**Table 64-37. FAD Registers (continued)**

| Field | R/W | Description |
|---|---|---|
| | | • 0: Selected FAD engine controls the antenna selection (mission mode)<br>• 1: ANTX_OVRD controls the antenna selection. 0 = ANT_A, 1 = ANT_B. |
| ANTX_OVRD | rw | **FAD ANTX Override -**<br>This bit is activated when ANTX_OVRD_EN=1, as per the following:<br>• 0: ANT_A is selected (software control)<br>• 1: ANT_B is selected (software control) |

**Note:** All register bits and fields listed in the table above, reside in the FAD_CTRL register, except FAD_THR, which resides in a register of the same name. Both FAD_CTRL and FAD_THR registers reside in XCVR address space.

## FRONT END MODULE

In 2.4GHz systems, the Radio Frequency (RF) Front-End Module is one of the most critical parts. Acting as an interface between the antenna and RF transceiver, the RF front-end module, or FEM, includes sensitive components such as an antenna Low Noise Amplifier (LNA) , power amplifiers (PA), antenna tuning switches, and a power management unit.

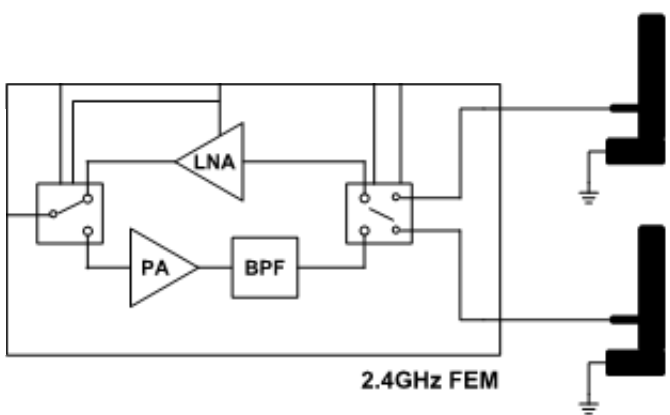

**Figure 64-73. FEM Block Diagram**

To accommodate multiple FEM interfaces and control schemes, Fast Antenna Diversity incorporates 2 Antenna Pin Control Modes, which are governed by the register control bit ANTX_CTRLMODE

Some FEM devices use a single input pin to switch the antenna selection. This is called single-mode operation. Operate Fast Antenna Diversity in this mode by programming ANTX_CTRLMODE=0. A timing diagram of single-mode operation is shown below (note: FAD output ANT_B is not used). In this example, one packet is received on Antenna A, followed by another packet received on Antenna B. Both packets require an auto-Acknowledge packet to be transmitted immmediately following reception.

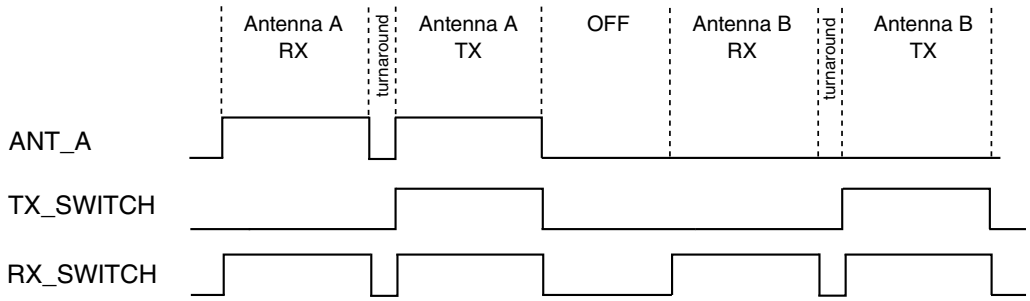

**Figure 64-74. FAD Single Mode Timing**

An example FEM Interface diagram, with FAD operated in single mode, is shown below.

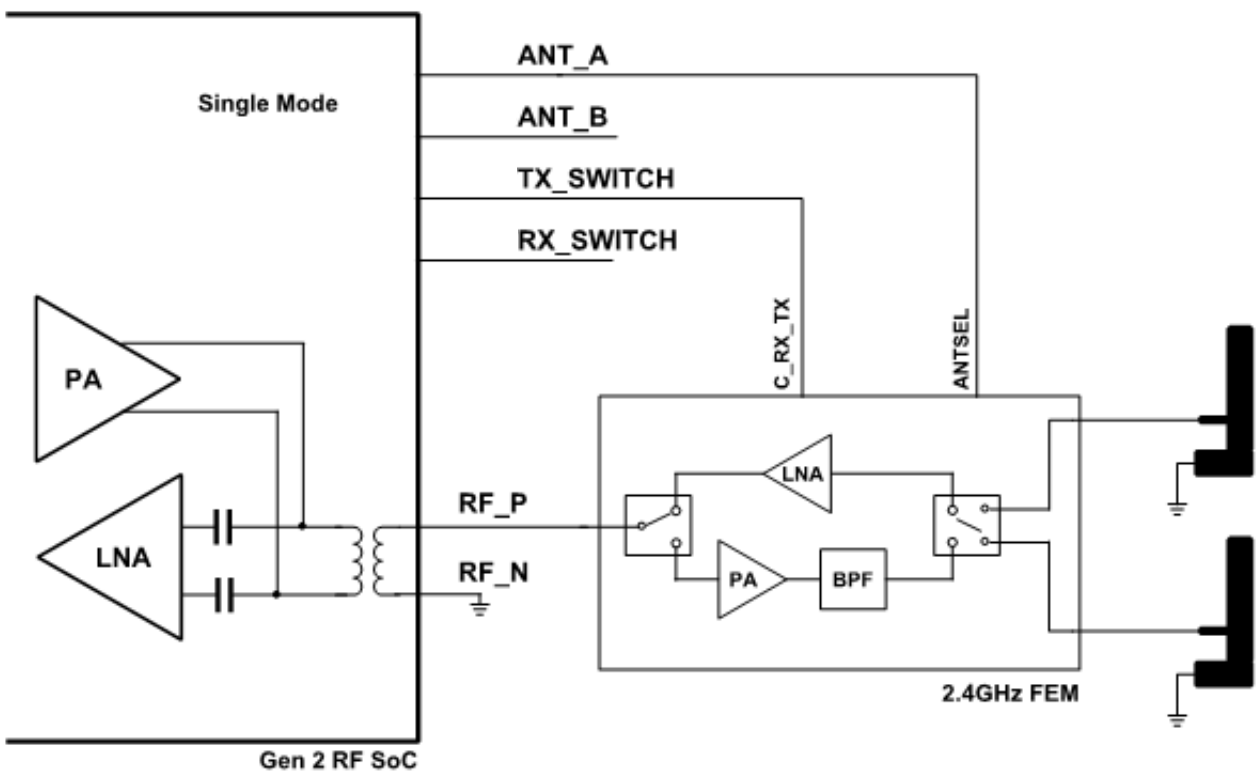

**Figure 64-75. FEM Interface Single Mode**

Other FEM devices use 2 input pins to switch the antenna selection. This is called dual-mode operation. Operate Fast Antenna Diversity in this mode by programming ANTX_CTRLMODE=1. A timing diagram of dual-mode operation is shown below. In this example, one packet is received on Antenna A, followed by another packet received on Antenna B. Both packets require an auto-Acknowledge packet to be transmitted immmediately following reception.

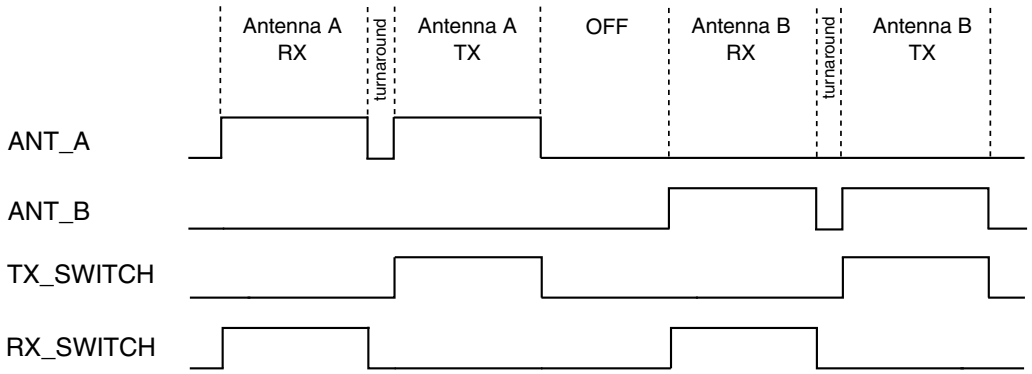

**Figure 64-76. FAD Dual Mode Timing**

An example FEM Interface diagram, with FAD operated in dual mode, is shown below.

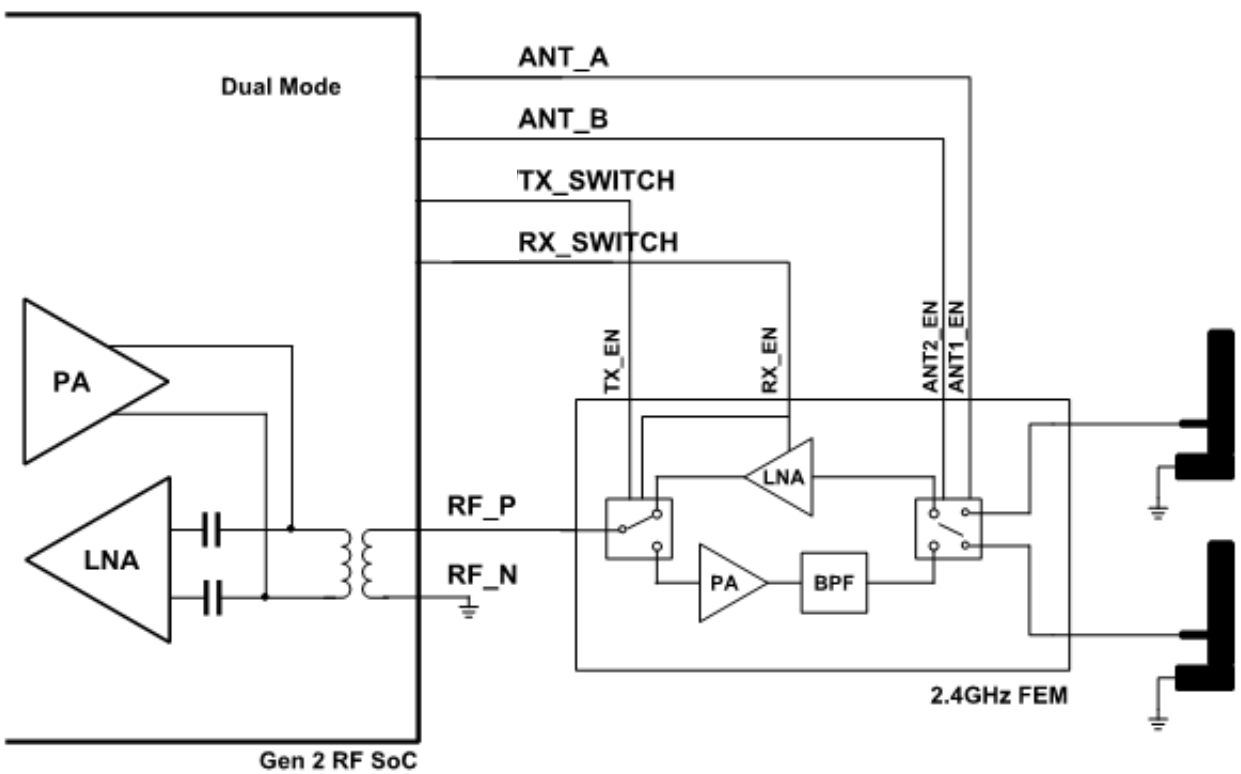

**Figure 64-77. FEM Interface Dual Mode**

Other FEM use cases, include external PA only, external LNA only, or external PA plus LNA. In such cases, ANT_A and ANT_B are not required, FAD can be disabled, and TX_SWITCH and RX_SWITCH pins can be operated in TSM mode (pure timing signals). This is called Single Antenna configuration. An example FEM interface diagram illustrating such a use case, is shown below.

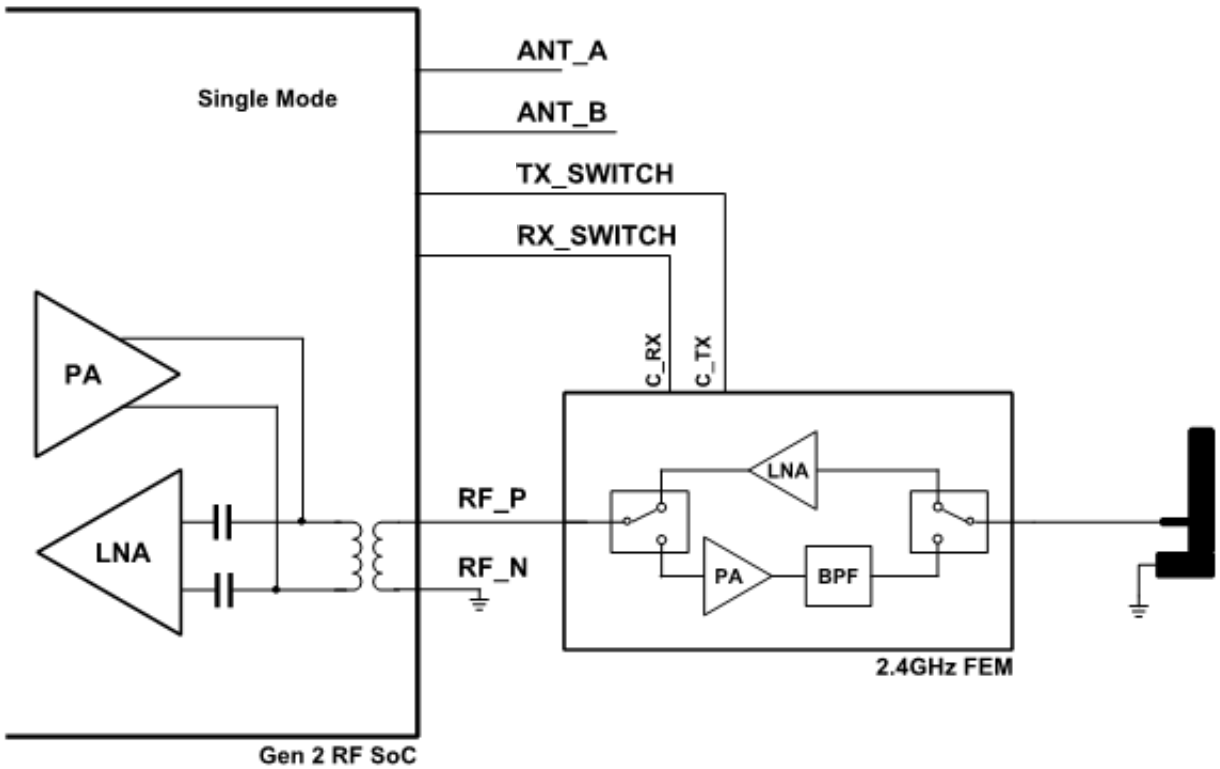

**Figure 64-78. FEM Interface Single Antenna Configuration**

### 64.3.5.2.14 Low Power Preamble Search (LPPS)

To reduce power consumption during 802.15.4 preamble-search receive state, a low-power-preamble-search (LPPS) mode can be optionally enabled. When engaged, the correlators are disabled approximately 50% of the time during preamble search. The same signal used to dynamically enable/disable the correlators, can be used to enable/disable selected analog and RF blocks in tandem, to further reduce power consumption. The LPPS_CTRL register in XCVR space, has one bit to master-enable LPPS mode (LPPS_ENABLE), and several other bits to allow selected analog and RF blocks to be "duty-cycled" in sync with the correlators. For more details on the LPPS algorithm, see Chapter Multi-standard PHY, Section *IEEE Low-power Preamble Search*.

By default, LPPS mode is not enabled.

During LPPS mode, correlators and RF blocks are duty-cycled with timing controlled by the LPPS signal **lpps_lp_en**, which is a single-wire output from the 802.15.4 demodulator. In general, eligible blocks will be powered off when **lpps_lp_en** is high, and perform normal operation when **lpps_lp_en** is low. Transitions on **lpps_lp_en** will be handled by the TSM in the following ways:

**lpps_lp_en 1 → 0:**

1. TSM outputs which are programmed to be eligible for LPPS duty-cycling (e.g, those associated with TZA, BBA, ADC) shall be reasserted at this point.
2. TSM shall recycle to a programmable point in the RX warmup. The TSM RECYCLE_COUNT2[7:0] register selects the TSM_COUNT to recycle to.
3. After jumping to the TSM_COUNT indicated in RECYCLE_COUNT2, TSM shall from this point forward execute a Fast RX Warmup (see Section FAST TSM Warmup and FAST RX2TX Transition later in this chapter). For the Fast RX Warmup, the registers LPPS_START_RX[7:0] and LPPS_DEST_RX[7:0] shall be used to program the TSM "jump" start and end points, as defined in the Fast RX Warmup section. The LPPS_START_RX and LPPS_DEST_RX registers reside in the LPPS_CTRL register. These registers are specific to LPPS fast warmups, and do not apply to non-LPPS fast warmups.

**lpps_lp_en 0 → 1:**

1. TSM outputs which are programmed to be eligible for LPPS duty-cycling (e.g, those associated with TZA, BBA, ADC) shall be deasserted at this point.
2. TSM outputs which are not eligible for LPPS duty-cycling shall remain asserted.

Note that several LPPS timing parameters are configurable (see Chapter Multi-standard PHY, Section *IEEE Low-power Preamble Search*), and LPPS_FILL_COUNT[6:0] is based on the LPPS fast warmup time. Software configuring LPPS parameters, such as LPPS_FILL_COUNT, must calculate the LPPS fast warmup time, in µs, based on the register programming described in the section above. Here is the equation:

**LPPS_FAST_WARMUP_DURATION = END_OF_RX_WU - RECYCLE_COUNT2 + 1 - (LPPS_DEST_RX - LPPS_START_RX - 1)**

*for example,*

**LPPS_FAST_WARMUP_DURATION = 104 - 28 + 1 - ( 102 - 40 - 1)**

**LPPS_FAST_WARMUP_DURATION = 16µs**

Note that the penalty for the reduced power consumption in LPPS mode during preamble search, is a slight degradation in receiver sensitivity. Note also that the TSM override bits, also override LPPS functionality. The override bits provide ultimate control over all TSM outputs.

Programming control for LPPS, includes a master-enable register bit for the LPPS state-machine, as well as individual control bits to enable selected analog and digital blocks to be turned on-and-off during LPPS operation. The following table lists the LPPS register bits, and the TSM outputs controlled by each.

**Table 64-38. LPPS Register Controls**

| LPPS Register Bit | Description |
|---|---|
| LPPS_ENABLE | Master enable for LPPS mode. Allows correlators to be duty-cycled during Preamble Search, and selected analog and digital blocks to be duty-cycled simultaneously. |
| LPPS_TZA_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_lna_en, rx_tza_i_en, rx_tza_q_en |
| LPPS_BBA_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_bba_i_en, rx_bba_q_en |
| LPPS_ADC_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_adc_en, rx_adc_i_en, rx_adc_q_en |
| LPPS_DCOC_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_bba_dcoc_en, rx_tza_dcoc_en |
| LPPS_PDET_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_bba_pdet_en, rx_tza_pdet_en |
| LPPS_SY_LO_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: sy_lo_rx_en |
| LPPS_SY_LO_BUF_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: sy_lo_rx_buf_en |
| LPPS_RX_DIG_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_dig_en |
| LPPS_DCOC_DIG_ALLOW | When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: dcoc_en |

### 64.3.5.2.15 FAST TSM Warmup and FAST RX2TX Transition

The previous sections illustrate the detailed control and timing generated by the TSM, operating in nominal-timing mode. There are situations that allow for the possibility to streamline and shorten the TSM warmup sequences. These situations arise when the transceiver is operating on the same RF channel for many consecutive transmit and/or

receive operations. Multiple closely-spaced TX operations on the same channel allow the HPM calibration to be skipped, after such a calibration is performed once on a given RF channel; similarly, multiple closely spaced RX operations on the same channel allow DC offset calibration to be skipped, after such a calibration is performed once on a given RF channel.

Fast TSM warmups have been devised to accomplish this streamlining. There is one fast warmup defined for TX, and one for RX. Once engaged, during a fast warmup, a portion of the nominal, programmed warmup is bypassed, or skipped over, by instructing the TSM counter to jump, once it reaches a certain count, to a new count that is not just an increment-by-one. The starting point for the "jump" as well as the destination count, or end point for the "jump", are TSM programmable registers. There are one pair of start/ destination registers for TX, and another for RX, allowing one such jump per sequence. In addition, enables bits provide software with fine control over precisely when fast warmups are allowed, versus nominal warmups.

In addition, TSM sequences have in the past been discrete TX or RX operations, with a required software command to initiate the sequence, and a return-to-idle after the sequence is complete, before a new sequence-start command can be issued. For 802.15.4, it is highly desirable to be able to jump directly from the end of a CCA measurement (CCA = Clear Channel Assessment), which is essentially an RX operation, to a packet transmit operation, without returning the TSM to IDLE in between, if CCA deems the channel to be free. A new TSM transition called "Fast RX2TX" accomplishes this. The 802.15.4 Link Layer will signal to TSM when to perform such a transition, and TSM will respond by jumping from the RX "ON" phase, to a programmable point within the TX warmup. At the very least, this will allow the re-warmup of the required analog regulators to be skipped, since they can stay on during the transition. Also, since the PLL is staying on the same channel, there is no need to cycle the VCO off, and then on again, so the VCO-related TSM controls can be programmed to maintain their states during the transition. Enable bits provide software with fine control over precisely when a "Fast RX2TX" is allowed, versus a nominal RX-to-IDLE-to-TX ordering of events.

Under software management, Fast RX2TX can be combined with Fast TX Warmup to yield an ultrafast TX warmup sequence in this 802.15.4 scenario, if, as is likely, the RF channel has not changed since the previous TX warmup.

Interaction with other blocks is required to support TSM fast warmup capability. The PLL digital block is responsible for selecting the correct frequency for RF operations, and will keep track of whether consecutive warmup operations utilize the same channel or not; it will signal this information to the TSM. The PLL digital block will maintain such tracking separately for TX and RX warmups. The TSM will then signal back to the PLL digital block when a TX warmup is actually "fast" or not; the PLL digital block will use

this information to instruct its state machine to skip HPM calibration. For RX warmups, the TSM will signal to the RX digital block, when to skip DC calibration, and instead use stored values.

The new inter-block signaling to support fast TSM warmups is illustrated in the following diagram, followed by a table which describes the new signaling.

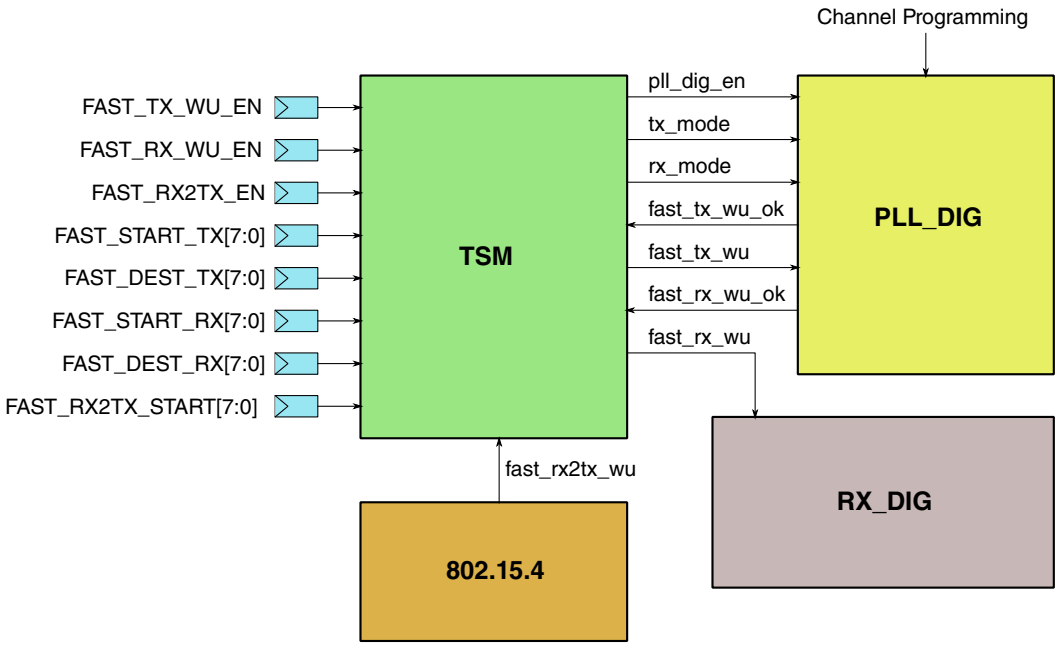

**Figure 64-79. XCVR SIGNALLING TO SUPPORT TSM FAST WARMUPS**

| "Fast Warmup" Signal | Source | Destination | Description |
|---|---|---|---|
| pll_dig_en | TSM | PLL Digital | Rising edge of this signal used by PLL_DIG to capture the Channel Programming for the current warmup |
| tx_mode | TSM | PLL Digital | Used in conjunction with pll_dig_en to capture the Channel Programming for TX sequences |
| rx_mode | TSM | PLL Digital | Used in conjunction with pll_dig_en to capture the Channel Programming for RX sequences |
| fast_tx_wu_ok | PLL Digital | TSM | Indicates that the Channel Programming on the *current* TX warmup has not changed since the *last* TX warmup |
| fast_tx_wu | TSM | PLL Digital | This is a fast TX warmup. PLL_DIG should skip HPM Cal. |

*Table continues on the next page...*

| "Fast Warmup" Signal | Source | Destination | Description |
|---|---|---|---|
| fast_rx_wu_ok | PLL Digital | TSM | Indicates that the Channel Programming on the *current* RX warmup has not changed since the *last* RX warmup |
| fast_rx_wu | TSM | RX Digital | This is a fast RX warmup. RX Dig should skip DCOC Cal. |
| fast_rx2tx_wu | ZSM (802.15.4) | TSM | ZSM has completed CCA and the RF channel is free to transmit. TSM should jump directly from RX "ON" phase to TX "WARMUP" phase, entering at the FAST_RX2TX_START point. |

TSM Registers to support Fast TSM Warmups and Fast RX2TX are described in the following table.

| Field | R/W | Description |
|---|---|---|
| FAST_TX_WU_EN | rw | 1: Enable Fast TX Warmup (if fast_tx_wu_ok asserted by PLL_DIG)<br>0: Disable Fast TX Warmups |
| FAST_RX_WU_EN | rw | 1: Enable Fast RX Warmup (if fast_rx_wu_ok asserted by PLL_DIG)<br>0: Disable Fast RX Warmups |
| FAST_RX2TX_EN | rw | 1: Enable Fast RX-to-TX transitions (if fast_rx2tx_wu is asserted by ZSM)<br>0: Disable Fast RX-to-TX transitions |
| FAST_START_TX[7:0] | rw | During a Fast TX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_TX[7:0], thereby executing the jump. |
| FAST_DEST_TX[7:0] | rw | During a Fast TX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, FAST_START_TX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump.<br>Example:<br>FAST_START_TX = 10 |

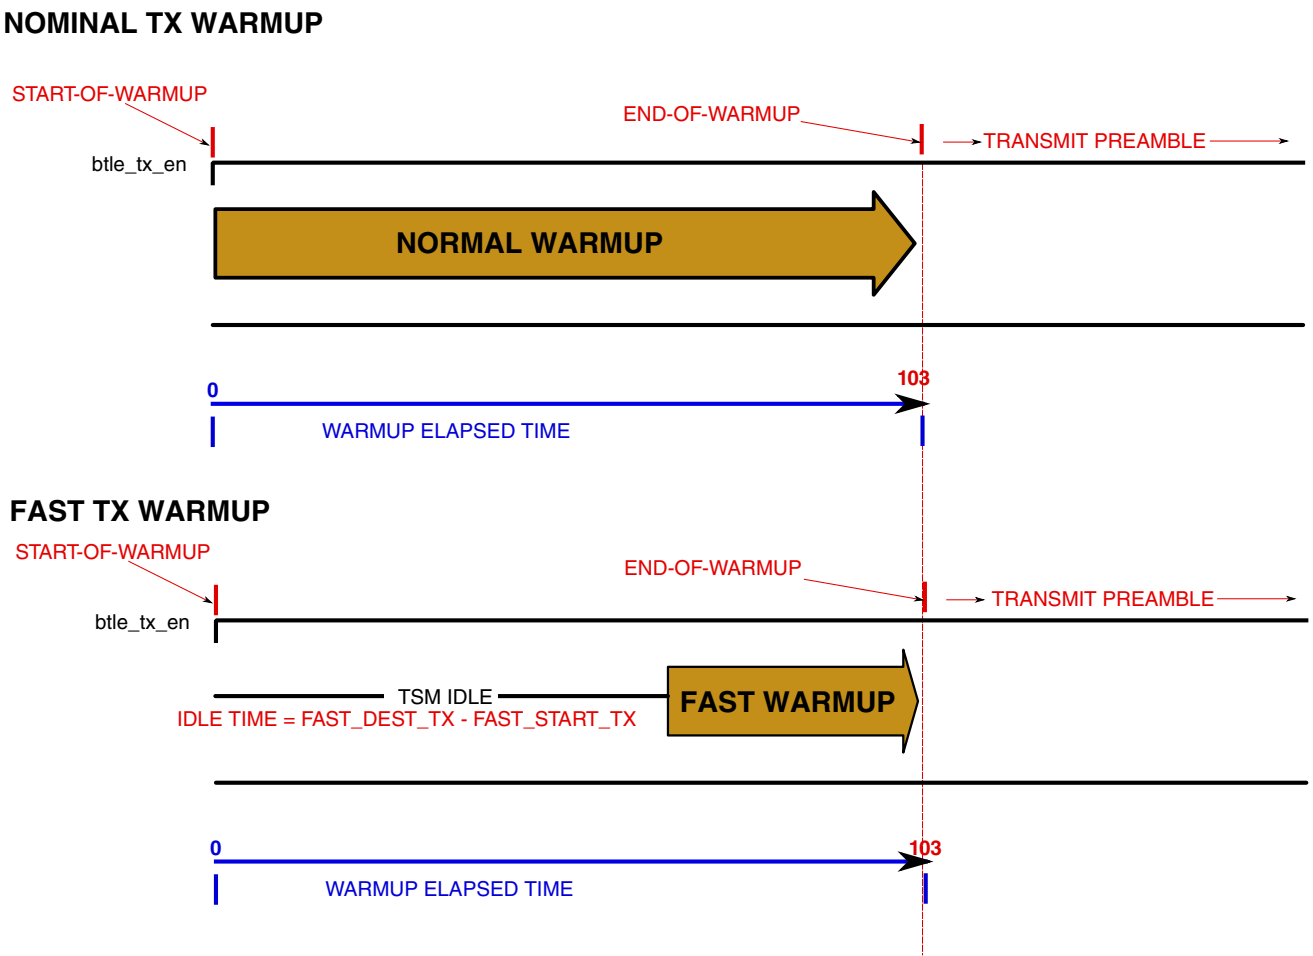
*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | FAST_DEST_TX = 15<br><br>The TSM will count as follows: … 7,8,9,15,16,17 … |
| FAST_START_RX[7:0] | rw | During a Fast RX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_RX[7:0], thereby executing the jump. |
| FAST_DEST_RX[7:0] | rw | During a Fast RX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, FAST_START_RX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump.<br><br>Example:<br><br>FAST_START_TX = 10<br>FAST_DEST_TX = 15<br><br>The TSM will count as follows: … 7,8,9,15,16,17 … |
| FAST_RX2TX_START[7:0] | rw | During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when ZSM asserts fast_rx2tx_wu.<br><br>The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count. |

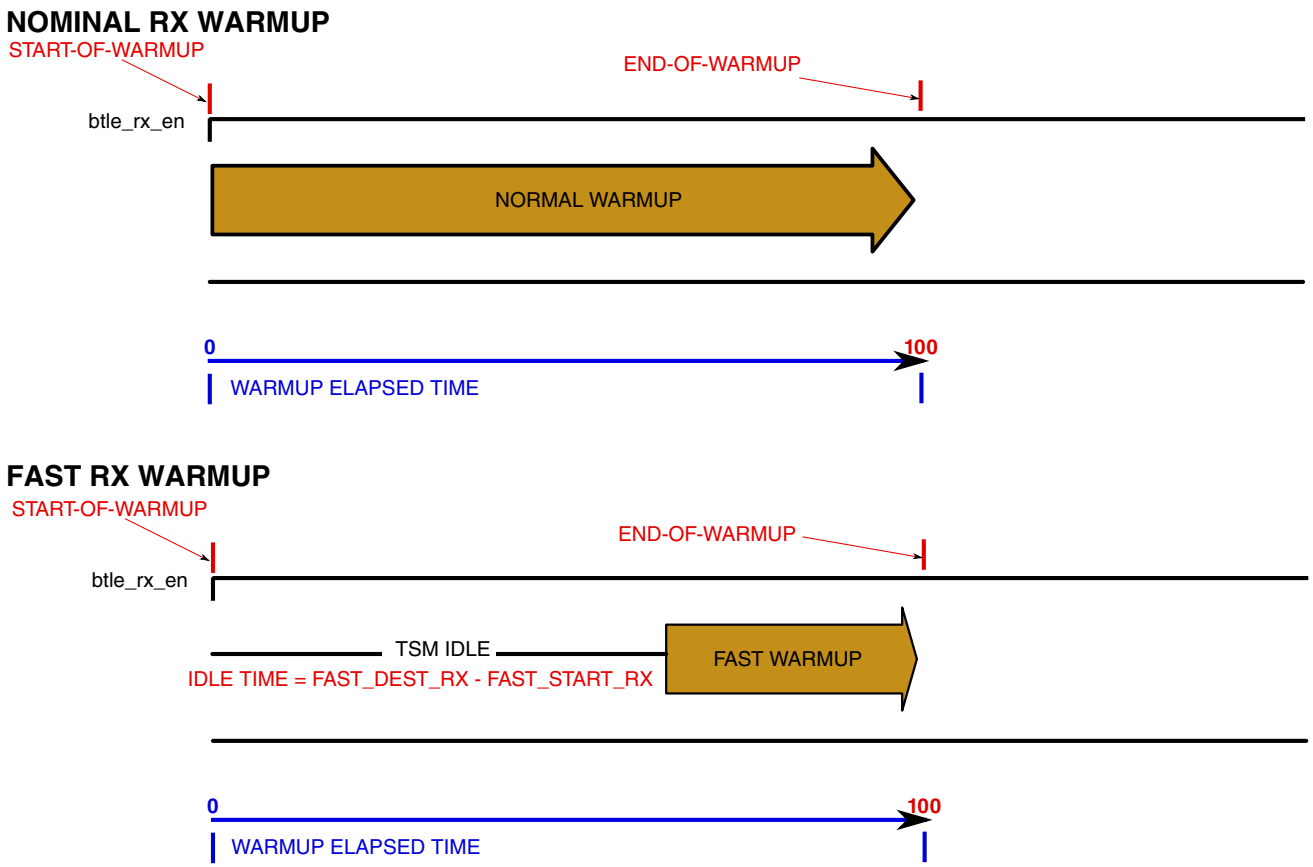
Software running on the various protocol engines which utilize the TSM to provide access to the channel, need not be aware that the total warmup time has been reduced, when the TSM executes a fast warmup, as opposed to a nominal warmup. Link Layer software expects TSM warmup times to be a fixed constant, actually 2 fixed constants, one for TX warmups and one for RX warmups. Software must account for these TX and RX warmup times when they are scheduling transceiver operations, so that the first symbol of preamble is transmitted at the correct instant for transmit operations, and that the receiver is ready to receive the first symbol of preamble at the correct instant for receive operations. Software views these warmup times as fixed lead times that must be accounted for in advance of a transceiver operation.

In order to make the fast warmup time reduction transparent to software, when a Fast TSM warmup is executed, the TSM will delay the start of the warmup, by the amount of time skipped by the jump. That keeps the total elapsed time, from the instant the software launches the TSM sequence, to the point at which the warmup completes, identical for fast and nominal warmups.

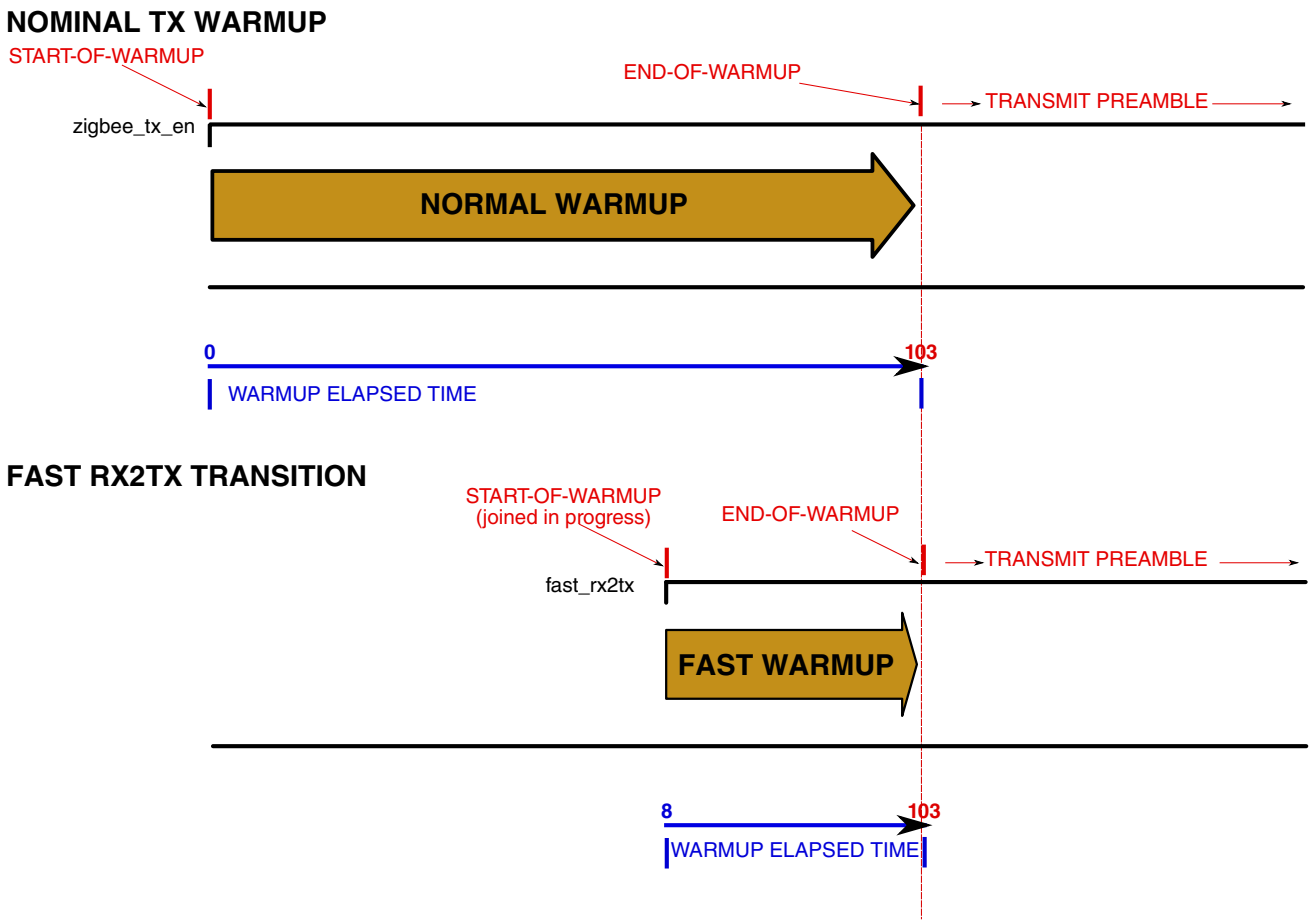
The following diagram illustrates how the TSM delays the start of the Fast TX sequence, relative to the nominal TX sequence, so that the delta time between btle_tx_en (TSM launch signal), and the transmission of the first bit of preamble, is the same in either case.



The following diagram illustrates how the TSM delays the start of the Fast RX sequence, relative to the nominal RX sequence, so that the delta time between btle_rx_en (TSM launch signal), and the ability to receive first bit of preamble, is the same in either case.



The FAST RX2TX transition is handled differently. The objective in such a transition is to get to the point of transmitting the first bit of preamble ASAP. There is no warmup time that software needs to account for in this case, since the RX-to-TX transition is handled completely by hardware. The following diagram compares a nominal TX warmup, with a foreshortened “Fast RX2TX” warmup.



## 64.3.5.2.16 Coexistence

The 2.4GHz radio includes mechanisms which facilitate packet traffic arbitration (PTA) between two collocated radios that will be sharing the same antenna for the 2.4GHz ISM band communications. For such mechanisms, IEEE 802.15.2 proposes MAC layer techniques to coordinate scheduling of packet transmission between the two wireless (WLAN and WPAN) networks by implementation of local controls. The mechanisms discussed in this document can be easily extended to work with the Bluetooth-LE radio, and in fact, all protocols currently supported by the 2.4GHz radio.

One such mechanism places the PTA arbiter on the WLAN device, and envisions a 3-wire interface to/from the WPAN device to the PTA. This protocol is supported by BT devices from some third-party vendors (Broadcom, CSR), and is shown in the image below ("BLUETOOTH" can be extrapolated to include any of the protocols supported by the 2.4GHz WPAN radio).

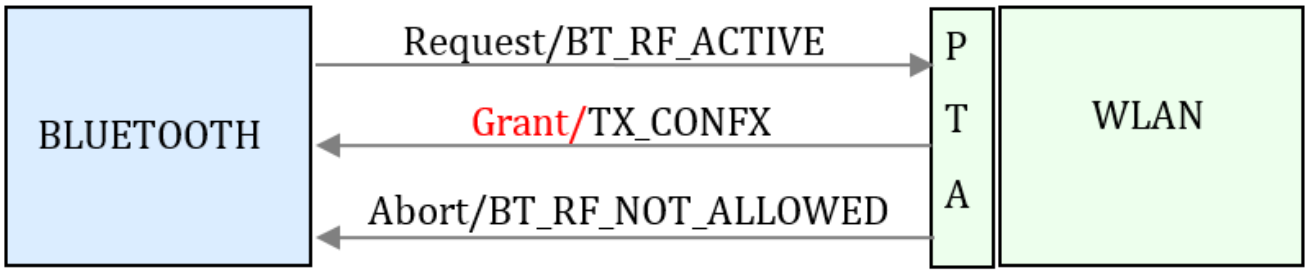


**Figure 64-80. 3-WIRE THIRD PARTY INTERFACE**

An alternative is the Nokia 4-wire interface, which is shown in the image below. (A 3-wire variant of the Nokia option exists, which merely omits the FREQ signal):

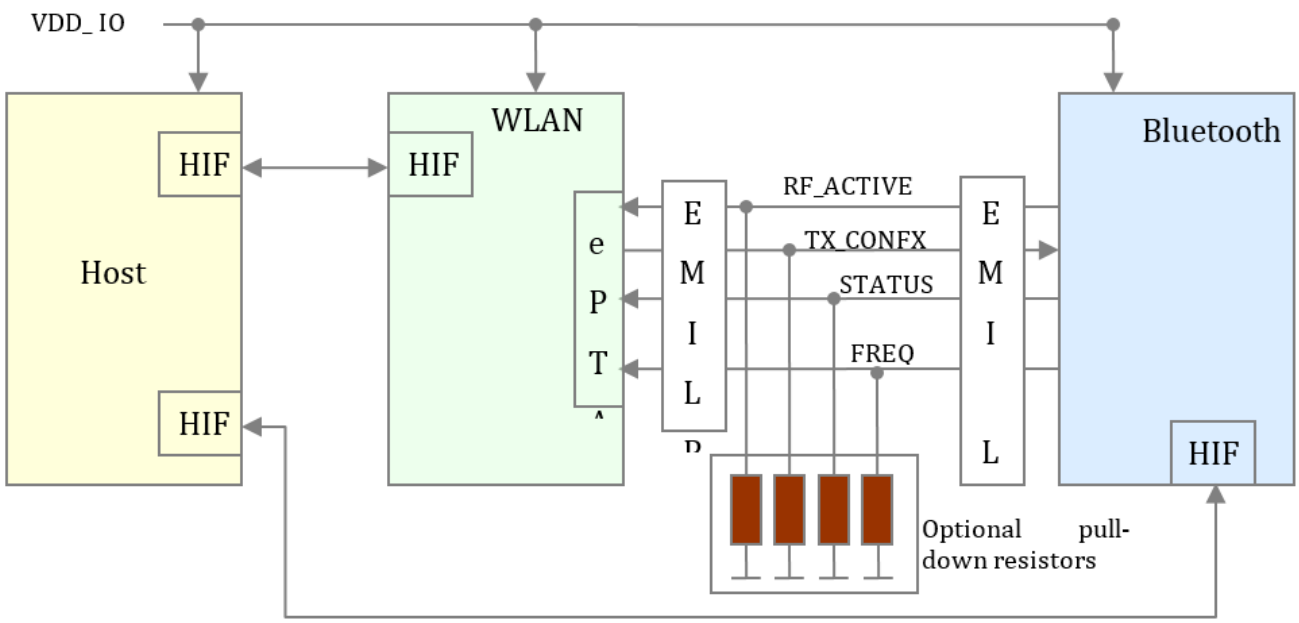

**Figure 64-81. 4-WIRE THIRD PARTY INTERFACE**

In either case, the signal RF_ACTIVE is asserted prior to any 2.4GHz WPAN radio transaction and it remains active for the duration of the transaction. Transaction is defined as a polling slot(s) and an immediately following response slot(s). Retransmissions are treated as separate transactions. The RF_ACTIVE pin at the SoC level can be driven by either an RSIM_RF_ACTIVE or a TSM_RF_ACTIVE source. TSM_RF_ACTIVE, since it is controlled by TSM, can be asserted at most ~200us before a radio event. TSM output TSM_SPARE1_EN is to be used as the TSM source for this purpose.

RF_ACTIVE needs to be asserted high a programmable amount of time before a radio event takes place and remains high until either the radio event has been completed or aborted. There should be no glitches/unwanted transitions between successive radio events (RX->TX or TX->TX or vice versa). This can be a problem for protocols, such as

BLE or 802.15.4, which require the transmission of an acknowledge packet shortly after reception. These protocols also require reception of an acknowledge packet shortly after transmission. BLE Advertising and Scan states offer other scenarios where closely-spaced (but not adjoining) TX and RX operations are required. The inter-frame spacing between the successive RX and TX operations, is long enough such that TSM_SPARE1_EN will deassert and reassert between operations, creating the unwanted transitions which must be avoided.

The following timing diagram shows the desired (glitch-free) assertion of RF_ACTIVE, encompassing a BLE RX operation followed by a TX operation.

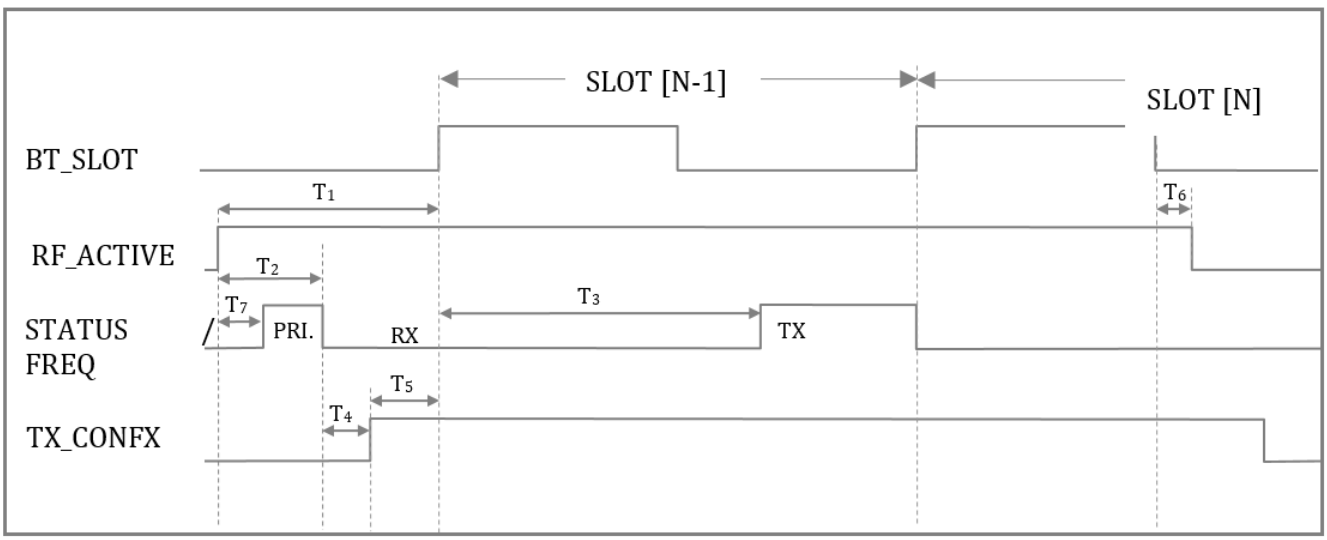

**Figure 64-82. IDEAL RF_ACTIVE TIMING (NO GLITCH)**

The following shows the actual signal timing which would occur on RF_ACTIVE (TSM_SPARE1_EN), in a typical BLE Advertising scenario, if no action were to be taken to address the unwanted, inter-frame transitions:

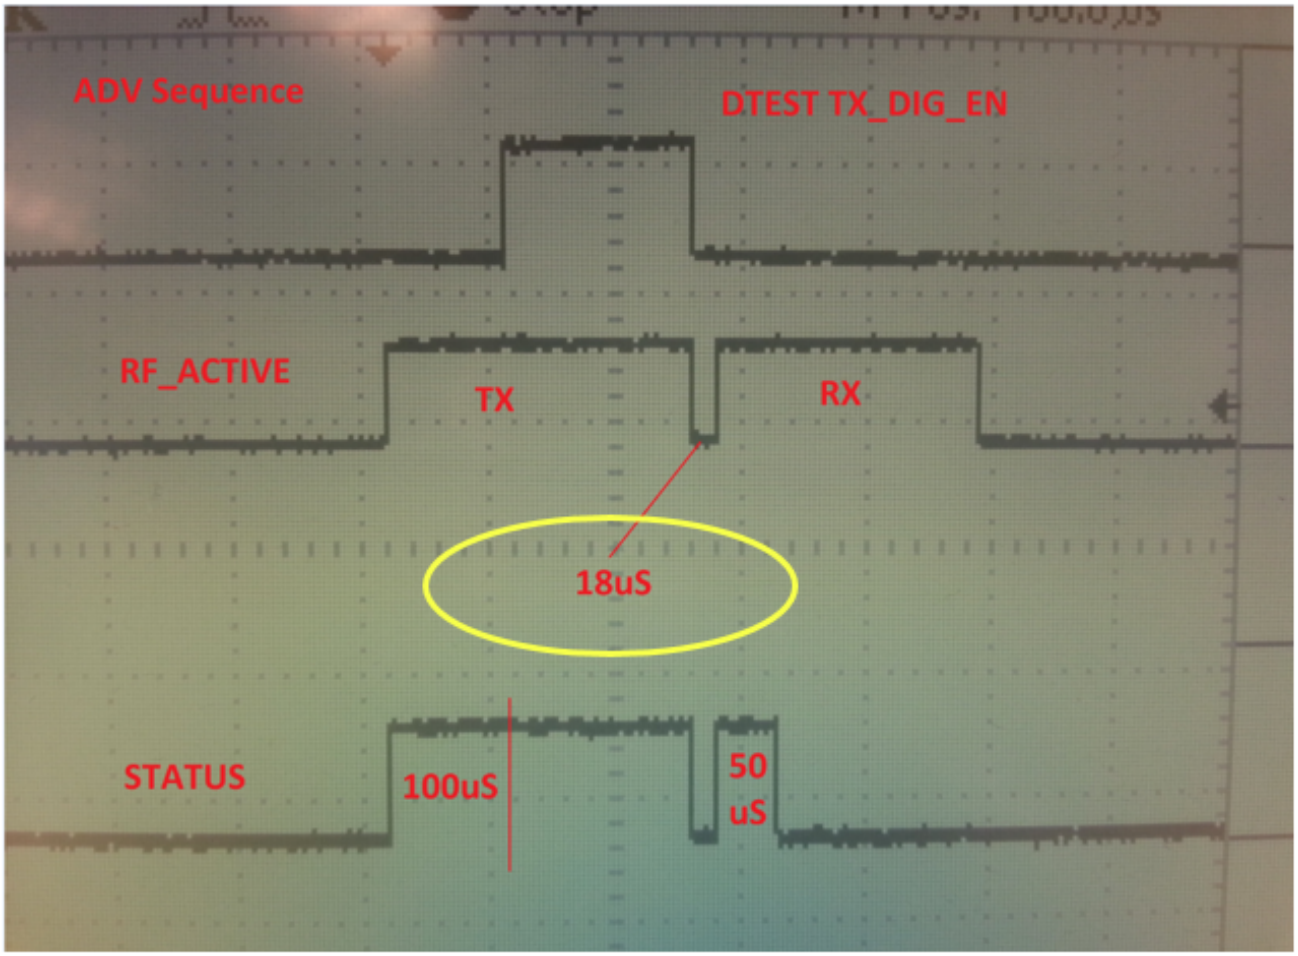

**Figure 64-83. ACTUAL RF_ACTIVE TIMING (UNCOMPENSATED)**

To remedy this, a feature has been added to TSM, to allow the assertion of TSM_SPARE1_EN output to be optionally extended by a programmable amount, after the nominal TSM sequence completes. The programmable limit is long enough to accommodate the RF_ACTIVE glitch which would otherwise occur using the 802.15.4 192µs turnaround time. The TSM_SPARE1_EN extension will occur for all sequences (TX and RX) for which TSM_SPARE1_EN is programmed to assert, whenever register TSM_SPARE1_EXTEND>0. The hardware mechanism for extending TSM_SPARE1_EN is illustrated in the following diagram:

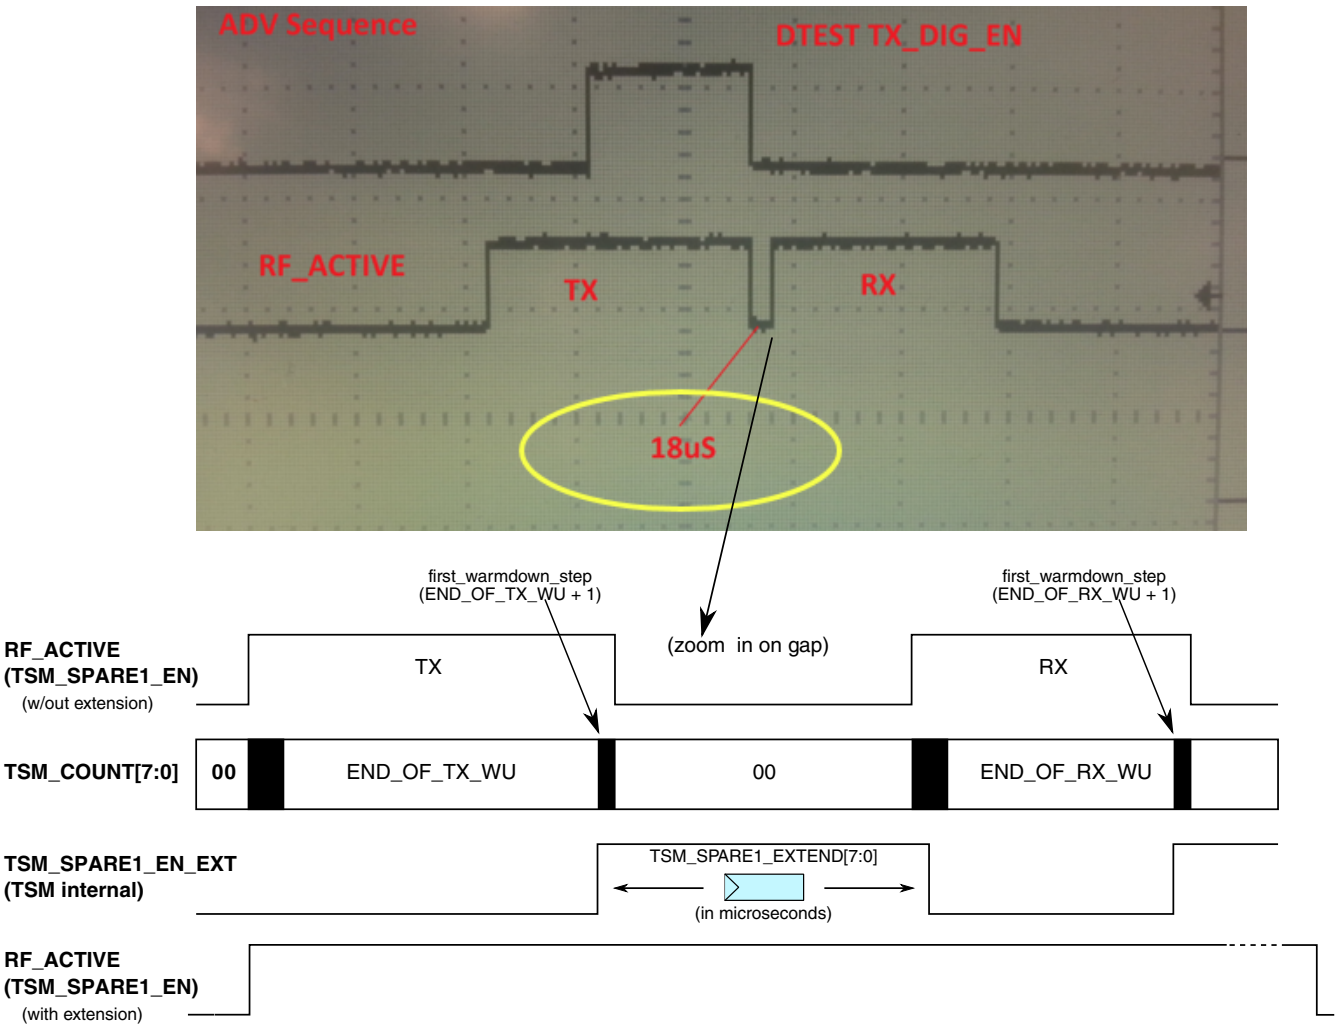

**Figure 64-84. TSM_SPARE1_EN EXTENSION**

The trigger for the extension is the TSM's first warmdown step (END_OF_xx_WU + 1), which will be reached whenever the Link Layer deasserts its TX/RX command, or on any abort. If enabled, the extension signal will assert (high) at this point, and will remain high for *TSM_SPARE1_EXTEND* microseconds. The extension signal (TSM_SPARE1_EN_EXT) is logically "OR-ed" with the existing TSM-controlled output TSM_SPARE1_EN, to generate the composite, extended RF_ACTIVE signal. Software can cut short the extension at any time by writing TSM_SPARE1_EXTEND=0. Setting this register to 0 also disables the extension feature from activating on any new TSM sequence. The register TSM_SPARE1_EXTEND[7:0] resides in the COEX_CTRL register of XCVR address space, and yields an extension range from 0 to 255µs.

### 64.3.5.2.17 Programming Restrictions

The following restrictions are imposed on TSM programming. Violating the restrictions may result in unpredictable behavior.

1. The maximum value for END_OF_TX_WU[7:0] is 253
2. The maximum value for END_OF_RX_WU[7:0] is 253
3. The maximum value for END_OF_TX_WD[7:0] is 254
4. The maximum value for END_OF_RX_WD[7:0] is 254
5. END_OF_TX_WD[7:0] – END_OF_TX_WU[7:0] >= 1
6. END_OF_RX_WD[7:0] – END_OF_RX_WU[7:0] >= 1
7. BKPT[7:0] != END_OF_TX_WD[7:0]
8. BKPT[7:0] != END_OF_RX_WD[7:0]
9. For any TSM output: OUTPUTNAME_TX_HI[7:0] <= OUTPUTNAME_TX_LO[7:0]
10. For any TSM output: OUTPUTNAME_RX_HI[7:0] <= OUTPUTNAME_RX_LO[7:0]

Restrictions 9 and 10 above, if violated, will result in the TSM-controlled output held in a deasserted state throughout the sequence.

To guarantee non-assertion of a particular TSM-controlled output throughout the course of a sequence, simply program its OUTPUTNAME_SEQ_HI = OUTPUTNAME_SEQ_LO = 255 (where SEQ = TX or RX).

#### 64.3.5.2.18 Clocks

The TSM uses 4 clocks:

1. ipg_clk
2. tsm_clk
3. tsm_dly_clk
4. tsm_4m_clk

The "**ipg_clk",** is a gated 32mhz (or 26mhz) clock from the reference oscillator. This clock only used to re-clock the tx_pwr_cntl[5:0] output, to ensure no glitching or skew between the bits, on this power control bus to the PA.

The main clock is the 1MHz **tsm_clk**. This clock establishes the TSM timebase (1us), and runs the TSM counter, as well as the control and abort-handling logic.

Another 1MHz clock is **tsm_dly_clk**. This clock is used to re-clock the 67 TSM-controlled outputs. This clock is time-shifted (delayed) by 1 ipg_clk cycle relative to tsm_clk.

The 4Mhz clock **tsm_4m_clk** runs the PA ramping logic.

All 4 TSM clocks derive from the same 32MHz (or 26mhz) source, the reference oscillator. They are divided down from this reference frequency in the CGM (Clocks Generator Module). Since all 4 are in the same clock domain, they will be balanced (skew-controlled) during clock-tree synthesis. There there are no clock-domain-crossings or asynchronous interfaces in the TSM.

#### 64.3.5.2.19 Reset

The TSM has a single, active-low, asynchronous reset input: **ipg_hard_async_reset_b** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

#### 64.3.5.2.20 Interrupts

For debug purposes, TSM can generate up to 2 interrupts to the host processor. Like all other TSM-controlled outputs, the point during the TX or RX warmup at which the interrupt is triggered, is fully programmable. Since there is no defined mission-mode use for TSM interrupts, no new dedicated timing registers have been provisioned. Instead, the 2 TSM interrupts share timing registers with TSM-controlled outputs **tsm_spare0_en** and **tsm_spare1_en**. The following diagram depicts the reuse scheme.

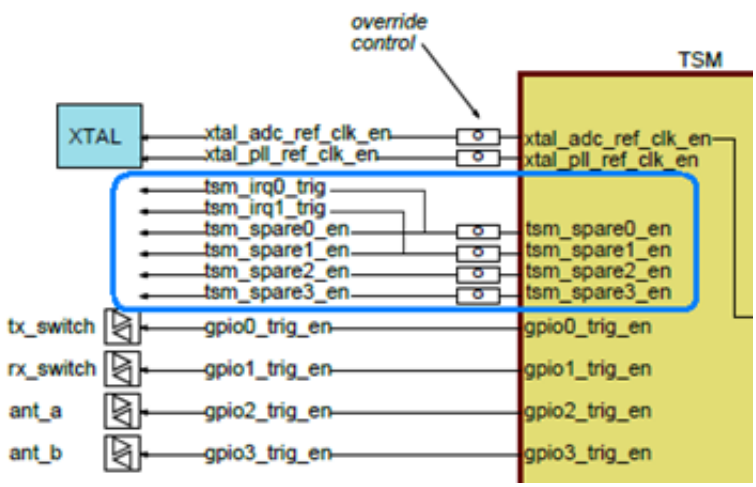

**Figure 64-85. TSM Interrupt Re-use Scheme**

Two new control bits have been added to TSM_CTRL to enable each TSM interrupt. The following table lists the TSM Interrupt, the TSM enable bit for the interrupt, and the TSM timing register which controls the timing of the interrupt.

**Table 64-39. TSM Interrupt Control**

| TSM Interrupt | Interrupt Enable Bit (TSM_CTRL) | Timing Control Register |
|---|---|---|
| TSM_IRQ0 | TSM_IRQ0_EN | TSM_TIMING43 |
| TSM_IRQ1 | TSM_IRQ1_EN | TSM_TIMING44 |

Because the TSM is part of XCVR space, and XCVR space does not have its own interrupt vector, the TSM interrupt is "assigned" to the Link Layer currently in possession of the 2.4GHz radio. Possession is determined by the state of the XCVR_CTRL[PROTOCOL] bits. Each of the Link Layer controllers (BLE, GENERIC_FSK, 802.15.4), has in its address space, a TSM_IRQ status bit, as well as a enable bit to allow/disallow the TSM interrupt to assert the Link Layer's interrupt line to the MCU. The bit positioning of the TSM_IRQ varies slightly amongst the various Link Layers, to optimally group the TSM_IRQ with existing, protocol-specific interrupt sources, and to minimize the software impact to existing service routines, by requiring as few additional register reads as possible to service the Link Layer's interrupts with TSM_IRQ enabled. The TSM_IRQ status bit, as it appears in each Link Layer's address space, is a logical "OR" of the TSM's TSM0_IRQ and TSM1_IRQ. The Link Layer TSM_IRQ is read-only. It can be cleared by clearing both TSM0_IRQ and TSM1_IRQ in the XCVR's XCVR_STATUS register. In the XCVR_STATUS register, TSM0_IRQ and TSM1_IRQ are both write-1-to-clear bits. See the Register Description for each individual Link Layer, for a description of the TSM_IRQ read-only interrupt status bit, and its bit positioning within the Link Layer's address space.

### 64.3.5.3 Memory Map and register definition

There are 59 sets of timing registers for the TSM, one set for each TSM-controlled output (or, for the signal controlling the group for the “grouped” outputs). Each register set consists of 4 registers: one to control the assertion time of the output for TX sequences, one to control the assertion time for RX sequence, one to control the deassertion time for TX sequences, and one to control the deassertion time for RX sequences. For TSM-controlled outputs that are grouped, one set of timing registers controls the timing for all members of the group. For each of these 59 sets, the following table lists the SoC register name (TSM_TIMING00 – TSM_TIMING58), and 4 timing register names associated with each. There are various other registers to control the overall TX and RX sequence lengths, configure for Fast Warmups, etc.

See below for the TSM register locations and detailed definitions.

### *64.3.5.3.1.9.4 Fields*

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-16<br>RECYCLE_COUNT2 | TSM RX Recycle Count 2<br>The RECYCLE_COUNT2[7:0] register determines the TSM count value to which the TSM "recycles" when, in LPPS mode, an LPPS power save cycle completes and the receiver is switched back on, necessitating a foreshortened RX warmup. The intention is for this register to be programmed to a TSM count value that is just prior to the assertion of rx_lna_en, but there are no restrictions on programming this register. An LPPS recycle is a command from the LPPS state machine to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there. |
| 15-8<br>RECYCLE_COUNT1 | TSM RX Recycle Count 1<br>The RECYCLE_COUNT1[7:0] register determines the TSM count value to which the TSM "recycles" when the 802.15.4 Sequence Manager (ZSM) state "RX_PAN1" is reached and the ZSM asserts tsm_recycle[1] to TSM. The intention is for this register to be programmed to a TSM count value such that the TSM de-asserts, and then re-asserts its "pll_dig_en" output, to effectuate a Dual PAN on-the-fly channel change, but there are no restrictions on programming this register. An RX recycle is a command from ZSM to TSM, requesting a jump from the TSM ON phase back to a programmable point in the |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | WARMUP phase, and resume counting from there. A recycle will result from the expiration of the Dual PAN Dwell Timer, at which point an RF-channel change is required. This necessitates the desassertion and reassertion of pll_dig_en, hence the return to the WARMUP phase at the appropriate point. |
| 7-0<br>RECYCLE_COUNT0 | TSM RX Recycle Count 0<br>The RECYCLE_COUNT0[7:0] register determines the TSM count value to which the TSM "recycles" when the 802.15.4 Sequence Manager (ZSM) state "RX_CYC" is reached and the ZSM asserts tsm_recycle[0] to TSM. This register also determines the TSM count value to which the TSM recycles when the ZSM state RX_CCCA is reached because tsm_recycle[0] is also asserted in this state. This register also determines the TSM count value to which the TSM recycles when theGeneric_FSK Link Layer asserts a tsm_recycle to TSM. The intention is for this register to be programmed to a TSM count value such that the TSM re-asserts its "rx_init" output, but there are no restrictions on programming this register. An RX recycle is a command from any protocol engine to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there. A recycle will result from the reception of a packet with bad CRC or one which fails packet-filtering rules, or the end of a CCA operation in Continuous CCA mode which results in a channel indicating "busy". |

## 64.3.5.3.1.10 TSM FAST WARMUP CONTROL 1 (FAST_CTRL1)

### *64.3.5.3.1.10.1 Offset*

| Register | Offset |
|---|---|
| FAST_CTRL1 | 28h |

### *64.3.5.3.1.10.2 Function*

This register provides enabling and control for Fast TSM Mode

### 64.3.5.3.1.11.4 Fields

| Field | Function |
|---|---|
| 31-24<br>FAST_DEST_RX | Fast TSM RX "Jump-to" Point<br>During a Fast RX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, FAST_START_RX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump.<br>Example:<br>FAST_START_RX = 10<br>FAST_DEST_RX = 15<br>The TSM will count as follows: … 7,8,9,15,16,17 … |
| 23-16<br>FAST_START_RX | Fast TSM RX "Jump-from" Point<br>During a Fast RX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_RX[7:0], thereby executing the jump. |
| 15-8<br>FAST_DEST_TX | Fast TSM TX "Jump-to" Point<br>During a Fast TX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, FAST_START_TX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump.<br>Example:<br>FAST_START_TX = 10<br>FAST_DEST_TX = 15<br>The TSM will count as follows: … 7,8,9,15,16,17 … |
| 7-0<br>FAST_START_TX | Fast TSM TX "Jump-from" Point<br>During a Fast TX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_TX[7:0], thereby executing the jump. |

## 64.3.5.3.1.12 TSM_TIMING00 (TIMING00)

#### 64.3.5.3.1.12.1 Offset

| Register | Offset |
|---|---|
| TIMING00 | 30h |

#### 64.3.5.3.1.12.2 Function

This register contains the timing values to control the assertion and deassertion times for both TX and RX sequences for the BB_LDO_HF_EN TSM signal or signal group.

#### 64.3.5.3.1.12.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

## 64.3.6 Transceiver DMA and Packet RAM Debug Modes

### 64.3.6.1 Introduction

For debug and evaluation purposes, the 2.4GHz Radio provides the capability to capture a variety of internal data during the reception process, and store it to either system memory (using Transceiver DMA mode) or radio Packet RAM (using Packet RAM Debug mode), for analysis and post-processing

#### 64.3.6.1.1 Overview

During silicon debug and evaluation, it is often desirable to gain access to data internal to the digital receiver, in order to, for example:

- troubleshoot packet loss issues
- troubleshoot unexpectedly high Bit Error Rate
- fine-tune receiver initialization and configuration parameters

The 2.4GHz radio offers 3 methods of accessing such internal data:

1. Transceiver DMA mode
2. Packet RAM Debug mode
3. Digital Teset Mux (DTEST)

This chapter describes the first 2 methods.

Examples of internal data desirable for capture are raw ADC samples, RX digital I and Q outputs, and PHY soft decision data. Transceiver DMA and Packet RAM Debug modes allow a source of internal data to be selected, automate the acquisition of the data, pack the data into a format suitable and optimized for its destination (system or radio memory), implement the interfaces required to access those memories, store the data to memory under program control, and subsequently allow host MCU access to the acquired data for analysis and post-processing. Selected data are organized into pages, to allow contextually related data to be simultaneously captured wherever possible, and allow for maximum utilization of available bandwidth to memory. For DMA mode, two transfer protocols are provided: a low-bandwidth protocol where the radio requests access to memory only when it has a new sample ready, and a high-bandwidth protocol that allows an entire block of radio data to be transferred to memory with a single radio request. For RAM debug mode, the entire radio RAM is made available for this debug mode, with hardware to pack data, generate RAM addressing, and detect RAM-full condition to prevent overwriting and loss of data.

#### 64.3.6.1.2 Features

- Captures any of 4 sources of RX_DIG data and 4 sources of PHY data
- DMA engine communicates with SoC DMA2 controller to access system memory
- DMA signalling compliant with IP Interface SRS DarkBlue Line convention
- DMA engine provides 2 options to optimize request signalling to required data rate
- Packet RAM Debug engine automates transfers to radio memory
- Efficient packing of source data optimized to destination memory dimensions
- Efficient packing of source data optimized to make best use of available bandwidth
- DMA and Packet RAM engine clocking disabled in mission mode to reduce power
- Simultaneous DMA and Packet RAM Debug operation possible
- Simultaneous Mission Mode and DMA operation possible
- Hardware start-triggering capability with 7 hardware sources
- Stop-on-trigger capability for Packet RAM Debug with 11 hardware sources

#### 64.3.6.1.3 Block Diagram

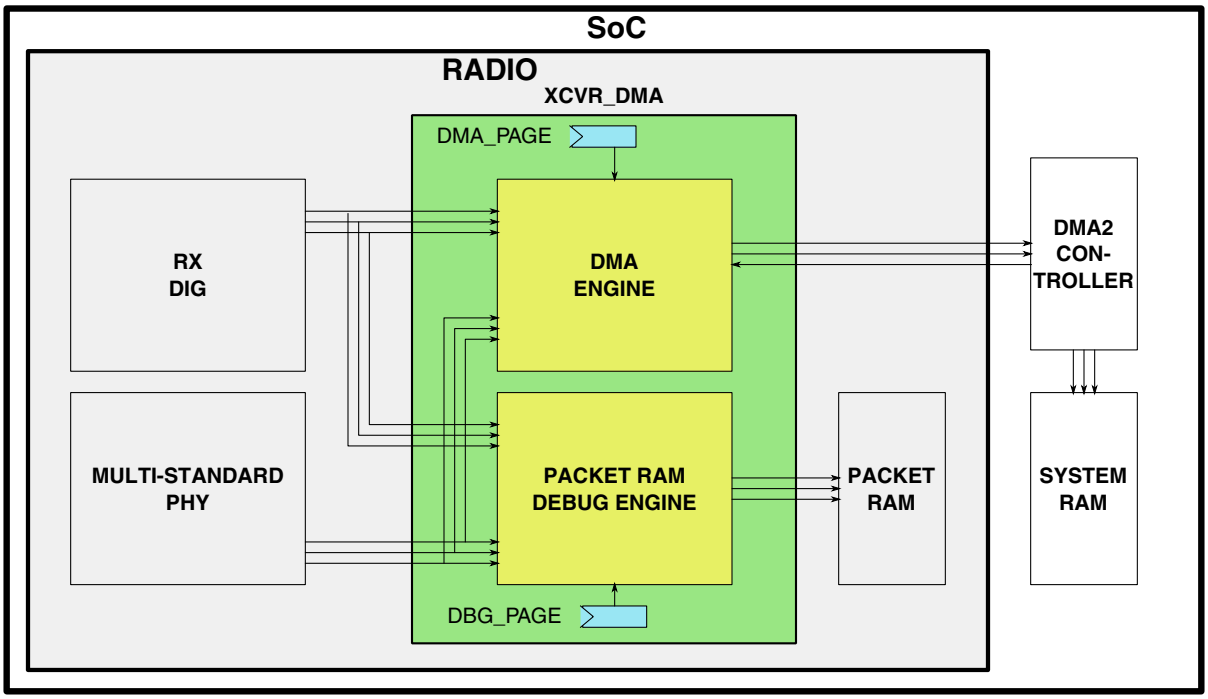

**Figure 64-86. Transceiver DMA and Packet RAM Debug**

### 64.3.6.2 Memory Map and Register Definition

#### 64.3.6.2.1 Register Summary

Below is an overview of the DMA and Packet RAM Debug control fields. More detail on these registers can be found in the XCVR_MISC register section.

#### 64.3.6.2.2 Register Descriptions

| Field | R/W | Description |
|---|---|---|
| DMA_PAGE[3:0] | rw | Transceiver DMA Page Selector. Selects the page of receiver data for storage to system memory when using Transceiver DMA Debug Mode. Setting this register to a non-zero value enables the DMA interface logic. Setting this register to zero disables the interface. The available DMA pages are listed in the following Table 64-39. |
| DMA_EN | rw | Transceiver DMA Enable. Setting DMA_EN=1 enables clock gating to the Transciever DMA engine. This bit should be set prior to the |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | start of a DMA session, and remain set for the duration of the session. |
| SINGLE_REQ_MODE | rw | DMA Single Request Mode. Configures the transceiver to transfer the entire block of DMA data with only a single initial request (ipd_req_radio_rx). The DMA2 controller must be configured accordingly. In this mode, the transceiver will use **ips_xfr_wait** to pace the individual transactions. Single Request Mode should not be used with DMA Pages 11, 12, or 13, because the data rate is too low and therefore ips_xfr_wait would remain assserted for excessively long periods. |
| BYPASS_DMA_SYNC | rw | Bypass External DMA Synchronization. When using transceiver DMA with SINGLE_REQ_MODE=0, synchronization external to the transceiver must be bypassed in order to minimize bus access latency. Using DMA in this mode also requires that the MCU and transceiver both are configured to operate in the RF Oscillator clock domain. |
| DMA_AA_TRIGGERED | r | DMA AA_TRIGGERED. This status bit becomes set when the PHY indicates that a Network Address match has occurred. In some cases it may be desirable to delay the start of DMA transfers until such a match occurs; in such cases, software can poll this bit, and once it becomes set, immediately select the desired DMA_PAGE to initiate DMA transfers. This bit is intended for use with DMA_PAGE=13, but is available on all pages. Its usage is optional. |
| DMA_TIMED_OUT | r | DMA Transfer Timed Out. Status bit indicates that the transceiver DMA, while operating in Single Request Mode, asserted ips_xfr_wait for a period in excess of the programmed **DMA_TIMEOUT** setting, resulting in a timeout condition where the transceiver has forced ips_xfr_wait low. After a timeout, before resuming DMA operations, set DMA_PAGE=0 to disable DMA, and write 1 to this bit to clear it. |
| DMA_TIMEOUT[3:0] | rw | DMA Timeout. In DMA Single Request Mode, adverse consequences may result if the transceiver's ips_xfr_wait signal is asserted for an excessively long period of time, which could occur due to mis-programming of the DMA2 controller, and/or the transceiver itself. DMA Timeout forces the transceiver's ips_xfr_wait low after *N* microseconds and sets the **DMA_TIMED_OUT** status bit, where *N*=DMA_TIMEOUT. DMA_TIMEOUT is only relavent when SINGLE_REQ_MODE=1, otherwise the transceiver does not assert ips_xfr_wait. |
| DMA_START_TRG[2:0] | rw | The DMA Start Trigger, if desired, can be selected from the sources in the following table:<br>0: no trigger<br>1: FSK PHY: gfsk_preamble_found<br>2: FSK PHY: aa_sfd_matched<br>3: ZBDEMOD: rx_preamble_det<br>4: ZBDEMOD: rx_sfd_detect<br>5: RXDIG: agc_dcoc_gain_chg<br>6: TSM: rx_dig_en<br>7: TSM: tsm_spare2_en |
| DMA_START_EDGE | rw | DMA_START_EDGE selects the edge sensitivity (rising or falling) of the selected start-trigger.<br>0: Trigger fires on a rising edge of the selected trigger source<br>1: Trigger fires on a falling edge of the selected trigger source |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| DMA_START_TRIGGERED | r | DMA Start Trigger Occurred. This read-only status bit becomes set, when, during a DMA session (DMA_PAGE > 0), the trigger source selected by DMA_START_TRG[2:0] occurs, with the edge sensitivity selected by DMA_START_EDGE. To clear this bit, set DMA_PAGE=0. |
| DBG_PAGE[3:0] | rw | Packet RAM Debug Page Selector. Selects the page of receiver data for storage to Packet RAM using Transceiver Packet RAM Debug Mode. Setting this register to a non-zero value enables the Packet RAM Debug mode interface logic. Setting this register to zero disables the interface. The available RAM Debug pages are listed in the following Table 64-39 |
| DBG_EN | rw | Packet RAM Debug Mode Enable. Setting DBG_EN=1 enables clock gating to the Packet RAM Debug engine. This bit should be set prior to the start of a Debug session, and remain set for the duration of the session. |
| XCVR_RAM_ALLOW | rw | Allow Packet RAM Transceiver Access. This bit must be set before performing accesses to the Packet RAM using transceiver address space. Transceiver space accesses to Packet RAM are intended for debug purposes only; the individual protocol engines, and the associated IPS busses, have exclusive access to Packet RAM in mission modes. Transceiver space accesses to Packet RAM include direct accesses to RAM at transceiver addresses 0x700 - 0xFFF, as well as Packet RAM Debug Mode. When this bit is set, control of RAM clock gating and RAM chip enables are forced on continuously, taking these controls away from the protocol engines.<br><br>**Note:** In Packet RAM Debug mode, this bit should be set to 1 first, prior to setting DBG_PAGE to any non-zero setting |
| XCVR_RAM_PAGE | rw | This bit selects which of the 2 Packet RAM blocks is mapped into XCVR address space starting at XCVR_BASE + 0x700.<br><br>0: RAM0 is mapped into XCVR address space, between XCVR_BASE + 0x700, and XCVR_BASE + 0xFFF<br>1: RAM1 is mapped into XCVR address space, between XCVR_BASE + 0x700, and XCVR_BASE + 0xFFF |
| DBG_AA_TRIGGERED | r | DBG_AA_TRIGGERED. This status bit becomes set when the PHY indicates that a Network Address match has occurred. In some cases it may be desirable to delay the start of Packet RAM debug transfers until such a match occurs; in such cases, software can poll this bit, and once it becomes set, immediately select the desired DBG_PAGE to initiate data transfers to Packet RAM. This bit is intended for use with DBG_PAGE=13, but is available on all pages. Its usage is optional. |
| DBG_RAM_FULL[1:0] | r | Packet RAM Debug RAM Full. Status Bits indicating that Packet RAM0 (or RAM1) is full, and the Packet RAM Debug engine has attempted to write another word to that RAM. This, and any subsequent write attempts, will not alter the contents of the RAM, once it has reached capacity. Set DBG_PAGE=0 to clear the DBG_RAM_FULL[1:0] bits.<br><br>**NOTE:** If a Debug Stop Trigger is selected (DBG_STOP_TRG > 0), writes to RAM do not stop when DBG_RAM_FULL bit(s) become set; instead, writes continue after an address wrap-around to 0, and will continue indefinitely until either a stop trigger condition occurs, or the debug session is ended by |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | taking DBG_PAGE=0. The DBG_RAM_FULL[1:0] remain a valid indicator that the RAM(s) has reached full status at least once during the debug session. |
| DBG_SOFT_INFO_SEL | rw | Packet RAM Debug PHY Soft Info Output Selector. When acquiring data in Packet RAM Debug Mode with the DBG_PAGE=DMDSOFT page, this bit selects the signal from the PHY used to capture the soft decision data.<br>0: PHY output bit_valid_int is used to capture soft decision data<br>1: PHY output demod_vout is used to capture soft decision data |
| DBG_START_TRG[2:0] | rw | The Packet RAM Debug Start Trigger, if desired, can be selected from the sources in the following table:<br>0: no trigger<br>1: FSK PHY: gfsk_preamble_found<br>2: FSK PHY: aa_sfd_matched<br>3: ZBDEMOD: rx_preamble_det<br>4: ZBDEMOD: rx_sfd_detect<br>5: RXDIG: agc_dcoc_gain_chg<br>6: TSM: rx_dig_en<br>7: TSM: tsm_spare2_en |
| DBG_START_EDGE | rw | Packet RAM Debug Start Trigger Edge Selector. DBG_START_EDGE selects the edge sensitivity (rising or falling) of the selected start-trigger.<br>0: Trigger fires on a rising edge of the selected trigger source<br>1: Trigger fires on a falling edge of the selected trigger source |
| DBG_STOP_TRG[3:0] | rw | Packet RAM Debug Stop Trigger Selector. ## 64.3.6.3 Functional Description

### 64.3.6.3.1 Transceiver DMA Mode

Tranceiver DMA mode takes internal receive data from the RX_DIG or PHY, packs the data into an optimal format for bandwidth or RAM dimensions, and hands off the data to an external (SoC) DMA controller for subsequent transfer to system memory. Control and configuration of transceiver DMA operation is governed by the bit fields in the DMA_CTRL register of XCVR address space. These bit fields are referenced in the description that follows. In a typical transceiver DMA debug session, the transceiver DMA hardware performs the following steps:

1. Selects a source of internal data from RX_DIG or PHY for capture based on DMA_PAGE[3:0] setting
2. Waits for a hardware start-trigger, if so configured
3. Uses a defined capture signal from RX_DIG or PHY to latch the internal data into a holding register
4. Sequentially packs 2 or more captures of internal data into a 32-bit register until the packing requirements for that DMA_PAGE setting are met
5. Uses the radio's SRS DarkBlue Line-compliant DMA interface to notify SoC DMA controller there is data ready for transfer
6. Repeats steps 3-5 until the debug session is complete (DMA_PAGE set to 0).

Each source of RX_DIG or PHY data has a capture signal associated with it. The capture signal is generated in the source block. The capture signal is a one-reference-clock wide pulse that indicates that the next sample (or samples) of source data is ready for capture. For RX_DIG data sources, the frequency of the capture signal is affected by the RX_DECT_FILT_OSR[2:0] (over-sampling rate) setting. Due to system bandwidth constraints not all RX_DECT_FILT_OSR settings are available, and in some cases the ideal mission mode setting can't be used. The maximum RX_DECT_FILT_OSR setting

is dependent on DMA_PAGE, and is listed in the table below. For any DMA_PAGE selecting source data from RX_DIG, set RX_DIG_CTRL[RX_DMA_DTEST_EN]=1 (in mission mode, this bit is clear to reduce power consumption.)

At the assertion of the capture signal, the transceiver takes the data sample(s) presented by RX_DIG or PHY and stores them in a holding register. Subsequent assertions on the capture signal fill different portions of the holding register, until the packing requirements for the selected DMA_PAGE setting are acheived. A description of the packing requirements for each DMA_PAGE setting is included in the table below. Packing is complete when the page-specific packing requirements are met, and the contents of the holding register are transferred into the DMA_DATA[31:0] register for pickup by the SoC DMA controller.

The DMA_DATA[31:0] is a memory-mapped, read-only IPS bus register. It is available for host access, but its primary function is to be read only by the DMA controller upon request from the radio. Once valid data is stored into the DMA_DATA register, the radio notifies the SoC DMA controller that a new sample is ready using one of 2 methods:

## REQUEST-PER-SAMPLE Mode

In this mode, the radio signals the external DMA controller with a new transfer request whenever a new 32-bit sample word is ready in DMA_DATA[31:0]. This is accomplished by setting SINGLE_REQ_MODE=0. The maximum DMA transfer rate in this mode is 2Msamples/sec. This mode is not optimal from the point-of-view of the DMA controller, because first-cycle-latency is incurred for every sample. The debug session block size (total data to be tranferred) need not be known in advance. To reduce IPS bus latency in this mode, in order to meet the 2Msamples/sec data rate, the following programming restrictions are mandatory:

1. Both radio and MCU must be programmed to run off the same clock source (no clock domain crossing)
2. That clock source must be the Reference Oscillator.
3. Synchronization of the DMA request and done signals must be bypassed, so set BYPASS_DMA_SYNC=1.
4. Synchronization of the IPS bus must be bypassed, so set RSIM_CTRL[GASKET_BYPASS_OVRD_EN]=RSIM_CTRL[GASKET_BYPASS_OVRD]=1.
5. MCU code should be executed out of internal RAM, not flash, since flash access requirements might not be met at this bus frequency.
6. No Radio IPS bus activity by the host is allowed during a DMA session
7. Once DMA debug session is complete, set RSIM_CTRL[GASKET_BYPASS_OVRD_EN]=RSIM_CTRL[GASKET_BYPASS_OVRD]=0.
8. Radio IPS accesses are now permitted

**Note:** From the SoC perspective, steps (1) and (2) put the SoC in a configuration that is a special case where full MCU-to-radio IPS bus timing has not been closed. In this mode, only paths associated with, and required for, DMA transfers, have closed timing. Therefore, no other IPS bus or ordinary mission-mode activity should be attempted in this mode. This restriction means host accesses to all radio registers is prohibited.

In REQUEST-PER-SAMPLE mode, whenever a new sample is ready, the radio asserts **ipd_req_radio_rx** to notify the external DMA controller. The controller will respond to the request, by reading the sample from the DMA_DATA register, and then asserts **ipd_done_radio_rx**. In order to ensure that the 2Msample/second transfer rate is met, the controller must respond with **ipd_done_radio_rx** within 15 reference oscillator clock periods after the radio asserts **ipd_req_radio_rx**. This timing is acheivable if the aforementioned configuration instructions are followed. IC-level simulation of this mode demonstrates that request-to-done timing is a maximum of 13 reference clock periods, after proper configuration. As long as the external controller asserts **ipd_done_radio_rx** no later than 14 reference clock periods after the radio asserts **ipd_req_radio_rx**, the radio shall deassert **ipd_req_radio_rx** on the next reference clock cycle, and hold it deasserted until a new sample is ready. If the external controller asserts **ipd_done_radio_rx** exactly 15 clock periods after the radio asserts **ipd_req_radio_rx**, the radio shall deassert **ipd_req_radio_rx** after the 14th consecutive clock cycle of **ipd_req_radio_rx** assertion, for one clock cycle, in order to generate a low-to-high transition on **ipd_req_radio_rx** on the following clock cycle, when a new sample will be ready for transfer. This is the zero-operating-margin case. If the external controller does not assert **ipd_done_radio_rx** within 15 reference clock periods, there is no guarantee that the controller retrieved the sample from DMA_DATA in time, before the radio updated DMA_DATA to the next sample. This is considered a system malfunction, yielding the possibility that samples have been missed by the controller. It is not a certainty that samples were skipped; it depends on the timing of the DMA IPS bus read relative to the request, but this condition should be avoided.

## SINGLE REQUEST Mode

In Single Request mode, the entire block of desired DMA data, is transferred to system memory based on a single request by the transceiver to the external DMA controller. The block size of the debug session must be known in advance, and this size must be programmed into the DMA controller. In this mode, DMA controller does not incur first-cycle latency on every sample, only on the first sample of a debug session. This is because there is only a single, initial request from the radio. In this mode, the MCU can be configured for any clock source, DMA-signal synchronization is not required (BYPASS_DMA_SYNC=0), and RSIM IPS gasket bypass is also not required. Host IPS accesses to radio registers propagate through the synchronizing IPS bus gaskets as in

mission mode; however IPS bus accesses to transceiver registers during DMA activity should be avoided in order to avoid delaying the controller accesses to the DMA_DATA register.

In this mode, once the radio has its first sample packed into DMA_DATA and ready to transfer to the external controller, it will assert **ipd_req_radio_rx**. The radio will hold **ipd_req_radio_rx** asserted until the first read access to the DMA_DATA register by the external controller. At this point, the radio shall deassert **ipd_req_radio_rx** and hold it low for the remainder of the debug session (until DMA_PAGE is set to 0). The external controller shall transfer the entire block of DMA data based on this single radio request. The radio shall ignore **ipd_done_radio_rx** in this mode. The external controller, operating with reduced latency in this mode, lacking the need to process new requests for every sample, will be able to consume samples from the radio faster than the radio can generate them (i.e., greater than 2Msamples/sec). Thus, the radio will assert **ips_xfr_wait_xcvr** to the controller to pace the transfers. When the external controller reads a sample from DMA_DATA, the radio will assert **ips_xfr_wait_xcvr** on the next reference clock cycle, and keep it asserted until a new sample is available on DMA_DATA; it will then deassert **ips_xfr_wait_xcvr** for 1 clock cycle to allow the controller to access DMA_DATA, then reassert it again. This process iterates until the debug session is complete: the pre-programmed block of data is transferred, and DMA_PAGE is set to 0 by program software.

The IPS SkyBlue signal **ips_xfr_wait** allows a peripheral to insert wait states on the IPS bus for cases in which it cannot deliver readback data (ips_rdata) in the same clock cycle that ips_module_en is asserted. The transceiver DMA interface uses **ips_xfr_wait_xcvr** to throttle the DMA transfers as described above. Because of the potential hazards that can arise due to an extended assertion of **ips_xfr_wait** on any IPS bus, which could result from an incorrectly programmed transceiver or DMA controller, a programmable timeout mechanism has been built in to the transceiver DMA hardware. The timeout mechanism measures the amount of time **ips_xfr_wait_xcvr** is asserted, in microseconds, by the transceiver DMA hardware, and compares it to the contents of the DMA_TIMEOUT[3:0] register, which is also calibrated in microseconds. When they match, the transceiver DMA will force **ips_xfr_wait_xcvr** low, and set the DMA_TIMED_OUT status bit. To clear this bit, disable transceiver DMA by writing DMA_PAGE=0, then write 1 to DMA_TIMED_OUT bit to clear it. Since the timeout condition arose from an erroneously configured transceiver or DMA controller, the data transferred during the DMA session, if any, should be considered invalid. Troubleshoot and rectify the conditions which led to the timeout condition, before initiating a new DMA debug session. DMA timeout applies only to Single Request mode, since **ips_xfr_wait_xcvr** is only asserted in this mode.

## PAGE TABLE

The following table describes the available DMA_PAGE settings. The internal source data selected, the capture signal employed, the data packing method, the OSR setting, and the data rate, are provided for each DMA_PAGE setting.

| DMA PAGE | MNEMONIC | PACKING | OSR | CAPTURE SIGNAL | REQUEST RATE | REMARKS |
|---|---|---|---|---|---|---|
| 0 | DMAIDLE | --- | --- | --- | --- | Transceiver DMA Idle. No DMA Activity. |
| 1 | RXDIGIQ | {4'd0, rx_dig_q[11:0], 4'd0, rx_dig_i[11:0]} | 4 | rx_dig_iq_vld (2MHz) | 2MHz | Q and I data captured. Max supported sample rate ref_osc/16 =2MHz for 32MHz clock. |
| 2 | RXDIGI | {4'd0, rx_dig_i[11:0], 4'd0, rx_dig_i[11:0]} | 2 | rx_dig_iq_vld (4MHz) | 2MHz | I data data captured. Max supported sample rate ref_osc/8 = 4MHz for 32MHz clock. Newer sample is in upper bytes. |
| 3 | RXDIGQ | {4'd0, rx_dig_q[11:0], 4'd0, rx_dig_q[11:0]} | 2 | rx_dig_iq_vld (4MHz) | 2MHz | Q data captured. Max supported sample rate ref_osc/8 = 4MHz for 32MHz clock. Newer sample is in upper bytes. |
| 4 | RAWADCIQ | {rx_dig_q[7:0], rx_dig_i[7:0], rx_dig_q[7:0], rx_dig_i[7:0]} | 2 | rx_dig_iq_vld (4MHz) | 2MHz | Raw ADC capture of I and Q channel but every other I and Q ADC sample are discarded The vld strobe will assert at ref_clock/8 = 4MHz rate. (OSR needs to be programmed for 16). Newest samples are in upper bytes |
| 5 | RAWADCI | {rx_dig_i[7:0], rx_dig_i[7:0], rx_dig_i[7:0], rx_dig_i[7:0]} | 1 | rx_dig_iq_vld (8MHz) | 2MHz | Raw ADC capture of I channel. The vld strobe will assert at ref_clock/4 = 8MHz rate. |

*Table continues on the next page...*

## EXAMPLE PROCEDURE

The following steps outline the setup and execution of a Transceiver DMA debug session. This example uses BLE protocol, acquires RX DIG I/Q data, and employs REQUEST-PER-SAMPLE DMA mode:

1. Configure MCU to run off the RF OSC clock source, with divider ratio = 1 (no division)
2. Program RX_DIG for BLE protocol, including RX_DIG_CTRL[RX_DECT_FILT_OSR]=4
3. Set RX_DIG_CTRL[RX_DMA_DTEST_EN]=1
4. Enable clocking to the DMA engine by setting DMA_CTRL[DMA_EN]=1
5. Select a DMA start-trigger source, if desired, by setting DMA_CTRL[DMA_START_TRG] to a non-zero value
6. Program DMA_CTRL[DMA_PAGE]=RXDIGIQ, DMA_CTRL[SINGLE_REQ_MODE]=0, and DMA_CTRL[BYPASS_DMA_SYNC]=1.
7. Set TSM_CTRL[FORCE_RX_EN]=1 to launch an RX sequence.

8. Set RSIM_CTRL[GASKET_BYPASS_OVRD_EN]=RSIM_CTRL[GASKET_BYPASS_OVRD]=1 (XCVR IPS gasket bypass)
9. Begin transmitting RF to the DUT
10. Wait for sufficient RX data to be collected to satisfy the requirements of the debug session
11. Clear RSIM_CTRL[GASKET_BYPASS_OVRD_EN]=RSIM_CTRL[GASKET_BYPASS_OVRD]=0 (XCVR IPS gasket bypass off)
12. Program DMA_CTRL[DMA_PAGE]=0 to terminate the acquisition
13. Download the captured data from system memory

**Note:** Steps 5 (establish the start trigger) and 6 (select the DMA_PAGE to enable the DMA engine), should be performed as sequential, discrete writes to DMA_CTRL, and not combined into a single write.

#### 64.3.6.3.2 Packet RAM Debug Mode

Packet RAM Debug mode takes internal receive data from the RX_DIG or PHY, packs the data into a format suitable for storage in the radio's Packet RAM, and then directly fills the 2 RAMs with source data, under program control. Control and configuration of Packet RAM Debug operation is governed by the bit fields in the PACKET_RAM_CTRL register of XCVR address space. These bit fields are referenced in the description that follows. In a typical Packet RAM debug session, the debug hardware performs the following steps:

1. Selects a source of internal data from RX_DIG or PHY for capture based on DBG_PAGE[3:0] setting
2. Waits for a hardware start-trigger, if so configured
3. Uses a defined capture signal from RX_DIG or PHY to latch the internal data into a holding register
4. Selects a RAM fill method: sequential or simultaneous, based on DBG_PAGE setting
5. Sequentially packs 2 or more captures of internal data into a 16- or 32-bit register until the packing requirements for that DBG_PAGE setting are met
6. Directly accesses the 2 Packet RAM instances to store the receive data (addressing, write enabling, chip enabling, etc.)
7. Repeats steps 3-6 until the debug session is complete (DBG_PAGE set to 0), or a stop-on-trigger event occurs

Each source of RX_DIG or PHY data has a capture signal associated with it. The capture signal is generated in the source block. The capture signal is a one-reference-clock wide pulse that indicates that the next sample (or samples) of source data is ready for capture. For RX_DIG data sources, the frequency of the capture signal is affected by the RX_DECT_FILT_OSR[2:0] setting. In general, there are no restrictions on the OSR setting for Packet RAM debug mode; the RAM fill rate should be able to track with the mission mode OSR settings used by the supported protocols. For any DMA_PAGE selecting source data from RX_DIG, set RX_DIG_CTRL[RX_DMA_DTEST_EN]=1 (in mission mode, this bit is clear to reduce power consumption.)

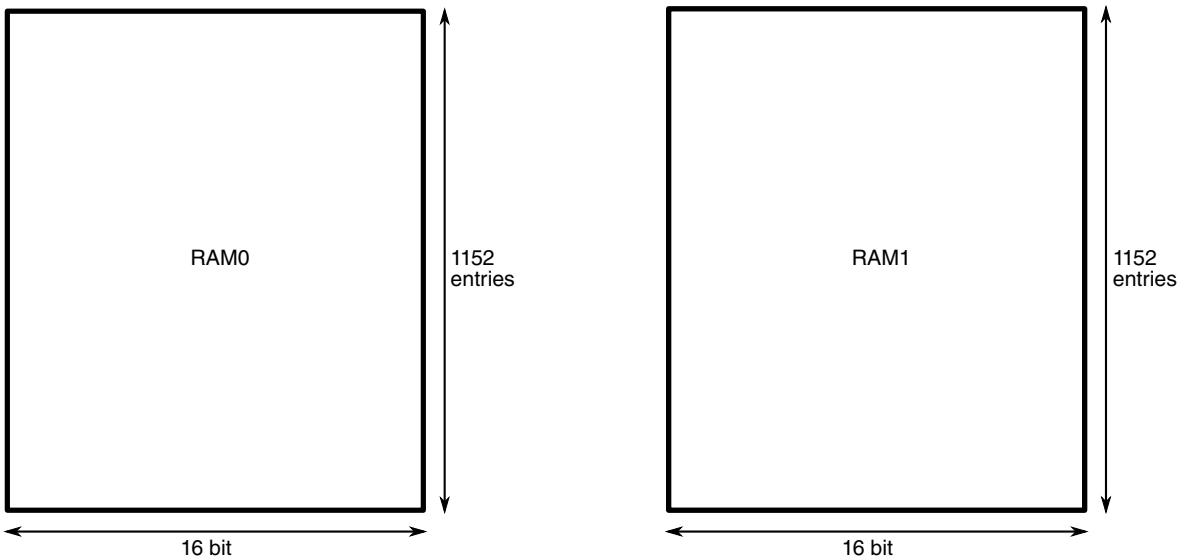
At the assertion of the capture signal, the transceiver takes the data sample(s) presented by RX_DIG or PHY and stores them in a holding register. Subsequent assertions on the capture signal fill different portions of the holding register, until the packing requirements for the selected DBG_PAGE setting are acheived. Packing of the receive data takes into account the RAM fill method employed, based on the DBG_PAGE setting. RAM fill can be sequential (RAM0 fills first completely, followed by RAM1) or simultaneous (both RAMs fill concurrently). A description of the packing requirements and the RAM fill method for each DBG_PAGE setting is included in the table below. Packing is complete when the page-specific packing requirements are met, and the contents of the holding register are written directly to the RAM instance(s).

The bandwidth to Packet RAM is much higher than Transceiver DMA, since the overhead of DMA-related synchronization and multi-master arbitration can be avoided. The maximum transfer rate for RAM debug mode, for a sample of width less than 8 bits (e.g., RAW ADC samples), and simultaneous RAM fill, can be as high as 128Msamples/sec (compared to 2Msamples/sec for DMA). The tradeoff is that the total Packet RAM space is smaller than the space available in system memory, restricting the size of the block of data that can be saved.

## PACKET RAM

The Packet RAM consists of 2 identical RAM blocks, with identical dimensions, as shown in the following diagram.

**RAM DIMENSIONS**
**2304B (RAM0) + 2304B (RAM1) = 4608B (total)**



The RAMs are referred to as RAM0 and RAM1. In mission mode, the RAMs are partitioned into segments to suit the needs of the various protocols, and the sectioning is protocol-dependent. However for the purpose of Packet RAM Debug mode, the entire RAM space is made available for receiver data storage, as one contiguous address space. In Packet RAM Debug mode, the debug engine commandeers both RAMs for buffering receive data, and access attempts by the (mission mode) protocol engines to the RAMs are blocked. For a Packet RAM Debug session, set XCVR_RAM_ALLOW=1. This affords the transceiver IPS bus and the RAM debug engine exclusive access to both RAM blocks comprising the Packet RAM. It also continuously asserts the Chip Enable to both RAMs, and enables a free-running clock to both RAMs, overriding these controls from the protocol link layers.

A Packet RAM debug session consists of 2 stages: Acquisition and Downloading.

## ACQUISITION

In a typical debug session, the selection of a receive data source is made by setting DBG_PAGE to a non-zero value (see the table below for a description of the debug pages). Setting DBG_PAGE to a non-zero value activates the Packet RAM Debug Engine. The engine has write-only access to both RAM's while receive data is being collected. (XCVR host IPS access is not blocked, but should be avoided during acquisition).

If a hardware start-trigger is selected (DBG_START_TRG > 0), the debug engine will wait until the selected triggering event occurs before acquiring any samples; otherwise, acquisition begins as soon as DBG_PAGE is set to a non-zero value.

The RAM's will fill with receive data, either sequentially or simultaneously, determined by the DBG_PAGE setting. If the receive data source selection involves simultaneous capture of symmetric I and Q channel data, RAM0 is dedicated to I channel capture and RAM1 to Q channel; in such cases, both RAMs fill simultaneously. In all other cases, the RAMs fill sequentially: RAM0 fills to capacity, followed by RAM1. RAM addressing always starts at address 0 of either (or both) RAMs; the address for both RAMs is always reset to 0 when DBG_PAGE=0.

**If a stop-trigger is not selected (DBG_STOP_TRG = 0):** When a RAM reaches capacity, further write attempts by the debug engine to that RAM are blocked, and the DBG_RAM_FULL[0] or [1] status bits become set, depending on which RAM is at capacity. When the fill method is simultaneous, both RAMs will reach the full state at the same instant. Otherwise, RAM0 will reach full first. When sufficient receive data has been acquired to satisfy the requirements of the debug session, or when both RAMs are full, the acquisition should be terminated by setting DBG_PAGE=0. The DBG_RAM_FULL[0] and [1] status bits are "sticky"; once set, they will remain set even after DBG_PAGE is set to 0 to end the session. Both bits will self-clear when a new acquisition is started by setting DBG_PAGE to a non-zero value. The XCVR_RAM_ALLOW bit should be set for the duration of the debug session.

**If a stop-trigger is selected (DBG_STOP_TRG > 0):** When a RAM (or both RAMs) reaches capacity, further write attempts by the debug engine to that RAM are not blocked, but the DBG_RAM_FULL[0] or [1] status bits do become set. After capacity is reached on both, or either RAM, depending on the fill method, the debug engine will wrap back to address 0 of the RAM (or RAM pair) and continue filling, until the selected stop-trigger event occurs. When the stop-trigger event occurs, the debug engine will stop filling the RAMs immediately, the DBG_STOP_TRIGGERED status bit will become set, and the registers RAM0_STOP_ADDRESS[10:0] and RAM1_STOP_ADDRESS[10:0] will hold the addresses of the last RAM word, for both RAMs, filled with a valid sample before the trigger. At this point, the acquisition should be terminated by setting DBG_PAGE=0. The DBG_STOP_TRIGGERED and RAMx_STOP_ADDRESS registers are "sticky"; they will hold their state even after DBG_PAGE is set to 0 to end the session. DBG_STOP_TRIGGERED will self-clear, and RAMx_STOP_ADDRESS will reset to 0, when a new acquisition is started by setting DBG_PAGE to a non-zero value. The XCVR_RAM_ALLOW bit should be set for the duration of the debug session.

A diagram of the acquisition process is shown below:

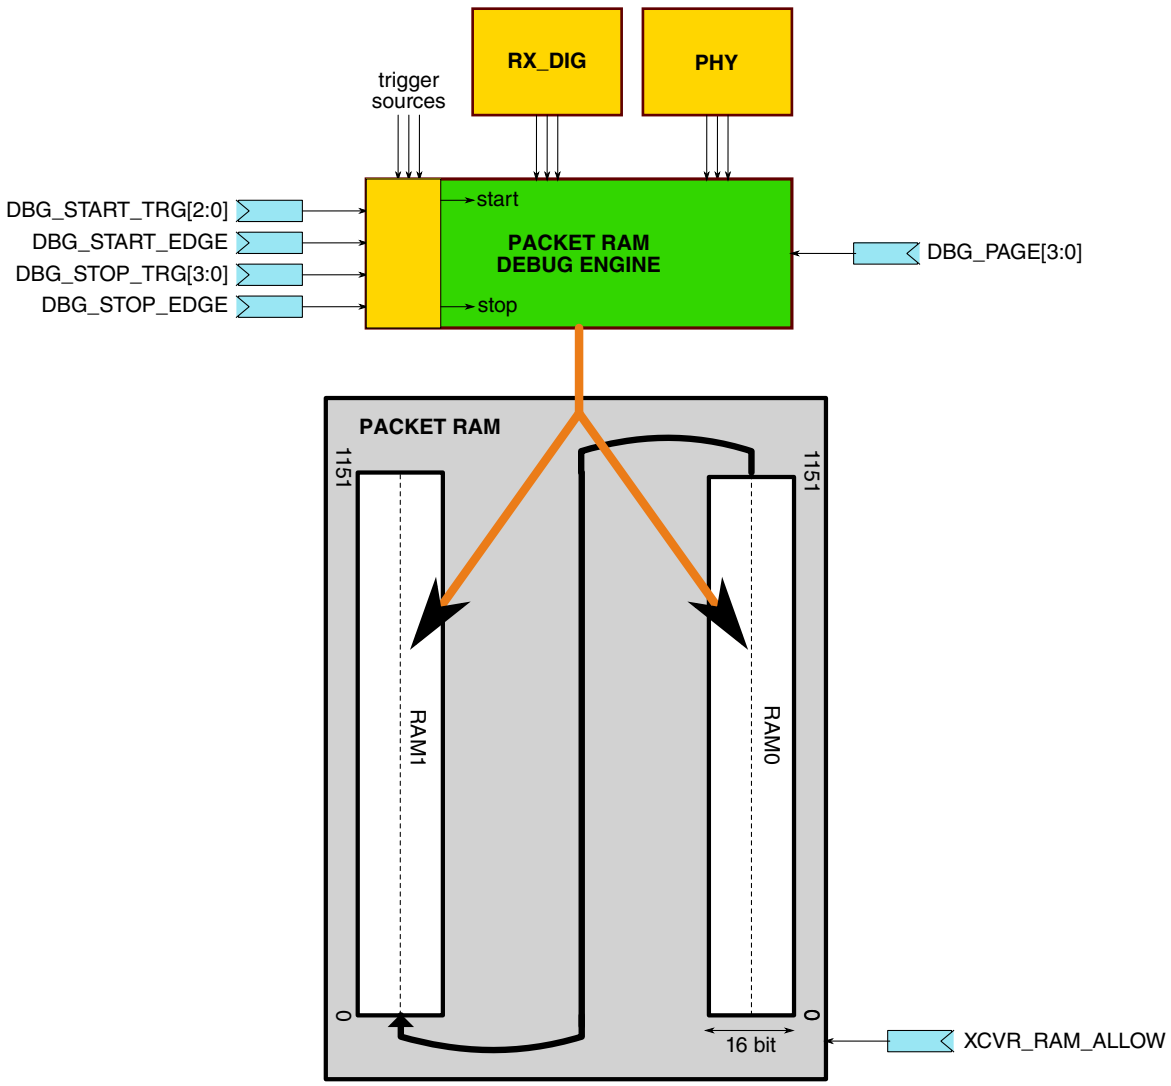


**Figure 64-87. Packet RAM Debug Mode Block Diagram**

## DOWNLOADING

As soon as sufficient data has been collected to satisy the requirements of the debug session, DBG_PAGE should be set to 0 to end the acquisition. The receive data stored in RAM may now be downloaded from the Packet RAM for analysis and post-processing. XCVR_RAM_ALLOW should stay set to allow XCVR IPS access to the RAM. The receive data in the RAM has been packed and distributed between the 2 RAMs in accordance with the DBG_PAGE selection.

Regardless of the DBG_PAGE selection, the host accesses the RAM between addresses XCVR_BASE+0x700 (base of RAM0 or RAM1) and XCVR_BASE+0xFFF (last address of RAM0 or RAM1). Which RAM block gets mapped into this space depends on

the setting of the PACKET_RAM_CTRL[XCVR_RAM_PAGE] bit. Set XCVR_RAM_PAGE=1 to access RAM1 in this space; otherwise RAM0 is accessed in this space.

A diagram depicting how the 2 RAM instances are situated within XCVR address space is shown below.

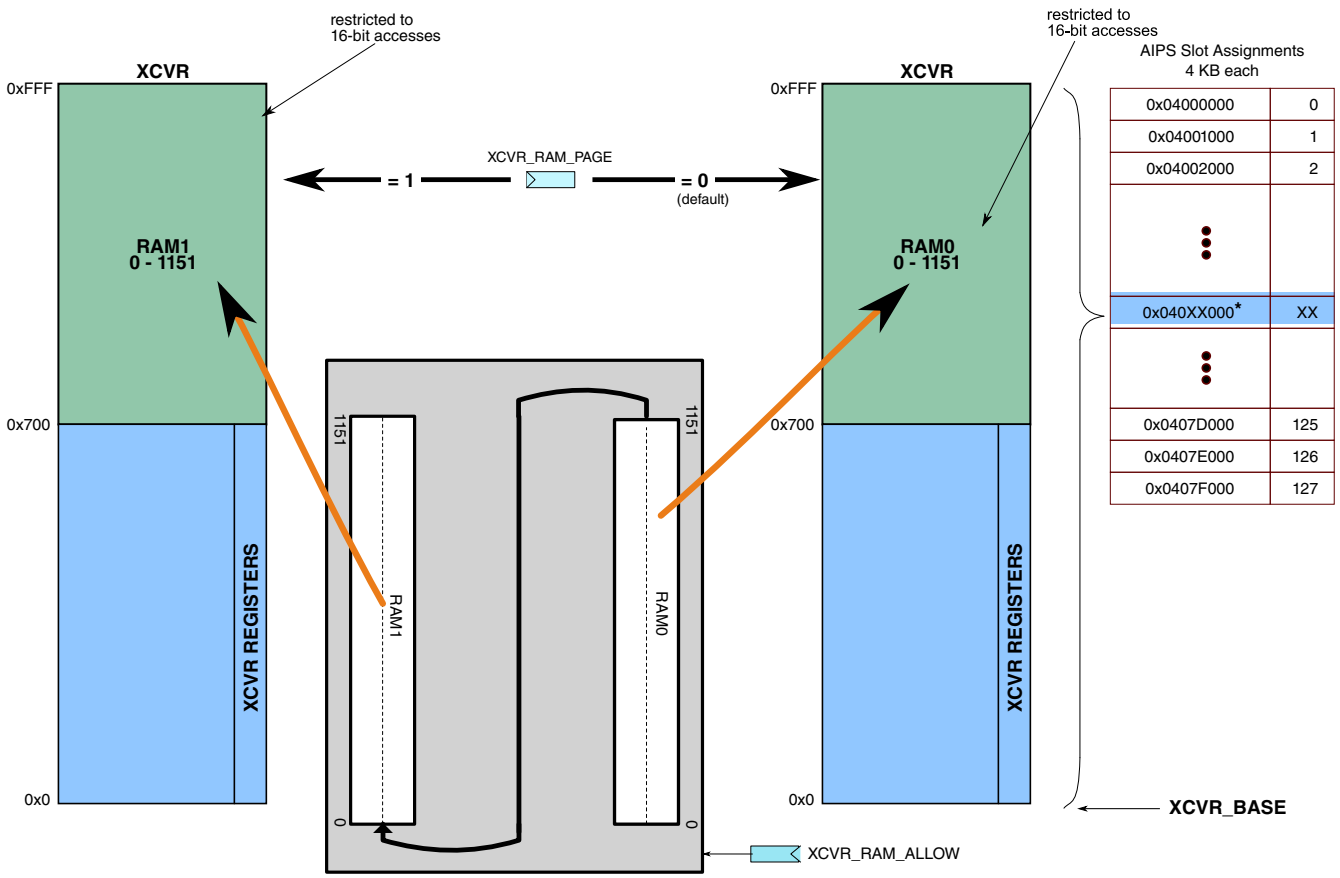

**Figure 64-88. Packet RAM Memory Mapping in XCVR Space**

## PAGE TABLE

The following table describes the available DBG_PAGE settings. In most cases, the DBG_PAGE settings track the Transceiver DMA's DMA_PAGE settings; however DMA_PAGE settings which capture I- and Q-channel-only data are redundant for RAM debug mode, because the bandwidth to packet RAM is high enough to capture I and Q simultaneously with no loss of samples. The internal source data selected, the capture signal employed, the data packing method, and the RAM fill method, and the data rate, are provided for each DBG_PAGE setting.

| DBG PAGE | MNEMONIC | PACKING | CAPTURE SIGNAL | FILL METHOD | REMARKS |
|---|---|---|---|---|---|
| 0 | DBGIDLE | --- | --- | --- | RAM Debug DMA Idle. No RAM Debug Activity. |
| 1 | RXDIGIQ | {4b0, rx_dig_i[11:0]} → RAM0<br>{4b0, rx_dig_q[11:0]} → RAM1 | rx_dig_iq_vld | Simul | Q and I data captured simultaneously. |

## EXAMPLE PROCEDURE

The following steps outline the setup and execution of a Packet RAM debug session. This example uses BLE protocol, and acquires RX DIG I/Q data

1. Program RX_DIG for BLE protocol
2. Set RX_DIG_CTRL[RX_DMA_DTEST_EN]=1
3. Set PACKET_RAM_CTRL[XCVR_RAM_ALLOW]=1 to allow exclusive XCVR access to radio RAMs
4. Enable clocking to the Packet RAM Debug engine by setting PACKET_RAM_CTRL[DBG_EN]=1
5. Select a DBG start-trigger source, if desired, by setting PACKET_RAM_CTRL[DBG_START_TRG] to a non-zero value
6. Select a DBG stop-trigger source, if desired, by setting PACKET_RAM_CTRL[DBG_STOP_TRG] to a non-zero value
7. Set TSM_CTRL[FORCE_RX_EN]=1 to launch an RX sequence.
8. Begin transmitting RF to the DUT
9. Program PACKET_RAM_CTRL[DBG_PAGE]=RXDIGIQ to begin acquisition
10. **If a stop-trigger is selected (DBG_STOP_TRG > 0) --**
11. Wait for DBG_STOP_TRIGGERED=1, indicating a stop-trigger occurred
12. **If a stop-trigger is not selected (DBG_STOP_TRG = 0) --**
13. Wait for sufficient RX data to be collected, or poll DBG_RAM_FULL[0] (and/or DBG_RAM_FULL[1]), to satisfy the requirements of the debug session
14. Program PACKET_RAM_CTRL[DBG_PAGE]=0 to terminate the acquisition
15. Download the captured data from Packet RAM

**Note:** Steps 3, 4, 5, and 6 can be combined into a single write to PACKET_RAM_CTRL.

**Note:** Step 9 (select the DBG_PAGE to enable the DBG engine) should be performed as a sequential, discrete write, after steps 5 and/or 6 (establishing the start/stop triggers) and not combined into a single write to PACKET_RAM_CTRL.

#### 64.3.6.3.3 Simultaneous Transceiver DMA and RAM Debug

Transceiver DMA mode and Packet RAM Debug mode are described in the previous sections. The DMA and Debug engines are separate, independent entities, which theoretically allows both to be employed simultaneously. The most practical case for simultaneous operation would be to select an RX_DIG source for DMA_PAGE and a PHY source for DBG_PAGE. During a such simul debug session, RX_DIG data would go to system memory and PHY data to Packet RAM. After acquisition, data would be downloaded from both memories. Post-processing software could consolidate the data, to take advantage of the synergy that results from combining data captured simultaneously from multiple sources. (DTEST allows a possible third simultaneous source, beyond the scope of this document).

In addition, it is also theoretically possible to combine either or both debug modes with mission-mode packet reception, with the caveat that the Packet RAM would not be available to receive mission-mode packet data in such a scenario. (Packet processing, filtering, CRC checking, and Link Layer interrupts don't rely on packet RAM and so would not be impacted by the debug modes). Such a combination has been demonstrated successfully in radio-level simulation, with the following setup:

1. The GENERIC_FSK Link Layer is engaged in RX mode
2. Transceiver DMA mode is engaged with DMA_PAGE set to RXINPH (RX phase capture)
3. Packet RAM Debug mode is engaged with DBG_PAGE set to DMDSOFT (PHY soft decision data)
4. A GENERIC_FSK packet is received, CRC passes, and GENERIC_FSK RX_IRQ and SEQ_END_IRQ are asserted (GENERIC_FSK packet data not stored)
5. RX phase data is downloaded from system memory and verified
6. Demod soft decision data is downloaded from Packet RAM and verified

#### 64.3.6.3.4 Trigger Sources

**START TRIGGER SOURCES**

Registers DMA_CTRL[DMA_START_TRG] and PACKET_RAM_CTRL[DBG_START_TRG], enable a hardware trigger that must assert before acquisition begins, for the transceiver DMA and Packet RAM debug engines, respectively. The same description applies to both registers (i.e., trigger sources are the same), as indicated in the following table:

| xxx_START_TRG[2:0] | HARDWARE TRIGGER |
|---|---|
| 0 | no trigger |
| 1 | FSK PHY: gfsk_preamble_found |

*Table continues on the next page...*

| xxx_START_TRG[2:0] | HARDWARE TRIGGER |
|---|---|
| 2 | FSK PHY: aa_sfd_matched |
| 3 | ZBDEMOD: rx_preamble_det |
| 4 | ZBDEMOD: rx_sfd_detect |
| 5 | RXDIG: agc_dcoc_gain_chg |
| 6 | TSM: rx_dig_en |
| 7 | TSM: tsm_spare2_en |

## STOP TRIGGER SOURCES

Register PACKET_RAM_CTRL[DBG_STOP_TRG], enables a hardware trigger such that, when it asserts, acquisition terminates immediately, in Packet RAM debug mode, as indicated in the following table:

| DBG_STOP_TRG[3:0] | HARDWARE TRIGGER |
|---|---|
| 0 | no trigger |
| 1 | FSK PHY: gfsk_preamble_found |
| 2 | FSK PHY: aa_sfd_matched |
| 3 | ZBDEMOD: rx_preamble_det |
| 4 | ZBDEMOD: rx_sfd_detect |
| 5 | RXDIG: agc_dcoc_gain_chg |
| 6 | TSM: rx_dig_en |
| 7 | TSM: tsm_spare3_en |
| 8 | TSM: pll unlock |
| 9 | BLE: crc_err_count_incr (increment DTM RX bad packet counter) |
| 10 | CRC FAIL: 802.15.4 or GEN_FSK only, selected by PROTOCOL[3:0] |
| 11 | HEADER FAIL: GEN_FSK only |
| 12-15 | Reserved |

**Note:** For DBG_STOP_TRIG=11 (HEADER FAIL), register GEN_WHITEN_SZ_THR[REC_BAD_PKT] must be set to 0 (default) to cause an RX recycle on a header violation.

### 64.3.6.4 Clocks

The module xcvr_dma includes the Transceiver DMA engine and the Packet RAM Debug engine. Each has its own clock:

1. ipg_clk_dma serves the Transceiver DMA hardware

2. ipg_clk_ram_dbg serves the Packet RAM debug hardware

The **ipg_clk_dma** is a gated 32mhz (or 26mhz) clock from the reference oscillator. This clock is activated when DMA_CTRL[DMA_EN]=1, or when DMA_CTRL[DMA_PAGE] is set to a non-zero value, and deactivated when set to 0. Several other conditions allow this clock to free-run; for example, if the DMA request ipd_req_radio_rx is asserted, or if the DMA_TIMED_OUT status bit is asserted awaiting software clearing, **ipg_clk_dma** will free-run until those conditions are no longer true

The **ipg_clk_ram_dbg** is a gated 32mhz (or 26mhz) clock from the reference oscillator. This clock is activated when PACKET_RAM_CTRL[DBG_EN]=1, or when PACKET_RAM_CTRL[DBG_PAGE] is set to a non-zero value.

These 2 clocks are synchronous to each other. All inputs to xcvr_dma module, including both those destined for the Transceiver DMA engine and the Packet RAM debug engine, are also synchronized to the reference oscillator domain. There are no clock domain crossings in this module.

The DMA DarkBlue line signals can cross clock domain boundaries, when SINGLE_REQ_MODE=1. The clock domain crossings are from the reference oscillator domain to the MCU clock domain for ipd_req_radio_rx, and vice versa for ipd_done_radio_rx. Synchronization, both ways, is accomplished outside the radio, in an SoC level block called radio_dma_sync_glue. These signals cross no clock domains inside the radio itself.

The DMA SkyBlue line signal ips_xfr_wait_xcvr can cross clock domain boundaries, when SINGLE_REQ_MODE=1. The clock domain crossing is from the reference oscillator domain to the MCU clock domain. Synchronization is accomplished in the XCVR IPS bus gasket.

There are no special requirements for these clocks, and no anticipated critical paths associated with them.

### 64.3.6.5 Reset

The xcvr_dma module has a single, active-low, asynchronous reset input: **ipg_hard_async_reset_b** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

### 64.3.6.6 Interrupts

There are no interrupts associated with either Transceiver DMA mode or Packet RAM Debug mode.

## 64.3.7 2.4 GHz PHY

### 64.3.7.1 Introduction

This documents describes the PHY and its operation. More detail and information on the theory of operation can be found in the Architecture Definition Document (ADD).

The Following protocols are supported:

- BLE
- custom FSK modulation schemes
- MSK

The PHY is designed such that it can support a variety of modulation schemes. Several parameters can be adjusted to suit each scheme as described in the configuration section.

#### 64.3.7.1.1 Block diagram

The block diagram below illustrates the basic architecture of the PHY, but several details are not depicted for simplicity.

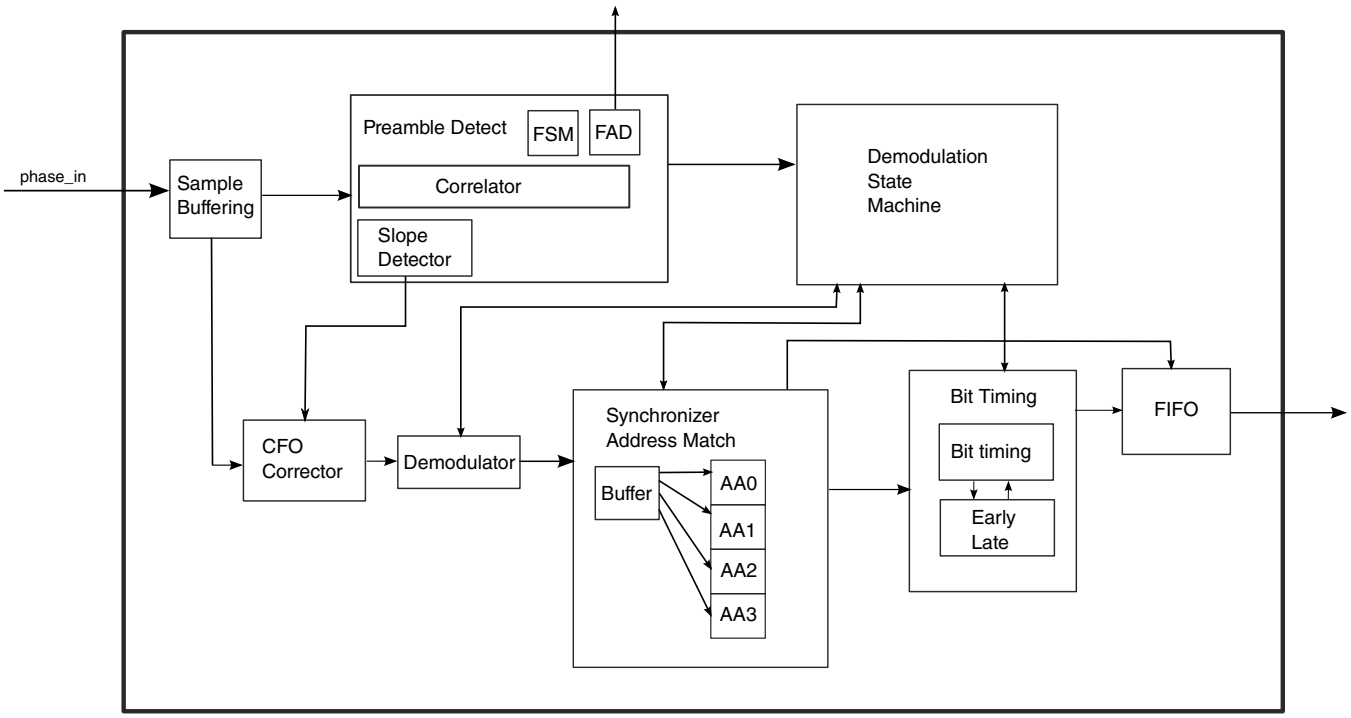

**Figure 64-89. PHY Block diagram**

## 64.3.7.1.2 Overview

The PHY is made up of several sub-modules. These modules can be viewed as members of two classes: datapath (the flow of the signal and the resultant bits) and control (enable/disable logic and state control).

### 64.3.7.1.2.1 PHY Datapath

The signal of interest is passed through the PHY along the data path. The overall objective is to process phase samples that are presented and create bits that are sent out. The significant sub-systems are here presented in generally chronological order as the signal passes through.

Initially, the phase samples are input, sequentially, at the sampling rate, one at a time. The first step is to buffer these samples, so they can be used all at once for certain computations. The buffer size is determined by the largest set of samples that will every be needed by any single component (48 samples).

The buffer of samples is then presented to the preamble detect (PD) logic. The PD module is responsible for detecting the presence of a signal and then indicating the timing and frequency offset when a signal is detected.

In parallel with the PD module, the CFO corrector is presented with the buffered samples. When a preamble is detected, the CFO estimate is presented to the corrector and the correction is applied to the incoming samples. In this fashion, the samples leaving the corrector will be optimally corrected for any frequency offset before beginning demodulation.

Demodulation is performed on frequency corrected samples after a preamble is detected. The produces soft information at the sample rate.

The soft information (soft bits) are then passed to the synchronization block. The primary objective of the synchronizer is to search the soft bits for a match to a sync pattern, typically referred to as an access address (AA). Up to 4 AA's can be searched for. When such a match occurs, the bit timing (the sample offset at which each bit is optimally demodulated) is recorded.

The bit timing block is then able to process the soft bits into hard bits by using the timing information from the synchronizer.

Finally the hard bits are prepared in a FIFO to allow an external block to read as desired. This is realized by a bit timing reference signal that times the output to match.

#### 64.3.7.1.2.2 PHY Control

The control system of the PHY is largely composed of state machines. There are various direct control signals, but the most sophisticated logic is represented in three blocks: demod state machine, preamble detect state machine, and the FAD state machine.

The demodulation state machine has the master control over the entire PHY. When activated, it initiates the preamble search and decides when to activate the demodulator and bit timing engines.

The preamble detect state machine controls the correlator logic and makes the decision when a preamble has been found. Different search mechanisms are used based on the PD_MODE selected.

The fast antenna diversity (FAD) state machine is essentially a replacement of the preamble detect state machine when FAD is enabled. It has the task of detecting the preamble and deciding which antenna to stay on for further processing.

### 64.3.7.2 Interfaces

The PHY interacts with the system in a few distinct ways. The interfaces can be grouped into 4 categories: configuration, signal input, demodulation output, and miscellaneous.

### PHY Configuration Interface

The PHY is configured by static signals that are observed and used throughout the receive process. It is important that these signals (typically originating from IP registers) remain static during a receive operation to avoid unpredictable behavior. Some examples of these types of configurations are PD thresholds, AA to search for, etc.

### Signal Input Interface

The PHY processes the inputs signal from a signed, 5-bit phase inputs. This input is expected to be marked as 'valid' on the phase_in_valid signal. The phase_in_valid signal must be synchronous with input 'clk', but should only assert for 1 clock cycle when a new sample is presented. It is also required that at lease 3 clocks (clk) be present per each phase_in_valid. This is to ensure that all pipe-lined operations can complete.

### Demodulation Output

The demodulator produces bits and, after re-timing, sends them out. The bits are re-timed to the input bit_timing_en which is assumed to be the system bit clock. It is required that the bit_timing_en is synchronous with the input clock and phase_in_valid signals, as synchronization is not performed in the PHY, only re-timing.

### Miscellaneous

There are various other outputs from the PHY that are mostly intended for debug. A few significant signals are described here:

- Soft Info (soft bits): A representation of the demodulator output in fixed-point format. These outputs can be used to see how strong the bits are and the inter-symbol behavior.
- CFO: Frequency offset as determined by the preamble detect engine.
- corr_mag: correlator magnitude, a representation of the correlation strength between the input signal and the reference preamble.
- aa_matched: indicates that an acceptable address synchronization has occurred.
- ant_sw: indicates the requested antenna when FAD is enabled. May be ignored when FAD is not enabled.

## 64.3.7.3 Functional Description

This section describes the functional operation of the PHY.

### 64.3.7.3.1 Protocol Configuration

The PHY has several configurable parameters that can be changed based on the desired protocol behavior. The details of these parameters are described in the following sections and a summary table is provided here for quick reference.

**Table 64-40. FSK schemes supported by the demodulator**

| Scheme | R<br>baud rate (kbps) | *h*<br>modulation index | Frequency pulse | Peak LO error<br>(kHz) |
|---|---|---|---|---|
| **BLE** | 1000 | 0.50 | Gaussian; BT=0.5 | ±300 |
| **Custom scheme 1** | 500 | 0.70 | Gaussian, BT=0.5 | ±200 |
| **Custom scheme 2** | 1000 | 0.50 | Gaussian, BT=0.3 | ±200 |
| **Custom scheme 3** | 500 | 0.50 | Half-sine pulse, L=1 | ±200 |
| **Custom scheme 4** | 250 | 0.50 | Gaussian, BT=0.5 | ±100 |
| **Custom scheme 5** | 250 | 1.00 | Gaussian, BT=0.5 | ±100 |
| **Custom scheme 6** | 1000 | 0.50 | Gaussian, BT=0.7 | ±300 |
| **Custom scheme 7** | 2000 | 0.50 | Gaussian, BT=0.5 | ±300 |
| **Custom scheme 8** | 250 | 0.50 | Half-sine pulse, L=1 | ±100 |
| **Custom scheme 9** | 2000 | 0.30 | Gaussian, BT=0.5 | ±200 |
| **Custom scheme 10** | 500 | 0.50 | Rectangular pulse, L=1 | ±200 |

**Table 64-41. PHY Configurations**

| Config | PD Mode Normal | PD Thresh | PD Mode Comp. | PD Thresh Compressed | AA Corr Gain | PD FREQ THRESH | Preamble Reference {PRE_REF7, PRE_REF6, PRE_REF5, PRE_REF4, PRE_REF3, PRE_REF2, PRE_REF1, PRE_REF0} |
|---|---|---|---|---|---|---|---|
| **BLE** | 2 | 0.8 = 0xCD | 2 | 0.9 = 0xE6 | 0.875 = 0x07 | 0x0A | {0x1e,0x1e,0x00,0x02,0x02,0x02,0x00,0x1e} |

#### 64.3.7.3.2 Scan and Preamble Detect

The initial operation of the PHY when it is enabled is in a SCAN state. The purpose of this operation is to scan the input samples for a preamble, so this state is alternately referred to as 'Preamble Detect' or 'PD'. Additionally, when a preamble is detected, the PHY acquires a coarse time reference for the incoming packet. So this process is also sometimes referred to as coarse timing search (CTS).

##### 64.3.7.3.2.1 Correlation

To accomplish preamble detection, a correlator is used to assess the similarity of the incoming phase samples with a reference waveform. The reference waveform is 6 symbols long. The PHY is configured to look for a particular waveform by programming phase values into the PRE_REF*n* IP register fields. However, there are only 8 fields. These represent 2 symbols of 4 samples each. Internally, the PHY replicates this reference to produce a 6 symbol reference. Therefore, it is required that the preamble be repetitive on a 2 symbol basis.

As the phase samples are received by the PHY, they are buffered. The buffer depth is 48 samples so it contains the last 12 potential symbols. From this buffer, samples are selected to compute a frequency offset (CFO) that may be present because of crystal inaccuracy, etc. The number of symbols over which the frequency estimate is computed is determined by the configuration of the PHY. For normal, 6-symbol preamble detect, the frequency estimate is calculated based on the frequency difference over 6 symbols (24 samples). For compressed, 4-symbol mode, the estimate is over 4 symbols (16 samples). For FAD, the estimate is computed over 2 or 4 symbols, depending on the current state of the search. This estimate is continually updated during a preamble search. It is latched when a preamble is declared found.

For clarity, normal, 6-symbol correlation is described, but the other modes operate similarly. As the CFO is calculated, it is applied immediately over the last 24 samples. This is done by generating a phase ramp that would be caused by the frequency offset and then subtracting it from the last 24 samples. This produces a frequency corrected buffer of 24 samples.

The reference waveform is then subtracted from the frequency corrected samples. These differences are converted to the I/Q domain using a look-up table so that a magnitude can be computed. The correlation magnitude is the result of calculating the I/Q mean over the previous 6 symbols and then squaring. The resultant value is referred to as the correlation magnitude or correlation value. It serves as an indicator of how well the previous 6 symbols correlate with the desired reference preamble and updates on every sample.

As previously mentioned, there are 2 distinct modes for the correlator, compressed and normal. The difference is that compressed mode only correlates based on 4 symbols.

#### 64.3.7.3.2.2 Detection

The correlation magnitude provides a measure of how well correlated the incoming signal is to the reference waveform. So, the higher the magnitude, the more likely there is a real preamble present. The magnitude is compared to a threshold that depends on the given protocol and configuration of compressed mode. For every sample that the magnitude is greater than the threshold, a 'pass' event is created. The pass events are processed differently depending on which PD mode is configured.

PD mode 3 is a detection mode that simply looks for the correlation magnitude to exceed the threshold. If it does, then another check is performed 2 symbols (8 samples) later to confirm the finding. If it is confirmed, a preamble is declared 'found' and the CFO estimate is locked for the demodulator.

PD mode 2 also searches for magnitudes that exceed the programmed threshold. However, is also looks for signature peaks. This means that a preamble is only declared 'found' if 3 peaks, above the threshold, and 2 associated 'dips' between the peaks, are observed. This peak and dip behavior is a result of the preamble being negatively correlated when shifted by one symbol.

In either case, when a preamble is declared 'found', a signal is sent to the rest of the PHY that the CFO is to be locked and demodulation can begin for address search and synchronization.

It is important to not that until an address is found, preamble search continues. This can allow for a refinement in the CFO value after initial declaration of a found preamble.

#### 64.3.7.3.2.3 FAD

A simple fast antenna diversity (FAD) mode is provided to allow for 2 antenna scanning. If FAD mode is enabled, the incoming stream of samples is scanned for a preamble just as in the normal mode, but on a significantly reduced scale. The initial operation of FAD checks for correlation over 3 symbols, using a CFO estimate calculated over 2 symbols.

The FAD search switching is configured by setting the FAD_PROC_DUR and FAD_PROC_DLY parameters. The delay parameter allows for antenna switch time and processing delay of the samples. The duration parameter determines the time at which the antenna should switch.

The antenna switch output will continue to toggle until a viable preamble detection occurs. When it does, the antenna will stay in the same state to allow for demodulation. Additionally, regular preamble search is resumed so a refined CFO estimate is possible.

#### 64.3.7.3.3 Demodulation

As the PD logic detects a preamble, the CFO estimate is locked and this estimate is used to correct all phase samples before entering the demodulator. The overall purpose of the demodulator is to process the frequency corrected phase samples and produce soft-bit values at each sample time. This results in a soft-bit stream at 4x the bit/symbol rate.

The corrected phase samples are passed into the demodulator and then buffered. The buffer size is 8, so 2 symbols will fit. The purpose of having 2 symbols is so that a probabilistic estimate can be used to predict the desired bit level.

The output of the demodulator is a signed sfix10n8 soft representation of the demodulated bit. The soft bits are output at the sample rate, so there are 4 soft values per bit. This allows for fractional timing and early/late adjustment elsewhere in the PHY.

#### 64.3.7.3.4 Address Search and Synchronization

When a preamble has been detected, the synchronization block is activated. The purpose of this block is to analyze the demodulated soft bits and look for an Access Address (AA). The PHY supports up to 4 AA's to be searched for and they can vary in size from 1 to 4 octets. When an address is detected, the system is notified, a fine timing estimate of the symbol boundary is produced, and hard bit decisions begin. For each AA to be searched for, an independent engine is enabled so that all 4 can potentially be searched in parallel.

As the soft bits enter the synchronization engine, they are buffered after being multiplied by AA_CORR_GAIN. This gain is protocol dependent to properly scale the soft bits for ideal detection. The buffer size is 128 to allow for the maximum size address to fit (32 bits x 4 samples/bit). The representation of the soft bits is reduced to sfix4n2 in the buffer.

The buffered soft bits are then compared in two ways to the desired AA: hard and soft.

For hard AA detection, the sign bit of the soft bit is used and a hamming distance is calculated using the programmed AA. If the calculated hamming distance is less than or equal to the programmed allowable hamming distance for the particular address, a hard AA match is indicated.

For soft detection, the soft bits are multiplied by the associated desired bit (as a sign) and then all the products are summed. The result is a correlated strength indication.

For a successful AA match to occur, the hamming distance must be met and there must be a peak in the soft correlation. The location of the peak determine the exact position of the AA and the fractional timing.

At this point the system is notified of an AA match and the synchronization machine is shut off.

**AA confirmation**

The synchronization block also contains a special engine that is used to turn off the preamble detector under certain conditions. If enabled, the AA confirm block will look at the soft bits for a sequence of bits that indicates that the AA has begun and will signal the PD engine to shut off. The purpose of this is to reduce the risk of further false preamble detections that may cause an erroneous frequency estimate to be stored. The 6-bit pattern that is searched for depends on where in the AA the first doublet occurs. For example, if the expected bit stream (including the preamble) is [0 1 0 1 0 1 0 1 0 0 1 0 1 1 ....], then the pattern to be confirmed is [0 1 0 1 0 0]. This feature is only available for AA0.

### 64.3.7.3.5 Bit Timing and Production

After an address is synchronized, the PHY begins to produce hard bits, using the demodulated soft bits and the timing information obtained during synchronization.

#### 64.3.7.3.5.1 Bit Production

Bits are produced nominally based on the sign of the soft bit, at the proper sample time. However, for enhanced performance, the PHY performs fractional adjustment to optimally decode the bit. The fractional timing initially provided by the synchronization engine is used to combine soft bits before and after the desired sample time. A weighted summation is performed based on this fraction and then the sign of the result is inverted to produce the bit. Along with the bit, an internal bit valid strobe is generated at one-fourth the sample rate to indicate a valid bit.

#### 64.3.7.3.5.2 Early/Late

The early/late (EL) engine allows for the bit timing module to adjust the timing of the eye of each bit to account for drift. When the EL engine detects that the eye of the bit has moved in time, an adjustment signal is generated and the bit timing is accordingly adjusted. The EL engine is configured for the window over which an EL measurement is taken (EL_WINDOW) and the duration for which each timing adjustment is considered valid (EL_INTERVAL).

#### 64.3.7.3.5.3 Bit Synchronization

Because the relationship between the sample clock and the bit eye is not knowable *a priori*, it is necessary to buffer the bits and then re-time them to the system bit clock. The PHY's version of the bit clock is guaranteed to be synchronous to the system clock as both are divided down from the same reference clock. However the alignment is not certain. Therefore a 16 entry FIFO holds bits as generated by the PHY and then outputs them at the clock edges indicated by the system.

#### 64.3.7.3.5.4 Special Case for Bit Processing: MSK

When MSK mode is enabled there are a couple special processing steps that take place. The desired AA that is programmed is first transformed to an equivalent bit pattern as it would be observed over the air using the FSK demodulator. This allows the synchronizer to properly search for the incoming address. Additionally, the final bit of the address is stored so that it may be used for the bit stream processing.

When a packet is detected in MSK mode, the bits are demodulated normally, then, starting with the last bit of the AA, they are transformed serially into a true MSK bit stream to account for the transformation that is caused by using the FSK demodulator. The actual bits that are presented out of the PHY are, therefore, the expected bits and no further transform should be required.

## 64.3.8 Wake-On-Radio

### 64.3.8.1 Introduction

The 2.4GHz Wake-On-Radio (WOR) Scheduler, is a new hardware automation block, intended to reduce radio and SoC dynamic power consumption, and facilitate radio frequency hopping.

#### 64.3.8.1.1 Overview

The 2.4GHz Radio Wake-On-Radio Scheduler provides hardware automation for the insertion of the radio digital logic into Deep Sleep Mode (DSM), and subsequent DSM exit, as well as the sequencing of RF operations, both TX and RX, between DSM cycles, without MCU intervention. Wake-On-Radio (WOR) substantially increases the autonomy of the radio within the SoC, taking advantage of the separated power domains for the MCU and the Radio in the SoC, by providing sufficient hardware automation to ensure very long MCU low-power intervals, encompassing multiple RF operations, whenever possible. Two different scheduling methods are supported: Timeslot-based scheduling, and Constant-Interval scheduling. WOR also includes hardware automation for RF Frequency Hopping. WOR supports the radio's 802.15.4, and GENERIC_FSK protocol engines, and interfaces to the radio's RSIM (Radio System Integration Module) for the scheduling of DSM entry/exit. WOR divides future RF operations into "timeslots", which can occur at regularly-, or non-regularly-scheduled intervals. WOR provides a descriptor-based format for software to program timeslot information. WOR interacts with the protocol engines to dynamically manage radio interrupts, allowing link layer interrupts to propagate only when it is necessary to notify the MCU of required action.

#### 64.3.8.1.2 Block Diagram

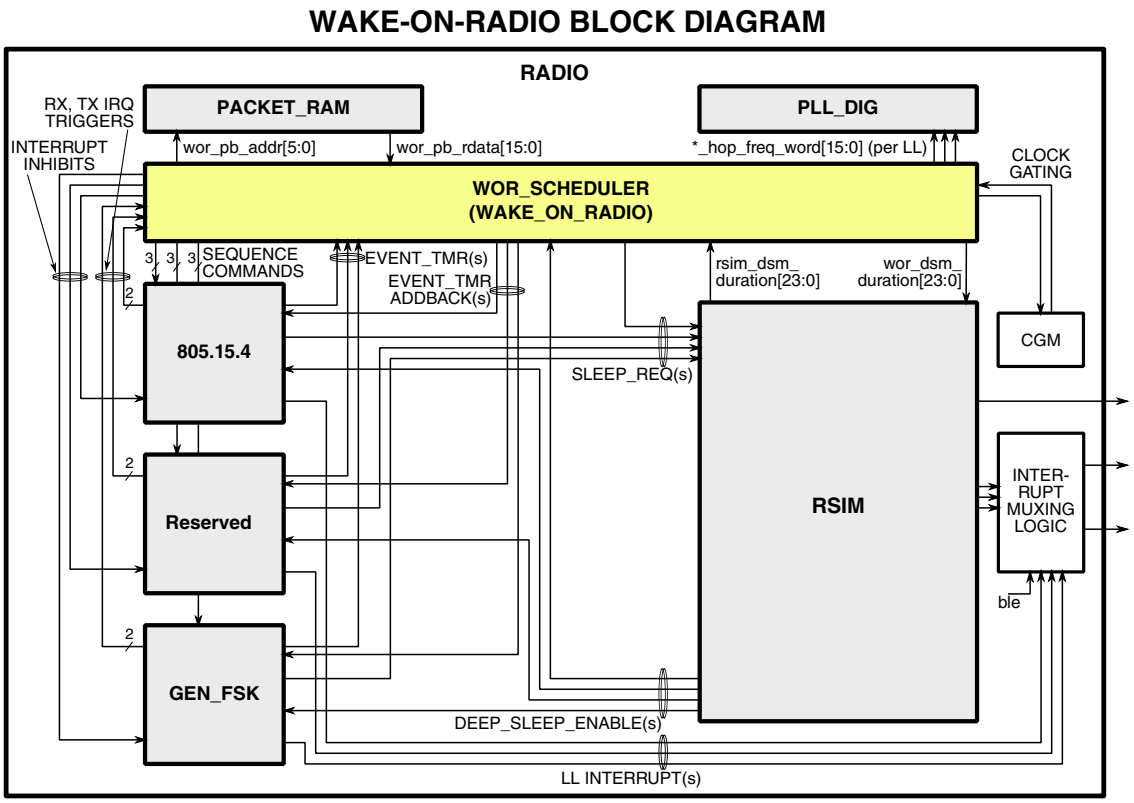

**Figure 64-90. WAKE-ON-RADIO BLOCK DIAGRAM**

### 64.3.8.2 Memory Map and Register Definition

Programmable registers to provide configuration and status for the Wake-On-Radio Scheduler are mapped into Transciever Address Space. WOR registers are described in the table below.

#### 64.3.8.2.1 XCVR_WOR register descriptions

##### 64.3.8.2.1.1 XCVR_WOR_ADDR Memory map

XCVR_WOR base address: 4103_04C0h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | WAKE-ON-RADIO CONTROL REGISTER (WOR_CTRL) | 32 | RW | 0007_0000h |
| 4h | WAKE-ON-RADIO TIMEOUT REGISTER (WOR_TIMEOUT) | 32 | RW | 00FF_0000h |
| 8h | WAKE-ON-RADIO TIMESTAMP 1 (TIMESTAMP1) | 32 | RO | 0000_0000h |
| Ch | WAKE-ON-RADIO TIMESTAMP 2 (TIMESTAMP2) | 32 | RO | 0000_0000h |
| 10h | WAKE-ON-RADIO TIMESTAMP 3 (TIMESTAMP3) | 32 | RO | 0000_0000h |
| 14h | WAKE-ON-RADIO STATUS REGISTER (WOR_STATUS) | 32 | RO | 0000_0000h |
| 18h | WINDOW-WIDENING CONTROL REGISTER (WW_CTRL) | 32 | RW | 0000_0002h |
| 1Ch | FREQUENCY HOP CONTROL REGISTER (HOP_CTRL) | 32 | RW | 0030_0000h |
| 20h | SLOT 0 DESCRIPTOR (LSB) (SLOT0_DESC0) | 32 | RW | 0000_0000h |

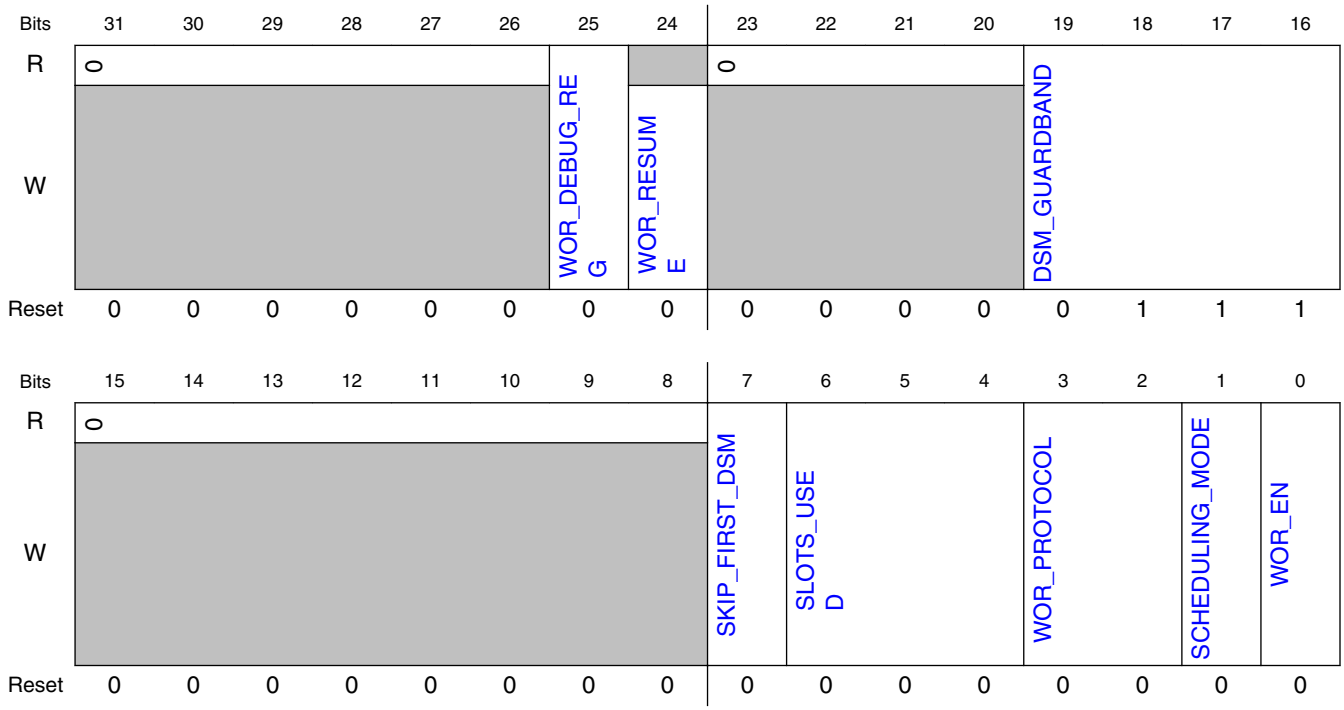
| 34h | SLOT 2 DESCRIPTOR (MSB) (SLOT2_DESC1) | 32 | RW | 0000_0000h |
| 38h | SLOT 3 DESCRIPTOR (LSB) (SLOT3_DESC0) | 32 | RW | 0000_0000h |
| 3Ch | SLOT 3 DESCRIPTOR (MSB) (SLOT3_DESC1) | 32 | RW | 0000_0000h |

## 64.3.8.2.1.2 WAKE-ON-RADIO CONTROL REGISTER (WOR_CTRL)

### *64.3.8.2.1.2.1 Offset*

| Register | Offset |
|---|---|
| WOR_CTRL | 0h |

### 64.3.8.2.1.2.2 Diagram



### 64.3.8.2.1.2.3 Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25<br>WOR_DEBUG_REG | WAKE-ON-RADIO Debug Register Enable<br>WOR_DEBUG_REG alters the readback values of several read-only registers, for debug purposes. The registers which have a different readback value when WOR_DEBUG_REG=1 are:<br>• TIMESTAMP1<br>• TIMESTAMP2<br>• TIMESTAMP3<br>See the description of those registers, which indicates their nominal, and debug-mode readback values. |
| 24<br>WOR_RESUME | WAKE-ON-RADIO Resume<br>This bit causes the WOR state machine to advance from its WAIT_RESUME state. The state machine will enter WAIT_RESUME on any slot in which an MCU wakeup occurs (based on descriptor WAKE_ON_COMPLETE and/or WAKE_ON_TIMEOUT fields). After waking up (interrupting) the MCU, WOR will hold in WAIT_RESUME, giving software whatever time it needs to complete all required activity. Software then sets WOR_RESUME=1, causing the state machine to break out of WAIT_RESUME, advance to the next slot, and enter DSM. This bit is write-only. Writes of '0' have no effect. Readback value is always 0. Setting WOR_RESUME has no effect if WOR state machine is not in WAIT_RESUME.<br>1: Causes WOR state machine to advance out of WAIT_RESUME state, and begin the next slot<br>0: No effect. |
| 23-20 | Reserved |

*Table continues on the next page...*

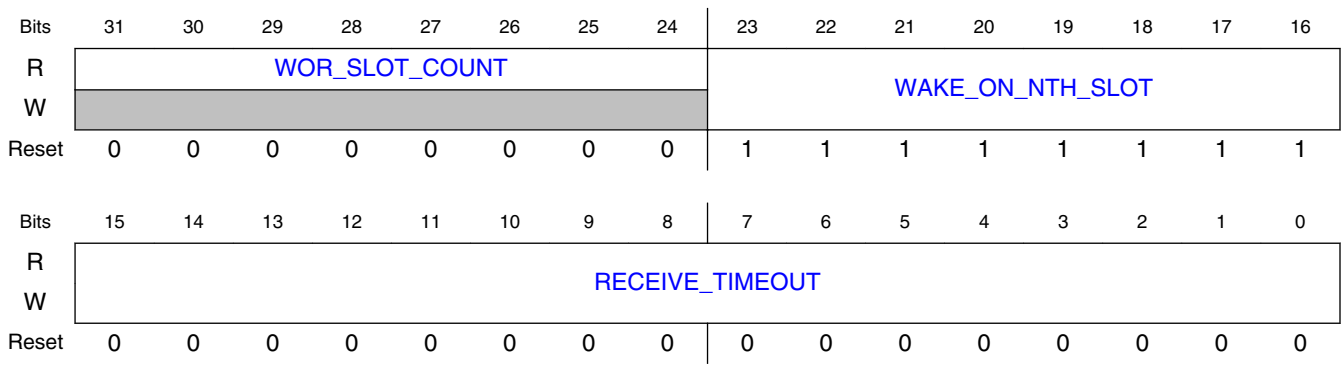
| Field | Function |
|---|---|
| — | |
| 19-16<br>DSM_GUARDBAND | WAKE-ON-RADIO DSM Guardband<br>Determines the number of 32.768KHz clock cycles of guardband used by the WOR state machine in computing duration of the DSM for any slot. Increasing this setting by 1 LSB causes WOR to shorten the DSM duration by 1 32.768KHz clock cycle. This guardband takes into account synchronization, and other, delays within the RSIM, and ensures that DSM will wakeup will never occur "too late" with respect to the slot descriptor's START_TIME field. The current default setting is 7. Values below 7 should not be used. |
| 15-8<br>— | Reserved |
| 7<br>SKIP_FIRST_DSM | WAKE-ON-RADIO Skip DSM On First Slot<br>Setting this bit causes the WOR State Machine to skip the DSM entry/exit cycle for the first SLOT (SLOT 0) encountered after setting SLOTS_USED > 0, regardless of the setting of the NO_DSM field of the slot's descriptor. Subsequent slots, including SLOT 0 when it is re-encountered, will enter/exit DSM based on the descriptor NO_DSM. The SKIP_FIRST_DSM feature is useful, especially in Constant Interval Scheduling mode, when the desire is to begin RF operations immediately (at the start of the first EVENT_INTERVAL), as programmed in the descriptor START_TIME, without waiting out a DSM cycle<br>1: WOR skips DSM entry/exit on the first SLOT 0 after setting SLOTS_USED > 0, regardless of descriptor NO_DSM<br>0: WOR always obeys descriptor NO_DSM<br>**Note:** SKIP_FIRST_DSM should not be used if the SLOT 0 descriptor FUNCTION is set to "NO_RF". |
| 6-4<br>SLOTS_USED | WAKE-ON-RADIO Number Of Slots Used<br>Determines the number of timeslots used to schedule future DSM and RF operations, for either scheduling mode. Up to 4 timeslots can be enabled. Increasing the number of timeslots used decreases average power consumption. Valid values are 0 ≤ SLOTS_USED ≤ 4. The SLOTS_USED register is the mechanism by which the WOR state machine is activated and de-activated. Setting SLOTS_USED to 0 disables the WOR state machine and puts the WOR functionality in an IDLE state. A subsequent write of a non-zero value to SL0TS_USED activates the state machine, initializing to SLOT 0, and starts a new WOR "session". |
| 3-2<br>WOR_PROTOCOL | WAKE-ON-RADIO Protocol Selector<br>Assigns the Wake-On-Radio function to one of the radio's protocol engines.<br>0: Not assigned<br>1: Assigned to 802.15.4<br>2: Assigned to GENERIC_FSK<br>3: Reserved |
| 1<br>SCHEDULING_MODE | WAKE-ON-RADIO Scheduling Mode<br>Determines the scheduling mode used by the WOR HW to organize future DSM and RF operations.<br>1: Constant-Interval Scheduling mode.<br>0: Timeslot Scheduling mode. |
| 0<br>WOR_EN | WAKE-ON-RADIO Enable<br>Wake-On-Radio Master Enable. In addition to enabling the block function, this bit gates the clock to the WOR module. This bit should be set, and remain set, whenever WOR is in use.<br>1: Wake-On-Radio is enabled.<br>0: Wake-On-Radio is disabled, and clocks to the module are gated off. |

# 64.3.8.2.1.3 WAKE-ON-RADIO TIMEOUT REGISTER (WOR_TIMEOUT)

## *64.3.8.2.1.3.1 Offset*

| Register | Offset |
|---|---|
| WOR_TIMEOUT | 4h |

## *64.3.8.2.1.3.2 Diagram*



## *64.3.8.2.1.3.3 Fields*

| Field | Function |
|---|---|
| 31-24<br>WOR_SLOT_COUNT | WAKE-ON-RADIO Absolute Slot Count<br>This read-only register indicates the number of slots that have elapsed since SLOTS_USED was set to a non-zero value to activate the WOR state machine. WOR_SLOT_COUNT can be considered an Absolute Slot Number. WOR_SLOT_COUNT counts slots up to a maximum of 255. If the number of elapsed slots exceeds 255, WOR_SLOT_COUNT will remain at 255. WOR_SLOT_COUNT is "sticky" in the sense that it will hold its value after the WOR session has ended by setting SLOTS_USED=0; WOR_SLOT_COUNT will clear to 0 when a new WOR session is started by taking SLOTS_USED from 0 to any non-zero value. |
| 23-16<br>WAKE_ON_NTH_SLOT | WAKE-ON-RADIO Force Wake On Nth Slot<br>If the WAKE_ON_COMPLETE bit is not set in any descriptor, WOR will not awaken the MCU even after a number of good packets are received. Additionally, if WAKE_ON_TIMEOUT is also not set in any descriptor, WOR will not wake up the MCU under any circumstances, which would not be desirable. This register provides a backup method to awaken the MCU, after *N+1* slots have elapsed, where *N* = WAKE_ON_NTH_SLOT[7:0], regardless of whether or not any good packets have been received, and regardless of the setting of the WAKE_ON_* descriptor bits. Applies to Constant-Interval Mode only. (For Timeslot mode, at least one slot *must* have a WAKE_ON_* bit set in its descriptor). |
| 15-0<br>RECEIVE_TIMEOUT | WAKE-ON-RADIO Receive Timeout<br>For any RX slot, determines how long RX stays on after the descriptor's START_TIME is reached, in microseconds. A timeout is declared if a good packet is not received before the expiration of this time period (START_TIME + RECEIVE_TIMEOUT + WINDOW_WIDENING). Applies to TIMESLOT mode only. |

## 64.3.8.2.1.4 WAKE-ON-RADIO TIMESTAMP 1 (TIMESTAMP1)

### 64.3.8.2.1.4.1 Offset

| Register | Offset |
|---|---|
| TIMESTAMP1 | 8h |

### 64.3.8.2.1.4.2 Function

Timestamp captured for a packet received on SLOT 1. During SLOT 1, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP1 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 1.

**Note:** Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

**Note:** If WOR_DEBUG=1, this register instead reads back WOR_ADDBACK[27:0], which is the number of microseconds that the WOR state machine "added back" to the assigned Link Layer's Event Timer, to correct for the amount of time that Link Layer was in DSM (Event Timer frozen). The WOR_ADDBACK readback value applies to the most recently-completed DSM cycle.

### 64.3.8.2.1.4.3 Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 64.3.8.2.1.4.4 Fields

| Field | Function |
|---|---|
| 31-8 | WAKE-ON-RADIO TIMESTAMP1 |

*Table continues on the next page...*

| Field | Function |
|---|---|
| TIMESTAMP1 | Timestamp captured for a packet received on SLOT 1. During SLOT 1, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP1 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 1. |
| 7-0<br>TIMESTAMP1_FRAC | WAKE-ON-RADIO TIMESTAMP 1 Fractional<br>TIMESTAMP1_FRAC[7:4] applies to 802.15.4 only. For other protocols, this field can be ignored. For 802.15.4, the captured timestamp represents a 28-bit number with 24 Integer bits and 4 Fractional bits. TIMESTAMP1_FRAC[7:4] is the fractional component, which appears to the right of the decimal point. The fractional component has been provided to allow for microsecond accuracy in capturing packet reception instants. The lower 4 bits, TIMESTAMP1_FRAC[3:0], shall always read back '0000'. |

## 64.3.8.2.1.5 WAKE-ON-RADIO TIMESTAMP 2 (TIMESTAMP2)

### *64.3.8.2.1.5.1 Offset*

| Register | Offset |
|---|---|
| TIMESTAMP2 | Ch |

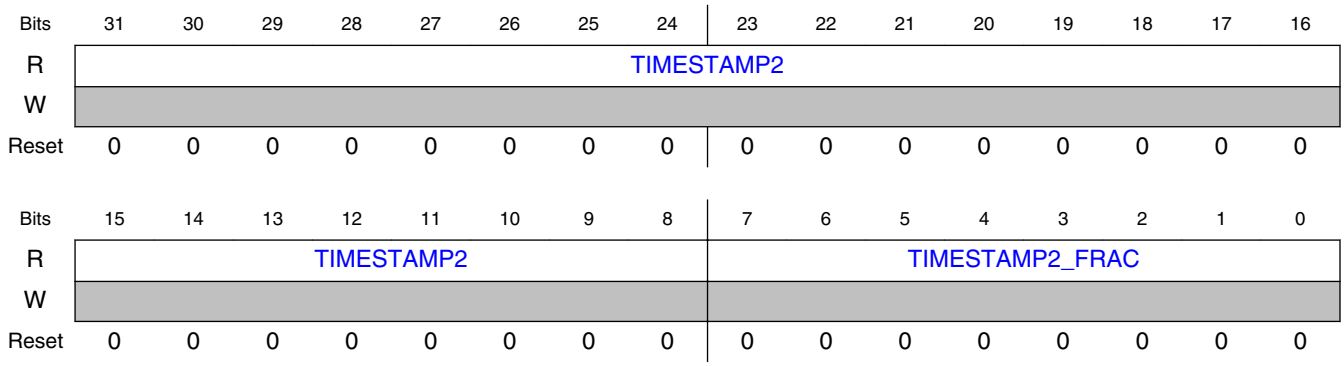
### *64.3.8.2.1.5.2 Function*

Timestamp captured for a packet received on SLOT 2. During SLOT 2, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP2 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 2.

**Note:** Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

**Note:** If WOR_DEBUG=1, this register instead reads back WW_DSM_ADJUST[19:0], which is the accumulated DSM component of the Window Widening adjustment value that is used to offset the start and end of receive operations during the timeslot.

#### 64.3.8.2.1.5.3 Diagram



#### 64.3.8.2.1.5.4 Fields

| Field | Function |
|---|---|
| 31-8<br>TIMESTAMP2 | WAKE-ON-RADIO TIMESTAMP2<br>Timestamp captured for a packet received on SLOT 2. During SLOT 2, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP2 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 2. |
| 7-0<br>TIMESTAMP2_FRAC | WAKE-ON-RADIO TIMESTAMP 2 Fractional<br>TIMESTAMP2_FRAC[7:4] applies to 802.15.4 only. For other protocols, this field can be ignored. For 802.15.4, the captured timestamp represents a 28-bit number with 24 Integer bits and 4 Fractional bits. TIMESTAMP2_FRAC[7:4] is the fractional component, which appears to the right of the decimal point. The fractional has been provided to allow for microsecond accuracy in capturing packet reception instants. The lower 4 bits, TIMESTAMP2_FRAC[3:0], shall always read back '0000'. |

### 64.3.8.2.1.6 WAKE-ON-RADIO TIMESTAMP 3 (TIMESTAMP3)

#### 64.3.8.2.1.6.1 Offset

| Register | Offset |
|---|---|
| TIMESTAMP3 | 10h |

#### 64.3.8.2.1.6.2 Function

Timestamp captured for a packet received on SLOT 3. During SLOT 3, any valid Access Address detection (for protocols other than 802.15.4), or SFD detection (for 802.15.4) will result in the contents of the respective Link Layer's Event Timer being captured into

this register at the instant of detection (there is no offset applied). TIMESTAMP3 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 3.

**Note:** Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

**Note:** If WOR_DEBUG=1, this register instead reads back WW_RUN_ADJUST[19:0], which is the accumulated "run time" component of the Window Widening adjustment value that is used to offset the start and end of receive operations during the timeslot.

## 64.3.8.3 Functional Description

### 64.3.8.3.1 Assign To Protocol

The 2.4GHz radio supports multiple protocols, each with its own protocol engine. All protocols can benefit from scheduling in advance several RF operations and DSM cycles, with the radio conducting the successive operations autonomously, allowing the MCU to remain in low power state for the duration. This is the concept behind Wake-On-Radio (WOR).

The WOR function can be assigned to any one of the following protocols: 802.15.4, GENERIC_FSK. (BLE has its own, internal DSM and wake-on-radio control scheme, as well as hardware-controlled frequency hopping, built into the IP, so it does not interact with the WOR Scheduler).

Assigning WOR to a protocol is done by way of the WOR_PROTOCOL register, as shown in the following table:

| WOR_PROTOCOL[2:0] | ASSIGNED PROTOCOL ENGINE |
|---|---|
| 0 | Not Assigned |
| 1 | 802.15.4 |
| 2 | GENERIC_FSK |
| 3 | Reserved |

Assigning to protocol means that the assigned Link Layer's WOR interface signals are routed, exclusively, to and from the WOR state machine. WOR interface signals include the event timers, sequence start- and stop-command signals, interrupt inhibits, and event timer addback commands. These interface signals are covered in more details in later sections.

The following diagram illustrates how 1 of the 3 WOR-capable Link Layers is assigned to the WOR function:

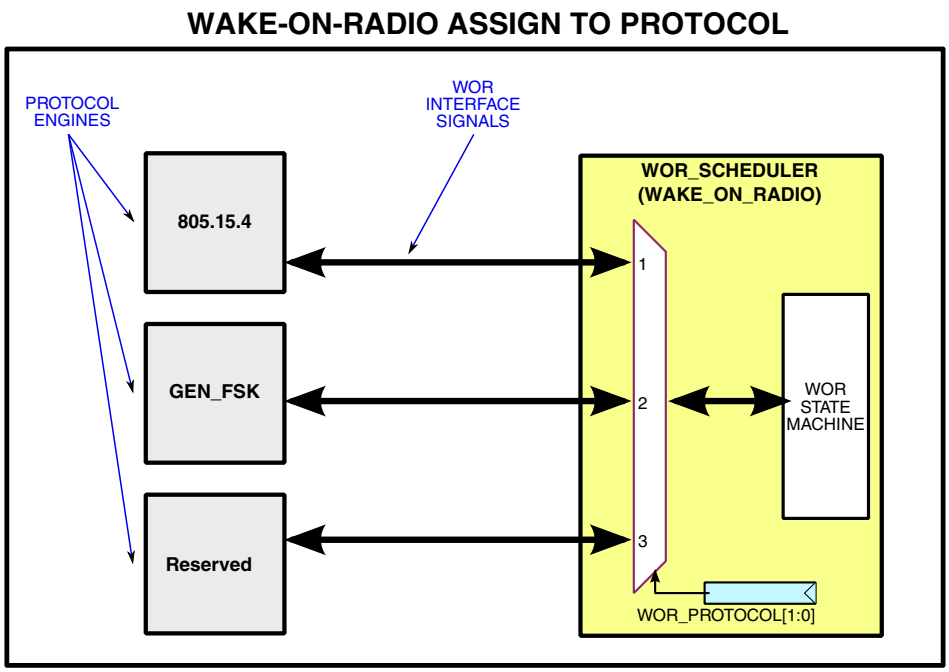

**Figure 64-91. WAKE-ON-RADIO ASSIGN TO PROTOCOL**

In a multi-protocol setting, assigning a protocol to Wake-On-Radio does not mean that unassigned protocols are incapable of DSM. There is a back-up method, Manual DSM, which uses software-driven DSM entry and exit. In a multi-protocol setting, any 2 of the radio's protocols can be assigned to different DSM control scheme, with the control schemes being Wake-On-Radio, Manual DSM, and BLE DSM.

### 64.3.8.3.2 Scheduling Modes

For maximum flexibility in scheduling future RF operations and Deep Sleep cycles, Wake-On-Radio (WOR) defines 2 scheduling modes: Timeslot Mode, and Constant Interval Mode. These modes are described in the sections below.

**Timeslot Mode**

Timeslot mode is desirable when the schedule for RF transactions is sporadic, varies over time, or is otherwise non-periodic. Timeslot mode is based loosely on the TSCH (Timeslotted Channel Hopping) concept, first defined in IEEE Std 802.15.4e-2012. Key principles of TSCH are adopted by WOR, but far short of full adherence.

In TSCH, time is divided into slots of fixed duration. Slots are grouped into slotframes, containing fixed number of slots. Once a TSCH PAN (network) is established, slotframes will repeat forever, back-to-back. Devices can be assigned to 1 or more slots within a slotframe. For any given device on any given slot, the assigned slot can be TX or RX. One device can be assigned to transmit in a given slot; another device can be assigned to receive in the same slot. Assigning Device A to Transmit, and Device B to Receive, in the same slot, creates a link. Links can be dedicated (one TX and one RX device assigned). Or, links can be shared (multiple TX devices, using CSMA, and multiple RX devices). Typically, each slot uses a different hop frequency.

Slotframes are TDMA structures, with time on one axis and hop frequency on the other. The diagram below shows one "row" of a typical slotframe, with links established for Devices A, B, and C, all on the same hop frequency. This slotframe consists of 3 timeslots: TS0, TS1, and TS2.

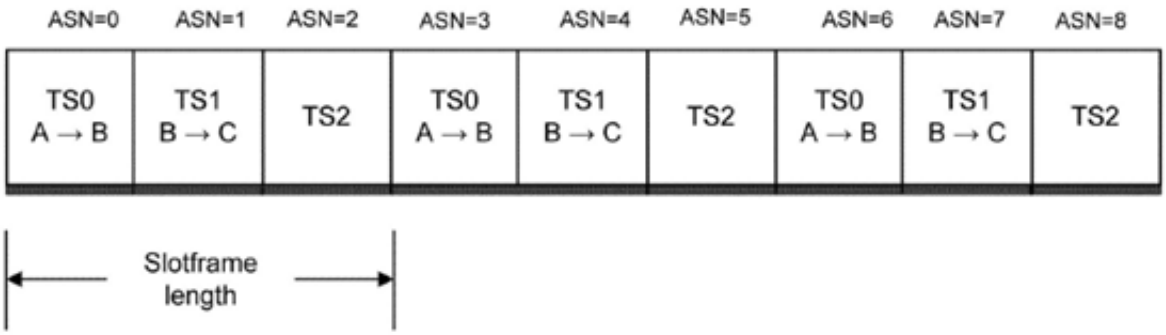

**Figure 64-92. 802.15.4 TSCH 1-D SLOTFRAME**

Another diagram below, shows a slotframe of 2 dimensions. The time axis has 100 slots, and the frequency axis has 4 indices into a table of available hop frequencies. Devices A, B, C, and D are assigned to various slots, and links are created amongst them.

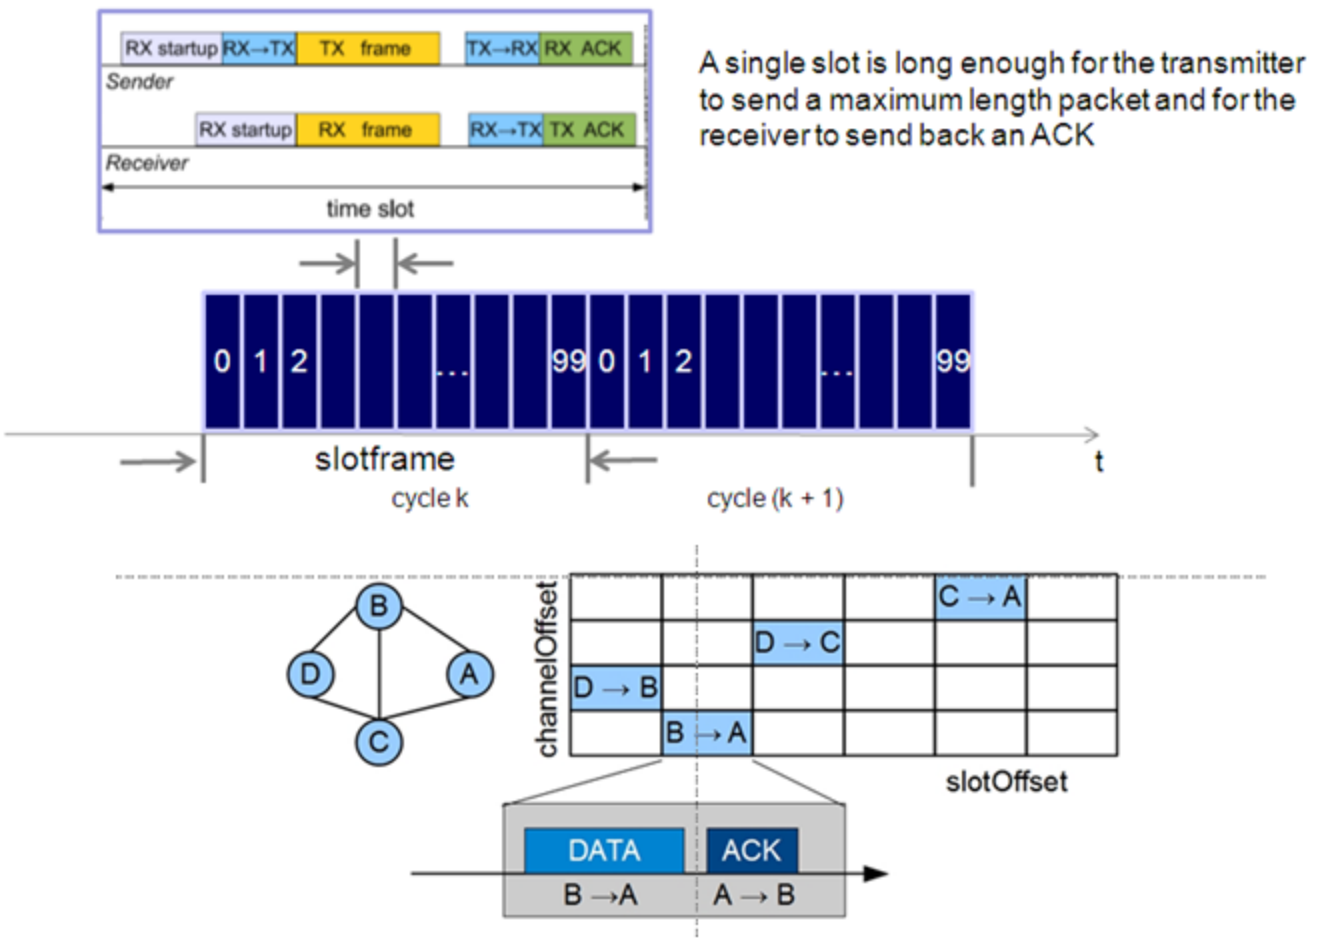

**Figure 64-93. 802.15.4 TSCH 2-D SLOTFRAME**

When RF operations are to be scheduled using Wake-On-Radio in a TIMESLOT context, the start times for the next *N* operations are programmed into the descriptor table to assign them to slots. One field of each slot descriptor, START_TIME, holds this information for WOR. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor. *N* is the number of slots used, and can be any integer from 2 to 4. The register SLOTS_USED is programmed with this value. The start times programmed into the descriptors, are relative to the Event Timer of the assigned Link Layer. WOR software will read the Event Timer, add to this value the desired time-to-next-event, and write the sum into the descriptor START_TIME. WOR hardware will monitor the assigned Link Layer's Event Timer; when it matches the START_TIME field of the current slot's descriptor, WOR hardware will initiate an RF sequence. The type of sequence is determined by the descriptor's FUNCTION field, and can be TX or RX. The RF operation will be allowed to continue, until it either self-terminates, or a timeout is reached. The timeout period for TIMESLOT scheduling mode is determined by the RECEIVE_TIMEOUT[15:0] register. The units of this register are microseconds. If a timeout is reached, i.e.,

EVENT_TMR = START_TIME + RECEIVE_TIMEOUT,

WOR hardware will terminate the sequence. Timeout applies to RX sequences only. RX sequences may result in no packet being received, a packet being received which is not addressed to the device, or a packet which is received corruptly. Any of these scenarios will result in a timeout and a WOR shutdown of the sequence. A correctly received packet addressed to the device will self-terminate the RX sequence before the timeout is reached. Timeout is not relavent to TX sequences, since these always self-terminate. The following diagram depicts how the WOR hardware processes the descriptor table, the assigned Event Timer, and the RECEIVE_TIMEOUT register, to start and terminate an RF operation.

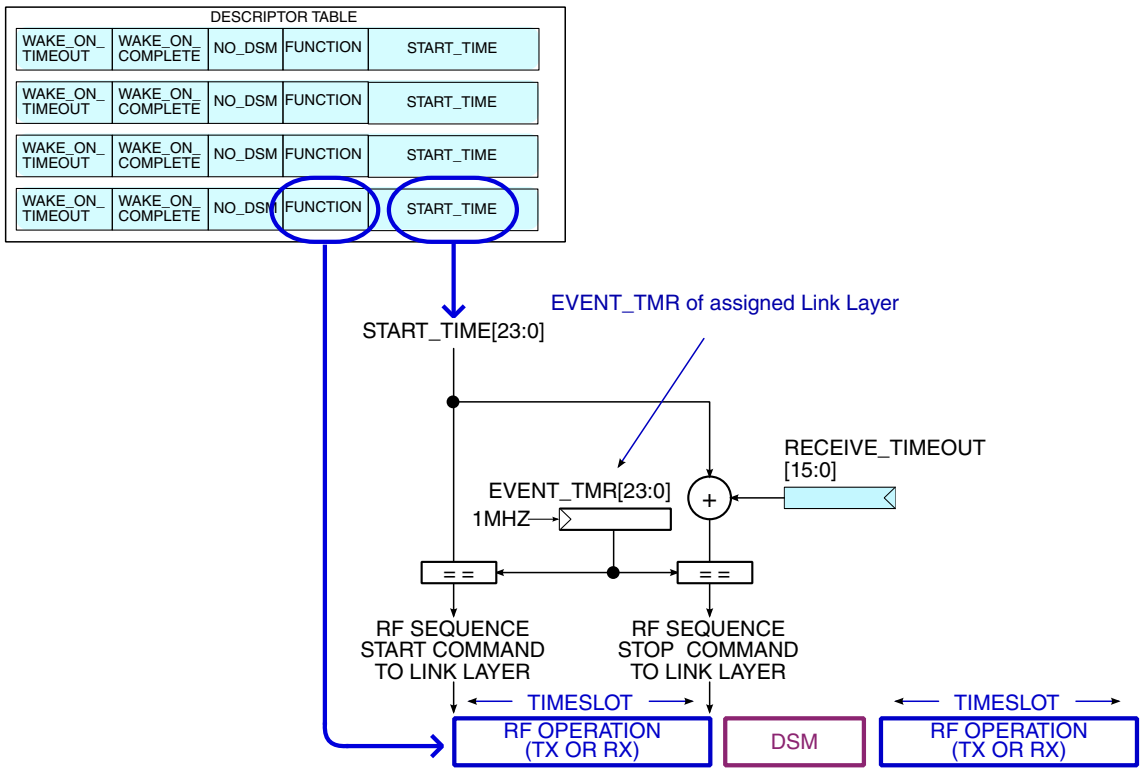

**Figure 64-94. EVENT SCHEDULING IN TIMESTLOT SCHEDULING MODE**

In any timeslot, the assigned FUNCTION is a simple TX or RX operation. There is no automatic acknowledgement of packets. If acknowledgement is required during a timeslot, the MCU must be awakened (by setting the WAKE_ON_COMPLETE bit of the slot's descriptor), and the software must handle the acknowledgement, using standard Link Layer (not WOR) resources, within the turnaround time requirement (if any). WOR hardware will hold its state and wait for software to complete the acknowledgement, and other required tasks, before advancing to the next slot on software command.

If the assigned protocol engine is 802.15.4, an autosequence is available which is a TX sequence preceded by a CCA (Clear Channel Assessment). If the CCA results in a busy channel, the autosequence terminates without transmission; otherwise the transmission proceeds. This autosequence can be used in WOR Timeslot mode by appropriately configuring the 802.15.4 Link Layer.

In any timeslot, if the assigned FUNCTION is RX, a TIMESTAMP can be captured to record the instant the packet's Access Address or SFD arrives at the Link Layer packet processor. There are 4 TIMESTAMP registers, once for each slot; hence, timestamps for the last 4 slots during which packets are received, can be recorded. See Section Timestamps for more details.

Typically, for RX timeslots, it is desirable to wake the MCU on good packets only. Thus, the slot descriptor's WAKE_ON_COMPLETE field should be set to 1. If it is desired to wake the MCU on no-packet, or on incorrecty-received packets, the WAKE_ON_TIMEOUT descriptor field can be set to 1. If WAKE_ON_TIMEOUT is set to 1 on any slot's descriptor, the WAKE_ON_COMPLETE field is *implied* to be set to 1 as well, regardless of its actual programmed value.

Typically, for TX timeslots, it is desirable to wake the MCU after each transmission, to service the Packet Buffer. In such scenarios, WAKE_ON_COMPLETE should be set to 1. If it is required to transmit the same packet repeatedly, across multiple slots, such that the Packet Buffer does not require regular service, WAKE_ON_COMPLETE can be set to 0, to skip the MCU wakeup, on any slot.

In Timeslot Scheduling mode, the MCU *must* be awakened at least once every *N* slots, to refresh the descriptor table (or at least, to refresh the START_TIME's), with *N* being the value of SLOTS_USED. This periodic wakeup requirement must be enforced by appropriate setting of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT fields of the 4 slot descriptors. This is a requirement imposed on WOR software. (The same period wakeup requirement does not necessarily apply to Constant Interval scheduling mode. See next section.)

## Constant-Interval Mode

Constant-Interval mode is appropriate when the schedule for RF transactions is perfectly periodic. A good example of such a scheduling regime, is the Bluetooth Low Energy Scanning State. In this state, a SCAN_INTERVAL is defined, which sets the interval between receive operations, and a SCAN_WINDOW is defined, which sets the duration of receiver "ON" time within the SCAN_INTERVAL. Wake-On-Radio adopts the principles of BLE SCAN_INTERVAL and SCAN_WINDOW, broadening their scope to apply to any type of RF operation (TX or RX), and modifying the nomenclature to better represent the nature of the operations, to WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW.

Instead of programming timeslot START_TIME's into the slot descriptors, Contant-Interval requires that WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW be programmed instead. An additional parameter, WOR_EVENT_START, determines the instant of the first RF operation of the Constant-Interval WOR session, in case the desired start time is not immediate. WOR_EVENT_START is also programmed into the descriptor table. In Constant-Interval scheduling mode, WOR hardware processes the descriptors, and uses WOR_EVENT_INTERVAL, WOR_EVENT_WINDOW, and WOR_EVENT_START, to calculate the start time (Event Timer match), for the first RF operation, as well as all subsequent RF operations, on a rolling basis. WOR software is not required to refresh the descriptor table on a periodic basis, and would only intervene

in the descriptors if a change was required to any parameter (e.g., a BLE "Anchor Point Move" during a connection would require descriptor updates). In Constant-Interval mode, the start of WOR_EVENT_WINDOW always aligns to the start of WOR_EVENT_INTERVAL.

Aside from replacing the Timeslot descriptor START_TIME parameters with WOR_EVENT_INTERVAL, WOR_EVENT_WINDOW, and WOR_EVENT_START, the descriptor format is identical across the 2 scheduling modes, and the descriptor storage space (registers) is completely shared, since only 1 scheduling mode can be in effect at any given time. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor, and how the descriptor table is shared between the 2 scheduling modes.

A diagram depicting an example of Constant-Interval scheduling mode is shown below. In this diagram, the scanning device is in Constant-Interval mode, with the WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW indicated.

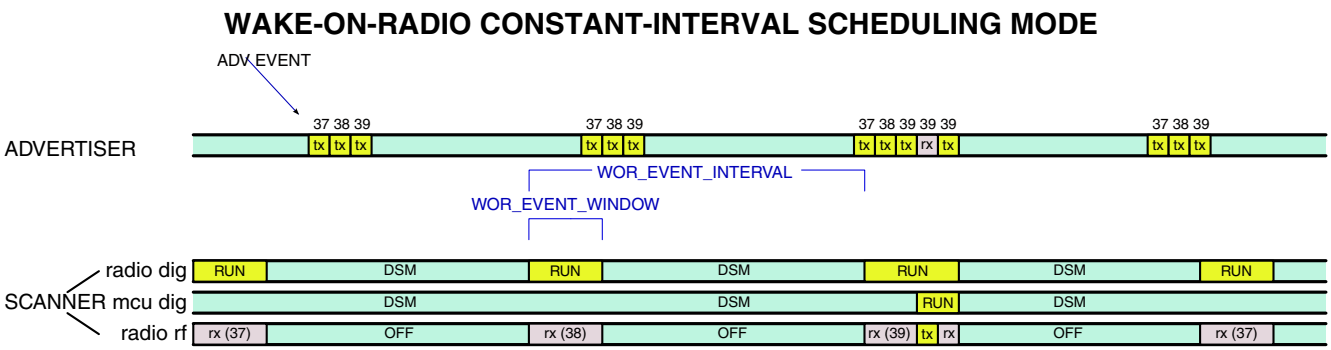

**Figure 64-95. CONSTANT-INTERVAL SCHEDULING MODE EXAMPLE**

When RF operations are to be scheduled using Wake-On-Radio in a Constant-Interval context, the WOR_EVENT_START, WOR_EVENT_INTERVAL, and WOR_EVENT_WINDOW parameters for the Constant-Interval operation are programmed into the descriptor table. These need be programmed only once, unless a change in network timing require an on-the-fly change to one of these parameters. The units for all 3 WOR_EVENT parameters are microseconds. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor. WOR hardware will process these 3 parameters to calculate the initial start time, and all subsequent start times, on a rolling basis. The start times computed by WOR hardware, are relative to the Event Timer of the assigned Link Layer. WOR hardware will monitor the assigned Link Layer's Event Timer; when it matches the next computed start time, WOR hardware will initiate an RF sequence. The type of sequence is determined by the current slot descriptor's FUNCTION field, and can be TX or RX. The

RF operation will be allowed to continue, until it either self-terminates, or a timeout is reached. The timeout period for Constant-Interval scheduling mode is determined by the WOR_EVENT_WINDOW descriptor field. If a timeout is reached, i.e.,

EVENT_TMR = START_TIME (computed) + WOR_EVENT_WINDOW (descriptor),

WOR hardware will terminate the sequence. Timeout applies to RX sequences only. RX sequences may result in no packet being received, a packet being received which is not addressed to the device, or a packet which is received corruptly. Any of these scenarios will result in a timeout and a WOR shutdown of the sequence. A correctly received packet addressed to the device will self-terminate the RX sequence before the timeout is reached. Timeout is not relavent to TX sequences, since these always self-terminate. The concept of slots still applies to Constant-Interval Mode. The number of slots used can be any integer from 3 to 4 for Constant-Interval mode. The register SLOTS_USED is programmed with this value. Consecutive RF operations are assigned to consecutive slots, with the slot descriptor's parameters (e.g. FUNCTION, or WAKE_ON_COMPLETE) applying to the current slot. As in Timeslot mode, in Constant-Interval mode, WOR hardware will increment the slot number for each new RF operation, modulo SLOTS_USED.

In any timeslot, the assigned FUNCTION is a simple TX or RX operation. There is no automatic acknowledgement of packets. If acknowledgement is required during a timeslot, the MCU must be awakened (by setting the WAKE_ON_COMPLETE bit of the slot's descriptor), and the software must handle the acknowledgement, using standard Link Layer (not WOR) resources, within the turnaround time requirement (if any). WOR hardware will hold its state and wait for software to complete the acknowledgement, and other required tasks, before advancing to the next slot on software command.

If the assigned protocol engine is 802.15.4, an autosequence is available which is a TX sequence preceded by a CCA (Clear Channel Assessment). If the CCA results in a busy channel, the autosequence terminates without transmission; otherwise the transmission proceeds. This autosequence can be used in WOR Timeslot mode by appropriately configuring the 802.15.4 Link Layer.

In any timeslot, if the assigned FUNCTION is RX, a TIMESTAMP can be captured to record the instant the packet's Access Address or SFD arrives at the Link Layer packet processor. There are 4 TIMESTAMP registers, once for each slot; hence, timestamps for the last 4 slots during which packets are received, can be recorded. See Section Timestamps for more details.

Typically, for RX timeslots, it is desirable to wake the MCU on good packets only. Thus, the slot descriptor's WAKE_ON_COMPLETE field should be set to 1. If it is desired to wake the MCU on no-packet, or on incorrecty-received packets, the

WAKE_ON_TIMEOUT descriptor field can be set to 1. If WAKE_ON_TIMEOUT is set to 1 on any slot's descriptor, the WAKE_ON_COMPLETE field is *implied* to be set to 1 as well, regardless of its actual programmed value.

Typically, for TX timeslots, it is desirable to wake the MCU after each transmission, to service the Packet Buffer. In such scenarios, WAKE_ON_COMPLETE should be set to 1. If it is required to transmit the same packet repeatedly, across multiple slots, such that the Packet Buffer does not require regular service, WAKE_ON_COMPLETE can be set to 0, to skip the MCU wakeup, on any slot.

Unlike Timeslot mode, in Constant-Interval mode, it is not required to wake up the MCU at least every *Nth* slot to refresh the descriptor start times, because WOR hardware is able to compute all future start times on a rolling basis. If all slots are of the same type (same FUNCTION, TX or RX, and same descriptor information), there is no hard limit on the number of consecutive slots that can be executed between MCU wakeups. To set such a upper limit, the WAKE_ON_NTH_SLOT[7:0] register can be programmed with a value. When the number of slots elapsed after setting SLOTS_USED to a non-zero value to begin a WOR session, reaches the value of WAKE_ON_NTH_SLOT, the MCU will automatically be awakened at the end of the current slot, regardless of the setting of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits in the descriptor. The WAKE_ON_NTH_SLOT register is only relavent to Constant-Interval scheduling mode, and has no effect in Timeslot mode. In Constant-Interval mode, if automatic wake on *Nth* slot is not desired, set WAKE_ON_NTH_SLOT=0 to disable this wakeup upper-limit. However, if a zero setting is used, software *must* program at least one of the slot descriptors to schedule an MCU wakeup by setting the either WAKE_ON_COMPLETE or WAKE_ON_TIMEOUT fields of the descriptor to 1; otherwise a situation could arise where the MCU is never awakened by WOR.

### 64.3.8.3.3 Descriptor Format

As mentioned in previous sections, Wake-On-Radio allows the next several RF operations to be scheduled in advance. For scheduling purposes, each of the next, several RF operations is assigned to a slot. Each slot is associated with a descriptor, which is a hardware-based data structure containing information about the characteristics of the slot, and instructions for how WOR hardware should execute it. Characterisics include start time of the RF operation, and type (function) or operation to be conducted by WOR. Software schedules the next *N* RF operations (slots) by programming the next *N* descriptors with the slots' characteristics. Software then sets the SLOTS_USED register to *N* to begin a WOR session. WOR hardware includes a 2-bit slot counter that cycles through the slots, in order, starting with SLOT 0; the slot counter is used to select the "current descriptor". The current descriptor's slot characteristics are forwarded to the WOR state machine, which executes the RF operation per the instructions in the

descriptor. After the RF operation is complete, the slot counter is incremented by 1 (modulo SLOTS_USED), and the next slot's descriptor becomes the "current" one. The process repeats indefinitely until the WOR session is ended by setting SLOTS_USED=0. WOR hardware automaticlly inserts (unless instructed otherwise in the descriptor) a DSM cycle, after the current slot's RF operation completes, with a DSM duration that lasts until the start time of the *next* slot, so that time between RF operations is always filled with DSM, for maximum power savings. After setting SLOTS_USED to a non-zero value to begin a WOR session, the MCU can be put into a low power state, and remain there, until the last (*Nth*) slot completes, assuming Timeslot scheduling mode. (For Constant Interval mode, MCU wake up on the *Nth* slot is not required. See Section Scheduling Modes for information on when and how the MCU is to be awakened for Constant-Interval mode.)

The descriptor format for Timeslot scheduling mode is shown in the diagram below, indicating the various fields in the descriptor, and the bits assigned to each field:

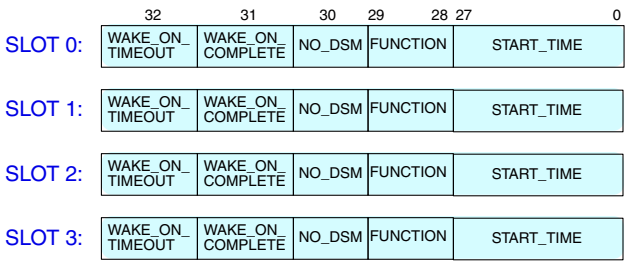

**Figure 64-96. DESCRIPTOR FORMAT (TIMESLOT MODE)**

The descriptor format for Constant-Interval scheduling mode is shown in the diagram below, indicating the various fields in the descriptor, and the bits assigned to each field:

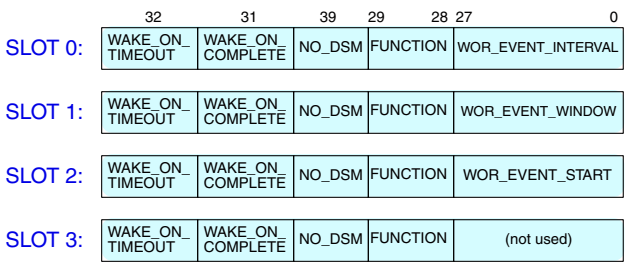

**Figure 64-97. DESCRIPTOR FORMAT (CONSTANT-INTERVAL MODE)**

The descriptor formats for Timeslot and Constant-Interval scheduling modes are almost identical, and so the desciptor hardware is almost completely shared by the 2 scheduling modes, as shown in the diagram below:

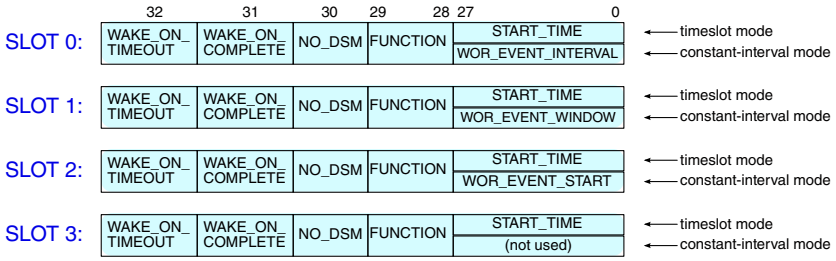

**Figure 64-98. DESCRIPTOR FORMAT (SHARED)**

Descriptor fields are described in the table below:

| FIELD | DESCRIPTION |
|---|---|
| START_TIME | The instant at which to begin the current slot's RF operation. START_TIME is relative to the assigned Link Layer's Event Timer. Units are microseconds. Because the Event Timers' bit widths vary with protocol, see START_TIME programming information later in this section. Applies to Timeslot mode only. WOR hardware will automatically adjust this value with window-widening, if enabled. |
| WOR_EVENT_INTERVAL | Sets the interval between the start of RF operations for consecutive slots. Units are microseconds. Applies to Constant-Interval mode only. WOR hardware will automatically adjust this value with window-widening, if enabled. |
| WOR_EVENT_WINDOW | Maximum duration of the transceiver "ON" time for the current slot. "ON" time will be less than this if the RF operation self-terminates. Units are microseconds. Applies to Constant-Interval mode only. The start of the WOR_EVENT_WINDOW aligns to the start of the WOR_EVENT_INTERVAL. WOR hardware will automatically adjust this value with window-widening, if enabled. |
| WOR_EVENT_START | The instant at which to begin the RF operation for the first SLOT 0 of the WOR session. WOR_EVENT_START is relative to the assigned Link Layer's Event Timer. Units are microseconds. Because the Event Timers' bit widths vary with protocol, see WOR_EVENT_START programming information later in this section. Applies to Constant-Interval mode only. WOR hardware will automatically adjust this value with window-widening, if enabled. |
| FUNCTION | This 2-bit field defines the RF function of the slot:<br>0: No RF<br>1: TX<br>2: RX<br>3: Reserved |
| NO_DSM | By default, a DSM cycle is automatically entered at the end of the current slot's RF operation, and the DSM cycle is timed to expire just before the start time of the next consecutive slot. If this field is set to 1, DSM is not entered, and the WOR state machine holds the radio in RUN state until the start time of the next slot is reached. NO_DSM can be used to execute back-to-back, or closely spaced RF operations, such as a BLE 3-channel advertising event. |

*Table continues on the next page...*

| FIELD | DESCRIPTION |
|---|---|
| WAKE_ON_COMPLETE | Instructs the WOR state machine to permit an interrupt to wake up the MCU at the end of a succesfully completed RF operation. RX operations are successfully completed if a packet is received before the timeout, which passes CRC and packet filtering rules. TX operations are always successfully completed. A successfully completed operation with WAKE_ON_COMPLETE=1 will cause the WOR state machine to temporarily remove its Link Layer interrupt inhibits, allowing the assigned Link Layer's RF interrupts (RXIRQ, TXIRQ, and/or SEQ_END_IRQ) to propagate, resulting in an MCU wakeup. If WAKE_ON_TIMEOUT=1, WAKE_ON_COMPLETE is *implied* to be 1 as well, regardless of the setting of this field. |
| WAKE_ON_TIMEOUT | Instructs the WOR state machine to permit an interrupt to wake up the MCU at the point of timeout of an RX operation. For Timeslot mode, timeout is determined by the RECEIVE_TIMEOUT[15:0] register; for Constant-Interval mode, timeout is determined by WOR_EVENT_WINDOW descriptor field. In either case, window-widening will automatically adjust the timeout instant, if enabled. A timeout which occurs with WAKE_ON_TIMEOUT=1 will cause the WOR state machine to temporarily remove its Link Layer interrupt inhibits, allowing the assigned Link Layer's SEQ_END_IRQ to propagate, resulting in an MCU wakeup, with a notification of timeout. |

Event Timer bit width various across protocols. For 802.15.4, Event Timer is 28 bits; for other protocols, Event Timer is 24 bits. In all cases, the Event Timer clock rate is 1MHz. For programming the non-802.15.4 START_TIME descriptor fields, 4 0's should prepend the 24-bit Event Timer match value. The same rule applies to programming the WOR_EVENT_START field.

When FUNCTION is set to "NO_RF", no RF operation is performed during the slot. In this scenario, the WOR state machine will wait until the slot's programmed (or computed) START_TIME, and then automatically re-enter DSM until the next consecutive slot's START_TIME is reached. This allows multiple (up to 4) DSM-only slots which effectively extends the maximum DSM duration fourfold, to 1073 seconds (about 18 minutes), for the 802.15.4 protocol, or 67 seconds (about 1 minute) for all other supported protocols. However the RF Oscillator is activated breifly at each slot's START_TIME so that the WOR can process the current slot descriptor, and update the assigned Link Layer's Event Timer. Extending the DSM duration using the "NO_RF" method is referred to as "DSM cascading".

During an RX operation on any slot, if an AA or SFD has been detected at the point of timeout, the timeout (and the automatic shudown of the sequence by the WOR state machine) is *deferred* until either:

1: The packet is fully received and determined to be good. In this case the WAKE_ON_COMPLETE bit determines if the MCU is to be awakened.
2: The packet is fully received and determined not to be good. In this case the WAKE_ON_TIMEOUT bit determines if the MCU is to be awakened.

There are no time restrictions on programming the descriptor table. All descriptor fields can be modified at any time. Needless to say, caution should be exercised with modifying descriptor START_TIME, and other parameters, for the *current* slot; START_TIME (or WOR_EVENT_START) must be in the future, and FUNCTION should not be modified once the START_TIME has been reached.

### 64.3.8.3.4 State Machine

In Wake-On-Radio, future RF operations are scheduled by programming instructions into the WOR Descriptor table. Based on descriptor specifications, WOR hardware organizes the scheduled RF operations into slots, with one RF operation per slot. The slot includes more than just the RF operation. Idle time between the current time, and the start of the RF operation, is filled with DSM. WOR hardware must compute the required DSM duration, and request DSM from RSIM (Radio System Integration Module). A diagram showing how WOR hardware processes the descriptor table, and organizes the required operations into consecutive slots, encompassing both DSM and RF, is shown below.

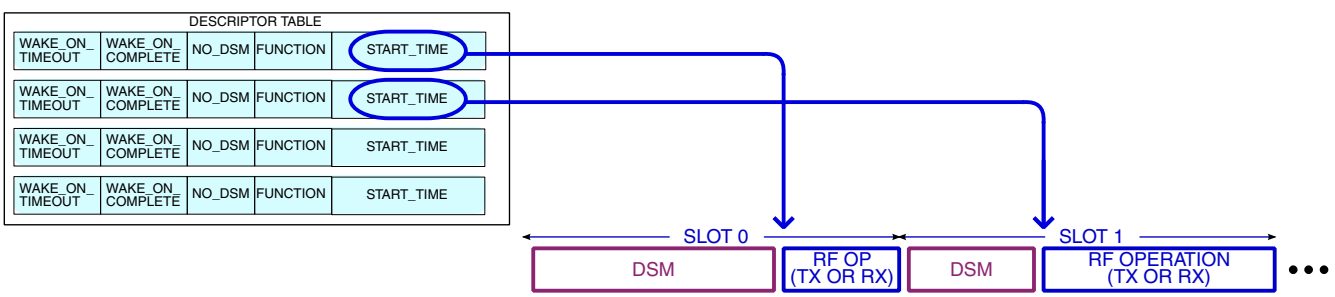

**Figure 64-99. TIMELINE OF CONSECUTIVE SLOTS**

Once a WOR session has been initiated by setting SLOTS_USED to a non-zero value, the timeline of consecutive slots shown, will repeat indefinitely, with the slot number increasing by 1 after each slot, modulo SLOTS_USED.

During each slot, WOR hardware must perform a series of tasks, e.g., computing the DSM duration, commanding the the assigned Link Layer to start and stop the RF sequence, etc. Some of the required WOR hardware tasks are superimposed on the slot timeline, in the diagram below.

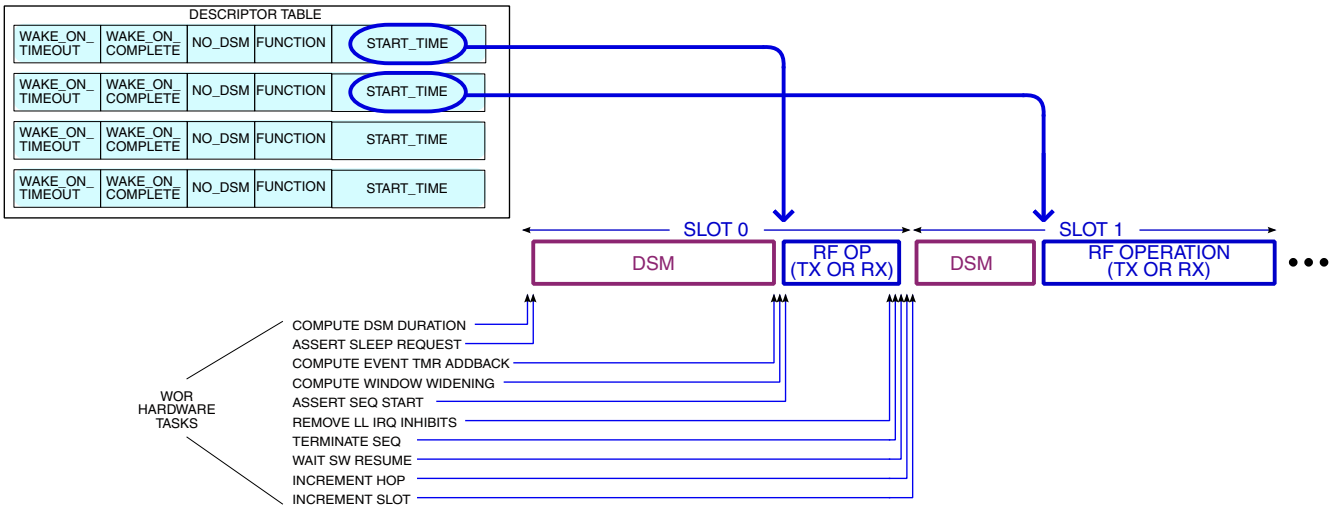

**Figure 64-100. SLOT TIMELINE WITH HARDWARE TASKS**

The WOR state machine is responsible for processing the descriptor table, and performing all the required tasks during each slot. The 10-state machine interfaces with the assigned Link Layer for sequence operations, and with RSIM for DSM operations. The state machine also controls the incrementing of the the slot counter, and the frequency hop table index. A state diagram of the WOR state machine is shown below.

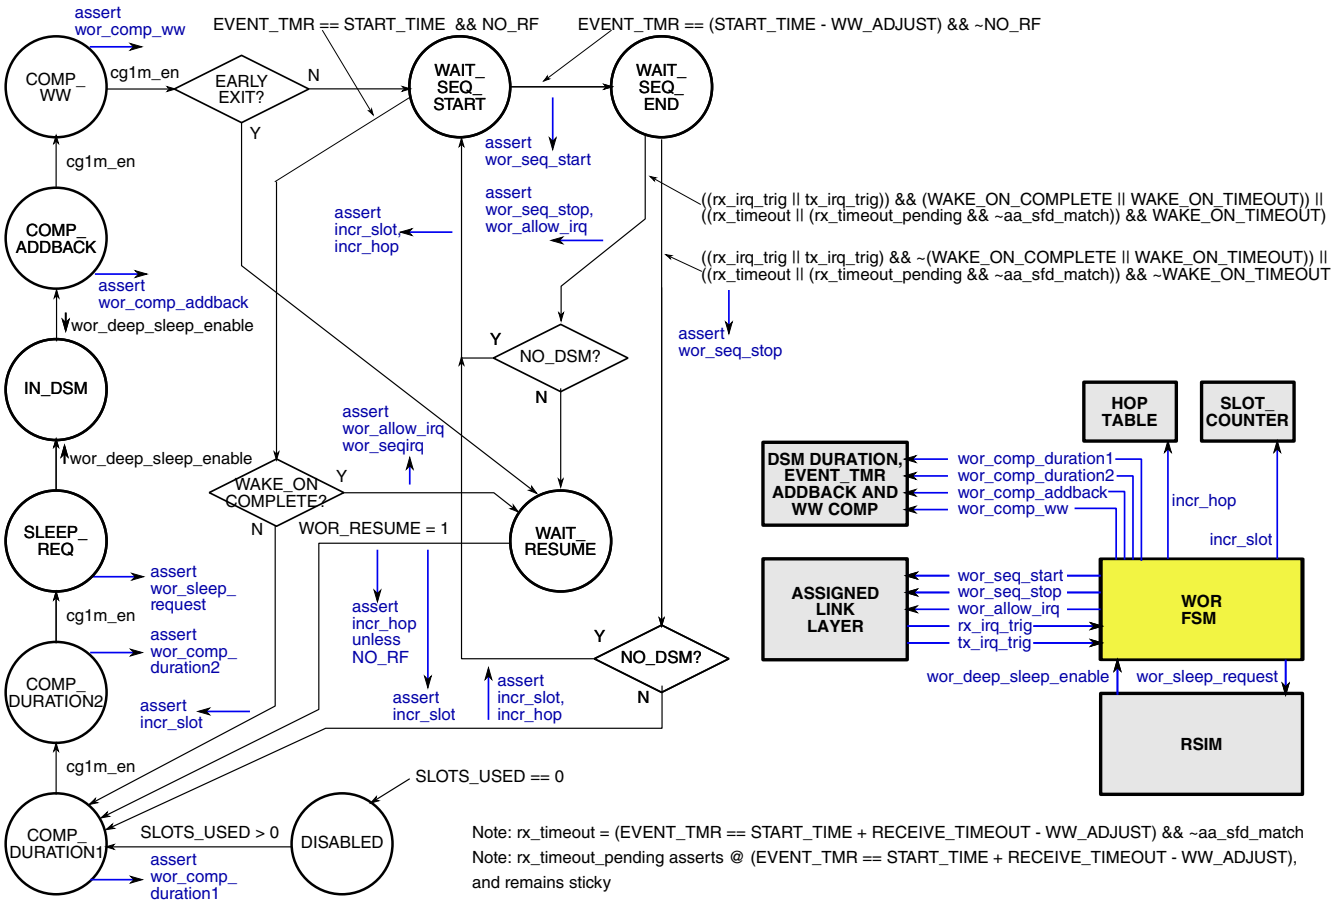

**Figure 64-101. WAKE-ON-RADIO STATE DIAGRAM**

A description of the WOR states follows.

## DISABLED

WOR is in its disabled state whenever SLOTS_USED=0. WOR can be taken to "DISABLED" from any state by setting SLOTS_USED=0. WOR can be enabled by setting SLOTS_USED to a non-zero value, which initiates a new WOR "session".

## COMP_DURATION1

WOR must compute the duration of the upcoming DSM cycle. This is done in 2 stages (states). COMP_DURATION1 is the first stage. Whenever the slot counter is incremented to begin a new slot, the slot's (descriptor's) START_TIME is in the future. In most cases, the START_TIME is distant enough that DSM is justified. During COMP_DURATION1, WOR computes the time to the next START_TIME, by subtracting both the current time (the assigned Link Layer's Event Timer) and the time-accumulated window-widening (if enabled) from the slot descriptor's START_TIME. (See Section Window Widening for more details on this feature.) The result of this subtraction is MICROSECONDS_TO_START_TIME[27:0]. This value must be converted to 32.768KHz cycles to be of use to RSIM. The multiplier is 0.032714844

(536 / 16384), which is an approximation to the ideal conversion factor, with a precision of 0.16%. The product is truncated to integer, the result represents the number of 32.768KHz cycles to remain in DSM prior to the next START_TIME. The hardware computations which take place during COMP_DURATION1 are shown in the following diagram.

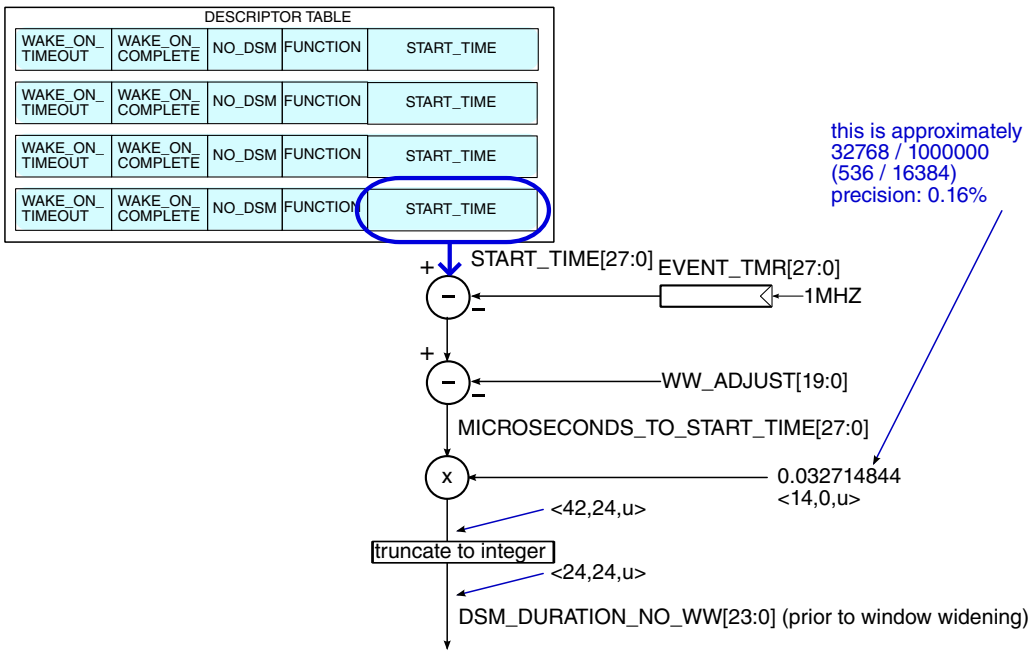

**Figure 64-102. COMP_DURATION1**

However this intermediate result does not account for the fact that window-widening for the upcoming DSM cycle itself, must be subtracted from this product. This is separate from the "accumulated" window-widening which has built up during the WOR session so far, which has already been accounted for. The estimate for the next DSM cycle's window widening is handled in the next state, COMP_DURATION2

The WOR output wor_clr_dsm_duration is asserted in this state, which is sent to the RSIM to proactively clear the DSM Duration Counter, which becomes active in the IN_DSM state (see below). The wor_clr_dsm_duration is an active-high, registered (glitch-proof) output signal.

## COMP_DURATION2

If window-widening is enabled, the DSM duration computed during COMP_DURATION1 may be long enough that it will need to be shortened slightly to account for window-widening which will accumulate during the DSM cycle itself. The computation for this window-widening is performed during this state. (See Section Window Widening for more details on this computation, and the usage of WW_DSM_FACTOR.) The (intermediate) duration from COMP_DURATION1 is

multiplied by the DSM window-widening factor, and the product is subtracted from the duration estimate. The difference is a more accurate duration that accounts for window-widening during the DSM cycle. In a final step, a guardband is subtracted from the DSM duration. The guardband, with units of 32.768KHz clock cycles, guarantees that the DSM will complete on time before the next START_TIME is reached, accounting for RSIM synchronization and other delays in processing the WOR's sleep request. The guardband, which applies to all DSM cycles initiated by WOR, is determined by the register DSM_GUARDBAND[3:0]. The result of this step, is the final DSM duration (wor_dsm_duration[23:0]) which is then sent to the RSIM, which is responsible for radio DSM entry and exit. The hardware computations which take place during COMP_DURATION2 (alongside those covered by COMP_DURATION1) are shown in the following diagram.

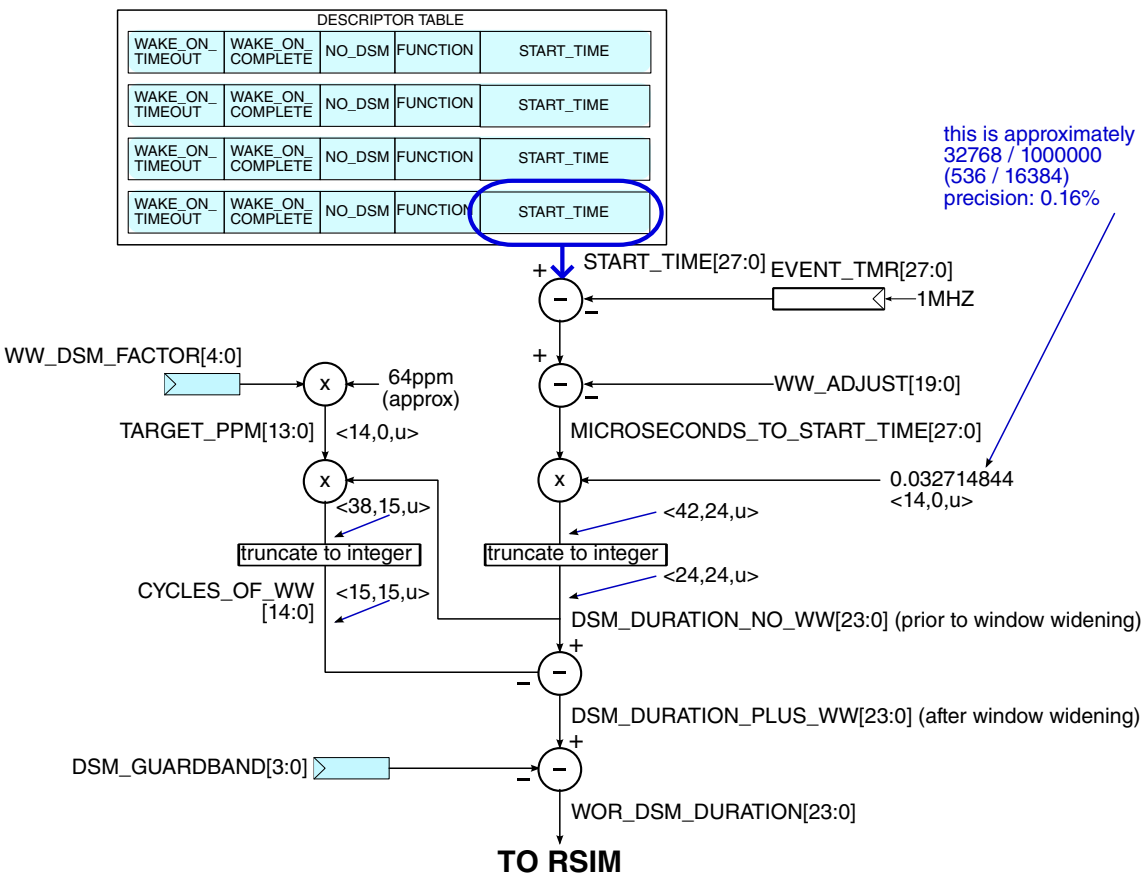

**Figure 64-103. COMP_DURATION2**

## SLEEP_REQ

In this state, WOR asserts its sleep request (wor_sleep_request) to the RSIM. This is a level, active-high, and registered (glitch-proof) signal to RSIM to indicate a DSM cycle is being requested of precise duration wor_dsm_duration[23:0], which was computed during the prior 2 WOR states. The units of wor_dsm_duration[23:0] are 32.768KHz

clock cycles. RSIM shall synchronize wor_sleep_request into the 32.768KHz clock domain, and use it to activate the RSIM's DSM state machine. The RSIM DSM state machine shall place the radio in DSM, and simultaneously assert the output: wor_deep_sleep_enable. This signal is the precise indicator of DSM being "in effect", and is used to gate the assigned Link Layer's clocks and freeze its Event Timer.

## IN_DSM

DSM is in effect during this state. Because the RF Oscillator has been disabled, there are no clocks to WOR, including its state machine, or the Link Layer, in this state. This is merely a holding state that prevails until DSM exits and the clocks to WOR and Link Layer are restarted. During this state, RSIM will use wor_deep_sleep_enable to enable a 24-bit counter which counts out the precise number of cycles in wor_dsm_duration[23:0]. When this counter reaches wor_dsm_duration, RSIM shall exit DSM and de-assert wor_deep_sleep_enable. RSIM shall provide the final count of the 24-bit counter which was used to time the DSM, using output signal rsim_dsm_duration[23:0]. In most cases, rsim_dsm_duration will be an exact match to wor_dsm_duration; the exceptional case is an unscheduled, early exit of DSM (see Section DSM Early Exit.) The interface signals between WOR and RSIM, and a high-level description of the hardware tasks performed by RSIM during IN_DSM state, is shown in the following diagram.

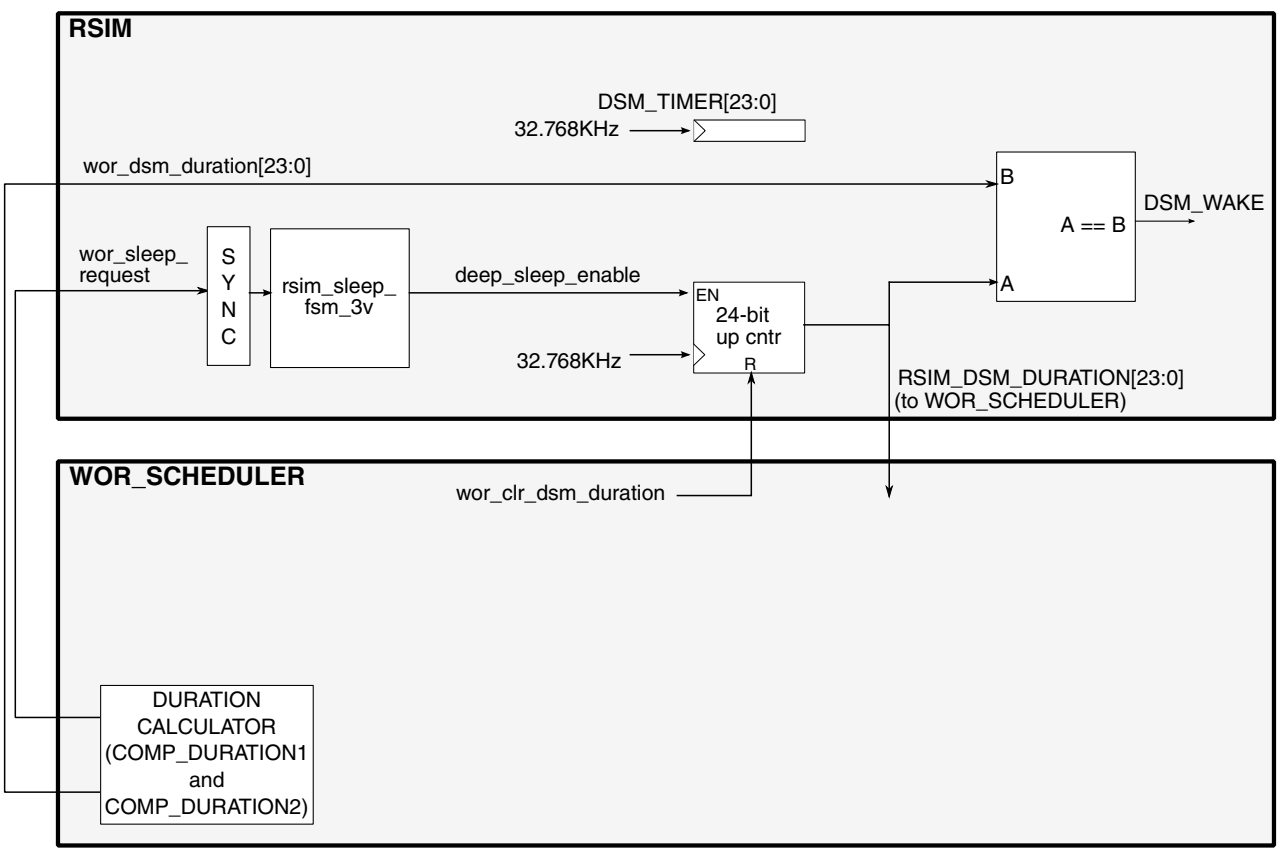

**Figure 64-104. IN_DSM**

## COMP_ADDBACK

During the previous state, IN_DSM, the Reference Oscillator was disabled, and so the Event Timer of the assigned Link Layer was frozen. After DSM completes, clocks are restored and Event Timer resumes counting, but it is "behind" by the amount of time that the radio was in DSM. WOR hardware must compute the amount of DSM time, convert it to microseconds, and "add it back" to the Event Timer, so that after the addback, the Event Timer timebase is restored to where it would have been, had there been no DSM. (Note: there is a maximum of 1us of "loss of precision" upon every DSM exit; this timebase error is random and will not accumulate, it will average out over many DSM cycles). In this state, WOR computes the addback value by multiplying the rsim_dsm_duration[23:0] (the precise number of 32.768KHz clock cycles during which RSIM held the radio in DSM) by 30.517578125 (the number of microseconds per 32.768KHz clock cycle). The 30.517578125 is an unsigned 14-bit value with 5 integer bits. The other multipicand, rsim_dsm_duration is an unsigned integer. The product is the DSM elapsed time in microseconds, a 38 unsigned bit value with 29 integer bits. The product is rounded to the nearest integer and the 5 MSB's are discarded, resulting in the final wor_addback[23:0] value. At the end of this state, this result is sent to the assigned Link Layer's Event Timer, along with the wor_addback command (pulse), indicating to the Link Layer that it must add this amount to the current state of its Event Timer. After this point the protocol's timebase has been restored and operations can now be performed referencing the Event Timer. The following diagram depicts the hardware tasks performed in the COMP_ADDBACK state.

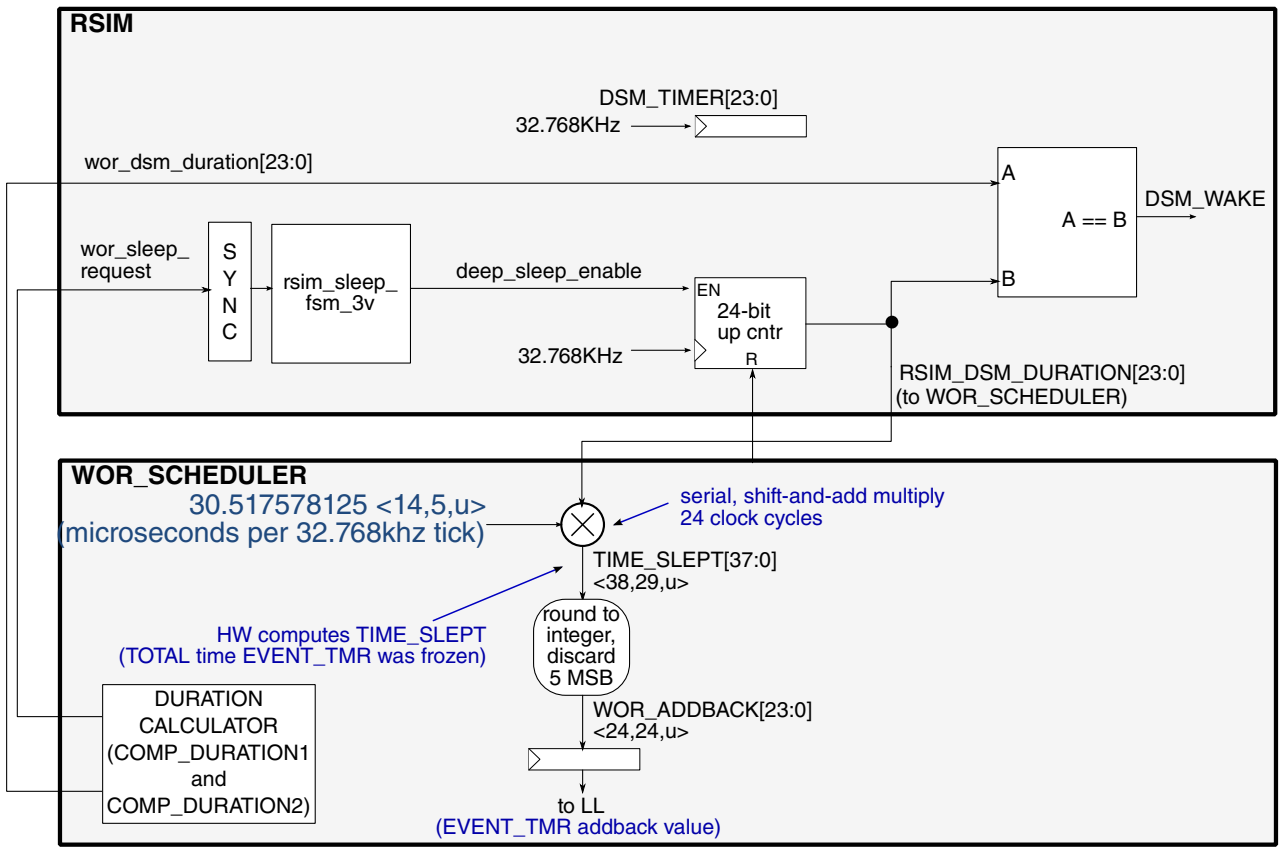

**Figure 64-105. COMP_ADDBACK**

## COMP_WW

If window-widening is enabled, WOR must compute how much to increase the receive window by, based on the duration of the just-completed DSM cycle, so that this early-start offset to the receive window is ready in advance of the slot descriptor's START_TIME. The window-widening increment is computed during this state. Details of this hardware task are described in Section Window Widening.

## WAIT_SEQ_START

After COMP_WW state, the WOR is ready to command an RF operation, and is only waiting for the slot descriptor's START_TIME to arrive. This start time will be in the near future since the DSM duration was timed to wake up "just in time" to start the RF operation, with sufficient guardband to guarantee that a DSM wake up can never occur too late. The WAIT_SEQ_START state merely waits for the assigned Event Timer to match the current slot descriptor's START_TIME. If the slot's FUNCTION is RX, and window widening is enabled, START_TIME is modified by the hardware to be:

START_TIME - ww_adjust[19:0],

where ww_adjust[19:0] is the time-accumulated window-widening "early start" amount for the RX operation (see Section Window Widening.) If the FUNCTION is not RX or if window-widening is disabled, START_TIME is unmodified. Once a START_TIME match to the Event Timer occurs, WOR asserts the Link Layer interface signal wor_tx_start_ext (if FUNCTION is TX), or wor_rx_start_ext (if FUNCTION is RX). Neither interface signal is asserted if FUNCTION is NO_RF. The assigned Link Layer will commence an RF operation, TX or RX, based on this WOR command. At this point, the WOR state machine arrives at a fork:

- If FUNCTION = NO_RF and the descriptor WAKE_ON_COMPLETE=1, the next state is WAIT_RESUME
- Else if FUNCTION = NO_RF and WAKE_ON_COMPLETE=0, the next state returns to COMP_DURATION1 to begin the next slot. The slot counter and hop table index are incremented.
- Else, this is an RF operation that must be waited for. The state machine advances to the WAIT_SEQ_END state.

### WAIT_SEQ_END

This state has been reached because an RF operation was launched during the previous state, and WOR is waiting for that operation to end. There are 3 ways for an RF operation to end:

- A TX operation self-terminates, indicated when the Link Layer asserts tx_irq_trig to WOR.
- A RX operation self-terminates due to a good packet reception, indicated when the Link Layer asserts rx_irq_trig to WOR.
- A RX operation times out. The rx_irq_trig is not asserted before the timeout. See Section Scheduling Modes for a description on the 2 methods WOR uses to compute the point-of-timeout, based on Scheduling Mode.

If either tx_irq_trig or rx_irq_trig is asserted, WOR advances to the next state (see below). If a point-of-timeout is reached without an rx_irq_trig, WOR hardware checks to see if Access Address Match has occurred (for protocols other than 802.15.4), or if SFD has been detected (for 802.15.4). If either is the case, timeout is deferred until either:

- The rx_irq_trig is ultimately asserted to indicate a good packet was received. This is a delayed good packet reception.
- The packet reception underway at point-of-timeout ultimately results in a CRC- or filtering-violation. This will automatically trigger a Link Layer RX recycle which will negate the AA-match or SFD-match indicator. WOR will detect this negation and declare a delayed timeout at this point.

If a timeout occurs, either nominal or delayed, WOR will assert wor_seq_stop_ext to the assigned Link Layer, causing an immediate abort of the RX sequence. This abort shall be handled by the protocol engine like a software abort. The wor_seq_stop_ext will not assert for a deferred timeout which results in a delayed good packet reception.

Nominally, WOR blocks the assigned Link Layer's RF-related interrupts from propagating to the MCU, to prevent unintended MCU wakeups during a WOR session. The RF-related interrupts for the supported protocol engines, are nearly identical in function across a 3 protocols, and are called RXIRQ, TXIRQ, and SEQ_END_IRQ. At the conclusion of an RF operation on a slot, WOR must decide whether to temporarily remove the Link Layer interrupt inhibits, to allow the Link Layer interrupt to be asserted to wake the MCU, based on which of the 5 outcomes to the RF operation occurred, and the state of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT descriptor fields. The following table specifies whether WOR blocks, or allows, the RF interrupts to propagate, at the conclusion of the RF operation.

| RF OPERATION OUTCOME | WAKE_ON_TIMEOUT=0, WAKE_ON_COMPLETE=0 | WAKE_ON_TIMEOUT=0, WAKE_ON_COMPLETE=1 | WAKE_ON_TIMEOUT=1, WAKE_ON_COMPLETE=x |
|---|---|---|---|
| tx_irq_trig | BLOCK | ALLOW | ALLOW |
| rx_irq_trig (nominal) | BLOCK | ALLOW | ALLOW |
| rx_irq_trig (delayed) | BLOCK | ALLOW | ALLOW |
| no rx_irq_trig @ nominal timeout | BLOCK | BLOCK | ALLOW |
| no rx_irq_trig @ delayed timeout | BLOCK | BLOCK | ALLOW |

At the conclusion of the RF operation, the WOR next state is a function of whether the Link Layer RF interrupts were BLOCKED or ALLOWED (see previous table), as well as the NO_DSM descriptor field as illustrated in the following table.

| RF OPERATION OUTCOME | INTERRUPTS BLOCKED, NO_DSM=0 | INTERRUPTS ALLOWED, NO_DSM=0 | NO_DSM=1 |
|---|---|---|---|
| tx_irq_trig | COMP_DURATION1 (increment slot, hop idx) | WAIT_RESUME | WAIT_SEQ_START (increment slot, hop idx) |
| rx_irq_trig (nominal) | COMP_DURATION1 (increment slot, hop idx) | WAIT_RESUME | WAIT_SEQ_START (increment slot, hop idx) |
| rx_irq_trig (delayed) | COMP_DURATION1 (increment slot, hop idx) | WAIT_RESUME | WAIT_SEQ_START (increment slot, hop idx) |
| no rx_irq_trig @ nominal timeout | COMP_DURATION1 (increment slot, hop idx) | WAIT_RESUME | WAIT_SEQ_START (increment slot, hop idx) |
| no rx_irq_trig @ delayed timeout | COMP_DURATION1 (increment slot, hop idx) | WAIT_RESUME | WAIT_SEQ_START (increment slot, hop idx) |

## WAIT_RESUME

If WOR has allowed the MCU to be awakened (interrupted) by temporarily negating the RF interrupt inhibits, WOR must enter a state which permits the MCU executing WOR or Link Layer software, to complete all its assigned tasks on the slot. These tasks may include processing and decrypting a received packet, servicing the packet buffer, and formulating and transmitting an acknowledge packet. The WAIT_RESUME state serves that purpose. The WAIT_RESUME state is reached whenever all of the following conditions are met:

- Current state is WAIT_SEQ_END
- FUNCTION is TX or RX
- RF operation completes with any outcome (rx_irq_trig, tx_irq_trig, nominal, or delayed timeout)
- NO_DSM=0
- RF Interrupts are ALLOWED (see table, WAIT_SEQ_END state)

WAIT_RESUME is also reached whenever all of these following conditions are met:

- Current state is WAIT_SEQ_START
- FUNCTION is NO_RF
- START_TIME match to the assigned Link Layer's Event Timer
- WAKE_ON_COMPLETE=1

Once WAIT_RESUME is reached, WOR software must authorize WOR hardware to resume the WOR session and advance to the next slot, by setting the WOR_RESUME register bit to 1. When WOR_RESUME is set to 1 in WAIT_RESUME state, WOR hardware takes the following steps:

1. Advances to the next slot (slot counter++ % SLOTS_USED)
2. Increments the frequency hop table index *unless* FUNCTION = NO_RF
3. Enters COMP_DURATION1 state on the new slot
4. Reimposes Link Layer interrupt inhibits

### 64.3.8.3.5 Window Widening

**OVERVIEW**

Because a device in a connected state is not receiving all the time, its timebase will invariably drift with respect to the timebase of other device(s) in the network, due to finite crystal oscillator tolerances amongst the networked devices. Reducing the duty cycle of the receiver, albeit necessary to achieve power savings, exacerbates the drift problem.

To compensate for drift, Receive Window Widening can be employed. As time elapses in a network connection between successful packet receptions, the window-widening algorithm gradually moves future receiver turn-on times to the left (advance) and the turn-off time to the right (retard) to allow the transmitted packet to fall within the

receiver's window in the presence of a drifting timebase. The effect of window-widening on successive receive cycles, none of which result in a good packet reception, is illustrated in the following diagram.

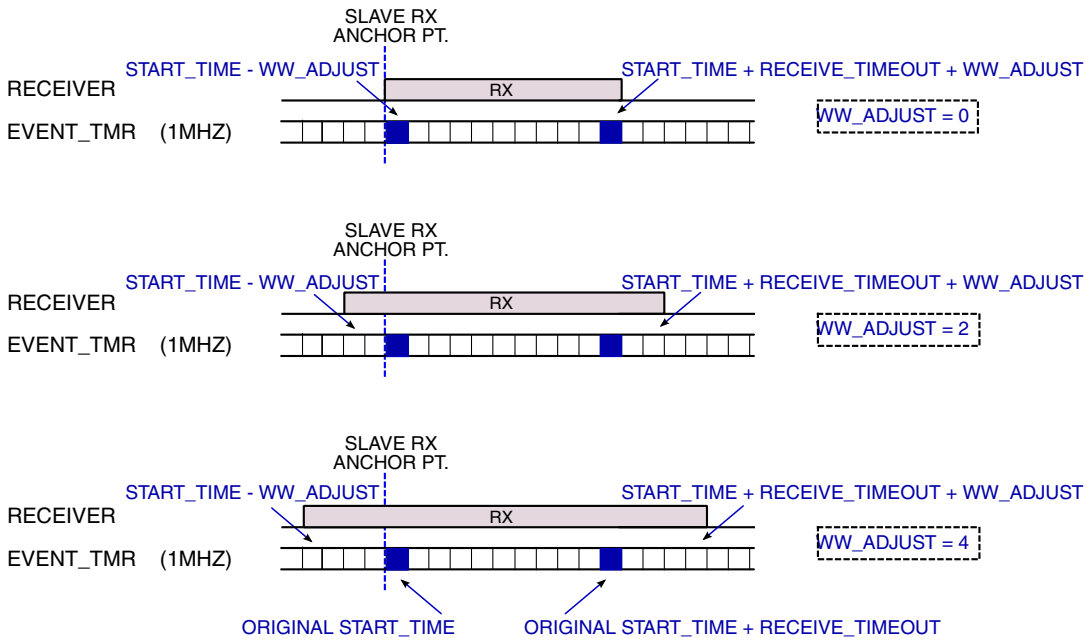

**Figure 64-106. EFFECT OF WINDOW WIDENING ON RECEIVE WINDOW**

Window widening is typically applicable only to the slave device(s) in a network, as the master (coordinator) of the network is normally the master of network timing. Thus, in Wake-On-Radio, window widening is optional, enabled by the by setting the WW_EN register bit to 1.

The Window widening algorithm needs to take into account the "Sleep Clock Accuracy" of the devices in the network. Sleep Clock Accuracy (SCA) is a *Bluetooth Low Energy* concept, and the BLE nomenclature is adopted by Wake-On-Radio, and extrapolated to all supported protocols.

In BLE, drift encountered by a slave device must be compensated by accounting for the SCA of both the master and the slave (self). The master transmits its SCA to the slave in the connection request (CONNECT_REQ), an advertising channel packet which informs an advertising slave of the master's desire to form a connection with it; the parameters on the CONNECT_REQ include the master's SCA. The slave device knows its own SCA, so the composite SCA is known at the point of connection establishment. Wake-On-Radio adopts this concept, although the precise method of informing the slave of Master SCA is protocol-dependent and takes place at a higher level, beyond the scope of this document.

BLE subdivides the allowed Master SCA into coarse ranges, to reduce the number of over-the-air bits required to inform the slave. The ranges are shown in the following diagram.

| SCA | *masterSCA* |
|---|---|
| 0 | 251 ppm to 500 ppm |
| 1 | 151 ppm to 250 ppm |
| 2 | 101 ppm to 150 ppm |
| 3 | 76 ppm to 100 ppm |
| 4 | 51 ppm to 75 ppm |
| 5 | 31 ppm to 50 ppm |
| 6 | 21 ppm to 30 ppm |
| 7 | 0 ppm to 20 ppm |

*Table 2.2: SCA field encoding*

**Figure 64-107. SCA RANGES**

The slave SCA must be accounted for as well, so the maximum composite SCA is 1000ppm. For Wake-On-Radio, this is the maximum allowed drift as well, and window-widening programmability will allow for drift amounts within these ranges to be compensated.

## FACTS

In the WOR hardware, the window-widening adjustment, is a value, ww_adjust[19:0], that is subtracted from the receiver START_TIME, and added to the receiver TIMEOUT, when the slot's FUNCTION = RX, as shown in the diagram below.

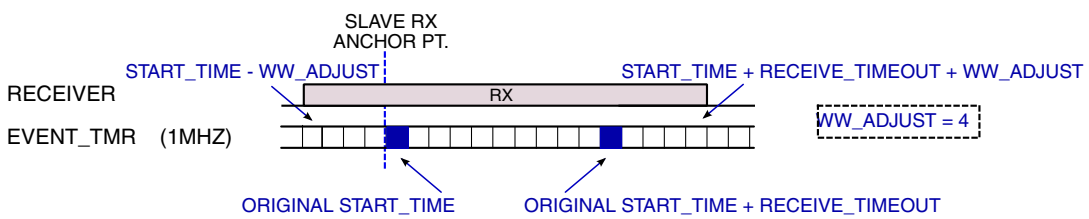

**Figure 64-108. WINDOW WIDENING EFFECT ON RX SEQUENCE**

The ww_adjust[19:0] adjustment, has no effect on START_TIME for slots using FUNCTION TX or NO_RF.

After system reset, if window-widening is enabled using WW_EN, ww_adjust[19:0] will increase linearly over time.

The adjustment, ww_adjust[19:0], will be reset to 0 under any of the following conditions:

1. system reset
2. good packet received (CRC verified and packet filtering passes)
3. Software writes a 1 to WW_NULL register bit

The reset-on-good-packet (item #2 above), can be inhibited by setting register bit WW_RESET_ON_RX=0. By default this bit is set.

The adjustment, ww_adjust[19:0], consists of 2 components, which are summed together:

1. **DSM adjustment:** computed at the conclusion of every DSM cycle based on rsim_dsm_duration[23:0]
2. **RUNTIME adjustment:** computed by periodically incrementing a binary counter by 1 every *N* EVENT_TMR ticks whenever NOT in DSM

The rates at which window-widening accumulates during DSM and RUNTIME, are controlled by 2 programmable registers. The programmed values of these registers should be informed by the combined (master + slave) SCA.

The 2 components of the window-widening adjustment, and the reset conditionality, are illustrated in the following diagram:

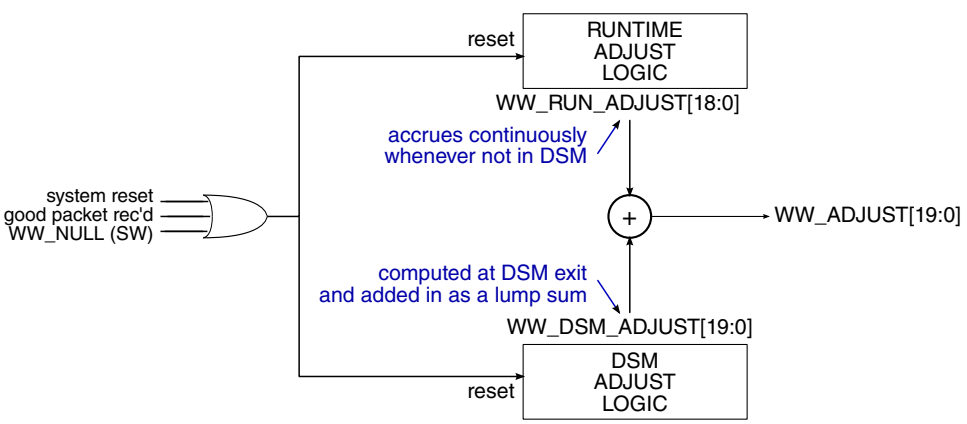

**Figure 64-109. WINDOW WIDENING COMPONENTS AND RESET CONDITIONALITY**

## WINDOW WIDENING DSM ADJUSTMENT

In Wake-On-Radio, every slot includes a DSM cycle (unless NO_DSM=1 in the descriptor). WOR hardware computes the window-widening DSM adjustment after the DSM cycle completes, during the WOR COMP_WW state. This state immediately follows the COMP_ADDBACK state which updates the Event Timer for time-slept. The WW DSM adjustment, ww_dsm_adjust[19:0], is computed, and then added to the composite, accumulated adjustment, ww_adjust[19:0], as a lump sum. During COMP_WW state, WOR hardware multiplies rsim_dsm_duration[23:0], which is the precise number of 32.768KHz cycles for which the RSIM held the radio in DSM, by a programmable factor which represents the number of microseconds per 32.768KHz clock cycle, scaled by the combined SCA of the master and slave (drift), i.e.,

**DSM_DURATION (from RSIM) * (masterSCA + slaveSCA), converted to µs**

Programmable register WW_DSM_FACTOR[4:0] maps the composite SCA (masterSCA + slaveSCA), in parts per million, to a multiplicand which represents

***N* * 64ppm * 30.5178125µs,**

where *N* = WW_DSM_FACTOR, and

30.5178125 is the *precise* number of microseconds per 32.76KHz tick, not an approximation.

Register WW_DSM_ADJUST allows SCA to be applied in coarse ranges, as described earlier in this section. Each LSB of WW_DSM_ADJUST is worth 64ppm of 30.5178125µs. Valid values are 0 ≤ WW_DSM_FACTOR ≤ 16. Consider the table below as a guide for selecting WW_DSM_FACTOR based on composite SCA:

| *masterSCA* + slaveSCA | Use this WW_DSM_FACTOR |
|---|---|
| 251 ppm to 500 ppm | 5 (320ppm) - 8 (512ppm) |
| 151 ppm to 250 ppm | 4 (256ppm) |
| 101 ppm to 150 ppm | 3 (192ppm) |
| 76 ppm to 100 ppm | 2 (128ppm) |
| 51 ppm to 75 ppm | |
| 31 ppm to 50 ppm | 1 (64ppm) |
| 21 ppm to 30 ppm | |
| 0 ppm to 20 ppm | |

**Figure 64-110. WW_DSM_FACTOR BASED ON COMPOSITE SCA**

A summary of all the hardware tasks performed to compute ww_dsm_adjust[19:0] during the COMP_WW state, is shown in the diagram below.

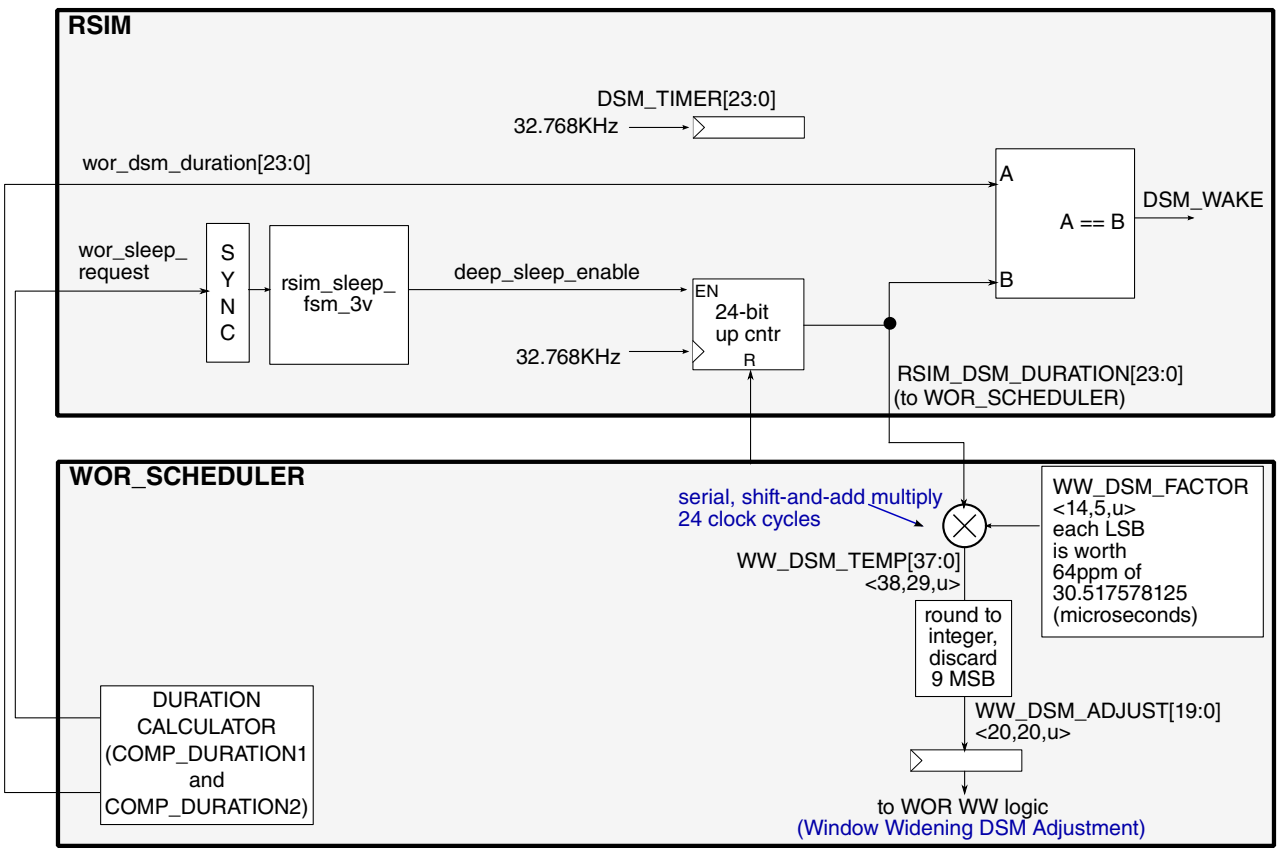

**Figure 64-111. HARDWARE TASKS DURING COMP_WW STATE**

## WINDOW WIDENING RUNTIME ADJUSTMENT

The window-widening RUNTIME adjustment is computed by incrementing a binary counter every *N* EVENT_TMR ticks whenever NOT in DSM (i.e., EVENT_TMR is running). *N* is a variable based on programmable register WW_RUN_ADJUST[4:0]. The programmable resolution, or granularity, of the DSM adjustment (64ppm), will be matched by the RUNTIME adjustment. Unlike the DSM adjustment, the RUNTIME adjustment is an approximation to the ideal value of *N*, since *N* is the result of a division operation whose quotient is not always an integer number of microseconds. However, the objective in Wake-On-Radio is to spend as little time in RUN between events as possible, so the DSM adjustment will dominate the sum. Therefore, additional resolution in the RUNTIME adjustment, although acheivable, would have little benefit in overall power savings.

*N* is a modulo for the binary counter which tracks the runtime adjustment, and represents the ideal number of microseconds between each increment to the adjustment, which is simply the reciprocal of the composite SCA, i.e.,

***N* = 1 / (master SCA + slave SCA)**

Using an example of composite SCA = 192ppm,

***N* = 1 / 192e-6 = 5208.333**

For implementation, each SCA range (the same table of ranges defined for the DSM adjustment) becomes an input to a look-up table (LUT) which approximates this division, rounding the quotient to the nearest integer. SCA range is represented by the WW_RUN_FACTOR. If WW_RUN_FACTOR=0, the RUNTIME adjustment never increments (special case). Valid values are 0 ≤ WW_RUN_FACTOR ≤ 16.

Every time the modulo *N* is reached, the binary counter resets to 0, and the RUNTIME adjustment is incremented by 1, meaning that the start of the next receive operation, has been advanced by 1µs. The hardware which implements the window widening RUNTIME adjustment is shown in the following diagram.

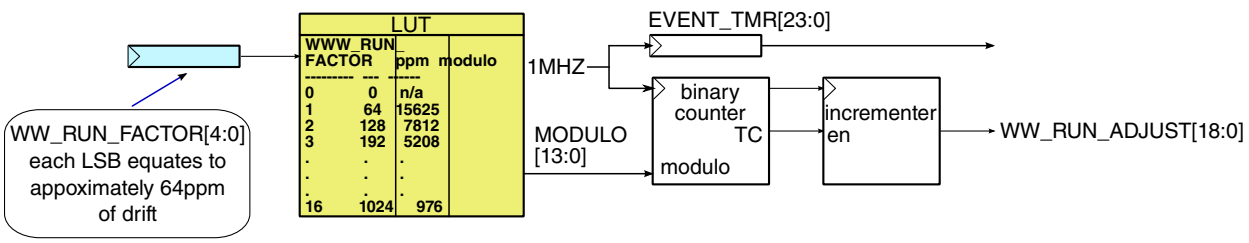

**Figure 64-112. WINDOW WIDENING RUNTIME ADJUSTMENT**

## COMPENSATING DSM DURATION FOR WINDOW WIDENING

In executing each slot as specified by the WOR descriptor, there is one other instance where window widening must be accounted for. During the COMP_DURATION1 state, WOR computes the DSM duration based on descriptor START_TIME and current (Event Timer) time. This duration is timed to complete the DSM cycle as close as possible to the desired START_TIME, but with sufficient guardband to ensure wakeup can never occur too late. But the duration computed during this state may be sufficiently long that the desired START_TIME needs to be advanced, due to drift within the DSM cycle itself. Thus, window widening needs to be estimated and subtracted from this computation. This window widening estimation is used only for the purpose of the duration estimation, and does not accumulate from one DSM cycle to the next (i.e., from one slot to the next). This window widening compensation to DSM duration occurs during the COMP_DURATION2 state. See Section State Machine for a description of WOR states.

The difference between this window widening computation, and the computation during COMP_WW, is that the result must be in units 32.768KHz clock cycles, because it is targetted for RSIM, instead of microseconds for an Event Timer offset. The COMP_DURATION2 computation multiplies the DSM duration (in 32K cycles) computed in COMP_DURATION1 by an estimate of the SCA (drift), to arrive at a

product which represents the number of 32.768KHz cycles by which to foreshorten the upcoming DSM cycle due to the widening requirement. So there is no conversion of units. In this case, 64ppm (0.000064) can be approximated by $1 * 2^{-14}$ and multiples of 64ppm can be approximated by $N * 2^{-14}$, with $2^{-14}$ representing a fixed bit-shift. So, for implementation, for all valid values, 0 ≤ WW_DSM_FACTOR ≤ 16, the value of *N* which most closely approximates the ideal multiple of 64ppm can be found in the following table:

| WW_RUN_FACTOR | *N* |
|---|---|
| 0 | 0 |
| 1 | 1 |
| 2 | 2 |
| 3 | 3 |
| 4 | 4 |
| 5 | 5 |
| 6 | 6 |
| 7 | 7 |
| 8 | 8 |
| 9 | 9 |
| 10 | 10 |
| 11 | 12 |
| 12 | 13 |
| 13 | 14 |
| 14 | 15 |
| 15 | 16 |
| 16 | 17 |

The second multiplicand then becomes $N * 2^{-14}$, leading to the equation for number of 32K cycles of window widening which needs to be subtracted from DSM duration:

**CYCLES_OF_WW[14:0] = DSM_DURATION_NO_WW[23:0] (result of COMP_DURATION1, neglecting widening) * *N* * $2^{-14}$**

This product is subtracted from the DSM duration estimate, along with the DSM_GUARDBAND[3:0], to arrive at the final wor_dsm_duration[23:0] sent to RSIM for execution:

**WOR_DSM_DURATION[23:0] = DSM_DURATION_NO_WW[23:0] - CYCLES_OF_WW[14:0] - DSM_GUARDBAND[3:0].**

The following diagram illustrates all of the hardware tasks performed during COMP_DURATION2 state:

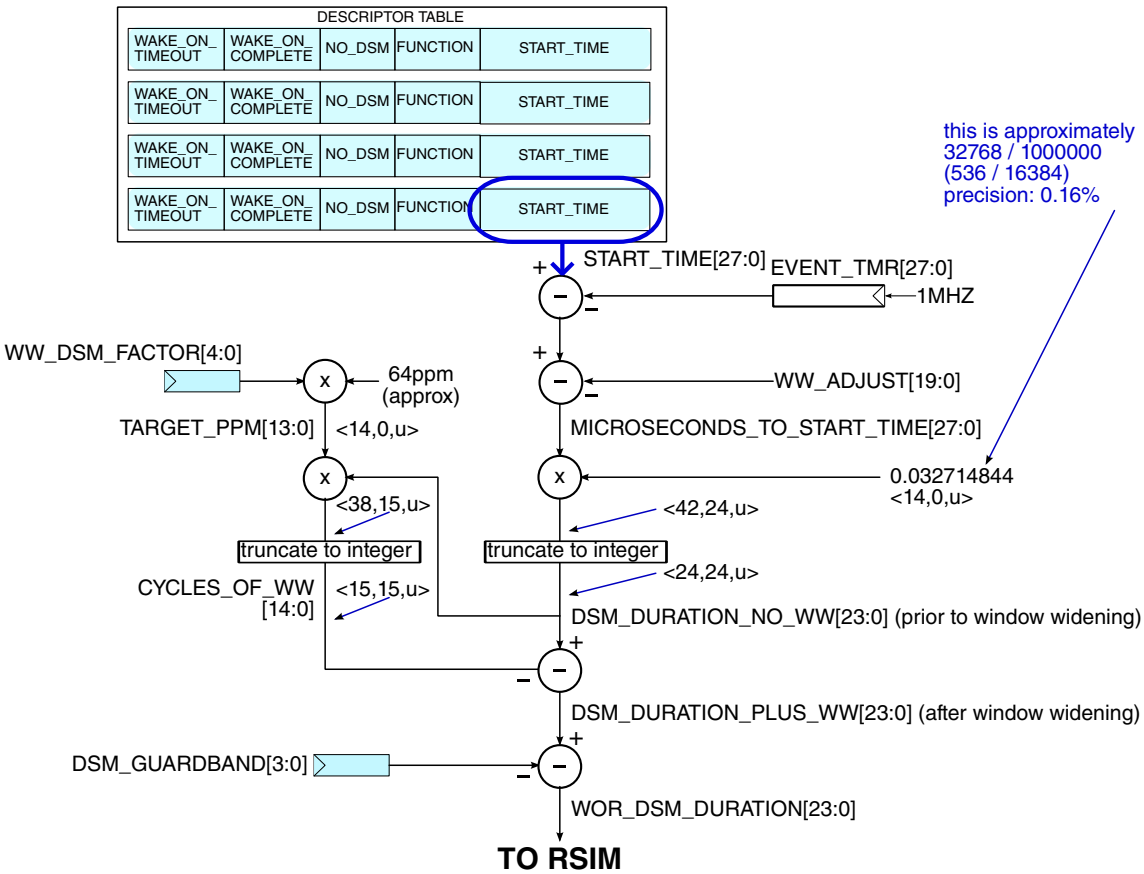

**Figure 64-113. COMP_DURATION2**

## APPLYING THE WINDOW WIDENING

Now that the window-widening adjustment has been computed, it must be put into effect, by modifying the START_TIME of the RF operation to advance it by the number of microseconds in ww_adjust[19:0], which is the combined DSM and RUNTIME window widening adjustment. This occurs during the WAIT_SEQ_START state. The same adjustment is applied again, by modifying the TIMEOUT of the RF operation (assuming timeout is reached), by delaying it by the same number of microseconds that START_TIME was advanced by. This occurs during the WAIT_SEQ_END state. The following diagram illustrates how window-widening is applied in Timeslot Scheduling mode.

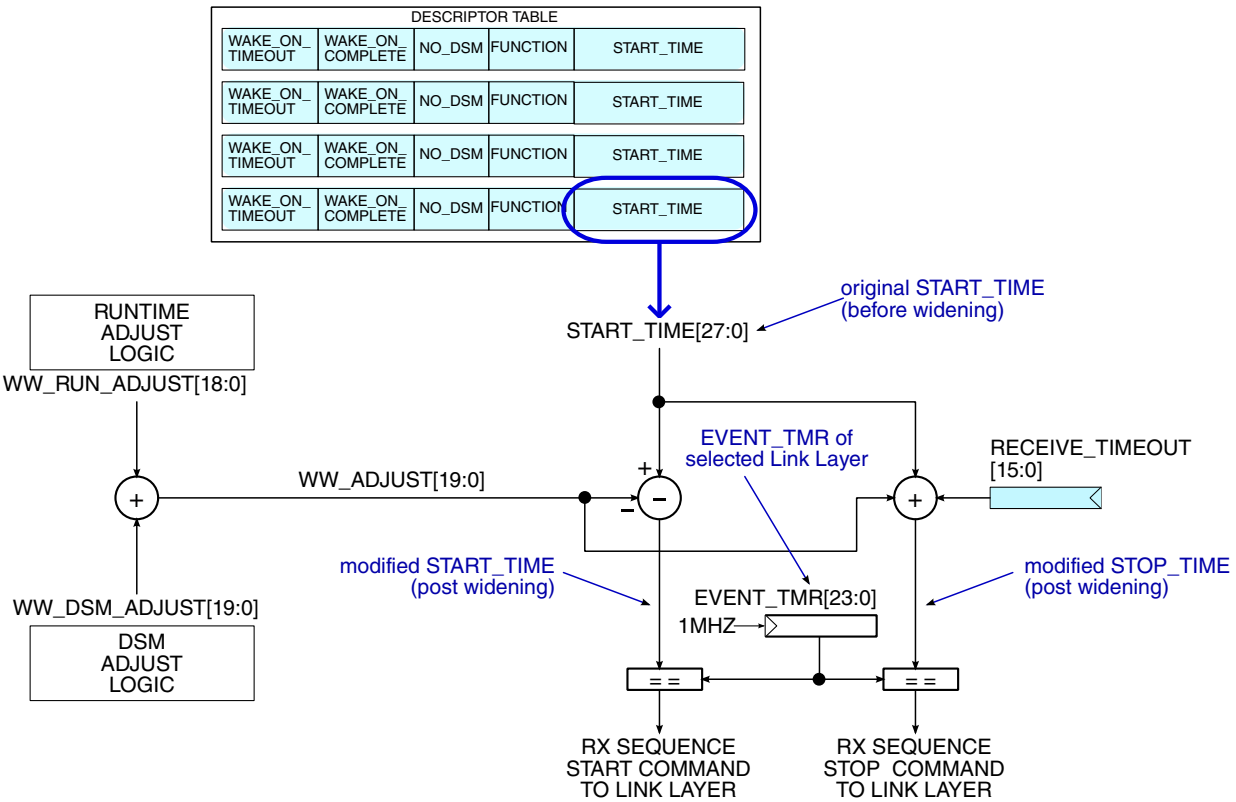

**Figure 64-114. APPLYING WINDOW WIDENING (TIMESLOT MODE)**

The application of window-widening in Constant-Interval scheduling mode, is largely the same as Timeslot mode; however the way the WOR hardware determines START_TIME and TIMEOUT is different, these need to be computed by WOR on a slot-by-slot basis. The following diagram illustrates how window-widening is applied in Constant-Interval Scheduling mode.

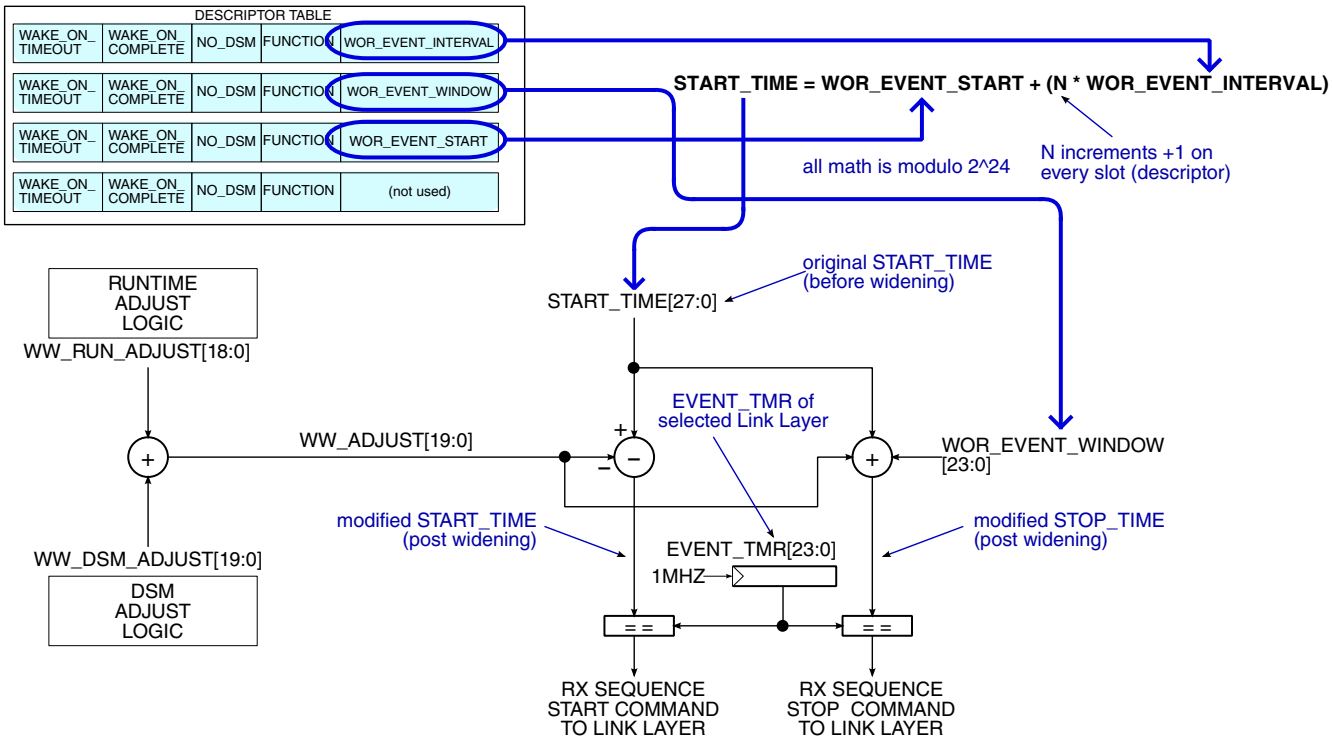

**Figure 64-115. APPLYING WINDOW WIDENING (CONSTANT-INTERVAL MODE)**

## NOTE

When dealing with the combination of high SCA (Sleep Clock Accuracy) as well as long requested DSM intervals, it is the responsibility of software to guarantee that the accumulation of window widening does not become excessively large. Window widening should not be allowed to accumulate to such an extent that the adjusted START_TIME is advanced so much that it moves to the left of the *previous* slot's START_TIME, or that the TIMEOUT is retarded so much that is moves to the right of the *next* slot's START_TIME, especially in scenarios where no good packets are received for an extended period of time. Software should periodically monitor window widening accumulation using mandatory MCU wakeups after every third or fourth slot (timeslot mode), or WAKE_ON_NTH_SLOT (constant interval mode), and use caution when scheduling long DSM intervals (distance between START_TIME on consecutive slots) with high WW_DSM_FACTOR values.

### 64.3.8.3.6 Timestamps

In Wake-On-Radio, every slot with FUNCTION=RX can capture a timeslot associated with any packet that is received in the slot. Any receive slot which results in an Access Address (for GENERIC_FSK protocol) or an SFD (for 802.15.4) detection will capture a timestamp into a register. Timestamps assist Link Layer software in maintaining and fine-tuning the network timebase across 2 or more networked devices.

**Timestamp Capture**

In Wake-On-Radio, each descriptor is associated with a slot. Any slot can be assigned an RX operation. RX operations require a timestamp to be captured. So, the timestamp can be thought of as being associated with the descriptor. The bit width of the timestamp is the same as the bit-width of the assigned Link Layer; i.e., 24 bits for GENERIC_FSK protocol, and 28 bits for 802.15.4. Association of timestamps to descriptors is illustrated in the following diagram.

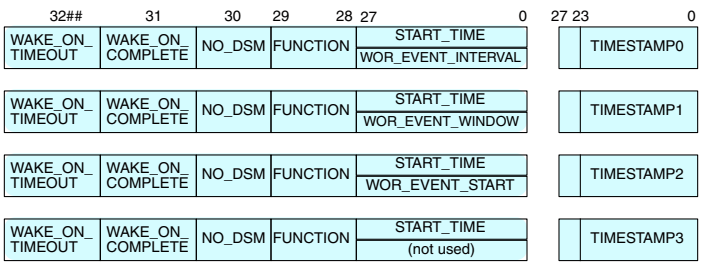

**Figure 64-116. TIMESTAMP CAPTURE**

Capture occurs at the instant AA or SFD is detected, and results in the current state of the assigned Link Layer's Event Timer being transferred to a TIMESTAMP register. WOR hardware does not apply any offset to the captured timestamp. A timestamp is captured for the last *N* RX operations, which result in (at least) one AA or SFD detection, where *N* = SLOTS_USED (typically 4).

Timestamp capture is area-intensive, due to:

- wide bit-width
- multiplicity (per descriptor)

Each of the supported protocol engines already has a TIMESTAMP register of the required bit-width. It is used for non-WOR (legacy) operations. To save area, when WOR is engaged, the TIMESTAMP register indigenous to the Link Layer, is used to capture the timestamp for WOR SLOT 0. Thus, in WOR mode (WOR_EN=1), the assigned Link Layer's TIMESTAMP register will only capture a timestamp when WOR SLOT=0, and will not change otherwise. If WOR is not engaged, the Link Layer TIMESTAMP register will capture all timestamps, the legacy behaviour. When WOR_EN, timestamps associated with SLOTS 1, 2, and 3 are captured in the TIMESTAMP1, TIMESTAMP2,

and TIMESTAMP3 registers, respectively, which are new, and resident in the WOR scheduler. This distribution of timestamp register resources is illustrated in the following diagram.

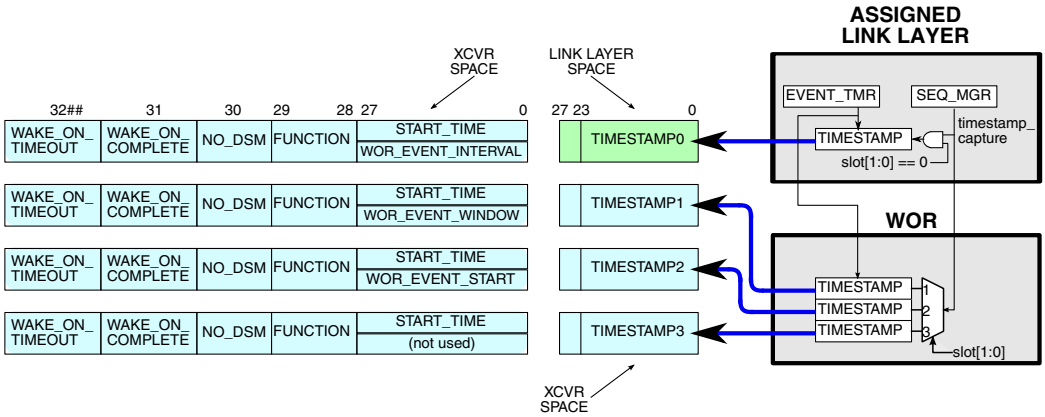

**Figure 64-117. TIMESTAMP REGISTER DISTRIBUTION**

Software should be aware of the fact that the designating the SLOT 0 timestamp to reside in the assigned Link Layer's TIMESTAMP register means that the TIMESTAMP regsters in Wake-On-Radio, are not all in one address space: TIMESTAMP0 resides in the assigned Link Layer's address space, while TIMESTAMP1-3 register reside in XVCR address space, alongside all the other WOR registers.

## TIMESTAMP STATUS

A timestamp will be captured into a TIMESTAMPx register on any slot assigned to FUNCTION RX, whenever an Access Address or SFD is detected during the receive window. Whenever a timestamp is captured as described above, a 3-bit read-only status register is updated with information regarding status of the reception which occured during the slot. The timestamp status, TIMESTAMPx_STS[2:0], becomes valid, and final (for the current slot), at the end of the receive window, and is made available to MCU when it is next awakened, along with the TIMESTAMP itself. The status information can be used by software to ascertain the validity of the timestamp. The following diagram describes timestamp status.

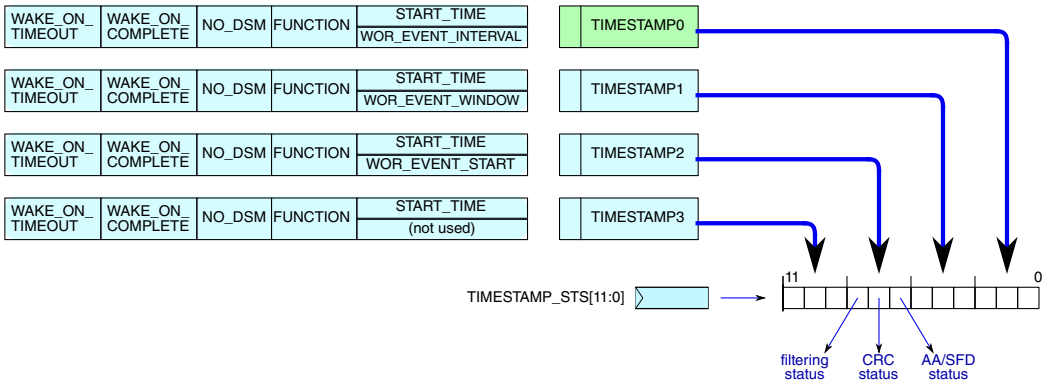

**Figure 64-118. TIMESTAMP STATUS**

A breakdown of the 3-bit status field, per timestamp, follows in the table below.

- 0: AA/SFD status
- 1: CRC status
- 2: Packet Filtering status

For any WOR slot assigned to RX, the 3-bit timestamp status field for that slot is cleared to 000 at the instant that WOR state WAIT_SEQ_START is reached. This is prior to the launch of the receive operation. (The bits are not cleared if the slot's function is not RX.) Once reception begins, the individual timestamp status bits are updated in realtime as the circumstances of the reception warrant. The 3-bit timestamp status is considered valid at the end of the receive window, and the bits reflect reception status per the following table.

| TIMESTAMPx_STS bit | Meaning if 0 | Meaning if 1 |
|---|---|---|
| [0] AA/SFD status | No AA or SFD was detected during the receive window. | At least one AA or SFD was detected. RX recycles can lead to multiple occurrences. |
| [1] CRC status | For the packet associated with last (most recently) detected AA or SFD, CRC verification failed. | For the packet associated with last (most recently) detected AA or SFD, CRC verification passed. |
| [2] Packet Filter status | For the packet associated with last (most recently) detected AA or SFD, at least 1 packet filtering rule was violated. | For the packet associated with last (most recently) detected AA or SFD, all packet filtering rules passed. |

Packet filtering rules, and hence the meaning of the TIMESTAMPx_STS[2] bit, vary across protocols, as summarized in the following table.

| PROTOCOL | MEANING OF TIMESTAMP_STSx[2] (PACKET FILTER) |
|---|---|
| 802.15.4 | Reflects the Packet Processor FILTERFAIL flag |
| GENERIC_FSK | There are 3 packet filter criteria:<br>1. H0 matching |

| PROTOCOL | MEANING OF TIMESTAMP_STSx[2] (PACKET FILTER) |
|---|---|
| | 2. H1 matching<br>3. LENGTH_MAX compliance (maximum packet length verification) |

Timestamp status bits are sticky. Once they become valid at the end of the receive window (end of WAIT_SEQ_END state), they remain valid until the *next* time the same slot number comes up again, and WOR reaches WAIT_SEQ_START state on that slot number.

In general, the MCU does not need to be notified on "bad packets." However, timestamp status may still be of value to WOR software even without Data Indication on any given slot. Notification policy can be modified at the protocol level, to enable RXIRQ on bad packets, mainly for debug purposes. If notification policy is modified by configuring the assigned Link Layer accordingly, this will affect Wake-On-Radio was well, as an rx_irq_trig will be generated on otherwise "bad" packets. See Section State Machine, specifically the WAIT_SEQ_END state, for details on how WOR responds to rx_irq_trig during this state, to determine how modifying notification rules would affect WOR response.

WOR software can use timestamp status to gauge the validity of the timestamp in any given slot. The following tables provides some guidelines.

| TIMESTAMPx_STS | TIMESTAMPx REGISTER VALIDITY | MEANING |
|---|---|---|
| 0b000 | stale | No AA or SFD was received during this timeslot. The TIMESTAMPx register was not updated by HW and continues to hold the timestamp captured after the last AA or SFD detection on this slot number. |
| 0bX01 | invalid | At least 1 AA or SFD was detected during this timeslot. For the last (most recent) AA or SFD detected, CRC verification failed. TIMESTAMP register holds the EVENT_TMR captured for this reception. Because CRC failed, the TIMESTAMP should be deemed invalid, but this decision is left to the application. |
| 0b011 | valid | At least 1 AA or SFD was detected during this timeslot. For the last (most recent) AA or SFD detected, CRC verification passed. TIMESTAMP register holds the EVENT_TMR captured for this reception, and can be deemed valid. However Packet Filtering failed, so typically there would be no Data Indication. |
| 0b111 | valid | At least 1 AA or SFD was detected during this timeslot. For the last (most |

| TIMESTAMPx_STS | TIMESTAMPx REGISTER VALIDITY | MEANING |
|---|---|---|
| | | recent) AA or SFD detected, CRC verification passed. TIMESTAMP register holds the EVENT_TMR captured for this reception, and is valid. Packet Filtering passed. |

#### 64.3.8.3.7 Interrupt Management

The Wake-On-Radio scheduler is protocol-neutral, so it has no interrupts of its own. WOR hardware utilizes the assigned Link Layer's interrupts for all MCU wakeups and notifications. In Wake-On-Radio, the MCU is in a low-power state most of the time. So, interrupts are allowed to assert only when it is mandatory to wake the MCU out of its low power state, to tend to required Link Layer or WOR tasks. WOR hardware modifies the interrupt activity of the assigned Link Layer by dynamically blocking and/or allowing Link Layer interrupts to propagate to the MCU, under control of the current slot descriptor specifications. Each of the 3 supported protocol engines have been modified to allow WOR to manage its RF-related interrupts. The RF-related interrupts have nearly identical functions and meanings across the 3 protocols:

- TXIRQ (or TX_IRQ)
- RXIRQ (or RX_IRQ)
- SEQ_END_IRQ (or SEQIRQ)

The modifications to the protocol engines, involve an AND gate inserted between each interrupt trigger, and the interrupt status bit, allowing or blocking the trigger from asserting the status bit. A gating signal, wor_allow_irq, is provided by WOR to each protocol engine to enable/disable the AND gate. The gating signal is updated dynamically by the WOR state machine based on state, RF operation status, and the current descriptor's WAKE_ON_* fields. See Section State Machine, specifically the description of the WAKE_SEQ_END state, for more details on how and when WOR allows and blocks RF-related interrupts. For protocols not assigned to WOR, interrupts are always allowed.

The raw interrupt triggers themselves (the inputs to the AND gates), namely, tx_irq_trig and rx_irq_trig, are passed directly to WOR hardware, so that WOR state machine can react to RF operation status in realtime, and sequence through the states as specified by the current slot's descriptor.

WOR manages one other Link Layer interrupt, for non-RF-related notifications. Each protocol engine has an existing interrupt, WAKE_IRQ, to notify MCU on wakeup from Manual DSM mode (not Wake-On-Radio). See Section Manual DSM for more details on

this DSM control scheme. For any protocol, Wake-On-Radio and Manual DSM are mutually-exclusive control schemes, so when a protocol is assigned to WOR, its WAKE_IRQ is re-purposed, and re-named, to WOR_IRQ.

Like the "allow/block" gating WOR uses to manage the RF-related interrupts, WOR uses 2 signals to either block or *force* a WAKE_IRQ / WOR_IRQ:

- **wor_block_wake_irq:** prevents the (legacy) WAKE_IRQ from asserting at DSM exit, this is *mandatory* for Manual DSM, but is *conditional* for WOR.
- **wor_force_wake_irq:** WOR needs to assert WOR_IRQ under 3 conditions (see below)

There are 3 conditions for which WOR needs to compel the Link Layer to assert WOR_IRQ. WOR maintains 3 read-only status flags to indicate each of these conditions. The status flags exist in XCVR (WOR) address space, even though the WOR_IRQ resides in the protocol-specific address space. The 3 conditions, and the associated status flag for each, are described in the following table.

- **WOR_NO_RF_FLAG:** START_TIME has been reached on a slot with FUNCTION = NO_RF and WAKE_ON_COMPLETE=1
- **WOR_MAX_SLOT_FLAG:** In Constant-Interval scheduling mode, the WOR_SLOT_COUNT[7:0] has reached WAKE_ON_NTH_SLOT[7:0]
- **WOR_DSM_EXIT_FLAG:** An unscheduled, asynchronous DSM "Early Exit" has occurred

To service an WOR_IRQ, the interrupt service routine should query the 3 read-only status flags to determine the cause of the MCU wake up. At least one of these flags will be set. It is possible that more than 1 of the flags is set. For the WOR_NO_RF_FLAG, WAKE_ON_COMPLETE would typically not be set on a NO_RF slot, since the purpose of NO_RF is to allow "DSM cascading"; only for debug purpose has this flag been provided. Servicing of the other 2 flags is beyond the scope of this document.

Clear the WOR_IRQ by writing a 1 to this bit in the protocol-specific address space. However the 3 WOR flags are "sticky". Any flag which is set will remain set until a new WOR session has begun, which means taking WOR to DISABLED by setting SLOTS_USED=0, followed by re-enabling by setting SLOTS_USED>0.

In initializing the assigned Link Layer for WOR operation, it is *essential* that software enable (unmask) the 3 RF-related interrupts, as well as WAKE_IRQ / WOR_IRQ. It is equally essential that all non-WOR related interrupt sources are *disabled* when a protocol is assigned to WOR, to prevent unnecessary MCU wakeups. The following tables describe all the Link Layer interrupts, their controllability (or lack of) by WOR, and the required enabling/unmasking by software.

## INTERRUPT CONFIGURATION (802.15.4)

| INTERRUPT | WOR CONTROL | SW INIT | COMMENTS |
|---|---|---|---|
| TXIRQ | gated by wor_irq_allow | ENABLE | Asserted after packet transmission when: WAKE_ON_COMPLETE \|\| WAKE_ON_TIMEOUT |
| RXIRQ | gated by wor_irq_allow | ENABLE | Asserted after good packet reception when: WAKE_ON_COMPLETE \|\| WAKE_ON_TIMEOUT |
| SEQIRQ | gated by wor_irq_allow | ENABLE | 1. Asserted after any good packet transmission or reception when: WAKE_ON_COMPLETE \|\| WAKE_ON_TIMEOUT<br>2. Asserted after bad (or no) packet reception when: WAKE_ON_TIMEOUT |
| CCAIRQ | unaffected | DISABLE | Not used in WOR |
| RXWTRMRKIRQ | unaffected | DISABLE | Not used in WOR |
| FILTERFAIL_IRQ | unaffected | DISABLE | Not used in WOR |
| PLL_UNLOCK_IRQ | unaffected | OPTIONAL | If enabled, would cause an immediate MCU LLWU on occurrence of a PLL unlock event. |
| WAKE_IRQ / WOR_IRQ | blocked by wor_block_wake_irq, forced by wor_force_wake_irq | ENABLE | 1. Asserted when START_TIME reached on a slot with FUNCTION=NO_RF and WAKE_ON_COMPLETE=1<br>2. Asserted in CI mode when WOR_SLOT_COUNT==WAKE_ON_NTH_SLOT<br>3. Asserted after an unscheduled "DSM Early Exit" |
| TMRxIRQ | unaffected | DISABLE | Not used in WOR |
| TSM_IRQ | unaffected | DISABLE | Not used in WOR |

## INTERRUPT CONFIGURATION (non-802.15.4)

| INTERRUPT | WOR CONTROL | SW INIT | COMMENTS |
|---|---|---|---|
| TX_IRQ | gated by wor_irq_allow | ENABLE | Asserted after packet transmission when: WAKE_ON_COMPLETE \|\| WAKE_ON_TIMEOUT |

*Table continues on the next page...*

| INTERRUPT | WOR CONTROL | SW INIT | COMMENTS |
|---|---|---|---|
| RX_IRQ | gated by wor_irq_allow | ENABLE | Asserted after good packet reception when: WAKE_ON_COMPLETE \|\| WAKE_ON_TIMEOUT |
| SEQ_END_IRQ | gated by wor_irq_allow | ENABLE | 1. Asserted after any good packet transmission or reception when: WAKE_ON_COMPLETE \|\| WAKE_ON_TIMEOUT<br>2. Asserted after bad (or no) packet reception when: WAKE_ON_TIMEOUT |
| NTW_ADR_IRQ | unaffected | DISABLE | Not used in WOR |
| T1_IRQ | unaffected | DISABLE | Not used in WOR |
| T2_IRQ | unaffected | DISABLE | Not used in WOR |
| PLL_UNLOCK_IRQ | unaffected | OPTIONAL | If enabled, would cause an immediate MCU LLWU on occurrence of a PLL unlock event. |
| WAKE_IRQ / WOR_IRQ | blocked by wor_block_wake_irq, forced by wor_force_wake_irq | ENABLE | 1. Asserted when START_TIME reached on a slot with FUNCTION=NO_RF and WAKE_ON_COMPLETE=1<br>2. Asserted in CI mode when WOR_SLOT_COUNT==WAKE_ON_NTH_SLOT<br>3. Asserted after an unscheduled "DSM Early Exit" |
| TSM_IRQ | unaffected | DISABLE | Not used in WOR |
| RX_WATERMARK_IRQ | unaffected | DISABLE | Not used in WOR |

### 64.3.8.3.8 Channel Hop Table

Typically, in either Timeslot or Constant-Interval scheduling mode, RF operations on consecutive slots use different RF channels. Using Wake-On-Radio to program slot specifications for the next few RF operations in advance, would be of little value if the MCU had to wake up on every slot to program the assigned Link Layer's CHANNEL_NUM register. Thus, Wake-On-Radio provides hardware automation for channel hopping on a slot-by-slot basis.

A table of channel hop frequencies is maintained by hardware. The number of entries in the table (hop sequence length) is programmable. Prior to starting a WOR session, software will program the desired sequence of channel numbers into the table. After WOR is activated by setting SLOTS_USED>0, The WOR state machine controls the index (read pointer) into the table. The index is typically incremented at the end of every slot, when the slot counter is incremented. The increment is +1 modulo "hop sequence length". The RF operation on the current slot, is then carried out on the RF channel pointed to by the hop table index. If necessary, WOR or Link Layer software can update the hop table index at any time.

Rather than adding a channel number field to the descriptor, to save area, the hop table is decoupled from the descriptor table. The hop tables utilizes a small section of Packet RAM which is not otherwise used by the supported WOR protocols. WOR uses the uppermost 48 of those words of Packet RAM #1 for the channel hop table, starting at RAM word address 1104 (decimal), of Packet RAM #1, and ending at address 1151.

The channel information entered into the hop table, can use the (legacy) 7-bit "mapped channel" format, which allows channels to be specified on a 1MHz boundary; or one of 2 new 16-bit formats that allows channel frequency of higher resolution. The option for the legacy format, provides backwards compatability to existing software, which does not use WOR, to program RF channel information the way it does today, without any changes. The inclusion of the new formats allows additional flexibility for programming channels which deviate from a 1MHz boundary, coupled with the automation built in to WOR. The format selected, determines:

1. how the hop table is organized in RAM
2. how software programs the hop table
3. how the WOR parses the table during execution of the current slot
4. and how the PLL digital block interprets the frequency word extracted from the table.

Selecting the hop table configuration is by way of the HOP_TBL_CFG[2:0] register. Based on this setting, the source of channel information, can either be the CHANNEL_NUM[6:0] bit register that exists in each protocol engine today (legacy), or the new hop table, according to the following table:

Source of RF channel information, based on HOP_TBL_CFG[2:0]:

0: Assigned Link Layer's CHANNEL_NUM register (legacy)
1: WOR Hop Table
2: WOR Hop Table
3: WOR Hop Table
4-7: Reserved

To allow for the legacy option, the 3 protocol-specific CHANNEL_NUM registers are now routed to WOR, which multiplexes them with the hop table output based on HOP_TBL_CFG and WOR_PROTOCOL settings. WOR then outputs 3 16 bit frequencies words, one per protocol, to PLL Digital, conveying the required channel information.

Hop table organization is determined by HOP_TBL_CFG, as per the following table:

Hop Table Organization, based on HOP_TBL_CFG[2:0]:

0: N/A
1: Table size is 96 entries. Two 7-bit CHANNEL_NUM fields are packed into a 16-bit hop frequency word for RAM storage
2: Table size is 48 entries. Each 16-bit hop frequency word in RAM contains a specification for a single RF channel
3: Table size is 48 entries. Each 16-bit hop frequency word in RAM contains a specification for a single RF channel
4-7: Reserved

The content of the hop frequency word provided to PLL Digital, and how it is interpreted by that block, also varies with HOP_TBL_CFG, as per the following table:

PLL Digital Interpretation of Hop Frequency Word, based on HOP_TBL_CFG[2:0]:

0: Lower 7 bits of hop frequency word contain a mapped channel (legacy format). Upper 9 bits are 0
1: Lower 7 bits of hop frequency word contain a mapped channel (legacy format). Upper 9 bits are 0
2: All 16 bits are valid. See Chapter *PLL Digital* for interpretation
3: All 16 bits are valid. See Chapter *PLL Digital* for interpretation
4-7: Reserved

The following diagram summarizes the routing of channel hop signalling amongst the supported protocol engines, the WOR scheduler, the PLL Digital, and Packet RAM. It also shows the 2 hop table configurations, and hop frequency word generation, based on HOP_TBL_CFG. The existing (legacy) configuration is on the left, and the new, WOR-based configuration is on the right.

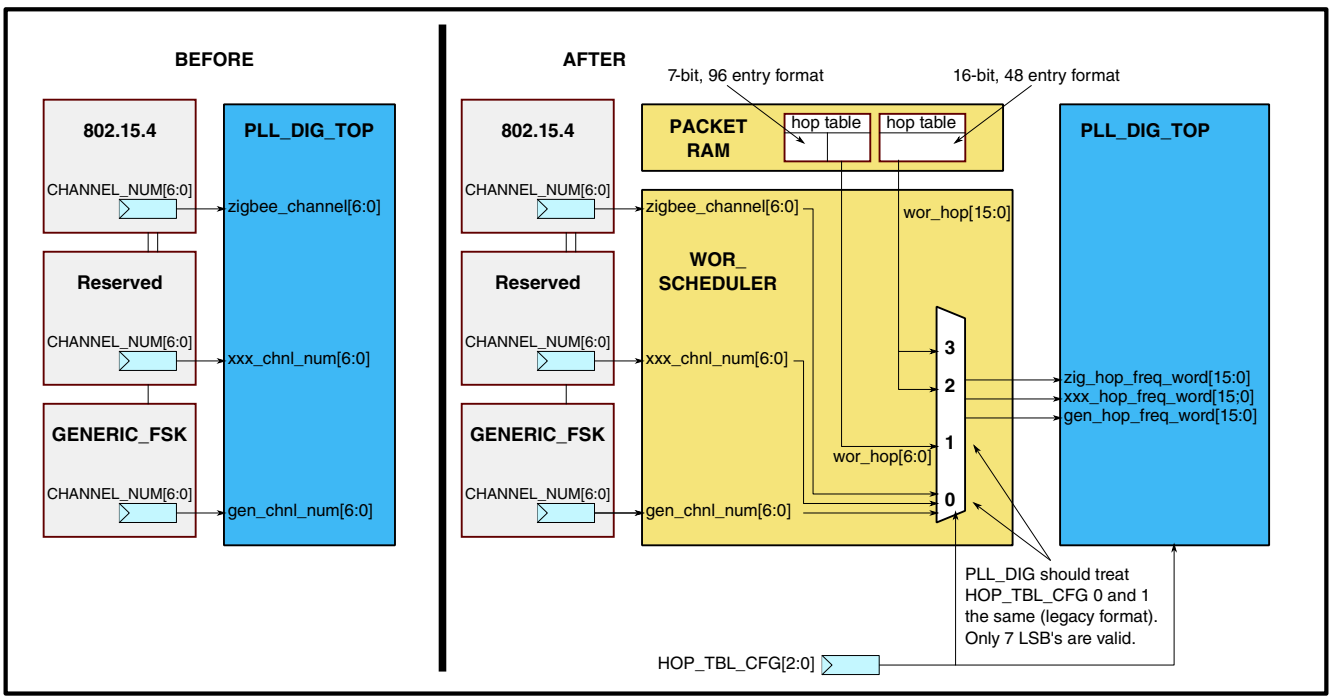

**Figure 64-119. CHANNEL HOP SIGNAL ROUTING AND CONFIGURATION**

The number of entries in the table is determined by programmable register HOP_SEQ_LENGTH[6:0]. If HOP_TBL_CFG=1, HOP_SEQ_LENGTH determines the number of 7-bit CHANNEL_NUM entries in the Packet RAM table, which are packed 2 per RAM word. HOP_SEQ_LENGTH must not exceed 96 in this case. If HOP_TBL_CFG=2 or HOP_TBL_CFG=3, HOP_SEQ_LENGTH determines the number of 16-bit format entries in the Packet RAM table, one per RAM word. HOP_SEQ_LENGTH must not exceed 48 in this case.

At the start of new WOR "session" (setting SLOTS_USED to a non-zero value), WOR hardware initalizes the table index (read pointer) to 0. (Software can modify this index, see below.) After slot execution completes, as the WOR state machine increments the slot counter to service the next slot, the hop table index is incremented by +1 (modulo HOP_SEQ_LENGTH). An exception is made to this rule, if the FUNCTION field of the slot descriptor is set to NO_RF, the hop index is *not* incremented when the slot counter is incremented to advance to the next slot. The NO_RF function is used for "DSM cascading".

Software can take control of the hop table index at any time, by writing a new desired index to the NEW_HOP_IDX[6:0], and with the UPDATE_HOP_IDX register set to 1. These 2 steps can be performed as a single, atomic IPS bus write. WOR hardware will update the index accordingly. From this point forward, the hop-table hardware incrementing rules, discussed in the previous paragraph, apply. This way, software can execute a one-time "jump" in the hop table indexing.

The read-only register WOR_HOP_IDX[6:0] allows software to read the instantaneous, hardware-controlled hop table index at any time. Similarly, the read-only register WOR_HOP_FREQ_WORD[15:0] allows software to read the instantaneous, hardware-generated frequency word sent to PLL digital. This word is the output of the hop table configuration selection mux shown in the diagram above, the protocol-specific word currently selected by WOR_PROTOCOL.

A diagram showing the RAM-based, 96-entry hop table (HOP_TBG_CFG=1), where it is situated in Packet RAM space, how the channel information is organized in the table, and how WOR hardware indexes the table, is shown below.

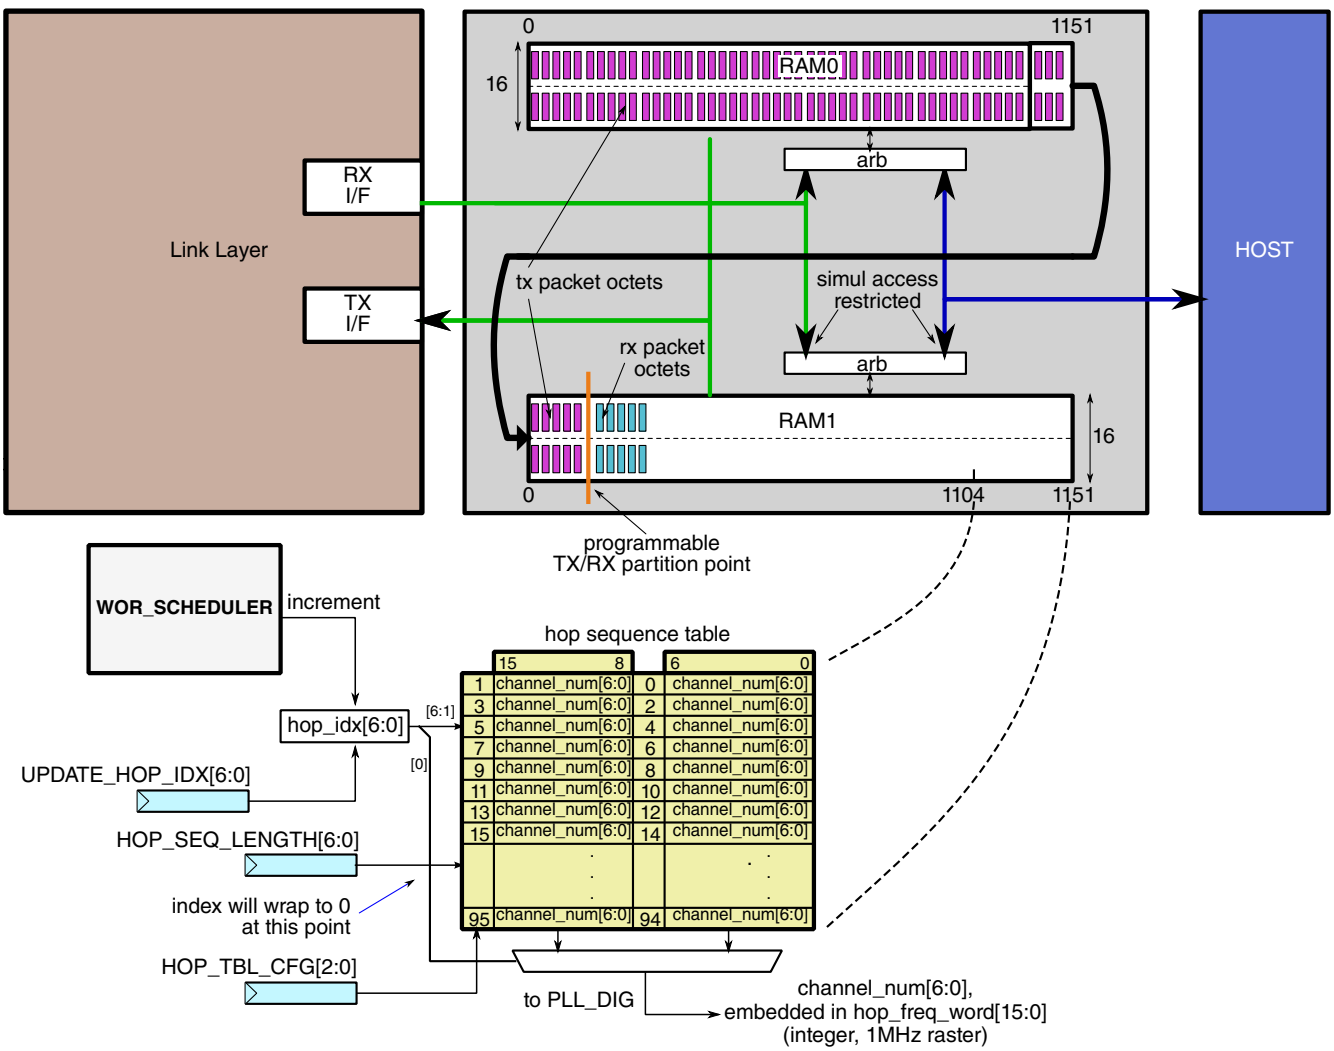

**Figure 64-120. 96-ENTRY HOP TABLE**

A diagram showing the RAM-based, 48-entry hop table (HOP_TBG_CFG=2 or 3), where it is situated in Packet RAM space, how the channel information is organized in the table, and how WOR hardware indexes the table, is shown below.

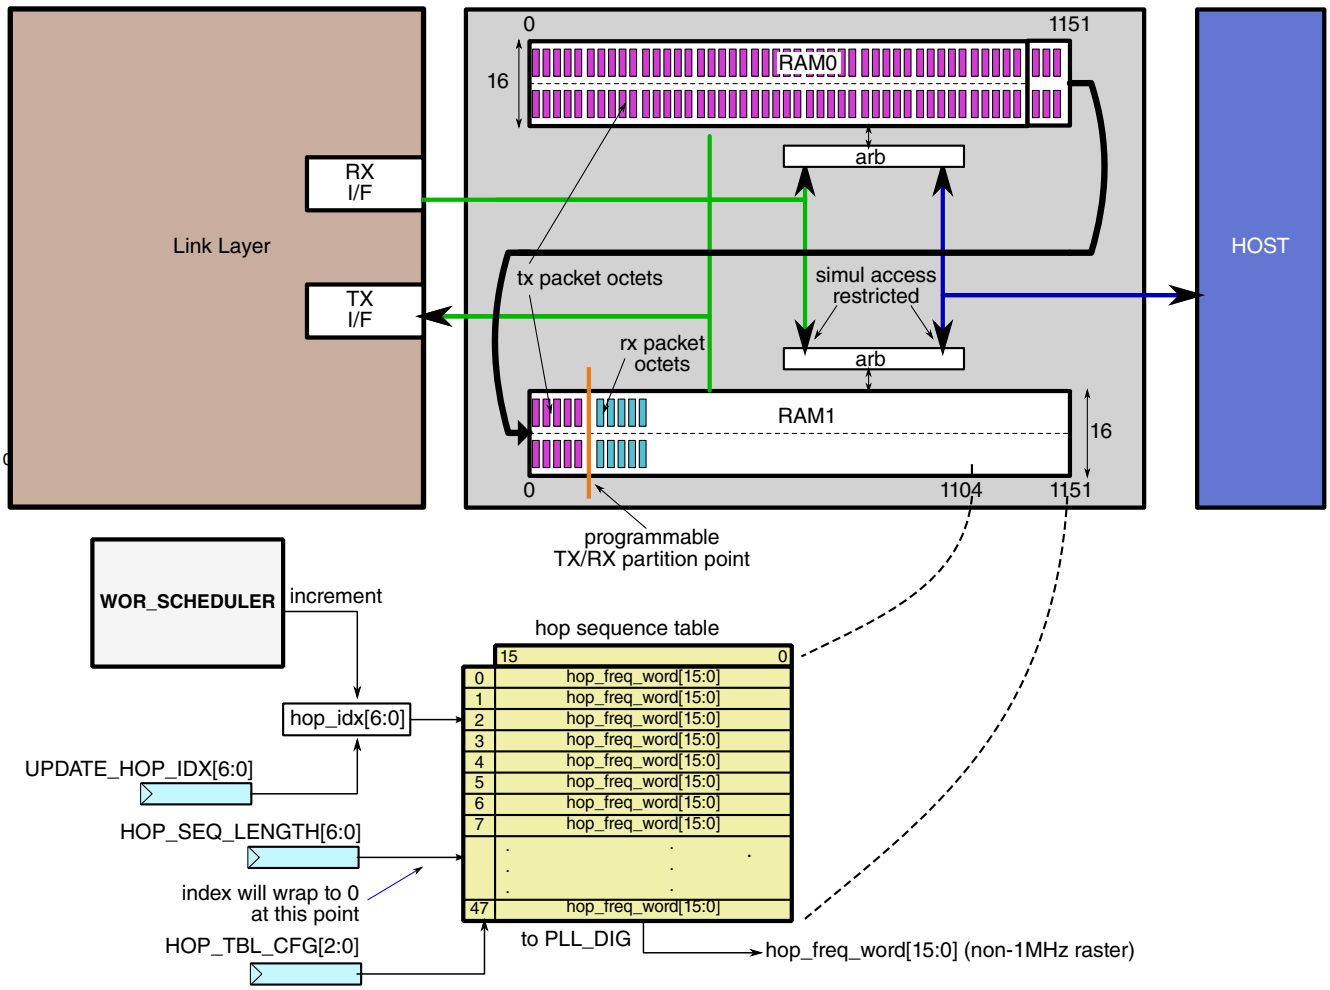

**Figure 64-121. 96-ENTRY HOP TABLE**

## PROGRAMMING INFORMATION AND MEMORY MAP

The upper 96 bytes of Packet RAM are reserved for the WOR hop table. The table is fixed in this position, and does not move based on HOP_TBL_CFG. For purposes of programming the hop table, Packet RAM should be accessed through XCVR address space (see instructions below), since the hop table is not protocol-specific. The following diagram illustrates how the hop table is memory-mapped into XCVR space.

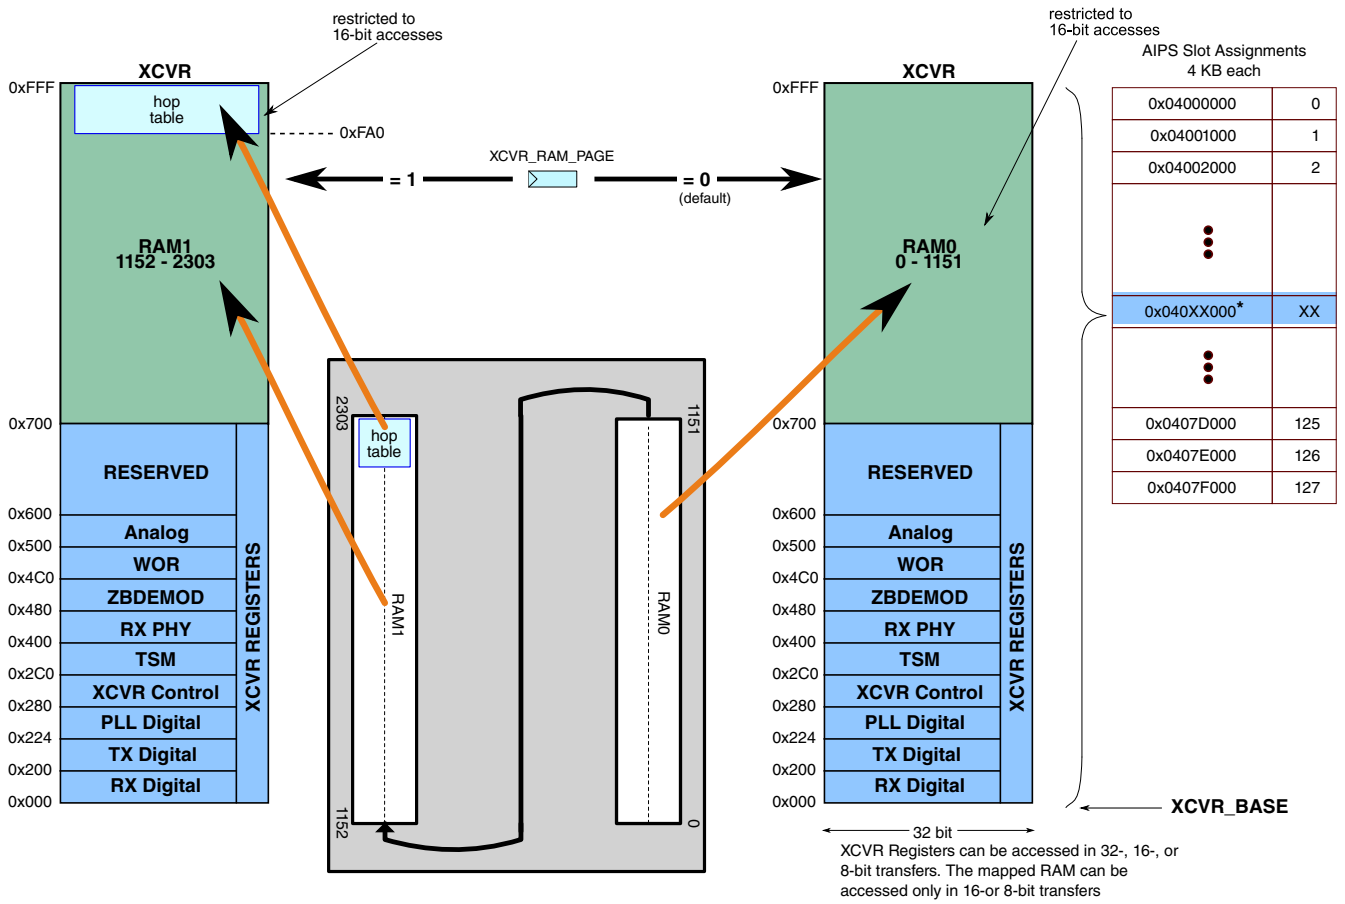

**Figure 64-122. MEMORY MAPPED HOP TABLE**

As shown, the hop table base is at: **XCVR_BASE + 0xFA0**, of Packet RAM #1 (PACKET_RAM_CTRL[RAM_PAGE]=1 in XCVR space)

The WOR hop table should not be accessed (no writes or reads) while an RF operation is underway. There is no hardware to de-conflict XCVR RAM accesses with those originating in the protocol engines. Aside from this restriction, the hop table can be accessed at any time. A convenient time to modify the hop table, if required, would be during the WOR WAIT_RESUME state.

To access Packet RAM through XCVR space, the PACKET_RAM_CTRL[XCVR_RAM_ALLOW] bit must be set. Follow the instructions below to program the WOR hop table.

1. Set PACKET_RAM_CTRL[XCVR_RAM_ALLOW]=1 (to allow exclusive XCVR access to Packet RAM)
2. Set PACKET_RAM_CTRL[RAM_PAGE]=1 (to select Packet RAM #1)
3. Program the hop table starting at XCVR_BASE + 0xFA0
4. Program HOP_CTRL[HOP_SEQ_LENGTH] with the desired size of the hop sequence

5. Program HOP_CTRL[HOP_TBL_CFG] to select the desired table configuration and enable hopping during WOR
6. Set PACKET_RAM_CTRL[XCVR_RAM_ALLOW]=0 (to allow Link Layer access to Packet RAM)

#### 64.3.8.3.9 DSM Early Exit

As described in Section State Machine, for every slot, WOR hardware computes the duration of the upcoming DSM cycle based on descriptor START_TIME, current time, and window-widening, during the COMP_DURATION1 and COMP_DURATION2 states. WOR outputs the desired duration on wor_dsm_duration[23:0]. The Radio System Integration Module (RSIM) then executes this DSM for the prescribed number of 32.768KHz clock cycles, and when complete, sends the actual duration back to WOR using rsim_dsm_duration[23:0]. Normally, these 2 durations will match precisely.

Conditions exist where the DSM cycle may occasionally need to be cut short, due to circumstances beyond the control of the radio. The SoC, starting with the MCU, must be awakened out of its low power state before the WOR DSM duration expires. When this happens, software handling the event which triggered the wakeup, will determine if the radio needs to be awakened as well. If this is the case, software will set the RSIM_WOR_DSM_EXIT bit. This will trigger an unscheduled wakeup process out of DSM by the RSIM deep sleep state machine. The wakeup will complete before the wor_dsm_duration[23:0] time has expired. RSIM will capture the *actual* DSM duration, cut short by the early exit, into rsim_dsm_duration[23:0]

After DSM wakeup, WOR hardware always performs this check during the COMP_WW state:

**rsim_dsm_duration[23:0] == wor_dsm_duration[23:0]**

If this check fails, WOR hardware declares an "DSM Early Exit", and takes the following steps:

1. Forces the assigned Link Layer to assert its WAKE_IRQ / WOR_IRQ (see Section Interrupt Management)
2. Sets the WOR_DSM_EXIT_FLAG in WOR space
3. Transitions to the WAIT_RESUME state and waits for software to service the WOR_IRQ.

Software should then take whatever steps are necessary to configure the radio to respond to the conditions which triggered the early exit. Servicing of a DSM early exit interrupt is beyond the scope of this document.

#### 64.3.8.3.10 Manual DSM

Prior to Wake-On-Radio, implementation of the 2.4GHz used a software-driven, "manual" DSM. This DSM control scheme does not have any of the hardware automation associated with WOR, and software must perform such tasks as computing the Event Timer addback time, window-widening, etc.

Manual DSM still exists as an alternative to Wake-On-Radio. Manual mode can be of value in a multiprotocol setting. See Section Multiprotocol for more details.

Any of the 3 protocols supported by Wake-On-Radio, can utilize Manual DSM as an alternative to Wake-On-Radio. In short, Manual DSM works by programming a desired DSM start time into the MAN_SLEEP register, and a desired DSM wake time into the MAN_WAKE register. The MAN_SLEEP and MAN_WAKE registers are referenced to the 32.768KHZ DSM_TIMER, the radio's low-power (DGO) timer. MAN_SLEEP, MAN_WAKE, and DSM_TIMER reside in RSIM address space.

When a match on DSM_TIMER to MAN_SLEEP occurs, RSIM places the radio in deep sleep mode. The RF Oscillator is shut off, and the Link Layer's Event Timer is frozen in place. When a match on DSM_TIMER to MAN_WAKE occurs, the Event Timer resumes from where it left off. The RF Oscillator, is re-started as part of the DSM wake up process, and is running before MAN_WAKE is reached. At the instant the Event Timer resumes, the Link Layer asserts its WAKE_IRQ. The MCU should use the WAKE_IRQ ISR to compute the precise amount of time the radio was in DSM, convert this value to microseconds, and add this value to the current Link Layer Event Timer, to restore the timer to where it would have been, had DSM not occurred. There is a 1us loss-of-precision in the Event Timer timebase incurred on every DSM wakeup. This timebase error is random, and averages out over many DSM cycles.

Regarding the DSM wakeup process, there is additional programmability to configure the lead time for power-domain wakeup and oscillator re-start, relative to DSM exit (MAN_WAKE). This configurability is covered by the RSIM_DSM_PWR_OFFSET register. See the *Radio System Integration Module* chapter for more details.

#### 64.3.8.3.11 Multiprotocol

The 2.4GHz radio supports 4 protocols, any 2 of which can be enabled for multiprotocol use on an alternating, time-shared basis. Both of the active protocols may require DSM. The following section describes the rules to be applied when assigning a protocol to a DSM control scheme.

The radio has 3 DSM control schemes:

1. BLE-internal
2. Wake-On-Radio

3. Manual DSM

The BLE-internal DSM controller applies to the BLE protocol engine only, and is the only DSM option for BLE.

Wake-On-Radio can be assigned to any one of the following protocols (see Section *Assign To Protocol*):

1. 802.15.4
2. GENERIC_FSK

Manual DSM can be assigned to any one of the following protocols (see Section *Manual DSM*):

1. 802.15.4
2. GENERIC_FSK

#### 64.3.8.3.12 Hardware Multiplier

Wake-On-Radio requires 4 multiplies while executing each slot. The multiplications take place in the following WOR states (See Section State Machine):

1. COMP_DURATION1: to compute the upcoming DSM duration, excluding window widening
2. COMP_DURATION2: to compute the subtractor to the upcoming DSM duration, for window widening
3. COMP_ADDBACK: to compute the Event Timer addback value based on RSIM-provided DSM duration
4. COMP_WW: to compute the DSM-component of window-widening incurred during the just-completed DSM cycle

For maximum area and power saving, there is 1 hardware multiplier instance, which is timeshared for the 4 multiplies. Also, because the state machine has been architected to allow sufficient time to perform these computations before the results are needed, the multiplier uses a serial, add-and-accumulate construction. The multiplicands are 24 bits and 14 bits. The 24 bit operand is appropriately sized for the "duration" calculations, since this is the bit-width of the DSM timer. The 14 bit operand is appropriately sized to achieve the precision of the required calculations, as described in the earlier sections.

For each calculation, the multiplier requires 14 clocks (14 shifts). Each multiply takes place within the confines of a single state of duration 1µs. There are 32 periods of the reference oscillator during that period (26 for a 26MHz crystal), more than enough to complete the multiply. The clock to the multiplier runs at the reference oscillator rate, but runs only during the 4 1µs states listed above, to maximize power savings.

The multiplier output is 42 bits. Depending on the calculation, the required precision, the positioning of the integer bits within the product, etc., the bits of the product tapped for each calculation varies. Also, depending on the calucation, combinational rounding or truncation of the product occurs, external to the multiplier.

#### 64.3.8.3.13 Clocks and Gating

Because of the intensive interaction between Wake-On-Radio and 3 protocol engines it supports, the WOR hardware runs at 1MHz. This facilitates signalling between the WOR and the assigned Link Layers, with no additional pulse-stretching or signal-conditioning required. Like the protocol engines and the TSM, the CGM's cg1m_en gating signal is used to generate the common 1MHz, so the phasing of the clocks across all the communicating modules remains in sync.

All WOR clocks are conditioned on WOR_EN=1. This bit should be set, and remain set, whenever Wake-On-Radio is in use (it should not be toggled or modified dynamically by software, since module clock-gating is based on it). This bit should not be set if WOR is not in use; that way, the WOR hardware block will consume zero dynamic power.

In total, there are 4 clocks used by WOR hardware:

1. **ipg_clk_wor_1m**: Most of the WOR hardware runs off this 1MHz clock, including the state machine, descriptor processing, and hop table indexing. All link layer interface outputs are generated with this clock, and link layer inputs sampled by it.
2. **ipg_clk_wor_ww_1m**: Identical in timing to ipg_clk_wor_1m, but used only by functions that require window widening to be enabled. The additional clock gating granularity saves power when widening is disabled.
3. **ipg_clk_wor_comp**: This is the "compute clock" used by the serial multilier. This clock runs at the reference oscillator frequency (derivative of xcvr_ref_clk_gated), but only during the 4 1µs-long states (per slot) during which the multiplier is in use; See Section Hardware Multiplier)
4. **ipg_clk_wor_timestamp**: This is the "timestamp clock". Because the protocol engines determine the timestamp-capture timing, based on AA/SFD detection, the clock-gate enable for the capture is sent to the CGM, which routes the resulting timetamp clock itself to WOR so that it can update its TIMESTAMP1,2, and 3 registers. This clock will typically pulse once per RX slot, and not at all for slots of other types.

All gating for the WOR clocks is performed in CGM. WOR provides the gating-enable signal, and CGM provides the clock.

All WOR clocks are in the Reference Oscillator domain. There are no clock domain crossings inside the module.

No WOR critical timing paths are anticipated, nor any timing exceptions (e.g., multicycle paths).

## 64.3.9 Cyclic Redundancy Check and Data Whitening Module (CRCW)

### 64.3.9.1 Introduction

The cyclic redundancy check and data whitening module (CRCW) contains logic necessary to provide CRC and Whitening for the radio link layer functions. Packet data is provided one bit at a time by the link layer functions on transmit, or by the radio physical layer on receive. Control and mode input signals dictate how the CRCW interprets and modifies the bit stream. The CRCW does not add any latency to the data as it is transmitted or received.

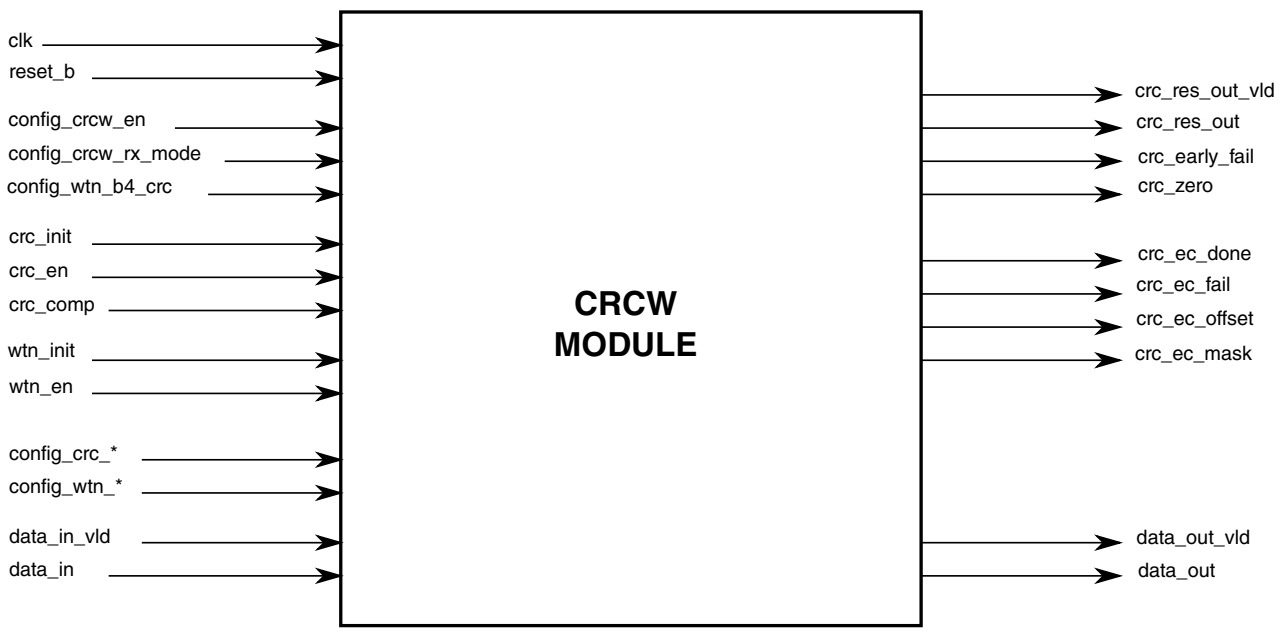

**Figure 64-123. CRCW Block Diagram**

#### 64.3.9.1.1 Features

- Zero added data latency
- One module used for both transmit and receive
- All modes work at bit rates up to 1/10$^{th}$ the system clock rate
- Configurable CRC
  - 8/16/24/32-bit CRC register width

- Programable polynomial and seed values
- CRC value byte and bit order
- Payoad input bit reflect

- Configurable Data Whitening
  - 1-bit to 9-bit LFSR width
  - Programable polynomial and seed values
  - Galois or Fibonacci type LFSR
  - Input data bit reflect
- Optional CRC Error Correction
  - Correct limited burst errors
  - Seperate settings for short and long packets
  - Offset/Mask reported to software for final data correction

#### 64.3.9.1.2 Operation

The CRCW module contains the functionality to perform transmit CRC insertion, receive CRC checking, and data whitening. Additionally, the module can perform data error correction on received packets using the CRC syndrome if configured appropriately.

##### 64.3.9.1.2.1 CRC Calculation

The CRC value is calculated using a configurable LFSR as depicted in Figure 64-124. The CRC calculation polynomial value is loaded into register *P*. The seed is loaded into register *SR* at initilization. The result is in register *SR* after all bits have been processed.

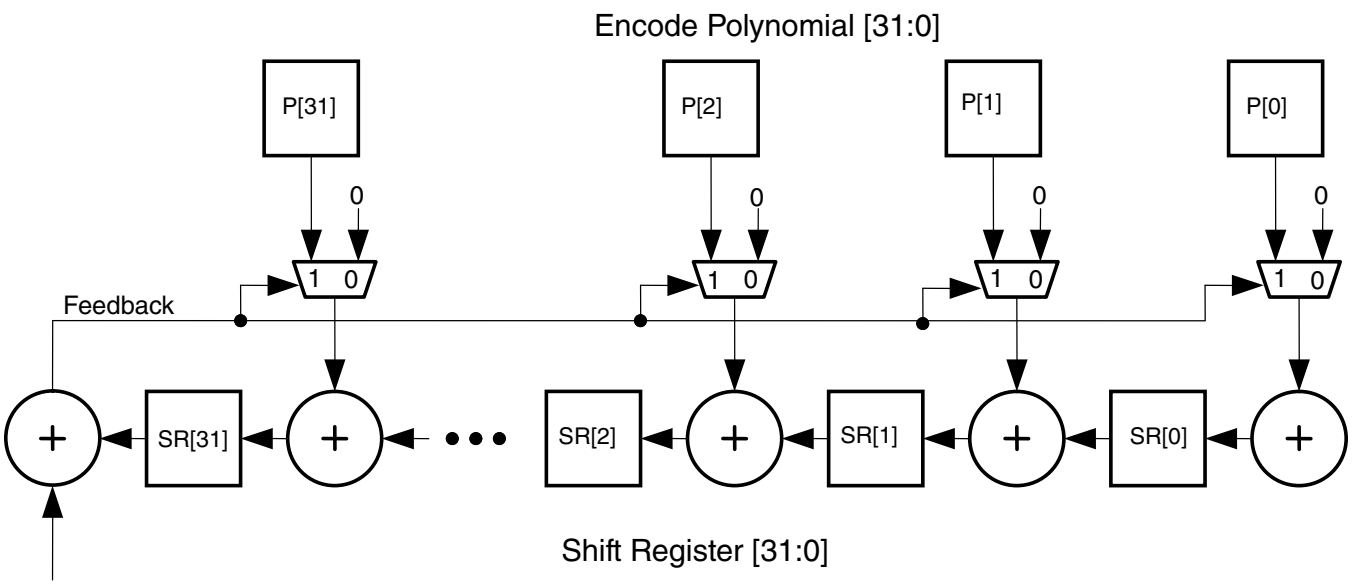

**Figure 64-124. CRC Calculation Shift Register**

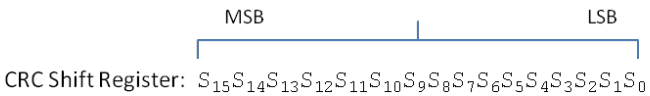
Data flows from the link layer function to the CRCW module during transmit before being sent to the radio physical layer. All bits in each packet are provided by the link layer function, including placeholder bits for the CRC value. The link layer function marks the CRC calculation start and stop points in the bit stream. The link layer also indicates the start of the CRC placeholder bits. The CRCW module overwrites the placeholder CRC bits with the CRC result, ordered as specified by the configuration options. Figure 64-125 is a list of example 16-bit CRC output modes.



| REF IN | BYTE ORDER | REF OUT | Order of Transmitted Bits (shifted out first ..... shifted out last) |
|---|---|---|---|
| X | 0 | 0 | $P_0P_1P_2P_3P_4P_5P_6P_7P_8P_9P_{10}P_{11}P_{12}P_{13}P_{14}P_{15}$ $S_{15}S_{14}S_{13}S_{12}S_{11}S_{10}S_9S_8S_7S_6S_5S_4S_3S_2S_1S_0$ |
| X | 0 | 1 | $P_0P_1P_2P_3P_4P_5P_6P_7P_8P_9P_{10}P_{11}P_{12}P_{13}P_{14}P_{15}$ $S_8S_9S_{10}S_{11}S_{12}S_{13}S_{14}S_{15}S_0S_1S_2S_3S_4S_5S_6S_7$ |
| X | 1 | 0 | $P_0P_1P_2P_3P_4P_5P_6P_7P_8P_9P_{10}P_{11}P_{12}P_{13}P_{14}P_{15}$ $S_7S_6S_5S_4S_3S_2S_1S_0S_{15}S_{14}S_{13}S_{12}S_{11}S_{10}S_9S_8$ |

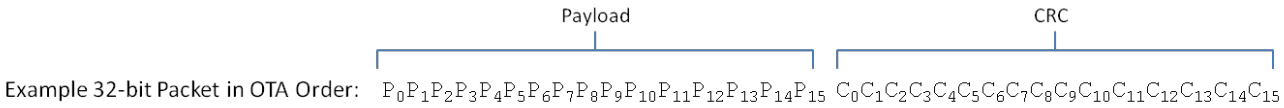
**Figure 64-125. CRC Output Bit Order**

### 64.3.9.1.2.2 CRC Check

During reception, data flows from the radio physical layer to the CRCW module before being sent to the link layer function. All bits in each packet are provided by the radio physical layer. Just as in transmit, the link layer function marks the CRC calculation start and stop points in the bit stream. The link layer also indicates the start of the received CRC bits.

The CRCW calculates the expected CRC result just as in transmit, but compares the received CRC bits as they arrive, ordered as specified by the configuration options, instead of inserting them into the packet. An early fail signal is asserted if a CRC bit miscompare is detected.

The CRC register will contain the expected CRC when either of the *config_crc_byte_order* or *config_crc_ref_in* CRC configuration options are set. The CRC register will contain the syndrome of the CRC error calculation when the both are not set.



| REF IN | BYTE ORDER | REF OUT | Order of Bits Used in CRC Calculation (shifted in first ..... shifted in last) |
|---|---|---|---|
| 0 | 0 | 0 | $P_0P_1P_2P_3P_4P_5P_6P_7P_8P_9P_{10}P_{11}P_{12}P_{13}P_{14}P_{15}$ $C_0C_1C_2C_3C_4C_5C_6C_7C_8C_9C_{10}C_{11}C_{12}C_{13}C_{14}C_{15}$ |

**Figure 64-126. CRC Input Bit Order**

### 64.3.9.1.2.3 Data Whitening

The data whitener behaves identically in both transmit (whiten) and receive (de-whiten) operating modes - there is no distinction. The LFSR used in this operation is designed to use either Fibonacci or Galois types of calculations. In either case, the LSB of the shift register is used to whiten each data bit as they are streamed through the CRCW.

An initialization signal for the data whiten logic loads the shift register with the seed value. The initialization signal can be used to re-initialize the shift register during a packet. A protocol specific state machine controls a signal to mark the start and stop points for data whitening in the data stream.

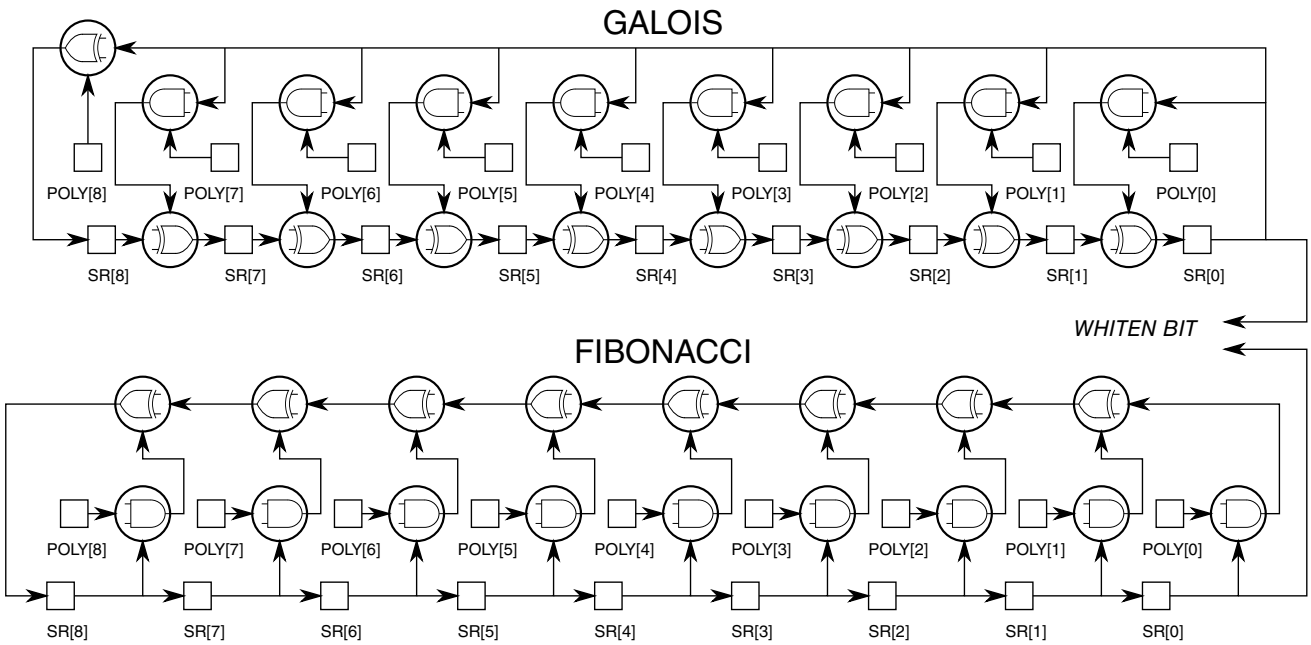

**Figure 64-127. Data Whitening Shift Register**

### 64.3.9.1.2.4 Error Correction

The CRC engine can optionally provide a level of error correction. This is accomplished by using the syndrome to locate the position of a possible burst error. This is especially useful for short burst errors. The error correction feature is controlled by configuration bits. A configuration setting defines the length of a short packet from zero to 31 bytes, and two different settings control the aggressiveness of error correction for short and long packets. More aggressive values attempt to correct longer burst errors, but potentially result in more false error correction solutions. Error correciton can be enabled for short packets and disasbled for long packets, or vice versa. The error correction feature is completely disabled when the CRC value is not received MSb first (*config_crc_byte_order* or *config_crc_ref_in*are enabled) because the error syndrome is not calculated.

While correcting random errors becomes difficult very quickly, it is fairly easy to correct a small burst error. Once the syndrome has been computed, all effects of the random message bits have been removed and the syndrome is the CRC value associated with the error signal. Reversing the CRC decoding process with the syndrome as the initial value of the LFSR will predict where the errors occurred in the payload. The structure of the CRC error correction LFSR is shown in Figure 64-128. The shifting process looks for a range of zeros in the least significant bits of the LFSR, counting the number of shifting operatations. The number of shifting operations determines the error location from the end of the packet accross all bits used in the CRC calculation.

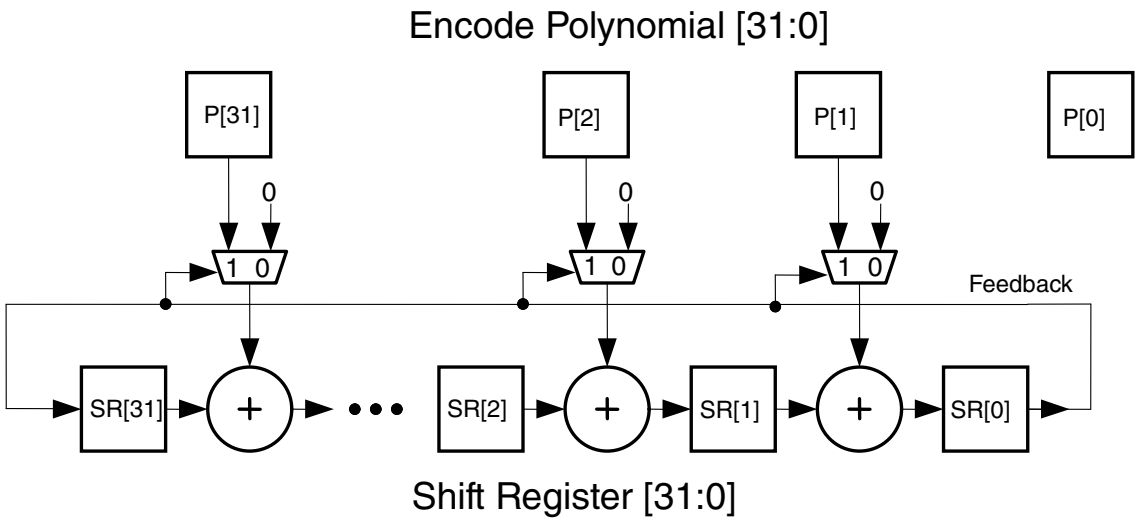

**Figure 64-128. CRC Correction Shift Register**

The CRCW module will perform the algorithm described above if enabled and the results of the CRC receive decode operation results in a syndrome that indicates an error. The logic performes one iteration per system clock cycle and can take up to *crc-included-bits* x *system clock cycles* to complete. The result of the error correction algorythm is an offset and XOR mask when successful. The offset is in bytes and counts only those bytes that are used in the CRC calculation, including the CRC value. The offset and mask values are zero on failure. The CRCW module will report if the algorythm was successful and the burst error position and mask so that upstream software can perform the correction.

### 64.3.9.2 Interface Timing

The CRCW interface timing requirements are described below. All signals except *reset_b* should be driven synchronous to *clk*. Some configuration options required a minumum number of clocks between data input bits or between the initialize input signals and the first data input bit.

The maximum input bitrate is 1/10$^{th}$ the system clock rate as shown in Figure 64-129.

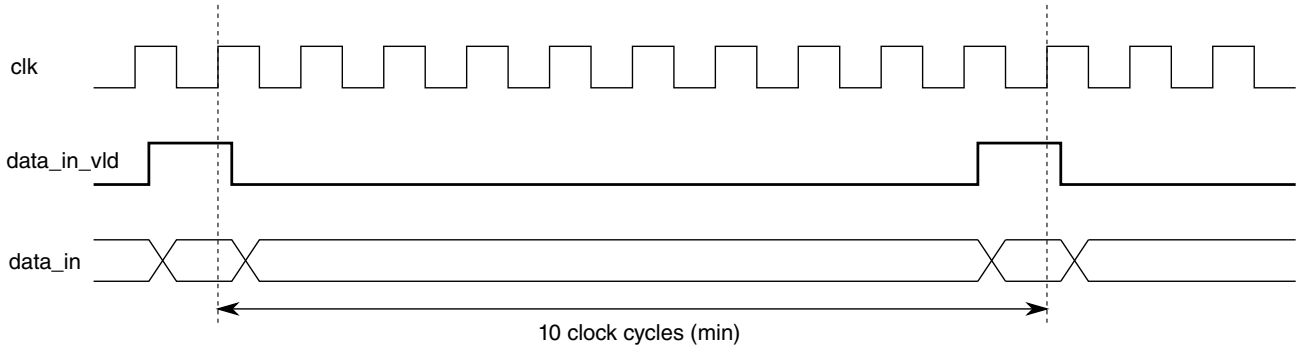

**Figure 64-129. Maximum Bitrate Timing Diagram**

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25<br>TSM_IRQ1 | TSM Interrupt #1<br>0b - TSM Interrupt #1 is not asserted.<br>1b - TSM Interrupt #1 is asserted. Write '1' to this bit to clear it. |
| 24<br>TSM_IRQ0 | TSM Interrupt #0<br>0b - TSM Interrupt #0 is not asserted.<br>1b - TSM Interrupt #0 is asserted. Write '1' to this bit to clear it. |
| 23-19<br>— | Reserved |
| 18<br>XTAL_READY | RF Osciallator Xtal Ready<br>Oscillator warmup count complete.<br>0b - Indicates that the RF Oscillator is disabled or has not completed its warmup.<br>1b - Indicates that the RF Oscillator has completed its warmup count and is ready for use. |
| 17<br>RIF_LL_ACTIVE | Link Layer Active Indication<br>Reflects the state of the BTLE “Link Layer Active” status bit. RIF_LL_ACTIVE is to be used by the host as an 'early' indication to prevent host to do any operations while BTLE IP is doing transceiver operations, so as to reduce the peak power and noise. |
| 16 | BTLE System Clock Request |

*Table continues on the next page...*

| Field | Function |
|---|---|
| BTLE_SYSCLK_REQ | Reflects the state of the BTLE oscillator request signal. BTLE_SYSCLK_REQ is the BTLE control for the RF Oscillator. BTLE will deassert this signal upon entering DSM (deep sleep mode) to request oscillator turn-off, and will re-assert it prior to exiting DSM. The turn-on leadtime on this signal for exiting DSM, is programmable with the BTLE block. This read-only bit can thus be queried to ascertain the power-state of BTLE. |
| 15-14<br>— | Reserved |
| 13<br>TX_MODE | Transmit Mode<br>Indicates an TX transceiver operation is in progress. |

| 0<br>BLE_RELINQUISH | BLE Relinquish Control<br>This bit forces the BLE protocol engine to immediately relinquish access to the RF Channel, in favor of another protocol with higher arbitration priority. BLE is denied RF channel access by blocking BLE access to the TSM; when this bit is subsequently cleared, BLE access is restored. |

### 64.3.10.1.5 OVERWRITE VERSION (OVERWRITE_VER)

#### 64.3.10.1.5.1 Offset

| Register | Offset |
|---|---|
| OVERWRITE_VER | Ch |

#### 64.3.10.1.5.2 Function

The Overwrite Version allows software to store a version number of trim and calibration values which are used to overwrite the chip default values in the registers. Typically,

software would perform the overwrite of the defaults in transceiver registers and then write the version number from the file containing the overwrite values into this register.

**NOTE**

This register has no hardware connections, it is simply a designated storage location for a version number.

#### 64.3.10.1.5.3 Diagram

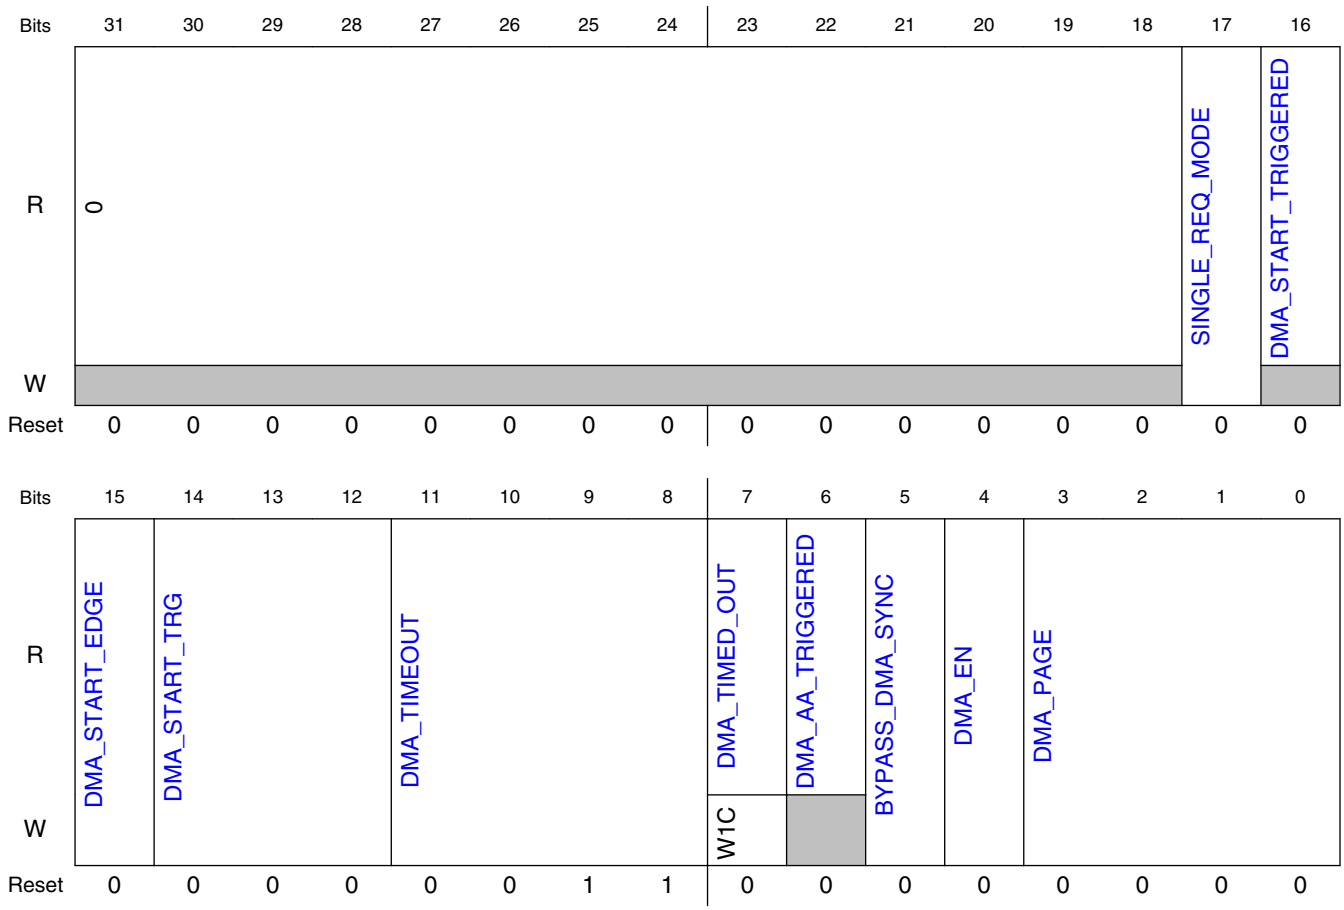
## 64.3.10.1.7 TRANSCEIVER DMA CONTROL (DMA_CTRL)

### 64.3.10.1.7.1 Offset

| Register | Offset |
|---|---|
| DMA_CTRL | 14h |

### 64.3.10.1.7.2 Diagram



### 64.3.10.1.7.3 Fields

| Field | Function |
|---|---|
| 31-18<br>— | Reserved |
| 17<br>SINGLE_REQ_MODE | DMA Single Request Mode<br>Configures the transceiver to transfer the entire block of DMA data with only a single initial request (ipd_req_radio_rx). The DMA2 controller must be configured accordingly. In this mode, the transceiver will use **ips_xfr_wait** to pace the individual transactions. Single Request Mode should not be used with DMA Pages 11, 12, or 13, because the data rate is too low and therefore ips_xfr_wait would remain asserted for excessively long periods.<br>0b - Disable Single Request Mode. The transceiver will assert ipd_req_radio_rx whenever it has a new sample ready for transfer.<br>1b - Enable Single Request Mode. A single initial request by the transceiver will transfer the entire DMA block of data |
| 16 | DMA Start Trigger Occurred |

*Table continues on the next page...*

| Field | Function |
|---|---|
| DMA_START_TRIGGERED | This read-only status bit becomes set, when, during a DMA session (DMA_PAGE > 0), the trigger source selected by DMA_START_TRG[2:0] occurs, with the edge sensitivity selected by DMA_START_EDGE. To clear this bit, set DMA_PAGE=0. |
| 15<br>DMA_START_EDGE | DMA Start Trigger Edge Selector<br>DMA_START_EDGE selects the edge sensitivity (rising or falling) of the selected start-trigger.<br>0b - Trigger fires on a rising edge of the selected trigger source<br>1b - Trigger fires on a falling edge of the selected trigger source |
| 14-12<br>DMA_START_TRG | DMA Start Trigger Selector<br>The DMA Start Trigger, if desired, can be selected from the sources in the following table:<br>0: no trigger<br>1: FSK PHY: gfsk_preamble_found<br>2: FSK PHY: aa_sfd_matched<br>3: ZBDEMOD: rx_preamble_det<br>4: ZBDEMOD: rx_sfd_detect<br>5: RXDIG: agc_dcoc_gain_chg<br>6: TSM: rx_dig_en<br>7: TSM: tsm_spare2_en |
| 11-8<br>DMA_TIMEOUT | DMA Timeout<br>In DMA Single Request Mode, adverse consequences may result if the transceiver's ips_xfr_wait signal is asserted for an excessively long period of time, which could occur due to mis-programming of the DMA2 controller, and/or the transceiver itself. DMA Timeout forces the transceiver's ips_xfr_wait low after *N* microseconds and sets the **DMA_TIMED_OUT** status bit, where *N*=DMA_TIMEOUT. DMA_TIMEOUT is only relavent when SINGLE_REQ_MODE=1, otherwise the transceiver does not assert ips_xfr_wait. |
| 7<br>DMA_TIMED_OUT | DMA Transfer Timed Out<br>Status bit indicates that the transceiver DMA, while operating in Single Request Mode, asserted ips_xfr_wait for a period in excess of the programmed **DMA_TIMEOUT** setting, resulting in a timeout condition where the transceiver has forced ips_xfr_wait low. After a timeout, before resuming DMA operations, set DMA_PAGE=0 to disable DMA, and write 1 to this bit to clear it.<br>0b - A DMA timeout has not occurred<br>1b - A DMA timeout has occurred in Single Request Mode since the last time this bit was cleared |
| 6<br>DMA_AA_TRIGGERED | DMA Access Address triggered<br>This status bit becomes set when the PHY indicates that a Network Address match has occurred. In some cases it may be desirable to delay the start of DMA transfers until such a match occurs; in such cases, software can poll this bit, and once it becomes set, immediately select the desired DMA_PAGE to initiate DMA transfers. This bit is intended for use with DMA_PAGE=13, but is available on all pages. Its usage is optional. |
| 5<br>BYPASS_DMA_SYNC | Bypass External DMA Synchronization<br>When using transceiver DMA with SINGLE_REQ_MODE=0, synchronization external to the transceiver must be bypassed in order to minimize bus access latency. Using DMA in this mode also requires that the MCU and transceiver both are configured to operate in the RF Oscillator clock domain.<br>0b - Don't Bypass External Synchronization. Use this setting if SINGLE_REQ_MODE=1.<br>1b - Bypass External Synchronization. This setting is mandatory if SINGLE_REQ_MODE=0. |
| 4<br>DMA_EN | DMA Enable<br>Setting DMA_EN=1 enables clock gating to the Transciever DMA engine. This bit should be set prior to the start of a DMA session, and remain set for the duration of the session. |
| 3-0<br>DMA_PAGE | Transceiver DMA Page Selector<br>Selects the page of receiver data for storage to system memory when using Transceiver DMA Debug Mode. Setting this register to a non-zero value enables the DMA interface logic. Setting this register to zero disables the interface. **Note:** DMA_PAGE should be set to a non-zero value to begin an acquisition, |

| Field | Function |

### 64.3.10.1.9.3 Fields

| Field | Function |
|---|---|
| 31<br>RAM1_CE_ON_OVRD | Override value for RAM1 CE (Chip Enable)<br>When RAM1_CE_ON_OVRD_EN=1, this value overrides the mission mode state of the RAM1 CE. This bit is ignored when RAM1_CE_ON_OVRD_EN=0. |
| 30<br>RAM1_CE_ON_OVRD_EN | Override control for RAM1 CE (Chip Enable)<br>0b - Normal operation.<br>1b - Use the state of RAM1_CE_ON_OVRD to override the RAM1 CE. |
| 29<br>RAM0_CE_ON_OVRD | Override value for RAM0 CE (Chip Enable)<br>When RAM0_CE_ON_OVRD_EN=1, this value overrides the mission mode state of the RAM0 CE. This bit is ignored when RAM0_CE_ON_OVRD_EN=0. |
| 28<br>RAM0_CE_ON_OVRD_EN | Override control for RAM0 CE (Chip Enable)<br>0b - Normal operation.<br>1b - Use the state of RAM0_CE_ON_OVRD to override the RAM0 CE. |
| 27<br>RAM1_CLK_ON_OVRD | Override value for RAM1 Clock Gate Enable<br>When RAM1_CLK_ON_OVRD_EN=1, this value overrides the mission mode state of the RAM1 Clock Gate Enable. This bit is ignored when RAM1_CLK_ON_OVRD_EN=0. |
| 26<br>RAM1_CLK_ON_OVRD_EN | Override control for RAM1 Clock Gate Enable<br>0b - Normal operation.<br>1b - Use the state of RAM1_CLK_ON_OVRD to override the RAM1 Clock Gate Enable. |
| 25<br>RAM0_CLK_ON_OVRD | Override value for RAM0 Clock Gate Enable<br>When RAM0_CLK_ON_OVRD_EN=1, this value overrides the mission mode state of the RAM0 Clock Gate Enable. This bit is ignored when RAM0_CLK_ON_OVRD_EN=0. |
| 24<br>RAM0_CLK_ON_OVRD_EN | Override control for RAM0 Clock Gate Enable<br>0b - Normal operation.<br>1b - Use the state of RAM0_CLK_ON_OVRD to override the RAM0 Clock Gate Enable. |
| 23<br>PB_PROTECT | Packet Buffer Protect<br>Protect Packet Buffer contents against overwriting by the next received packet. Applies to all protocols except BLE<br>0b - Incoming received packets overwrite Packet Buffer RX contents (default)<br>1b - Incoming received packets are blocked from overwriting Packet Buffer RX contents |
| 22<br>DBG_STOP_TRIGGERED | Packet RAM Debug Stop Triggered<br>This read-only status bit becomes set, when, during a Packet RAM Debug session (DBG_PAGE > 0), the trigger source selected by DBG_STOP_TRG[3:0] occurs, with the edge sensitivity selected by DBG_STOP_EDGE. To clear this bit, set DBG_PAGE=0. |
| 21<br>DBG_START_TRIGGERED | Packet RAM Debug Start Triggered<br>This read-only status bit becomes set, when, during a Packet RAM Debug session (DBG_PAGE > 0), the trigger source selected by DBG_START_TRG[2:0] occurs, with the edge sensitivity selected by DBG_START_EDGE. To clear this bit, set DBG_PAGE=0. |
| 20<br>DBG_STOP_EDGE | Packet RAM Debug Stop Trigger Edge Selector<br>DBG_STOP_EDGE selects the edge sensitivity (rising or falling) of the selected stop-trigger.<br>0b - Trigger fires on a rising edge of the selected trigger source<br>1b - Trigger fires on a falling edge of the selected trigger source |
| 19-16 | Packet RAM Debug Stop Trigger Selector<br>The Packet RAM Debug Stop Trigger, if desired, can be selected from the sources in the following table: |

*Table continues on the next page...*

| Field | Function |
|---|---|
| DBG_STOP_TRG | 0: no trigger<br>1: FSK PHY: gfsk_preamble_found<br>2: FSK PHY: aa_sfd_matched<br>3: ZBDEMOD: rx_preamble_det<br>4: ZBDEMOD: rx_sfd_detect<br>5: RXDIG: agc_dcoc_gain_chg<br>6: TSM: rx_dig_en<br>7: TSM: tsm_spare3_en<br>8: TSM: pll unlock<br>9: BLE: crc_err_count_incr (increment DTM RX bad packet counter)<br>10: CRC FAIL: 802.15.4 or GEN_FSK only, selected by PROTOCOL[3:0]<br>11: HEADER FAIL: GEN_FSK only<br>12-15: Reserved |
| 15<br>DBG_START_EDGE | Packet RAM Debug Start Trigger Edge Selector<br>DBG_START_EDGE selects the edge sensitivity (rising or falling) of the selected start-trigger.<br>0b - Trigger fires on a rising edge of the selected trigger source<br>1b - Trigger fires on a falling edge of the selected trigger source |
| 14-12<br>DBG_START_TRG | Packet RAM Debug Start Trigger Selector<br>The Packet RAM Debug Start Trigger, if desired, can be selected from the sources in the following table:<br>0: no trigger<br>1: FSK PHY: gfsk_preamble_found<br>2: FSK PHY: aa_sfd_matched<br>3: ZBDEMOD: rx_preamble_det<br>4: ZBDEMOD: rx_sfd_detect<br>5: RXDIG: agc_dcoc_gain_chg<br>6: TSM: rx_dig_en<br>7: TSM: tsm_spare2_en |
| 11<br>DBG_SOFT_INFO_SEL | Packet RAM Debug PHY Soft Info Output Selector<br>When acquiring data in Packet RAM Debug Mode with the DBG_PAGE=DMDSOFT page, this bit selects the signal from the PHY used to capture the soft decision data.<br>0b - PHY output bit_valid_int is used to capture soft decision data<br>1b - PHY output demod_vout is used to capture soft decision data |
| 10<br>DBG_AA_TRIGGERED | Packet Ram Debug Access Address triggered<br>This status bit becomes set when the PHY indicates that a Network Address match has occurred. In some cases it may be desirable to delay the start of Packet RAM debug transfers until such a match occurs; in such cases, software can poll this bit, and once it becomes set, immediately select the desired DBG_PAGE to initiate data transfers to Packet RAM. This bit is intended for use with DBG_PAGE=13, but is available on all pages. Its usage is optional. |
| 9-8<br>DBG_RAM_FULL | DBG_RAM_FULL[1:0]<br>Status Bits indicating that Packet RAM0 (or RAM1) is full, and the Packet RAM Debug engine has attempted to write another word to that RAM. This, and any subsequent write attempts, will not alter the contents of the RAM, once it has reached capacity. Set DBG_PAGE=0 to clear the DBG_RAM_FULL[1:0] bits.<br>**NOTE:** If a Debug Stop Trigger is selected (DBG_STOP_TRG > 0), writes to RAM do not stop when DBG_RAM_FULL bit(s) become set; instead, writes continue after an address wrap-around to 0, and will continue indefinitely until either a stop trigger condition occurs, or the debug session is ended by taking DBG_PAGE=0. The DBG_RAM_FULL[1:0] remain a valid indicator that the RAM(s) has reached full status at least once during the debug session.<br>00b - Neither Packet RAM0 nor RAM1 is full<br>1xb - Packet RAM1 has been filled to capacity.<br>x1b - Packet RAM0 has been filled to capacity. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 7<br>ALL_PROTOCOLS_ALLOW | Allow IPS bus access to Packet RAM for any protocol at any time.<br>Each supported protocol has an associated IPS bus, with which it can access protocol-specific registers, as well as Packet RAM. Normally IPS bus access to the Packet RAM is restricted to the protocol currently selected by the XCVR_CTRL[PROTOCOL] register, and access attempts by other protocols will result in an assert of **ips_xfr_err** on the offending IPS interface. When ALL_PROTOCOLS_ALLOW=1, these inhibits are removed, and any IPS bus can access Packet RAM at any time without any error signalling.<br>0b - IPS bus access to Packet RAM is restricted to the protocol engine currently selected by XCVR_CTRL[PROTOCOL].<br>1b - All IPS bus access to Packet RAM permitted, regardless of XCVR_CTRL[PROTOCOL] setting |
| 6<br>XCVR_RAM_ALLOW | Allow Packet RAM Transceiver Access<br>This bit must be set before performing accesses to the Packet RAM using transceiver address space. Transceiver space accesses to Packet RAM are intended for debug purposes only; the individual protocol engines, and the associated IPS busses, have exclusive access to Packet RAM in mission modes. Transceiver space accesses to Packet RAM include direct accesses to RAM at transceiver addresses 0x700 - 0xFFF, as well as Packet RAM Debug Mode. When this bit is set, control of RAM clock gating and RAM chip enables are forced on continuously, taking these controls away from the protocol engines.<br>0b - Protocol Engines, and associated IPS busses, have exclusive access to Packet RAM (mission mode)<br>1b - Transceiver-space access to Packet RAM, including Packet RAM debug mode, are allowed |
| 5<br>XCVR_RAM_PAGE | RAM Page Selector for XCVR Access<br>This bit selects which of the 2 Packet RAM blocks is mapped into XCVR address space starting at XCVR_BASE + 0x700.<br>0b - RAM0 is mapped into XCVR address space, between XCVR_BASE + 0x700, and XCVR_BASE + 0xFFF<br>1b - RAM1 is mapped into XCVR address space, between XCVR_BASE + 0x700, and XCVR_BASE + 0xFFF |
| 4<br>DBG_EN | Packet RAM Debug Mode Enable<br>Setting DBG_EN=1 enables clock gating to the Packet RAM Debug engine. This bit should be set prior to the start of a Debug session, and remain set for the duration of the session. |
| 3-0<br>DBG_PAGE | Packet RAM Debug Page Selector<br>Selects the page of receiver data for storage to Packet RAM using Transceiver Packet RAM Debug Mode. Setting this register to a non-zero value enables the Packet RAM Debug Mode interface logic. Setting this register to zero disables the interface. **Note:** DBG_PAGE should be set to a non-zero value to begin an acquisition, only after the start and stop triggers have been programmed (DBG_START_TRG and DBG_STOP_TRG), if a trigger is desired. The available RAM Debug pages are listed below.<br>0000b - Packet RAM Debug Mode Idle<br>0001b - RX_DIG I and Q<br>0010b - Reserved<br>0011b - Reserved<br>0100b - RAW ADC I and Q<br>0101b - Reserved<br>0110b - Reserved<br>0111b - DC Estimator I and Q<br>1000b - Reserved<br>1001b - Reserved<br>1010b - RX_DIG Phase Output<br>1011b - Reserved<br>1100b - Demodulator Soft Decision<br>1101b - Demodulator Data Output<br>1110b - Demodulator CFO Phase Output<br>1111b - Reserved |

| 7-0<br>LSBYTE | LSBYTE |

### 64.3.10.3 XCVR_PHY register descriptions

**Note**

To decipher number formats such as ‘ufix4en2’ or ‘sfix8en3’:

General form: [u/s]fix[Nb]e[n][Nx]

Where,

| | |
|---|---|
| [<br>u<br>/<br>s<br>] | denotes whether the number is signed or not |
| f<br>i<br>x | denotes that the number is fixed point, 2's complement |
| N<br>b | indicates total number of bits, including a sign bit if signed |
| e | indicates that the number is exponentiated like num x 2^(exponent) |
| n | indicates the exponent is negative |
| N<br>x | indicates the value of the exponent |

For example :

- ufix4en2(1101) = 1101 x 2^(-2) = 11.01 = 3.25 (decimal)
- sfix8en3(10011011) = -1100101 x 2^(-3) = -1100.101 = -12.625 (decimal)

### 64.3.10.3.1 XCVR_RX_PHY_ADDR Memory map

XCVR_PHY base address: 4103_0400h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Preamble Detect Config 0 (PHY_FSK_PD_CFG0) | 32 | RW | 0021_081Eh |
| 4h | Preamble Detect Config 1 (PHY_FSK_PD_CFG1) | 32 | RW | 0ACD_2BDEh |

#### 64.3.10.3.3.4 Fields

| Field | Function |
|---|---|
| 31-25<br>PD_FREQ_THRESH | Preamble Detect frequency threshold<br>Frequency range within which 2 preamble detects are considered similar in frequency and, thus, correlated. Format is ufix7en9 and can be estimated by: PD_FREQ_THRESH = round(1024*(Freq_Thresh/(OSR*SYMBOL_RATE)) |
| 24<br>— | Reserved. |
| 23-16<br>PD_THRESH | Preamble detect threshold<br>Preamble detect correlation threshold (ufix8en8). This threshold is used to define high correlation for the preamble detect logic. It is the default threshold used and corresponds to PD MODE A. |
| 15<br>— | Reserved. |
| 14-10<br>PD_TIMEOUT | Preamble Detect Timeout<br>Timeout parameter for preamble detect (in samples). After timeout occurs, a better correlation is no longer searched for, and the acquired frequency estimate is committed. |
| 9-5<br>PRE_REF7 | Reference waveform sample 7 (sfix5en5) |
| 4-0<br>PRE_REF6 | Reference waveform sample 6 (sfix5en5) |

## 64.3.10.3.4 PHY Configuration (PHY_FSK_CFG)

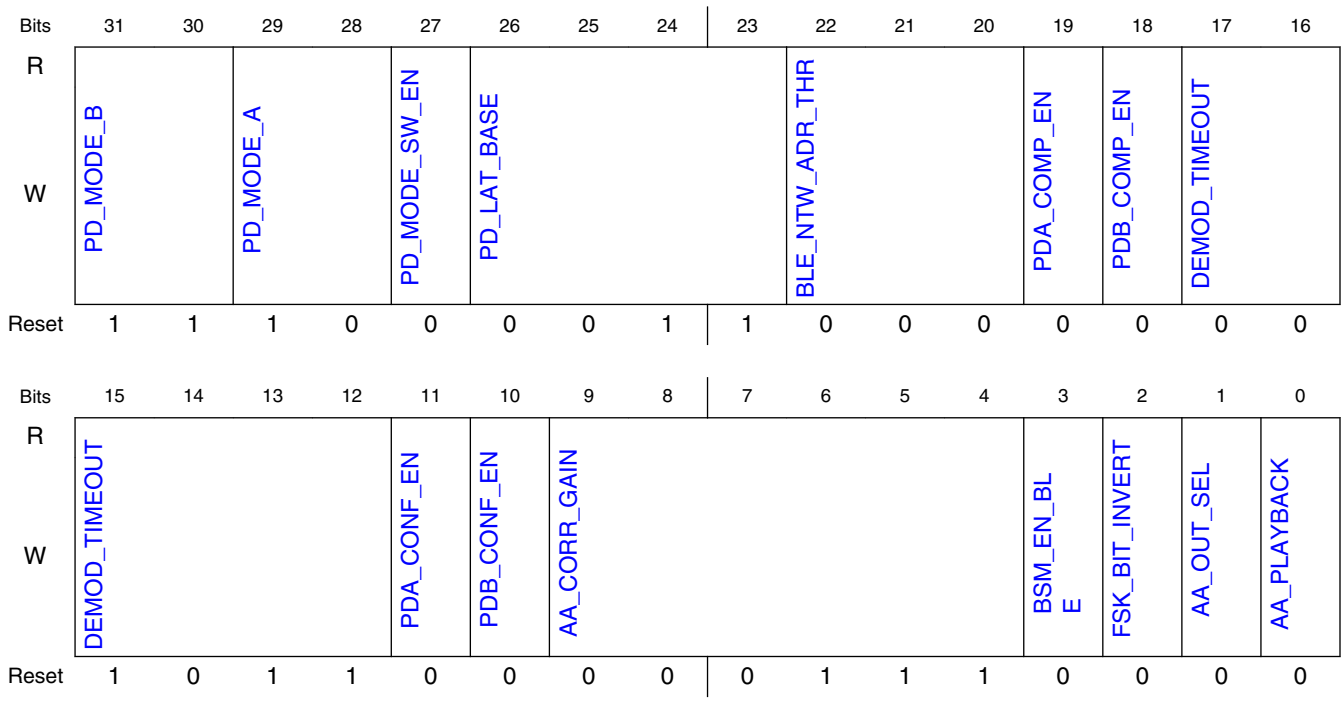
### 64.3.10.3.4.1 Offset

| Register | Offset |
|---|---|
| PHY_FSK_CFG | 8h |

### 64.3.10.3.4.2 Function

PHY configuration.

### 64.3.10.3.4.3 Diagram



### 64.3.10.3.4.4 Fields

| Field | Function |
|---|---|
| 31-30<br>PD_MODE_B | Preamble detect configuration for PD Mode B.<br>10b - PD mode 2, pattern based preamble detection.<br>11b - PD mode 3, peak based preamble detection. |
| 29-28<br>PD_MODE_A | Preamble detect configuration for PD Mode A.<br>10b - PD mode 2, pattern based preamble detection.<br>11b - PD mode 3, peak based preamble detection. |
| 27<br>PD_MODE_SW_EN | Allow PD mode switching. When enabled, an external signal is observed to switch between PD mode A and PD mode B. If not enabled, PD mode A is always used. |
| 26-23<br>PD_LAT_BASE | User configurable adjustment to the PD latency, in samples. |
| 22-20<br>BLE_NTW_ADR_THR | Allowable hamming distance for BLE AA search. |
| 19<br>PDA_COMP_EN | Enables compressed correlation in PD Mode A. |
| 18<br>PDB_COMP_EN | Enables compressed correlation in PD Mode B. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| 17-12<br>DEMOD_TIMEOUT | Number of symbols for which the state machine will wait past the expected end of the AA to declare a false PD and resume scanning. The actual timeout for the AA search is calculated as: TIMEOUT = (max_AA_length + DEMOD_TIMEOUT + 1.5) * OSR |
| 11<br>PDA_CONF_EN | Enables preamble AA confirmation for preamble detect mode A. |
| 10<br>PDB_CONF_EN | Enables preamble AA confirmation for preamble detect mode B. |
| 9-4<br>AA_CORR_GAIN | AA correlator gain. Format ufix6en3. This gain is applied to soft bits from the demodulator before they are used for address search synchronization. |
| 3<br>BSM_EN_BLE | Enable BSM mode for BLE. |
| 2<br>FSK_BIT_INVERT | Reserved.<br>0b - Normal demodulation.<br>1b - Invert demodulated bits. This applies at the demodulator, so it affects both AA and the data portions of the packet. |
| 1<br>AA_OUT_SEL | Reserved.<br>0b - When AA playback is enabled, play back desired AA.<br>1b - When AA playback is enabled, play back received AA. |
| 0<br>AA_PLAYBACK | Reserved.<br>0b - PHY will only output bits after the AA.<br>1b - PHY will output the AA, followed by the rest of the packet bits. |

## 64.3.10.3.5 PHY Misc. Configuration (PHY_FSK_MISC)

# 64.4 Transceiver Analog

## 64.4.1 Introduction

The 2.4 GHz radio is comprised of both an analog and digital portion. The analog portion of the radio provides the local oscillator (LO), transmit modulation, and receiver down conversion, along with the various circuits needed to support those functions.

The analog block also provides a clock to the digital domain that is to be used as a reference. This clock is derived from an external reference and, in the case of a crystal, should be trimmed to be as accurate as possible. The two supported frequencies for this reference are 26 MHz and 32 MHz.

RF input and output are combined with an integrated balun located on the device. Thus, only a single RF port is needed.

It is also of note that the analog contains several LDO circuits to supply various blocks within the design.

The analog radio is configured and commanded by the digital domain using both static configuration signals and dynamic control signals.

### 64.4.1.1 Features

The 2.4 GHz analog radio block includes the following features:

- Fractional-N Frequency Synthesizer PLL shared by receive and transmit

- Integrated balun
- Transmitter supporting constant envelope modulation for 2.4 GHz ISM and 2.36 GHz MBAN frequency bands (2360 to 2483.5 MHz)
- Direct PLL modulation for transmit
- Direct conversion reciever for 2.4 GHz ISM and 2.36 GHz MBAN frequency bands (2360 to 2483.5 MHz)
- Receive line-up comrised of a Low Noise Amplifier & Mixer, Baseband amplifier and filter, and sigma-delta ADC
- Direct analog diagnostic lines for debug and test
- Multiple LDOs to power analog circuits from line supply
- XO (REF_OSC) ciruit to use and external crystal and provide a reference clock internally at 26 MHz or 32 MHz
- AuxPLL to provide a 2x reference clock
- DC correction DACs for the TZA and BBA stages
- Programmable receiver gains in both the LNA and BBA stages

### 64.4.1.2 Block diagram

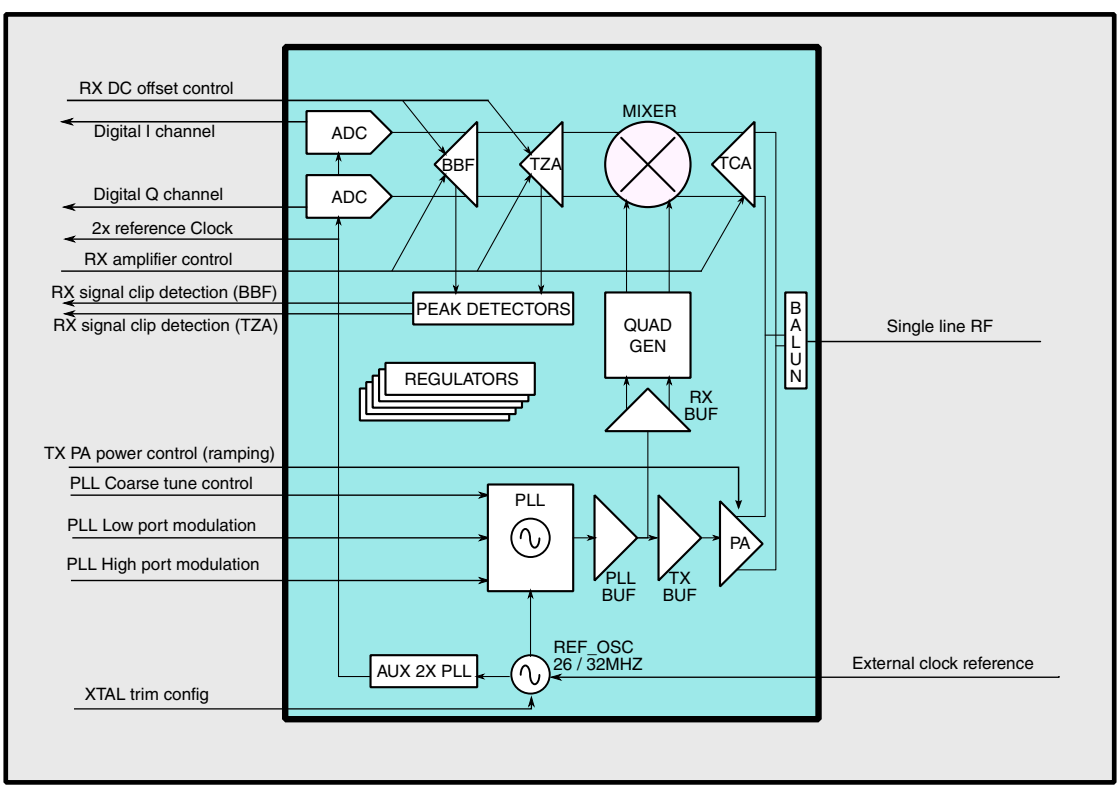

**Figure 64-136. Analog Radio Block diagram**

## 64.4.2 Functional description

The following section briefly describes the functionality of the 2p4GHz analog radio. It is not intended to be a complete description as many of the details are covered by descriptions of the control signals that are provided from the digital domain.

The analog block serves several purposes. Primarily, it provides the necessary circuitry to transmit at 2.4 GHz and receive in the same bands. When configured for transmission, the PLL is locked to the desired frequency (band and channel) as controlled by the PLL digital module. The digital radio then modulates the high port and low port of the PLL to generate the desired RF transmission. For receiver operation, the PLL is locked to the desired band and channel just as in transmit. The mixer provides a down-converted signal at baseband. The signal then goes through the baseband amplifier and is presented to the ADC. The ADC then converts the analog signal to a digital format, where it is observed by the digital domain. The receiver uses a 2x frequency clock to convert, so this clock is also provided to the digital domain from the AuxPLL. The receive path also contains several configurable parameters. For the gain, the LNA and BBA stages can be adjusted by signals from the digital domain. This is typically performed by the AGC circuit. DC offset can be corrected by controlling offset DACs at both stages, as well.

Both transmit and receive utilize an integrated balun. This results in a single RF port for the device and eliminates the need for a board level balun.

Several LDO blocks within the analog block provide the necessary supply to corresponding circuits. There is an LDO for the BBA, etc.

The XO block uses a reference crystal (typically) to produce a stable reference clock for the analog blocks and the digital domain. More details are provided in the section describing this block.

To assist in measurements and debug, multiple diagnostic analog signals are provided. These signals can be configured by inputs from the digital domain and then observed externally or with an ADC resident in the device.

### 64.4.2.1 XO Block

The XO block generates a 26 MHz or a 32 MHz reference clock for the digital domain, PLL, DAC, and AuxPLL blocks of the radio. It generates the output clocks from a crystal mounted externally to the device.

This block is alternatively known as REF_OSC, OSC, or XTAL, ocassionally.

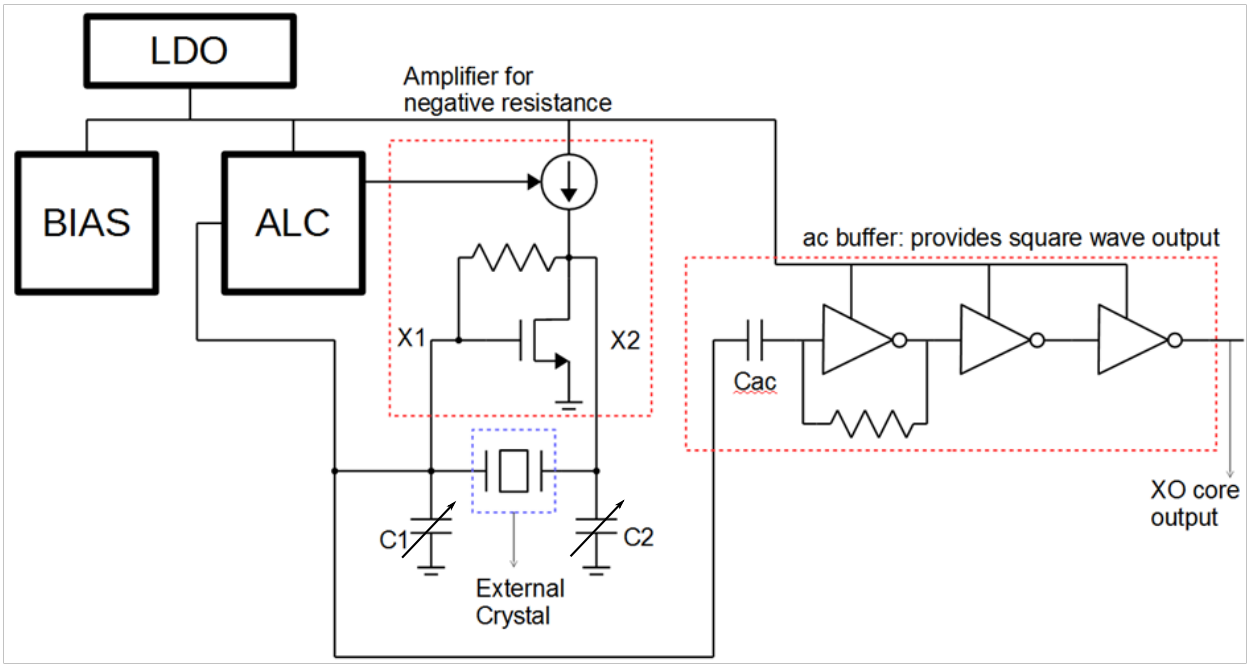

**Figure 64-137. XO circuit diagram**

#### 64.4.2.1.1 XTAL Trim

To enable optimum performance, it is required to trim the XO such that an accurate clock is produced based on the external crystal used. C1 and C2 are tuneable and intended for this purpose. They can be adjusted by configuring the XTAL_TRIM bits in the digital domain.

## 64.5 Link Layer

### 64.5.1 BLE Link Layer

#### 64.5.1.1 Register Descriptions

##### 64.5.1.1.1 Platform Registers

Platform Register Descriptions for the Bluetooth Link Layer

Instruction Register

| Addr | Addr | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| 16-bit | 32-bit | | | | |
|---|---|---|---|---|---|
| 0x00 | 0x000 | COMMAND_REGISTER | WO | Instructions register to send commands to link layer hardware for controlling hardware operations. | 0xXX00 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:11 | | XX |
| conn_index[2:0] | 10:8 | Connection index to specify the command is for which connection engine. | 0 |
| command | 7:0 | 8-bit command from firmware to the link layer controller. See appendix 1 for the list of instructions and their opcodes. The instruction results in the link layer hardware starting/stopping an operation.<br>Notes on use<br>1. Few of the commands will require other configuration registers to be set, before the command is written. Refer to appendix 1 for details of the registers to be set before setting these instructions. | 00 |

## Event clear Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x04 | 0x008 | EVENT_CLEAR | WO | Clears the source of the interrupt. This register is written by firmware to clear interrupts set in the EVENT_STATUS register.<br>One or more interrupts can be cleared in a single write operation, by writing a 1 at the bit fields specific to the interrupts being cleared. It is not required to write a follow-up write with zero as the previous write is not actually stored. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:9 | Not used. | XX |
| Dtm_intr_clr | 8 | Clear DTM packet reception interrupt. Write to the register with this bit set to 1, clears the interrupt source. | |
| Reserved | 7:6 | Not used. | |
| Dsm_intr_clr | 5 | Clear deep sleep mode exit interrupt. Write to the register with this bit set to 1, clears the interrupt source. | |
| Sm_intr_clr | 4 | Clear sleep-mode-exit interrupt. Write to the register with this bit set to 1, clears the interrupt source. | |
| Reserved | 3:0 | Not used. | |

## Event status register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x04 | 0x008 | EVENT_STATUS | RO | Event (Interrupt) status. Indicates pending events which require servicing by firmware. Each of the status bits is set by the link layer hardware. The bits are set till they are cleared by firmware by writing to appropriate event clear registers. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:9 | Not used. | XX |
| Dtm_intr | 8 | DTM packet reception interrupt. | 0 |
| Reserved | 7 | Not used. | XX |
| Enc_intr | 6 | Encryption module interrupt. | 0 |
| Dsm_intr | 5 | Deep sleep mode exit interrupt. This bit is set, when link layer hardware exits from deep sleep mode. The bit is cleared when firmware writes to EVENT_CLEAR register with this bit position set to 1. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Sm_intr | 4 | Sleep-mode-exit interrupt. This bit is set, when link layer hardware exits from sleep mode. The bit is cleared when firmware writes to EVENT_CLEAR register with this bit position set to 1. | 0 |
| Conn_intr | 3 | Connection interrupt. If bit is set to 1, it indicates an event occurred in the connection operation. This interrupt is aggregation of interrupts for all the connections. The source of the event for the specific connection needs to be read from the CONN_INTR_STATUS register specific to the connection. This bit is cleared, when firmware clears ALL interrupts by writing to the CONN_INTR_CLEAR register. | 0 |
| Init_intr | 2 | Initiator interrupt. If bit is set to 1, it indicates an event occurred in the initiating procedure. The source of the event needs to be read from the INIT_STATUS register. This bit is cleared, when firmware clears ALL interrupts by writing to the INIT_INTR_CLEAR register. | 0 |
| Scan_intr | 1 | Scanner interrupt. If bit is set to 1, it indicates an event occurred in the scanning procedure. The source of the event needs to be read from the SCAN_STATUS register. This bit is cleared, when firmware clears ALL interrupts by writing to the SCAN_INTR_CLEAR register. | 0 |
| Adv_intr | 0 | Advertiser interrupt. If bit is set to 1, it indicates an event occurred in the advertising procedure. The source of the event needs to be read from the ADV_STATUS register. This bit is cleared, when firmware clears ALL interrupts by writing to the ADV_INTR_CLEAR register. | 0 |

## Event enable register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x08 | 0x010 | EVENT_ENABLE | RW | Event indications enable. The register enables/masks each of the possible event sources from causing an interrupt. The bit fields mask only the events from interrupting the firmware. However hardware can still generate the interrupt. Firmware, when detects one interrupt, can mask all the interrupts temporarily, by clearing the register value to 0x0000. The interrupts can be masked till the first interrupt is processed and enable the interrupts back. This ensures no new interrupts is missed while firmware is processing one. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:7 | Not used. | XX |

## Wakeup Configuration register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x5C | 0x0B8 | WAKEUP_CONFIG | RW | Wakeup configuration to configure the various offsets while waking up from sleep mode or deep sleep mode. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Dsm_offset_to_wakeup_instant | 15:10 | Number of “slots” before the wake up instant before which the hardware needs to exit from deep sleep mode. The slot is of 0.625ms period. This is a one-time configuration field, which is used every time hardware does an auto-wakeup before the next wakeup instant. | 0 |
| Sm_offset_to_wakeup_instant | 9 | Number of “slots” (1slot = 625 microseconds) before the wake up instant before which the hardware needs to exit from sleep mode. This is a onetime configuration field, | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | which is used every time hardware does an auto-wakeup before the next wakeup instant. | |
| Retain_in_dsm2 | 8 | “1” indicates Connection RAM to be retained during DSM2. | 0 |
| Reserved | 7:5 | Reserved for future use. | 0 |
| Osc_startup_delay[4:0] | 4:0 | Oscillator stabilization/startup delay. This is in X.Y format where X is in terms of number of BT slots (625 us) and Y is in terms of number of clock periods of 16KHz clock input, required for RF oscillator to stabilize the clock output to the controller on its output pin, after oscillator is turned ON. In this period the clock is assumed to be unstable, and so the controller does not turn on the clock to internal logic till this period is over. This means, the wake up from deep sleep mode must account for this delay before the wakeup instant.<br><br>Osc_startup_delay[4:0] is number of clock periods of 16KHz clock<br><br>(Warning: Min. value of Osc_startup_delay [4:0] supported is 1 and Max. value is 9. Therefore programmable range is 1 to 9) | 00 |

## Wakeup Configuration2 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x278 | 0x4F0 | WAKEUP_CONFIG2 | RW | Wakeup configuration to configure the various offsets while waking up from sleep mode or deep sleep mode. | 0x00 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:7 | Not used. | XX |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Osc_startup_delay[11:5] | 6:0 | Oscillator stabilization/startup delay. This is in X.Y format where X is in terms of number of BT slots (625 us) and Y is in terms of number of clock periods of 16KHz clock input, required for RF oscillator to stabilize the clock output to the controller on its output pin, after oscillator is turned ON. In this period the clock is assumed to be unstable, and so the controller does not turn on the clock to internal logic till this period is over. This means, the wake up from deep sleep mode must account for this delay before the wakeup instant.<br><br>`Osc_startup_delay[11:5] is number of slots(625us)` | 00 |

*Note: In case of firmware DSM exit mode: Exit from DSM shall be in synchronization with ref_clk (625 us slots timing) and shall not come out of DSM mode before meeting the oscillator start up delay.It is expected to have 0 to 625 us extra delay to wake-up from DSM, depends upon the assertion of the dsm_exit signal (firmware exit).*

## Sleep Threshold register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x5E | 0x0BC | SLEEP_THRESHOLD | RW | Sleep Threshold register. Stores threshold values for entering sleep mode or deep sleep mode. The threshold values are compared with the inactivity period to determine entry into one of the modes. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Sm_threshold[3:0] | 15:12 | Number of inactive “slots” above which the device can enter sleep mode. If the number of slots is below this threshold, then device will not enter sleep mode. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Dsm_threshold[11:0] | 11:0 | Number of inactive “slots” above which the device can enter sleep mode. If the number of slots is below this threshold, then device will not enter deep sleep mode. | 0 |

*Note: Typically dsm_threshold > sm_threshold value. This means the following behavior is expected*

*No. of inactive slots(N) Behavior*

*N < sm_threshold No power save*

*Sm_threshold < N < dsm_threshold Sleep Mode*

*N > dsm_threshold Deep sleep mode*

Wakeup control register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x60 | 0x0C0 | WAKEUP_CONTROL | RW | Wakeup instant register. Program the 16-bit reference clock value for auto-wakeup from deep sleep mode. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Wakeup_instant[15:0] | 15:0 | Instant, with reference to the internal 16-bit clock reference, at which the hardware must wakeup from deep sleep mode. This is calculated by firmware based on the next closest instant where a controller operation is required (like advertiser/ scanner). Firmware reads the next instant of the procedures in the corresponding *_NEXT_INSTANT registers. This value is used only when hardware auto wakeup from deep sleep mode is enabled in the clock control register. | 0 |

*Note: it is recommended to program wakeup_instant such a way that the actual instant to wakeup shall be at least two counts (two slots of 625 us) ahead of reference clock when entering DSM. The actual instant to wakeup is "wakeup_instant – dsm_offset_to_wakeup_instant – osc_startup_delay, and it shall be greater than "reference clock + 2"*

## Clock control register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

| Deep_sleep_mode_en | 15 | Enable deep sleep mode. 1 – enable, 0 – disable.<br>Enables hardware logic related to deep sleep mode to control the deep sleep mode operation. If disabled, the related logic is not executed and hardware cannot enter deep sleep mode. | 0 |
| Sleep_mode_en | 14 | Enable sleep mode. 1 – enable, 0 – disable.<br>Enables hardware to control sleep mode operation. | 0 |
| Dsm_intr_en | 13 | Enable DSM exit interrupt. 1 – enable, 0 – disable.<br>Enables hardware to generate an interrupt while exiting deep sleep mode. When enabled, interrupt is generated independent of whether exit procedure is initiated by hardware or firmware. | 0 |
| sm_intr_en | 12 | Enable SM exit interrupt. 1 – enable, 0 – disable.<br>Enables hardware to generate an interrupt while exiting sleep mode – irrespective of whether it is initiated by hardware or firmware. The interrupt is captured and stored till it gets cleared. | 0 |

*Table continues on the next page...*

| Field | Bit | Description | Reset |
|---|---|---|---|
| | | Disabling this bit mask the sleep mode exit event from hardware & firmware. | |
| Dsm_auto_sleep_en | 11 | Enable deep sleep mode auto entry in hardware.<br>1 – enable hardware to enter DSM automatically<br>0 – disable hardware to enter DSM automatically. | 0 |
| Sm_auto_wkup_en | 10 | Enable sleep mode auto wakeup enable. 1- enable, 0 – disable.<br>Enables hardware to automatically wakeup from sleep mode at the instant = *wakeup_instant – sm_offset_to_wakeup_instant.* The wakeup_insant is the field in the *wakeup control register* described earlier. The *sm_offset_to_wakeup_instant* value is the field described in the *wakeup configuration register.* | 0 |
| Lpo_sel_external | 9 | Select external sleep clock. 1 – External clock, 0 - internal generated clock.<br>The field is used to select either the low power clock input on sleep_clk input pin(of frequency 16.384KHz) directly to run the DSM logic or to use the internal generated reference clock(of 16KHz) for the same. | 0 |
| Lpo_clk_freq_sel | 8 | Clock frequency select. 0 – 32KHz, 1 – 32.768KHz.<br>Base frequency of the sleep_clk input used for generating the internal reference clock of approximate 16Khz frequency. | 0 |
| LLH_idle<br>(READ ONLY field) | 7 | Indicates if hardware is doing any transmit/receive operation or there is a pending interrupt from hardware. This information is used by firmware to decide to program the hardware into deep sleep mode.<br>1 – LL hardware is idle. | 1 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| | | 0 – LL hardware is busy. In this case LL hardware will not enter deep sleep mode, even if firmware gives an enter DSM command. (In this situation hardware generates dsm exit interrupt to inform firmware that DSM entry was not successful). | |
| Phy_clk_gate_en | 6 | Digital PHY clock enable. 1- enable, 0-disable.<br>Enable the Digital PHY to shutdown the clock. When 1, it indicates that controller has an upcoming activity so PHY clock must be turned ON. When 0, it indicates inactivity in the controller. This bit is not used as of now. | 0 |
| Sysclk_gate_en | 5 | Sysclk gate enable. 1- enable, 0 – disable.<br>Enables clock gating of system clock input to the link layer. If 1, it enables the DSM logic to control the clock gate for system clock input from pin. If 0, the DSM logic has no control and the system clock is always ON. | 0 |
| Coreclk_gate_en | 4 | Core clock gate enable. 1 – enable, 0 – disable.<br>Enables gating of clock to the llh_core module in hardware. If 1, the sleep mode/deep sleep mode logic can control the clock gate to shutdown/ wakeup the clock to the module. If 0, the logic has no control and clock is always turned ON. | 0 |
| Conn_clk_gate_en | 3 | Connection block clock gate enable. 1 – enable, 0 – disable.<br>Enables gating of clock to the connection module (llh_connch_top) in hardware. If 1, the sleep mode logic can control the clock gate to shutdown/wakeup the clock to | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | the engine. If 0, the logic has no control and clock to the module is always turned ON. | |
| Init_clk_gate_en | 2 | Initiator block clock gate enable. 1 – enable, 0 – disable.<br>Enables gating of clock to the initiator module (llh_init). If 1, the sleep mode logic can control the clock gate to shutdown/wakeup the clock to the module. If 0, the logic has no control and clock to the module is always turned ON. | 0 |
| Scan_clk_gate_en | 1 | Scan block clock gate enable. 1 – enable, 0 – disable.<br>Enables gating of clock to the scanner module (llh_scan) in hardware. If 1, the sleep mode logic can control the clock gate to shutdown/ wakeup the clock to the module. If 0, the logic has no control and clock to the module is always turned ON. | 0 |
| Adv_clk_gate_en | 0 | Advertiser block clock gate enable. 1 – enable, 0 – disable.<br>Enables gating of clock to the advertiser module (llh_adv) in hardware. If 1, the sleep mode logic can control the clock gate to shutdown/ wakeup the clock to the module. If 0, the logic has no control and clock to the module is always turned ON. | 0 |

## Reference Clock register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x64 | 0x0C8 | TIM_COUNTER_L | RO | 16-bit reference clock used for timing reference in the operation of the hardware. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Clock[15:0] | 15:0 | 16-bit internal reference clock. The clock is a free running clock, incremented by a | 0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| | | 0.625ms periodic pulse. It is used as a reference clock to derive all the timing required as per protocol. | |

## BLE Time Control

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0X6C | 0XD8 | TIME_CONTROL | WO | LLH clock frequency configuration. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| RFU | 15:8 | Not used | 0x0 |
| bb_clk_freq_minus_1 | 7:3 | The frequency information (FREQ – 1) of the clock input to LL Hardware is configured in this register by the firmware during initialization. This information is used inside LL Hardware to derive timing information for the Bluetooth operations.<br>For example, if the frequency of the input clock is 12 MHz this field shall be programmed to 0xB. (1 less than frequency) | 0x0 |
| RFU | 2:0 | Not used | 0x0 |

## DSM configuration register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0X51A | 0XA34 | DSM_CONFIG | RW | DSM configuration register. | 0x0008 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Not used | 15 | Not used | 0x0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| enable_conn_clk_ctrl[7:0] | [14:7] | Each bit corresponds to one connection engine (bit 7 for conn engine 0). Each of the bits if set to 1 will enable LLH to turn on corresponding CONNECTION engine clock on EXIT_SM command from firmware. To use this feature CON-NECTION NAP modes shall be enabled in LLH. | 0x0 |
| enable_init_clk_ctrl | 6 | If this bit is set to ‘1’ then LLH will turn on INIT engine clock on EXIT_SM command from firmware. To use this feature INIT NAP modes shall be enabled in LLH. | 0x0 |
| enable_scan_clk_ctrl | 5 | If this bit is set to ‘1’ then LLH will turn on SCAN engine clock on EXIT_SM command from firmware. To use this feature SACN NAP mode shall be enabled in LLH. | 0x0 |
| enable_adv_clk_ctrl | 4 | If this bit is set to ‘1’ then LLH will turn on ADV engine clock on EXIT_SM command from firmware. To use this feature ADV NAP mode shall be enabled in LLH. | 0x0 |
| enable_eng_clk_ctrl | 3 | Configuration bit for turning off all engine specific clocks after wakeup from SHUTDOWN (after register restore is complete). If this bit is set to ‘1’ then LLH will turn off all engine specific clocks after restore_done. To use this feature all NAP modes shall be enabled in LLH. | 0x1 |
| restore_done_bypass | 2 | Configuration bit for bypassing wait for restore_done signal to exit from RESTORE state. If this bit is set to ‘1’ then power control FSM will move to next state without waiting for restore_done from RESTORE state and if this bit is set to ‘0’ then power state machine will wait in RESTORE state till restore_done comes. This bit can be effectively used to reduce wakeup time if restore gets completed in one LP clock cycle. | 0x0 |
| store_done_bypass | 1 | Configuration bit for bypassing wait for store_done | 0x0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | signal to enter in to SHUTDOWN. If this bit is set to '1' then power control FSM will move to next state without waiting for store_done from STORE state and if this bit is set to '0' then power state machine will wait in STORE state till store_done comes. This bit can be effectively used to reduce SHUTDOWN entry time if store gets completed in one LP clock cycle. | |
| dsm_config | 0 | Configuration bit for DSM SHUTDOWN LLH store and restore control. If this bit is set to '1' then LLH will do the store and restore of its registers on its own during entry and after exit from shutdown. To use this feature DSM SHUTDOWN mode is to be supported and also LLH shall have access to RETENTION RAM. | 0x0 |

Note To enable dynamic power saving though selective clock gating of different engines LL firmware will set the configuration bits corresponding to BT procedures which are active. This will ensure that clocks to only active blocks are enabled during EXIT_SM command from LL firmware to LL hardware. User can over-ride this mode by setting the bits.

Nearest Instant register

| **Addr 16-bit** | **Addr 32-bit** | **Register Name** | **RW** | **Description** | **Reset** |
|---|---|---|---|---|---|
| 0X520 | 0XA40 | NEAREST_INST | RO | This register reports the next immediate instant in terms of bt_clock value (actual value being reported is INSTANT – 3) where hardware has any scheduled BT activity. Firmware reads this register along with the TIM_COUNTER_L register to calculate the possibility of power save mode entry. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| global_nearest_instant | 15:0 | This field holds the immediate future value of BT_CLOCK where a scheduled Bluetooth activity is supposed to happen.<br>When no Bluetooth activity is running the register will hold current BT_CLOCK value – 3. | 0x0000 |

## Auto DSM Configuration register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0X274 | 0X4E8 | AUTO_DSM_CONFIG | RW | Auto DSM configuration register. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Not Used | 15:6 | Not Used | 0x0 |
| Auto_entry_fsm_store_val | 5:4 | Store/Restore of Auto entry FSM states. | 0x0 |
| Dms3_mode_en | 3 | Enable DSM3 mode for Auto DSM entry feature. 1 – enable, 0 – disable. | 0x0 |
| Dsm2_mode_en | 2 | Enable DSM2 mode for Auto DSM entry feature. 1 – enable, 0 – disable. | 0x0 |
| Fw_wakeup_en | 1 | Enable wakeup at every FW_WAKEUP_INSTANT by firmware when HW is in sleep mode. 1 – enable, 0 – disable. | 0x0 |
| Dsm_auto_sleep_en | 0 | Reserved | 0x0 |

## Firmware wakeup Instant register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0X276 | 0X4EC | FW_WAKEUP_INSTANT | RW | Wakeup instant register. Program the 16-bit reference clock value for auto-wakeup from deep sleep mode. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Fw_wakeup_instant | 15:0 | This field holds the clock instant value when LLH need to exit auto dsm mode. | 0x0000 |

### 64.5.1.1.2 Advertising Channel Registers

Advertising Channel Register Descriptions for the Bluetooth Link Layer

##*Advertising parameters register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x0C | 0x018 | ADV_PARAMS | RW | Advertising parameters register. Firmware sets the necessary parameters for the advertising procedure into this register before issuing start advertise command. The fields in this register correspond to the fields in the LE_Set_Advertising_Parameters HCI command. | 0x00E0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| ##peer_rx_txaddr<br>(Read Only) | 15 | Transmit address field of the received packet indicating the peer address type as public/ random. This field is used by firmware to report peer_addr_type parameter in the connection complete event.<br>0 – addr type is public.<br>1 – addr type is random. | 0 |
| ##peer_addr_resolved_reg<br>(Read Only) | 14 | Address resolution status of the received packet if the received address was RPA.<br>0 – RPA resolution fail<br>1 – RPA resolution pass.<br>Else this bit is set to zero. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| #slv_index | 13:11 | Slave index is programmed by FW before initiation procedure for selecting connection engine in slave role connection.<br>Number of supported engines is 8. (Index from 0x0 to 0x7) | 0 |
| *adv_low_duty_cycle | 10 | This bit field is used to specify to the Controller the Low Duty Cycle connectable directed advertising variant being used.<br>1 – Low Duty Cycle Connectable Directed Advertising.<br>0 – High Duty Cycle Connectable Directed Advertising. | 0 |
| Force_scan_rsp<br>(Write Only) | 9 | Force scan response packet always. *Used only if TESTER build is enabled.*<br>• Override ADV packet type and send scan response packet type in the header field in all ADV packets<br>0 – no effect. | 0 |
| Rx_addr | 8 | Peer addresses type. This is the Direct_Address_type field programmed, only if ADV_DIRECT_IND type is sent.<br>• Rxaddr type is random.<br>0 - Rxaddr type is public. | 0 |
| Adv_channel_map | 7:5 | Advertising channel map indicates the advertising channels used for advertising. By setting the bit, corresponding channel is enabled for use. At least one channel bit should be set.<br>Bit 7- enable channel 39.<br>Bit 6 - enable channel 38.<br>Bit 5 - enable channel 37. | 7 |

| Field | Bit | Description | Reset |
|---|---|---|---|

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Adv_filt_policy | 4:3 | Advertising filter policy. The set of devices that the advertising procedure uses for device filtering is called the White List .<br>0x00 - Allow scan request from any device, allow connect request from any device.<br>0x01- Allow scan request from devices in white list only, allow connect request from any device.<br>0x10--Allow scan request from any device, allow connect request from devices in white list only.<br>0x11--Allow scan request from devices in white list only, allow connect request from devices in white list only. | 0 |
| Adv_type | 2:1 | The Advertising type is used to determine the packet type that is used for advertising when advertising is enabled.<br>00b- Connectable undirected advertising. (adv_ind)<br>01b- Connectable directed advertising (adv_direct_ind).<br>10b- Discoverable undirected advertising (adv_discover_ind)<br>11b- Non connectable undirected advertising (adv_nonconn_ind). | 0 |
| Reserved | 0 | Reserved for future use. | 0 |

## Advertising Interval register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x0E | 0x01C | ADV_INTERVAL_TIMEOUT | RW | Advertising interval register. It is the i nterval between two consecutive advertising events. For directed advertising, this register holds the timeout value.<br>Has a resolution of 0.625ms.<br>Time = N * 0.625 msec | 0x0020 |

| | | | | | |
|---|---|---|---|---|---|
| | | | | Time Range: 20 ms to 10.24 sec.<br>Firmware updates this value before issuing start advertise command. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Adv_interval | 15:0 | Range:<br>0x0020 to 0x4000 (For ADV_IND)<br>0x00A0 to 0x4000 (For ADV_SCAN_IND and NONCONN_IND)<br>For directed advertising, firmware programs the default value of 1.28seconds. | 0x0010 |

## Advertising interrupt clear register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x10 | 0x020 | ADV_INTR_CLEAR | WO | Clears the source of the interrupt. This register is written by firmware to clear interrupts set in the ADV_STATUS register. One or more interrupts can be cleared in a single write operation, by setting the bit field to 1 for corresponding interrupt. It is not required to write a follow-up write with bit 0, as the previous bit 1 is not actually stored. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:8 | Not used. | XX |
| adv_timeout | 7 | Clear adv_timeout interrupt. Applicable in ADV_DIRECT_IND advertising. Write to the register with this bit set to 1, clears the interrupt source. | 0 |
| slv_connected | 6 | Clear slave connected interrupt. Write to the register | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | with this bit set to 1, clears the interrupt source. | |
| conn_req_rx_intr | 5 | Clear connect request packet received interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| scan_req_rx_intr | 4 | Clear scan request packet received interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| scn_rsp_tx_intr | 3 | Clear scan response packet transmitted interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| adv_tx_intr | 2 | Clear adv packet transmitted interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| adv_close_intr | 1 | Clear advertising event stop interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| adv_strt_intr | 0 | Clear advertising event start interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |

## Advertising status register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x10 | 0x020 | ADV_STATUS | RO | Advertising status register shows the status of the interrupts .Each of the status bits is set by the advertising procedure in hardware. The bits are set till they are cleared by firmware by writing to appropriate interrupt clear registers. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:9 | Not used. | XX |
| Adv_on | 8 | Advertiser procedure is ON in hardware. Indicates that advertiser procedure is ON in hardware.<br>1 – on | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | 0 – off | |
| adv_timeout | 7 | If this bit is set it indicates that the directed advertising event has timed out after 1.28 seconds. Applicable in adv_direct_ind advertising only. | 0 |
| slv_connected | 6 | If this bit is set it indicates that connection is created as slave. | 0 |
| conn_req_rx_intr | 5 | If this bit is set it indicates connect request packet is received. | 0 |
| scan_req_rx_intr | 4 | If this bit is set it indicates scan request packet received. | 0 |
| scn_rsp_tx_intr | 3 | If this bit is set it indicates scan response packet transmitted in response to previous scan request packet received. | 0 |
| adv_tx_intr | 2 | If this bit is set it indicates ADV packet is transmitted. | 0 |
| adv_close_intr | 1 | If this bit is set it indicates current advertising event is closed. | 0 |
| adv_strt_intr | 0 | If this bit is set it indicates a new advertising event started after interval expiry. | 0 |

## Advertising next instant register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x12 | 0x024 | ADV_NEXT_INSTANT | RO | Shows the instant at which the next advertising event begins. This is with reference to internal reference clock of resolution 625 us.. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| next_adv_instant | 15:0 | Shows the next start of advertising event with reference to the internal reference clock. | 0 |

## Scan Interval register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x14 | 0x028 | SCAN_INTERVAL | RW | Scan interval register. Interval between two consecutive scanning events. Firmware sets the scanning interval value to this register before issuing start scan command. | 0x0010 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| scan_interval | 15:0 | Interval between two consecutive scanning events.<br>Range: 0x0004 to 0x4000<br>Default: 0x0010 (10 ms)<br>Time = N * 0.625 msec<br>Time Range: 2.5 msec to 10.24 sec . | 0X0010 |

## Scan Window register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x16 | 0x02C | SCAN_WINDOW | RW | Scan window register. Duration of scan in a scanning event, which should be less than or equal to scan interval value . Firmware sets the scan window value to this register before issuing start scan command. | 0x0010 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| scan_window | 15:0 | Duration of scan in a scanning event, which should be less than or equal to scan interval value.<br>Range: 0x0004 to 0x4000<br>Default: 0x0010 (10 ms)<br>Time = N * 0.625 msec<br>Time Range: 2.5 msec to 10.24 sec . | 0X0010 |

## ##Scan parameters register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x18 | 0x030 | SCAN_PARAM | RW | Scanning parameters register. Firmware sets the necessary parameters for scanning procedure into this register before issuing start scan command. The fields are derived from the LE_Set_Scan_Parameters HCI command. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:7 | Not used. | XX |
| scan_tx_addr[1] | 6 | MSB of the device's Own address. This bit along with scan_tx_addr[0] decides the own address used for scanner. | 0 |
| Dup_filt_en | 5 | Filter duplicate packets.<br>1 -Duplicate packet filtering enabled.<br>0- Duplicate packet filtering not enabled.<br>This field is derived from the *LE_set_scan_enable* command. | 0 |
| scan_filt_policy | 4:3 | The scanner filter policy determines how the scanner processes advertising packets .<br>0x00 – Accept advertising packets from any device. A connectable Directed advertising packet not containing the scanner's device address is ignored.<br>0x01 - Accept advertising packets from only devices in the whitelist . A connectable Directed advertising packet not containing the scanner's device address is ignored.<br>0x10 - Accept advertising packets from any device. A connectable Directed advertising packet is not ignored if the InitA is a resolvable private address. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | 0x11 - Accept advertising packets from only devices in the whitelist. A connectable Directed advertising packet is not ignored if the InitA is a resolvable private address.<br>Adv_direct_ind packets which are not addressed to this device are ignored. | |
| scan_type | 2:1 | 0x00- passive scanning. (default)<br>0x01- active scanning.<br>0x10- RFU<br>0x11- RFU | 0 |
| scan_tx_addr[0] | 0 | Device's own address type.<br>1 - addr type is random.<br>0 - addr type is public.<br>Note :<br>Scan_tx_addr[1:0]<br>0x0 – use public address<br>0x1 – use random address<br>0x2 – use RPA if matching entry is available in Resolving list else use public address.<br>0x3 - use RPA if matching entry is available in Resolving list else use random address. | 0 |

## Scan interrupt clear register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1C | 0x038 | SCAN_INTR_CLEAR | WO | Clears the source of the interrupt. This register is written by firmware to clear interrupts set in the SCAN_STATUS register. One or more interrupts can be cleared in a single write operation. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:5 | Not used. | XX |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| scan_rsp_rx_intr | 4 | Clear scan_rsp packet received interrupt. Write to the register with this bit set to 1, clears the interrupt source. | 0 |
| adv_rx_intr | 3 | Clear adv packet received interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| scan_tx_intr | 2 | Clear scan request packet transmitted interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| scan_close_intr | 1 | Clear scan event close interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| scan_strt_intr | 0 | Clear scan event start interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |

## Scan status register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1C | 0x038 | SCAN_STATUS | RO | Shows the status of the interrupt. This register is read by firmware to learn the pending scan interrupts that are set and are to be served. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:9 and 7:6 | Not used. | XX |
| Scan_on | 8 | Scan procedure is active. 1 – scan procedure is active. 0 – scan procedure is not active. | |
| scan_rsp_adv_rx_intr | 5 | If this bit is set after both SCAN_RSP and ADV packets are received. This interrupt may be enabled, if firmware desires to be interrupted after complete reception, instead of interrupt for each packet – which are enabled by bits 4 and 3. | 0 |
| scan_rsp_rx_intr | 4 | If this bit is set it indicates SCAN_RSP packet is received. Firmware can read the content of the packet from | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | the INIT_SCN_ADV_RX_FIFO. | |
| adv_rx_intr | 3 | If this bit is set it indicates ADV packet received. Firmware can read the content of the packet from the INIT_SCN_ADV_RX_FIFO. | 0 |
| scan_tx_intr | 2 | If this bit is set it indicates scan request packet is transmitted. | 0 |
| scan_close_intr | 1 | If this bit is set it indicates scan window is closed. | 0 |
| scan_strt_intr | 0 | If this bit is set it indicates scan window is opened. | 0 |

*Note:*

*scan_rsp_adv_rx_intr—This interrupt is generated while active scanning ,after receiving both the adv and scan response packets, in case of receiving adv_ind and adv_discover_ind. Currently not in use.*

*scan_rsp_rx_intr-- This interrupt is generated while active scanning upon receiving scan response packet.*

*adv_rx_intr-- This interrupt is generated while active/passive scanning upon receiving adv packets.*

## Scan next instant register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1E | 0x03C | SCAN_NEXT_INSTANT | RO | Shows the instant w.r.t internal reference clock of resolution 625us at which next scanning event begins. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| next_scan_instant | 15:0 | Shows the instant w.r.t internal reference clock at which next scanning window begins. | 0 |

## Initiator Interval register

| Addr | Addr | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| 16-bit | 32-bit | | | | |
|---|---|---|---|---|---|
| 0x20 | 0x040 | INIT_INTERVAL | RW | Initiator interval register. Firmware sets the initiator's scanning interval value to this register before issuing create connection command. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Init_scan_interval | 15:0 | Interval between two consecutive scanning events.<br>Range: 0x0004 to 0x4000<br>Time = N * 0.625 msec<br>Time Range: 2.5 msec to 10.24 sec . | 0X0000 |

## Initiator window register

|---|---|---|---|---|---|
| 0x22 | 0x044 | INIT_WINDOW | RW | Initiator window register. Firmware sets the scan window value to this register before issuing the create connection command. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Init_scan_window | 15:0 | Duration of scan in a scanning event, which should be less than or equal to scan interval value.<br>Range: 0x0004 to 0x4000<br>Default: 0x0010 (10 ms)<br>Time = N * 0.625 msec<br>Time Range: 2.5 msec to 10.24 sec . | 0X0000 |

## ##Initiator parameter register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0x24 | 0x048 | INIT_PARAM | RW | Initiator parameters register. Firmware sets the necessary parameters for initiation procedure to this register before issuing the create connection command. The fields in this register are derived from the parameters in the LE_Create_Connection HCI command. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:10 | Not used. | XX |
| peer_rpa_resolved_capt<br>(Read only) | 9 | If received peer address is an RPA, this bit represents the RPA resolution status. ie.,<br>1 – RPA resolution pass.<br>0 – RPA resolution fail.<br>Else this bit is set to zero. | 0 |
| init_tx_addr[1] | 8 | MSB of the device's Own address type. This bit along with init_tx_addr[0] decides the own address of the device. | 0 |
| #Init_conn_index | 7:5 | Firmware programs the index of the conn engine for the master connection at init start. Index can be in the range 0x0 to 0x7 depending on the number of connections supported. | 0x0 |
| Reserved | 4 | Not used | x |
| init_filt_policy | 3 | The Initiator_Filter_Policy is used to determine whether the White List is used or not used.<br>0 -White list is not used to determine which advertiser to connect to. Instead the Peer_Address_Type and Peer Address fields are used to specify the address type and address of the advertising device to connect to.<br>1 - White list is used to determine the advertising device to connect to. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | Peer_Address_Type and Peer_Address fields are ignored when whitelist is used. | |
| init_rx_addr[1] | 2 | MSB of the device's peer address type (FW programmed). This bit along with init_rx_addr[0] decides the peer address of the device. | 0 |
| rx_addr/rx_tx_addr<br>init_rx_addr[0 ] | 1 | Peer address type.<br>The rx_addr field is updated by the receiver with the address type of the received connectable advertising packet.<br>1- addr type is random.<br>0-addr type is public.<br>LSB of the device's peer address type (FW programmed).<br>Init_rx_addr[1:0] –<br>0x0 - public address<br>0x1 - random address<br>0x2 - public identity address<br>0x3 - random(static) identity address | 0 |

| | | | |
|---|---|---|---|
| Tx_addr<br>init_tx_addr[0] | 0 | Own address type.<br>1- addr type is random.<br>0-addr type is public.<br>LSB of the device's Own address type.<br>Init_tx_addr[1:0] -<br>0x0 – use public address (addr type is zero)<br>0x1 – use public address (addr type is one)<br>0x2 – use RPA if matching entry is available in Resolving list else use public address.<br>0x3 - use RPA if matching entry is available in Resolving list else use random address. | 0 |

## Initiator interrupt clear register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x28 | 0x050 | INIT_INTR_CLEAR | WO | Clears the source of the interrupt. This register is written by firmware to clear interrupts set in the INIT_STATUS register. One or more interrupts can be cleared in a single write operation. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:5 | Not used. | XX |
| master_conn_created | 4 | Clear master connection created interrupt. Write to the register with this bit set to 1, clears the interrupt source. | 0 |
| Reserved | 3 | Not used. | X |
| Init_tx_start | 2 | Clear init transmission start interrupt. Write to the register with this bit set to 1, clears the interrupt source. | 0 |
| init_close_window | 1 | Clear Initiator scan window close interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |
| init_interval_expire | 0 | Clear Initiator scan window start interrupt. Write to the register with this bit set to 1, clears the interrupt source | 0 |

## Initiator status register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x28 | 0x050 | INIT_STATUS | RO | Shows the status of the interrupt. This register is read by firmware to learn the pending initiator interrupts that are set and are to be served. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:5 | Not used. | XX |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| master_conn_created | 4 | If this bit is set it indicates connection is created as master. | 0 |
| Reserved | 3 | Not used. | X |
| Init_tx_start | 2 | If this bit is set it indicates initiator packet (CONREQ) transmission has started. | 0 |
| init_close_window | 1 | If this bit is set it indicates initiator scan window has finished. | 0 |
| init_interval_expire | 0 | If this bit is set it indicates initiator scan window has started. | 0 |

## #Initiator next instant register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x2A | 0x054 | INIT_NEXT_INSTANT | RO | Shows the instant w.r.t internal reference clock of 625us resolution at which next initiator scanning event begins. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| next_init_instant | 15:0 | Shows the instant w.r.t internal reference clock at which next initiator scanning event begins. | 0 |

## #Initiator Anchor Point register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x100 | 0x200 | INIT_ANCHOR_POINT | RW | Firmware programs this register (while programming INIT parameters) with the instant (value of bt_clock) at which the initiator should start the procedure for the first time. This will give firmware a better control in effectively scheduling the new connections in the multiple connection scenarios. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Init_anchor_point | 15:0 | The value of bt_clock (625us period) at which initiator should start the procedure. | 0 |

## Device Random address lower register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x2C | 0x058 | DEV_RAND_ADDR_L | RW | Lower 16 bit random address of the device. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Rand_addr | 15:0 | Lower 16 bit of 48-bit random address of the device. | 0 |

## Device Random address middle register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x2E | 0x05C | DEV_RAND_ADDR_M | RW | Middle 16 bit random address of the device. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Rand_addr | 15:0 | Middle 16 bit of 48-bit random address of the device. | 0 |

## Device Random address higher register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x30 | 0x060 | DEV_RAND_ADDR_H | RW | Higher 16 bit random address of the device. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Rand_addr | 15:0 | Higher 16 bit of 48-bit random address of the device. | 0 |

## Peer address lower register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x34 | 0x068 | PEER_ADDR_L | RW | Lower 16 bit address of the peer device. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| peer_addr | 15:0 | Lower 16 bit of 48-bit address of the peer device. | 0 |

## Peer address middle register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x36 | 0x06C | PEER_ADDR_M | RW | Middle 16 bit address of the peer device. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| peer_addr | 15:0 | Middle 16 bit of 48-bit address of the peer device. | 0 |

## Peer address higher register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x38 | 0x070 | PEER_ADDR_H | RW | Higher 16 bit address of the peer device. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| peer_addr | 15:0 | Higher 16 bit of 48-bit of address of the peer device. | 0 |

## #Initiator Peer Address Lower Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0x66 | 0x0CC | INIT_PEER_ADDR_L | RW | Lower 16 bit of init peer address. This register is used only if multiple connections are supported. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Init_peer_addr | 15:0 | Lower 16 bit of the 48 bit init peer address. | 0 |

## #Initiator Peer Address Middle Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x68 | 0x0D0 | INIT_PEER_ADDR_M | RW | Middle 16 bit of init peer address. This register is used only if multiple connections are supported. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Init_peer_addr | 15:0 | Middle 16 bit of the 48 bit init peer address. | 0 |

## #Initiator Peer Address Upper Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x6A | 0x0D4 | INIT_PEER_ADDR_H | RW | Lower 16 bit of init peer address. This register is used only if multiple connections are supported. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Init_peer_addr | 15:0 | Upper 16 bit of the 48 bit init peer address. | 0 |

The peer address registers are used for multiple purposes. The register is written by firmware to provide the peer address to be used for a hardware procedure. When firmware reads the register, it reads back peer address values updated by hardware.

While doing directed Advertising, the firmware writes the peer address of the device specified by the Direct_Address parameter of the LE_Set_Advertising_Parameters command.

While device is configured as an initiator without white list filtering, the peer address specified in the peer_address field of the create connection command is programmed into this register, which is used by hardware procedures.

While device is configured as an initiator and white list is enabled, firmware can read this register to get the address of the peer device from which connectable ADV packet was received and to which the connection is created.

When a connection is created as a slave, the firmware can read this register to get the address of the peer device to which connection is created.

*INIT_PEER_ADDR is used only for multiple connection support where peer address for initiation is kept at INIT_PEER_ADDR register and ADV peer address is kept/read from PEER_ADDR register.*

White List address type register lower word

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xA2 | 0x144 | WL_ADDR_TYPE_L | RW | Stores the address type of the device addresses stored in whitelist | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| type | 15:0 | 16 address type bits corresponding to first 16 device address stored in whitelist.<br>1-Address type is random.<br>0-Address type is public. | 0 |

White List address type register upper word

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xA4 | 0x148 | WL_ADDR_TYPE_U | RW | Stores the address type of the device addresses stored in whitelist | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| | 15:10 | Reserved for future use | |
| type | 9:0 | 10 address type bits corresponding to 17 to 26 device address stored in whitelist.<br>1-Address type is random.<br>0-Address type is public. | 0 |

## White list enable register lower word

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xA6 | 0x14C | WL_ENABLE_L | RW | Stores the valid entry bit corresponding to each of the device address stored in the whitelist. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| en | 15:0 | Stores the valid entry bit corresponding to each of the first 16 device addresses stored in the whitelist memory in the hardware.<br>1-White list entry is valid.<br>0-White list entry invalid. | 0 |

## White list enable register upper word

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xA8 | 0x150 | WL_ENABLE_U | RW | Stores the valid entry bit corresponding to each of the device address stored in the whitelist. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| | 15:10 | Reserved for future use | |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| en | 9:0 | Stores the valid entry bit corresponding to each of the 17 to 26 device addresses stored in the whitelist memory in the hardware.<br>1-White list entry is valid.<br>0-White list entry invalid. | 0 |

## Advertising data transmit FIFO

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x70 | 0x0E0 | ADV_TX_DATA_FIFO | WO | IO mapped FIFO of depth 16 (2 byte wide), to store ADV data of maximum length 31 bytes for transmitting. Firmware writes consecutive words by writing to the same address location. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| data | 15:0 | Advertising data for transmission. | 0 |

## Adv scan response data transmit FIFO

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x74 | 0x0E8 | ADV_SCN_RSP_TX_FIFO | WO | IO mapped FIFO of depth 16 (2 byte wide), to store scan response data of maximum length 31 bytes for transmitting. Firmware writes consecutive words by writing to the same location. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| data | 15:0 | scan response data for transmission. | 0 |

Note: ADV_TX_DATA_FIFO and ADV_SCN_RSP_TX_FIFO shares same physical FIFO of depth 32. 16 locations for each FIFO are allocated.

| | | |
|---|---|---|
| ADV_TX_DATA_FIFO<br>address 16'h70 | Data byte 1 | Length of adv host data |
| | Data byte 3 | Data byte 2 |
| | Data byte 31 | Data byte 30 |
| ADV_SCN_RSP_TX_FIFO<br>address 16'h74 | Data byte 1 | Length of scan response host data |
| | Data byte 3 | Data byte 2 |
| | Data byte 31 | Data byte 30 |

The length of the payload combined with first payload data and loaded to the advertise channel data transmit FIFO followed by rest of the host data.

Example: Structure of advertising channel transmit FIFO.

bit15 bit8 bit7 bit0

| | |
|---|---|
| Data byte 1 | Length of the payload stored in FIFO |
| Data byte 3 | Data byte 2 |
| Data byte 5 | Data byte 4 |
| Data byte 7 | Data byte 6 |

## Conn request data Transmit FIFO

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x78 | 0x0F0 | CONN_REQ_TX_FIFO | WO | IO mapped FIFO of depth 48, to store connection request data of maximum length 34 bytes for transmitting. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data | 15:0 | Connection request data during transmit operation. | 0 |

## Adv scan response data receive FIFO

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x7C | 0x0F8 | INIT_SCN_ADV_RX_FIFO | RO | IO mapped FIFO of depth 64, to store ADV and SCAN_RSP header and payload received | 0x0000 |

| | | | | | |
|---|---|---|---|---|---|
| | | | | by the scanner. The RSSI value at the time of reception of this packet is also stored. Firmware reads from the same address to read out consecutive words of data. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data | 15:0 | adv, scan response data during receive operation. | 0 |

Note: The 16 bit header is first loaded to the advertise channel data receive FIFO followed by the payload data and then 16 bit RSSI.

Example: Structure of advertising channel receive FIFO with payload with even number of bytes.

bit15 bit8 bit7 bit0

| | |
|---|---|
| Header 2 | Header 1 |
| Data byte 2 | Data byte 1 |
| Data byte 4 | Data byte 3 |
| Data byte 6 | Data byte 5 |
| RSSI | RSSI |

Example: Structure of advertising channel receive FIFO with payload with odd number of bytes.

bit15 bit8 bit7 bit0

| | |
|---|---|
| Header 2 | Header 1 |
| Data byte 2 | Data byte 1 |
| Data byte 4 | Data byte 3 |
| | Data byte 5 |
| RSSI | RSSI |

Device public address lower register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0XE0 | 0X1C0 | DEV_PUB_ADDR_L | RW | Lower 16 bit public address of the device. | 0x3412 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| public_addr | 15:0 | Lower 16 bit of 48-bit public address of the device. | 0x3412 |

## Device public address middle register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0XE2 | 0X1C4 | DEV_PUB_ADDR_M | RW | Middle 16 bit public address of the device. | 0x0056 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| public_addr | 15:0 | Middle 16 bit of 48-bit public address of the device. | 0x0056 |

## Device public address higher register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0XE4 | 0X1C8 | DEV_PUB_ADDR_H | RW | Higher 16 bit public address of the device. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| public_addr | 15:0 | Higher 16 bit of 48-bit public address of the peer device. | 0 |

## Advertising channel transmit power register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0XE6 | 0X1CC | ADV_CH_TX_POWER | RW | The advertising channel transmit power register sets the transmit power level used | 0x874F |

| | | | | | |
|---|---|---|---|---|---|
| | | | | for LE advertising channel packets and for DTM mode transmissions.<br><br>The same register is used for setting Transmit power level of all non-connection channels. This includes: Advertising, scanning, Initiating, and Direct test mode (DTM Transmitter tests). | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| adv_transmit_power | 15:0 | Size: 1 Octet (signed integer)<br><br>Range: -20 ≤ N ≤ 10<br><br>Units: dBm<br><br>Accuracy: +/- 4 dBm in general.<br><br>In implementation this is a radio specific value. | 0x874F |

## Offset to first instant register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0XE8 | 0X1D0 | OFFSET_TO_FIRST_INSTANT | RW | Offset to the first instant register. The first event instant is determined by firmware based on other procedures which may be on with various intervals, so as to not overlap on the existing procedure instants. For this, firmware determines the offset to the first instant from the current clock and programs the offset in OFFSET_TO_FIRST_INSTANT register.<br><br>Unit is in time slots of 625us<br><br>ex: if current clock value is 0004,and offset is 0008,then first event will begin when clock value becomes 000c. | 0x0006 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| offset_to_first_event | 15:0 | The offset w.r.t the internal reference clock at which instant the first event occurs.<br><br>This register will give flexibility to the firmware to position the connection at a desired point with respect to the internal free running clock. It is optional to be updated by firmware. This is not updated in the current firmware. This is for future use. | 0x0006 |

## Advertiser configuration register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xEA | 0x1D4 | ADV_CONFIG | RW | Advertiser procedure configuration register. Firmware sets the configuration parameters to this register before issuing start adv command. | 0x20FF |

| Field | Bit | Description | Reset |
|---|---|---|---|
| adv_pkt_interval | 15:11 | Time between the beginnings of two consecutive advertising PDU's.<br>Time = N * 0.625 msec<br>Time Range: <=10msec. | 00100b |
| Reserved | 10:9 | Not used. | 0 |
| Adv_rand_disable | 8 | Disable randomization of adv interval. When disabled, interval is same as programmed in adv_interval register. | 0 |
| adv_timeout_en | 7 | Enable adv_timeout interrupt. Applicable in adv_direct_ind advertising. | 1 |
| slv_connected_en | 6 | Enable slave connected interrupt. | 1 |
| adv_conn_req_rx_en | 5 | Enable connect request packet received interrupt. | 1 |
| adv_scn_req_rx_en | 4 | Enable scan request packet received interrupt. | 1 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| scn_tx_en | 3 | Enable scan response packet transmitted interrupt. | 1 |
| adv_tx_en | 2 | Enable adv packet transmitted interrupt. | 1 |
| adv_cls_en | 1 | Enable advertising event stop interrupt. | 1 |
| adv_strt_en | 0 | Enable advertising event start interrupt. | 1 |

## Scan configuration register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xEC | 0x1D8 | SCAN_CONFIG | RW | Scanner procedure configuration register. Firmware sets the configuration parameters to this register before issuing start scan command | 0xE07F |

| Field | Bit | Description | Reset |
|---|---|---|---|
| scan_channel_map | 15:13 | Advertising channels that are enabled for scanning operation.<br>15- Enables channel 39 for use.<br>14- Enables channel 38 for use.<br>13- Enables channel 37 for use. | 111 |
| Reserved | 12 | Not used. | X |
| backoff_enable | 11 | Enable random backoff feature in scanner.<br>1-enable.<br>0-disable. | 0 |
| Reserved | 10:5 | Not used. | XX |
| scn_rsp_rx_en | 4 | Enable scan_rsp packet received interrupt. | 1 |
| adv_rx_en | 3 | Enable adv packet received interrupt. | 1 |
| scn_tx_en | 2 | Enable scan request packet transmitted interrupt. | 1 |
| scn_close_en | 1 | Enable scan event close interrupt. | 1 |
| scn_strt_en | 0 | Enable scan event start interrupt. | 1 |

## #Initiator configuration register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xEE | 0x1DC | INIT_CONFIG | RW | Initiator procedure configuration register. Firmware sets the configuration parameters to this register before issuing create connection command | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| init_channel_map | 15:13 | Advertising channels that are enabled for initiator scanning operation.<br>15- Enables channel 39 for use.<br>14- Enables channel 38 for use.<br>13- Enables channel 37 for use. | 0 |
| Reserved | 12:8 | Not used. | XX |
| conn_created | 4 | Enable master connection created interrupt | 0 |
| Reserved | 3 | Reserved | |
| conn_req_tx_en | 2 | Enables connection request packet transmission start interrupt. | 0 |
| init_close_en | 1 | Enable Initiator scan window close interrupt. | 0 |
| init_strt_en | 0 | Enable Initiator scan window start interrupt. | 0 |

## Whitelist base address register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0X462 | 0x8C4 | WHITELIST_BASE_ADDR | RW | It is the starting address of white list memory which holds the white listed device address.<br>For a 48 bit device address, three writes of 16 bits is required at the appropriate offset from this base address. | 0x0000 |

| | | | | | |
|---|---|---|---|---|---|
| | | | | The whitelist device addresses are stored as group of 3-words at offset of N*3, where N=0 to 7, from this base address.<br>While writing the device address, the firmware writes the address in the following order for storage.<br>1st write - [15:0],<br>2nd write - [31:16],<br>3rd write - [47:32] bits of the device address. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Device_addr | 15:0 | Device address values written to white list memory are written as 16-bit wide address. | 0 |

## Whitelist end address register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0X4FE | 0x9FC | WHITELIST_END_ADDR | RW | It is the last address of white list memory which holds the white list device address. It holds last [47:32] bits of 26th white list device address. It is not accessed by firmware, only used for hardware reference. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Device_addr | 15:0 | Device address values written to white list memory are written as 16-bit wide address. | 0 |

## Advertiser Tx memory base address register – Reserved for future use

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0X160 | 0X2C0 | ADV_TX_MEM_BASE_ADDR | RW | It is the starting address of ADV Tx memory which holds the data to be transmitted during Advertising operation. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data | 15:0 | Data values written to Tx memory are written as 16-bit wide data. | 0 |

## Connection Tx memory base address register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0X700 | 0XE00 | CONN_TXMEM_BASE_ADDR | WO | It is the starting address of Connection Transmit data memory which holds the data to be transmitted during connection.<br>The connection Transmit memory is individually addressable location for firmware. So firmware writes to consecutive even address values to write the next word (2-byte) of data. Hardware accesses this memory as a FIFO. The hardware buffer index is managed in hardware. No buffer index needs to be maintained for firmware access. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data | 15:0 | Data values written to Tx memory are written as 16-bit wide data. | 0 |

## Connection Rx memory base address register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0X400 | 0X800 | CONN_RXMEM_BASE_ADDR | RO | It is the starting address of Connection Receive data memory/FIFO which holds the data to be received during connection.<br>The connection receive memory/FIFO is used as a FIFO by both hardware and firmware. Firmware needs to read from the same address to read out the consecutive words in the FIFO. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data | 15:0 | Data values read from Rx memory are read as 16-bit wide data | 0 |

## Conn_req_word0 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1E0 | 0x3C0 | CONN_REQ_WORD0 | RW | The connect request word0 register must be programmed with the access address value of the connect request packet, before initiating connection. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Access_addr[15:0] | 15:0 | This field defines the lower 16 bits of the access address that is to be sent in the connect request packet of the initiator. | 0x0000 |

## Conn_req_word1 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1E2 | 0x3C4 | CONN_REQ_WORD1 | RW | The connect request word1 register must be programmed | 0x0000 |

| | | | | | |
|---|---|---|---|---|---|
| | | | | with the access address value of the connect request packet, before initiating connection. After slave connection this value can be obtained by reading this register on the advertiser side. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Access_Address[31:16] | 15:0 | This field defines the upper16 bits of the access address that is to be sent in the connect request packet of the initiator. | 0x0000 |

## Conn_req_word2 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1E4 | 0x3C8 | CONN_REQ_WORD2 | RW | This field defines the lower byte [7:0] of the CRC initialization value, and tx_window_size [7:0], to be sent in the connect request packet of the initiator. After slave connection these values can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| crc_init[7:0] | 15:8 | This field defines the lower byte [7:0] of the CRC initialization value. | 0 |
| Tx_window_size[7:0] | 7:0 | window_size along with the window_offset is used to calculate the first connection point anchor point for the master.<br>This shall be a multiple of 1.25 ms in the range of 1.25 ms to the lesser of 10 ms and (connInterval – 1.25 ms).<br>Values range from 0 to 10 ms. | 0 |

## Conn_req_word3 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1E6 | 0x3CC | CONN_REQ_WORD3 | RW | This field must be programmed with the upper byte [23:8] of the CRC initialization value.After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| crc_init[23:8] | 15:0 | This field defines the upper byte [23:8] of the CRC initialization value that is to be sent in the connect request packet of the initiator. | 0x0000 |

## Conn_req_word4 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1E8 | 0x3D0 | CONN_REQ_WORD4 | RW | This field defines the 16 bits of the transmit window offset that is to be sent in the connect request packet of the initiator. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Tx_window_offset | 15:0 | This is used to determine the anchor point for the master transmission.<br>Range: This shall be a multiple of 1.25 ms in the range of 0 ms to connInterval value. | 0 |

## Conn_req_word5 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0x1EA | 0x3D4 | CONN_REQ_WORD5 | RW | This field defines the 16 bits of the connection interval value that is to be sent in the connect request packet of the initiator. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Conn_interval_val | 15:0 | The value configured in this register determines the spacing between the connection events.<br>This shall be a multiple of 1.25 ms in the range of 7.5 ms to 4.0 s. | 0x0000 |

## Conn_req_word6 register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1EC | 0x3D8 | CONN_REQ_WORD6 | RW | This field defines the 16 bits of the slave latency value that is to be sent in the connect request packet of the initiator. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Slv_latency_val | 15:0 | The value configured in this field defines the number of consecutive connection events that the slave device is not required to listen for master. The value of connSlaveLatency should not cause a Supervision Timeout. This shall be an integer in the range of 0 to ((connSupervision Timeout/ connInterval)-1). connSlaveLatency shall also be less than 500. | 0x0000 |

## Conn_req_word7 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1EE | 0x3DC | CONN_REQ_WORD7 | RW | This field defines the 16 bits of the supervision timeout value that is to be sent in the connect request packet of the initiator. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Sup_to_val | 15:0 | This field defines the maximum time between two received Data packet PDUs before the connection is considered lost.<br>This shall be a multiple of 10 ms in the range of 100 ms to 32.0 s and it shall be larger than (1+connSlaveLatency)*connInterval. | 0x0000 |

## Conn_req_word8 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1F0 | 0x3E0 | CONN_REQ_WORD8 | RW | This field defines the channel map for channels [15:0], that is to be sent in the connect request packet of the initiator. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data_channels[15:0] | 15:0 | This register field indicates which of the data channels are in use. This stores the information for the lower 16 (15:0) data channel indices. | Data_channels |

| | | | |
|---|---|---|---|
| | | '1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | |

## Conn_req_word9 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1F2 | 0x3E4 | CONN_REQ_WORD9 | RW | This field defines the channel map for channels [31:16], that is to be sent in the connect request packet of the initiator. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data_channels[31:16] | 15:0 | This register field indicates which of the data channels are in use. This stores the information for the middle 16 (31:16) data channel indices.<br>'1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | Data_channels |

## Conn_req_word10 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1F4 | 0x3E8 | CONN_REQ_WORD10 | RW | This field defines the channel map for channels [36:32], that is to be sent in the connect request packet of the initiator. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Data_channels[36:32] | 4:0 | This register field indicates which of the data channels are in use. This stores the information for the upper 5 (36:32) data channel indices.<br>'1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | Data_channels |

## Conn_req_word11 register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1F6 | 0x3EC | CONN_REQ_WORD11 | RW | The connect request word0 register must be programmed with Connection parameters sca, hop_increment value of the connect request packet, before initiating connection. After slave connection this value can be obtained by reading this register on the advertiser side. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Sca[2:0] | 7:5 | This field defines the sleep clock accuracies given in ppm. | 0 |
| hop_increment[4:0] | 4:0 | This field is used for the data channel selection process. | 0 |

## ##RPA timer interval register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x582 | 0xB04 | RPA_TIMER_INTERVAL | RW | The RPA timer interval register stores the RPA refresh time interval. (FW programmed). | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| rpa_timer_interval_val | 15:0 | This field holds the value of the RPA refresh time interval in seconds. | 0 |

## ##Privacy Configuration register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x108 | 0x210 | LL_PRIVACY_CONFIG | RW | This register fields can be set to enable/disable Privacy feature in LLH. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:2 | Reserved for future use. | 0 |
| allow_rpa_in_whitelist | 1 | Allow initiator to receive advertising packets even if peer address resolution fails by adding the received advertiser RPA to the whitelist and to the resolving list as per Errata 6984. | 0 |
| privacy_config | 0 | Whenever this bit is set LLH will try to resolve the address for all ADVCH procedures. | 0 |

## ##RPA selection index register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x10A | 0x214 | CURRENT_LOCAL_IRK_INDEX | RW | This register is programmed by firmware before advertising and Initiation procedures. This bit is used to indicate the local IRK to be used by HW during advertising and Initiation procedures. | 0xFF |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:8 | Reserved for future use. | 0 |
| init_local_irk_index | 7:4 | This field holds the resolving list index corresponding to the IRK to be used for the INIT procedure. This field is invalid when white list is enabled. | 0xF |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | Value 0xF – valid IRK for INIT procedure is not set in resolving list. | |
| adv_local_irk_index | 3:0 | This field holds the resolving list index corresponding to the IRK to be used for the ADV procedure. This field is also valid when white list is enabled.<br>Value 0xF – valid IRK for ADV procedure is not set in resolving list. | 0xF |

## ##Peer identity address type register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x10C | 0x218 | PEER_IDENTITY_ADDR_TYPE | RW | This register stores the peer identity address type (Public or Random) corresponding to the IRK pair populated in the resolving list. The value is valid if the resolving list entry is valid. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:4 | Reserved for future use. | 0 |
| peer_id_addr_type | 3:0 | Peer_id_addr_type [i] = 0/1 => ith resolving list entry corresponds to a peer whose address is public/random. | 0 |

## ##Resolving list entry valid register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x10E | 0x21C | RES_LIST_VALID | RW | This register is used to indicate to HW which resolving list entries are valid/ invalid. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:4 | Reserved for future use. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| device_valid_entry | 3:0 | Device_valid_entry [i] = 0/1 => ith resolving list entry is invalid/valid. | 0 |

## ##Advertising parameters 2 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x0A | 0x14 | ADV_PARAMS_2 | RW | This register stores the own address type for the Advertising procedure. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:2 | Reserved for future use. | 0 |
| adv_tx_addr | 1:0 | Device Own_address_type field.<br>0x0 - Own address type is public address.<br>0x1 - Own address type is random address.<br>0x2 - Own address type is RPA. If resolving list contains no matching entry, use public address.<br>0x3 - Own address type is RPA. If resolving list contains no matching entry, use random address. | 0 |

## ##Local IRK n registers

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1100-0x11FE | - | L_IRK_n_x | RW | These registers store the local IRK value for nth resolving list entry. IRK value is of 128 bits and stored in Little Endian format (lowest address register has the LSW). | 0x00000000000000000000000000000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| dev_localirk[n] | 127:0 | This field has the 128 bit value of local IRK for nth resolving list entry. | 0 |

| | | | |
|---|---|---|---|
| | | Note: Refer to appendix 6 for full addressing with respect to each resolving entry. | |

## ##Peer IRK n registers

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1200-0x12FE | - | P_IRK_n_x | RW | These registers store the peer IRK value for nth resolving list entry. IRK value is of 128 bits and stored in Little Endian format (lowest address register has the LSW). | 0x00000000000000000000000000000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| dev_peerirk[n] | 127:0 | This field has the 128 bit value of peer IRK for nth resolving list entry.<br>Note: Refer to appendix 6 for full addressing with respect to each resolving entry. | 0 |

## ##Peer identity address n registers

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1300-0x135E | - | PEER_ID_ADDR_n_x | RW | These registers store the peer identity address for nth resolving list entry. Identity address is of 48 bits and stored in Little Endian format (lowest address register has the LSW). | 0x000000000000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| dev_identity_addr[n] | 47:0 | This field has the 48 bit value of peer ID address for nth resolving list entry.<br>Note: Refer to appendix 6 for full addressing with respect to each resolving entry. | 0 |

## ##Local RPA n registers

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1360-0x13BE | - | L_RPA_n_x | RO | These registers store the local RPA generated by the HW using the local IRK of the nth resolving list entry. RPA is of 48 bits and stored in Little Endian format (lowest address register has the LSW). | 0x0000000000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| self_rpa_list_n | 47:0 | This field has the 48 bit value of local RPA for nth resolving list entry.<br>Note: Refer to appendix 6 for full addressing with respect to each resolving entry. | 0 |

## ##Peer RPA n registers

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x13C0-0x141E | 0x1CC0 – 0x1CC8 | P_RPA_n_x | RO | These registers store the peer RPA generated by the HW using the peer IRK of the nth resolving list entry. RPA is of 48 bits and stored in Little Endian format (lowest address register has the LSW). | 0x0000000000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| peer_rpa_list_n | 47:0 | This field has the 48 bit value of peer RPA for nth resolving list entry.<br>Note: Refer to appendix 6 for full addressing with respect to each resolving entry. | 0 |

## ##RPA timer wrap count register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0x586 | 0xB0C | RPA_TIMER_WRAP_COUNT | RO | The RPA timer wrap count register stores the wrap count value. A wrap is a complete bt_clock roll from 0x0000 to 0xFFFF. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| **Reserved** | **15:10** | | **0** |
| rpa_timer_wrap_count | 9:0 | This field holds the bt_clock wrap count value. | 0 |

## ##RPA timer current wrap register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x584 | 0xB08 | RPA_TIMER_CURRENT_WRAP | RO | The RPA timer current wrap register stores the current wrap count value. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:12 | | 0 |
| rpa_timer_current_wrap | 11:2 | This field holds RPA timer's current wrap count value. | 0 |
| rpa_timer_en | 1 | Indicates whether RPA timer is ON in hardware.<br>1 – on<br>0 – off | 0 |
| wrap_valid | 0 | Indicates whether RPA timer's warp is valid.<br>1 – wrap is valid<br>0 – wrap is invalid | 0 |

## ##RPA timer next instant register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x588 | 0xB10 | RPA_TIMER_NEXT_INSTANT | RO | Holds the next RPA timer instant value. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| **Reserved** | **15:10** | | **0** |
| rpa_timer_next_instant | 9:0 | Holds the next RPA timer instant value. This instant is valid when wrap valid = 1. | 0 |

## ##RPA LFSR seed lower register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x9C | 0x138 | RPA_LFSR_L | RW | Lower seed value of the LFSR for RPA generation. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Rpa_lsfr_l | 15:0 | Firmware can writes to this register to update the seed value of the LFSR for random RPA generation after the reset. | 0 |

## ##RPA LFSR seed middle register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x9E | 0x13C | RPA_LFSR_M | RW | Middle seed value of the LFSR for RPA generation. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Rpa_lsfr_m | 15:0 | Firmware can writes to this register to update the seed value of the LFSR for random RPA generation after the reset. | 0 |

## ##RPA LFSR seed higher register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xA0 | 0x140 | RPA_LFSR_H | RW | Upper seed value of the LFSR for RPA generation. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:12 | RFU | **0** |
| Rpa_lsfr_u | 11:0 | Firmware can writes to this register to update the seed value of the LFSR for random RPA generation after the reset. | 0 |

## ##Privacy Mode register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x280 – 0x28E | 0x500 – 0x51C | PRIVACY_MODE_0 – PRIVACY_MODE_7 | RW | Mode of the privacy address added for each entry in the resolving list. | 0x0 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:1 | RFU | **0** |
| Privacy_mode | 0 | This bit defines the mode of the device is network privacy or device privacy.<br>0 – Network Privacy Mode<br>1 – Device Privacy Mode | 0 |

### 64.5.1.1.3 Data Channel Registers

Data Channel Register Descriptions for the Bluetooth Link Layer

Transmit window offset register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x40 | 0x080 | TRANSMIT_WINDOW_OFFSET | RW | Stores the transmit window offset parameter used during connection setup and connection update procedures.<br>The register is updated by hardware when device is slave. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| window_offset | 15:0 | This is used to determine the first anchor point for the master transmission, from the time of connection creation.<br>Range: This shall be a multiple of 1.25 ms in the range of 0 ms to connInterval value. | 0 |

## Transmit window size register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x42 | 0x084 | TRANSMIT_WINDOW_SIZE | RW | Stores the transmit window size parameter used during connection setup and connection update procedures. The register is updated by hardware when device is slave. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| window_size | 7:0 | window_size along with the window_offset is used to calculate the first connection point anchor point for the master.<br>This shall be a multiple of 1.25 ms in the range of 1.25 ms to the lesser of 10 ms and (connInterval – 1.25 ms).<br>Values range from 0 to 10 ms. | 0 |

## Data channel map 0 (lower word) register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x44 | 0x088 | DATA_CHANNELS_L0 | RW | Stores the channel map for channels [15:0]. The register is updated by firmware whenever a new/updated channel map is available for the connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data_channels | 15:0 | This register field indicates which of the data channels are in use. This stores the information for the lower 16 (15:0) data channel indices.<br>'1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | 0x0000 |

## Data channel map 0(middle word) register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x46 | 0x08C | DATA_CHANNELS_M0 | RW | Stores the channel map for channels[31:16]. The register is updated by firmware whenever a new/updated channel map is available for the connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data_channels | 15:0 | This register field indicates which of the data channels are in use. This stores the information for the middle 16 (31:16) data channel indices.<br>'1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | 0x0000 |

## Data channel map 0(upper word) register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x48 | 0x090 | DATA_CHANNELS_H0 | RW | Stores the channel map for channels[36:32]. The register is updated by firmware whenever a new/updated channel map is available for the connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:5 | Unused | 0 |
| Data_channels | 4:0 | This register field indicates which of the data channels are in use. This stores the information for the upper 5 (36:32) data channel indices.<br>'1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | 0x00 |

## Data channel map 1 (lower word) register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x4C | 0x098 | DATA_CHANNELS_L1 | RW | Stores the channel map for channels[15:0]. The register is updated by firmware whenever a new/updated channel map is available for the connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data_channels | 15:0 | This register field indicates which of the data channels are in use. This stores the information for the lower 16 data channel indices.<br>'1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | 0x0000 |

## Data channel map 1 (middle word) register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x4E | 0x09C | DATA_CHANNELS_M1 | RW | Stores the channel map for channels[31:16]. The register is updated by firmware whenever a new/updated channel map is available for the connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data_channels | 15:0 | This register field indicates which of the data channels are in use. This stores the information for the middle 16 data channel indices.<br>'1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | 0x0000 |

## Data channel map 1 (upper word) register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x50 | 0x0A0 | DATA_CHANNELS_H1 | RW | Stores the channel map for channels[36:32]. The register is updated by firmware whenever a new/updated channel map is available for the connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Data_channels | 15:5 | Unused | 0 |
| Data_channels | 4:0 | This register field indicates which of the data channels are in use. This stores the information for the upper 5 data channel indices.<br>'1' indicates the corresponding data channel is used and '0' indicates the channel is unused. | 0x00 |

*Note: The Data channel map 0 and data channel map 1 are two sets of channel maps stored, common for all the connections. At any given time, only two maps can be maintained and the connections will use one of the two sets as indicated by the channel map index field in the CE_CNFG_STS registers specific to the link. Firmware must also manage to update this field along with the map.*

## Connection channel Status register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0x56 | 0x0AC | CONN_STATUS | RO | Indicates the status of the connection channel data path and other common connection channel operations. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Rx_packet_counter | 15:12 | This field stores the count for the number of receive packets in the receive FIFO that are still not ready by firmware.<br>The counter value is incremented by hardware for every good packet it stores in the FIFO.<br>After firmware reads a packet, it decrements the counter by issuing the PACKET_RECEIVED command from the commander. | 0 |
| Reserved | 11:0 | Reserved for future use | 0 |

## Connection configuration register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xF0 | 0x1E0 | CONN_CONFIG | RW | This register fields can be set to configure the LLH in data transfer scenarios. | 0x631F |

| Field | Bit | Description | Reset |
|---|---|---|---|
| pdu_index_auto_updt | **15** | This bit enable the LL hardware to update the index of the PDU being queued in the data buffer.<br>0x0- LL Hardware to update the index of the PDU being queued.<br>0x1- LL firmware to update the index when PDU is queued. | 0x0 |
| mask_suto_at_update | 14 | This bit is used to enable/ disable masking of internal hardware supervision timeout | 0x01 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | trigger when switching from old connection parameters to new parameters.<br>1 - Enable<br>0 - Disable | |
| extend_cu_tx_win | 13 | This bit is used to enable/ disable extending the additional rx window on slave side during connection update in event of packet miss at the update instant.<br>1 - Enable<br>0 - Disable | 0x01 |
| slv_md_config | 12 | Configuration is provided to send last data packet with MD bit set/zero or one (only for slave mode).<br>SLV_MD_CONFIG bit has effect only when md_bit_ctr bit is not set<br>0 – The MD bit is set based on the transmit buffer empty condition. The last packet goes with a MD bit set since the FIFO would not be empty as we have to retain the data in the buffer till we realize the ACK from the remote side.<br>1 - MD bit will be controlled based on the availability of next data in the FIFO. So send last data packet with MD bit zero or one. If the data transmitted is the last packet in the FIFO the MD bit will be '0' in that packet. Only if the next location holds data then MD bit will be '1'. | 0x0 |
| aww_en | 11 | This field indicates whether window widen optimization is enable or not.<br>0 – It indicates AWW is enable<br>1 – It indicates AWW is disable | 0x0 |
| sl_dsm_en | 10 | This resiter field indicates whether slave latency dsm is enable or not.<br>0 – It indicates SL_DSM is enable<br>1 – It indicates SL_DSM is disable | 0x0 |

| | | | |
|---|---|---|---|
| index_not_in_addr | 9 | This register field indicates whether connection index is present in address or not.<br>1 – Index is not in address<br>0 – Index is in address | 0x1 |
| Sw_cntrl_md | 8 | This register field indicates whether the MD (More Data) bit needs to be controlled by 'software' or, 'hardware and software logic combined'.<br>1 - MD bit is exclusively controlled by software, ie based on status of *CE_CNFG_STS_REGISTER[6] - md bit.*<br>0 - MD Bit in the transmitted pdu is controlled by software and hardware logic. MD bit is set in transmitted packet, only if the software has set the md bit in CE_CNFG_STS_REGISTER[6] and either of the following conditions is true,<br>1. If there are packets queued for transmission.<br>2. If there is an acknowledgement awaited from the remote side for the packet transmitted. | 0x1 |

| | | | |
|---|---|---|---|
| rx_intr_threshold | 7:4 | This register field allows setting a threshold for the packet received interrupt to the firmware.<br>For example if the value programmed is<br>0x2 – then LLH will generate interrupt only on receiving the second packet.<br>In any case if the received number of packets in a conn event is less than the threshold or there are still packets (less than threshold) | 0x1 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | pending in the Rx FIFO, LLH will generate the interrupt at the ce_close.<br>Min value possible is 1. Max value depends on the Rx FIFO capacity. | |
| rx_pkt_limit | 3:0 | Defines a limit for the number of Rx packets that can be received by the LLH. Default maximum value is 0xF.Minimum value shall be '1' or no packet will be stored in the Rx FIFO. | 0xF |

*Note:*

*The DUT should not send empty packets with MD bit set to 1. This will extend the connection event and increase the power consumption which is unnecessary. However there could be scenarios where maximum throughput is the target. In that case we would need to extend the connection event and allow additional time for the software to queue additional data. So both the behaviors are kept in the implementation and can be selected using* md_bit_ctr *(ie CONN_CONFIG[8]).*

md_bit_ctr *= 1 - MD bit is exclusively controlled by software.*

*If this bit is set, the MD bit in the transmitted packets is exclusively based on the status of md bit (CE_CNFG_STS_REGISTER[6]).*

*In this mode, empty packets with MD bit set would be transmitted by us during the time an acknowledgement is being processed in the other end. This feature will extend the connection event since the remote end host will get see the MD bit and so stays in the same connection event, and this will allow us more time for our software to process the acknowledgement and queue additional data from the host to hardware. This is useful when we need to maximize the data transmitted in a connection interval.*

*sw_cntrl_md = 0 - MD bit is controlled by software and hardware logic.*

*Note that MD bit is not set in the transmitted packet if software has not set the md bit in CE_CNFG_STS_REGISTER[6] as 0b.*

*In this mode of operation an empty packet will still be sent since the send status clearing and more data check is at same time.*

Connection channel transmit power register

| Addr | Addr | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| 16-bit | 32-bit | | | | |
|---|---|---|---|---|---|

| Field | Bit | Description | Reset |
|---|---|---|---|
| Conn_tx_power[15:0] | 15:0 | Transmit power to be used for all packets transmitted on the connection channel. | 0x0000 |

## *Connection Interrupt mask register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xF8 | 0x1F0 | CONN_INTR_MASK | RW | Connection Interrupt enable register. This register controls enabling of interrupts and other enables common for all connections. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| *ping_nearly_expired_intr | 15 | If this bit is set ping timer nearly expired interrupt is enabled. | 0 |
| *ping_timer_expired_intr | 14 | If this bit is set ping timer expired interrupt is enabled. | 0 |
| Reserved | 13:10 | Unused. | 0 |
| rx_bad_pdu_int_en | 9 | If this bit is set packet receive bad pdu interrupt is enabled. Effective only when bit 6 is set. | 0 |
| rx_good_pdu_int_en | 8 | If this bit is set packet receive good pdu interrupt is enabled. Effective only when bit 6 is set. | 0 |
| conn_updt_intr_en | 7 | If this bit is set connection update interrupt is enabled. | 0 |
| ce_rx_int_en | 6 | If this bit is set interrupt is enabled for reception of packet in a connection event. Bit 8 and 9 are sub-mask bits below this mask. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| ce_tx_ack_int_en | 5 | If this bit is set transmission acknowledgement interrupt is enabled:<br>This interrupt is generated to indicate to the firmware that a non-empty packet transmitted is successfully acknowledged by the remote device.<br>For negative acknowledgements from remote device, this interrupt indication is not generated. | 0 |
| close_ce_int_en | 4 | If this bit is set connection event closed interrupt is enabled. | 0 |
| start_ce_int_en | 3 | If this bit is set connection event start interrupt is enabled | 0 |
| map_updt_int_en | 2 | If this bit is set, channel map update interrupt is enabled. | 0 |
| conn_estb_int_en | 1 | If this bit is set connection establishment interrupt is enabled. | 0 |
| conn_cl_int_en | 0 | If this bit is set connection closed interrupt is enabled. | 0 |

## Slave timing control register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xFA | 0x1F4 | SLAVE_TIMING_CONTROL | RW | Slave timing control register. This register controls slave related timing. | 0xBE96 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Slave_time_adj_val | 15:8 | Timing adjust value. The internal micro second counter is adjusted to this value whenever slave receives a good access address match at connection anchor point. This will ensure the slave gets synchronized to master timing. | 0xBE |
| Slave_time_set_val | 7:0 | Programmable adjust value to the clock counter when slave is connected | 0x96 |

## Window widen for offset register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xB2 | 0x164 | WINDOW_WIDEN_WINOFF | RW | Window widen value corresponding to transmitwindowoffset. Firmware calculates the possible drift due to transmitwindowoffset to the first packet after connection/ connection update and programs the value into this register. The value is in microseconds. | 0x000A |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:12 | Unused | |
| Window_widen | 11:0 | This field stores the additional number of microseconds the slave must conn_config its listening window to listen for a master packet for receiving the first packet after connection creation. This value is calculated based on the window offset value to the first anchor point. This is used at connection setup directly. During connection setup, this value is added with window_widen_intvl register value to calculate the window widening size. | 00A |

## Connection Index register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x58 | 0x0B0 | CONN_INDEX | RW | Index of the connection to which the connection-specific parameter is being written to or read from. Firmware shall update this register with proper index before writing/ reading the connection-specific registers (refer to register summary before for the connection specific register set). | 0x0000 |

| | | | | | |
|---|---|---|---|---|---|
| | | | | This register is relevant only for multiple connection support. If multiple connection is supported but number of connections is made one then the register value needs to be kept 0x0. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| RFU | 15:3 | Reserved | 0 |
| fw_conn_index | 2:0 | This field is used to index the multiple connections existing. Range is 0 to one less than maximum number of connections supported (limited to 4 as of now).<br>0x0 – Connection Engine 0 in LLH<br>0x1 – Connection Engine 1 in LLH | 0 |

*Note – An alternative for programming of the conn index register for every access to the connection registers is to pass the conn index along with the LLH address itself which requires address space to be available for this mapping.*

*Connection Interrupt clear register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x54 | 0x0A8 | CONN_INTR_CLEAR | WO | Clear connection interrupts. Write to the register to clear one more connection interrupts. This register is implemented per connection. To clear interrupt for a specific connection, connection index register must be programmed before writing to this register. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| *conn_ping_timer_nearly_expire | 15 | If this bit is written with 1, it clears the conn_ping_timer_nearly_expire interrupt. | 0 |
| *conn_ping_timer_expire | 14 | If this bit is written with 1, it clears the | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | conn_ping_timer_expire interrupt. | |
| Reserved | 13:8 | Unused | 0 |
| con_updt_done | 7 | If this bit is written with 1, it clears the connection updated interrupt. | 0 |
| ce_rx | 6 | If this bit is written with 1, it clears the connection event received interrupt. | 0 |
| ce_tx_ack | 5 | If this bit is written with 1, it clears the ce transmission acknowledgement interrupt. | 0 |
| close_ce | 4 | If this bit is written with 1, it clears the connection event closed interrupt. | 0 |
| start_ce | 3 | If this bit is written with 1, it clears the connection event started interrupt. | 0 |
| map_updt_done | 2 | If this bit is written with 1, it clears the map update done interrupt. | 0 |
| conn_estb | 1 | If this bit is written with 1, it clears the connection established interrupt. | 0 |
| conn_closed | 0 | If this bit is written with 1, it clears the connection updated interrupt. | 0 |

## *Connection Interrupt status register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x54 | 0x0A8 | CONN_INTR_STATUS | RO | Connection Interrupt status register. To read interrupt for a specific connection, connection index register must be programmed before reading from this register. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| *ping_nearly_expird_intr | 15 | If this is set, it indicates that ping timer has nearly expired. | 0 |
| *ping_timer_expird_intr | 14 | If this is set, it indicates that ping timer has expired. | 0 |
| rx_pdu_status | 13:11 | Status of PDU received. This information is valid along with receive interrupt. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | Xx1 – Bad Packet (packet with CRC error)<br>000 – empty PDU<br>010 - new data (non-empty) PDU<br>110 – Duplicate Packet | |
| discon_status | 10:8 | Reason for disconnect – indicates the reason the link is disconnected by hardware.<br>001 – connection failed to be established<br>010 - supervision timeout<br>011 – kill connection by host<br>100 – kill connection after ACK transmitted<br>101 – PDU response timer expired | 0 |
| con_updt_done | 7 | This bit is set when the last connection event with previous connection parameters is reached. The bit is set immediately after the receive operation at the anchor point of the last connection event. | 0 |
| ce_rx | 6 | If this bit is set it indicates that a packet is received in the connection event. | 0 |
| ce_tx_ack | 5 | If this bit is set it indicates that the connection event transmission acknowledgement is received for the previous non-empty packet transmitted. | 0 |
| close_ce | 4 | If this bit is set it indicates that the connection event closed interrupt has happened. | 0 |
| start_ce | 3 | If this bit is set it indicates that the connection event started interrupt has happened. | 0 |
| map_updt_done | 2 | If this bit is set it indicates that the channel map update is completed at the instant specified by the firmware. | 0 |
| conn_estb_updt | 1 | If this bit is set it indicates that the connection has been established. The bit is also set when a connection update procedure is completed, at the start of the first anchor point with the updated parameters. | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| conn_closed | 0 | If this bit is set it indicates that the link is disconnected. | 0 |

## Connection Interval register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x80 | 0x100 | CONN_INTERVAL | RW | Connection Interval registers. Firmware writes the connection interval specific to the connection. The connection index register must be programmed with index of the connection, before programming the register. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| connection Interval | 15:0 | The value configured in this register determines the spacing between the connection events.<br>This shall be a multiple of 1.25 ms in the range of 7.5 ms to 4.0 s. | 0x0000 |

## Supervision timeout register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x82 | 0x104 | SUP_TIMEOUT | RW | Supervision timeout for the connection. The connection index register must be programmed with index of the connection, before programming the register. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| supervision_timeout | 15:0 | This field defines the maximum time between two received Data packet PDUs before the connection is considered lost. | 0x0000 |

| | | | |
|---|---|---|---|
| | | This shall be a multiple of 10 ms in the range of 100 ms to 32.0 s and it shall be larger than (1+connSlaveLatency)*connInterval. | |

## Slave Latency register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x84 | 0x108 | SLAVE_LATENCY | RW | Slave latency for the connection. The connection index register must be programmed with index of the connection, before programming the register. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| slave_latency | 15:0 | The value configured in this field defines the number of consecutive connection events that the slave device is not required to listen for master.<br>The value of connSlaveLatency should not cause a Supervision Timeout.<br>This shall be an integer in the range of 0 to ((connSupervision Timeout/ connInterval)-1). connSlaveLatency shall also be less than 500. | 0x0000 |

## Connection event length register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x86 | 0x10C | CE_LENGTH | RW | Connection event length for the connection. The connection index register must be programmed with index of the connection, before programming the register. | 0x00<br>00 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Connection event Length | 15:0 | This field defines the length of Connection event. This value is derived from the CE length HCI parameters received from the host. This determines the number of master transmit slots in a connection event, subject to either of the MD bits being set. If both MD bits are set to 0, this has no effect.<br>Units : 625 us.<br>Note: The connection event length as specified by the CE_LENGTH shall not exceed CONN_INTERVAL – 1.25 ms. | 0x0000 |

The CE-length parameter, according to the Bluetooth specification, is the length of the connection event.

Take an example to illustrate this scenario:

Assume a connection with interval = 100ms. that the application has put allowed 20ms of CE-length.

Here, the CE-length can be up to 100ms (100ms - 150us to be exact).

If the connection is maintained for 5 minutes, there could be 10*60*5 = 3000 connection-intervals.

The CE-length need not maintained constant during all the 3000 connection events.

Here are the typical cases that determine the value of CE-length:

(1) No data packets exchanged. we are just maintaining time and frequency synchronization. In this case, only a packet pair will be exchanged every connection interval. Here, CE-length = 1.

(2) Average of 10 packets to be sent per connection event.

We can pump data in multiple ways here:

2.1: Send data at uniform rate : In this case, the CE-length will be enough to accommodate 10 packets, which will take about 7ms. As this is less than application enforced limit of 20ms, we can comfortably push all the 10 data packets in this connection interval. So data will be pumped to the other BT device at the same rate as is received from my application.

2.2: Can send data in bursts. Assume that we accumulate data for 1 second and pump out at the end of 1 second(this is not done by our Bluetooth stack, the application needs to buffer the data). So, at 10th connection interval, we have 100 packets accumulated. We are now ready to pump this data. 100 packets take about 70 ms. This is above the application enforced 20ms. So, the hardware can pump data that can fill up 20ms. The remaining data will be deferred to the next connection interval.

So, in this case, you would see a CE-length spread over time like this (Per connection interval):

0,0,0,0,0,0,0,0,0,0, 20,20,20,10,0,0,0,0,0,0, 20,20,20,10,0,0,0,0,0,0,
20,20,20,10,0,0,0,0,0,0,

and so on.

(3) We are receiving data at the same rate as in (2). This case is to honor data sent by the other BT-device by giving it more time in the current connection interval.

In (2) and (3) you will see non-empty packets either transmitted or received. We can also utilize the CE-length for different reasons:

(4) A transaction is in progress, and we are expecting a response packet very soon. In this case, we may be exchanging only empty packets now, and in the next few packet-pairs.

In this case, you will the CE-length to be large, and a non-empty packet may not be exchanged in all the slots.

Access address (lower) register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x88 | 0x110 | PDU_ACCESS_ADDR_L_REGISTER | RW | Access address bits 15:0 for the connection. The connection index register must be programmed with index of the connection, before programming the register. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| PDU Access Address Lower bits | 15:0 | This field defines the lower 16 bits of the access address for each Link layer connection between any two devices. | 0x0000 |

Access address (upper) register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x8A | 0x114 | PDU_ACCESS_ADDR_H_REGISTER | RW | Access address bits 32:16 for the connection. The connection index register must be programmed with index of the connection, before programming the register. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| PDU Access Address Lower bits | 15:0 | This field defines the higher 16 bits of the access address for each Link layer connection between any two devices. | 0x0000 |

## Connect Event Instant register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x8C | 0x118 | CONN_CE_INSTANT | RW | This is the instant used for connection update procedure and channel map update procedure. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Ce_instant | 15:0 | This is the value of the free running Connection Event counter when the new parameters of ‘connection update’ and/or ‘Channel map update’ will be effective.<br>Range : 0x0000 to 0xFFFF | 0x0000 |

## Connect Event Counter register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x92 | 0x124 | CONN_CE_COUNTER | RO | This is the free running counter, connEventCounter as defined by Bluetooth spec. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| connectionEventCounter | 15:0 | Firmware will read the instantaneous Event counter from this register, during connection update and channel map update procedure. Firmware will use this value to calculate the instant from which the new parameters (for connection update and channel map update) will be effective. | 0x0000 |

## Connection configuration & status register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x8E | 0x11C | CE_CNFG_STS_REGISTER | RW | Connection specific configuration and status information register.<br>This register facilitates the pause/resume mechanism of data PDUs by LL , typically used during “enable encryption” procedure.<br>In case multiple connections are supported, “connection index register” has to be written by the f/w before programming/reading this register | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| current_pdu_index | 15:12 | Read Only field. The index of the transmit packet buffer that is currently in transmission/ waiting for transmission. | 0 |
| Reserved | 11 | Reserved for future use. | 0 |
| conn_active | 10 | Read Only field . This bit is ‘1’ whenever the connection is active. | 0 |
| force_nesn0 | 9 | not used | 0 |
| pause_data | 8 | Pause data. 1 – pause data, 0 – do not pause.<br>Pause the data transfer on the connection. The current_pdu_index in | 0 |

*Table continues on the next page...*

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xF4 | 0x1E8 | CONN_PARAM1 | RW | Connection parameters like sca, hop_increment and crc_init exchanged in connect_request of this connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| crc_init[7:0] | 15:8 | This field defines the lower byte (7:0) of the CRC initialization vector. | 0 |
| hop_increment[4:0] | 7:3 | Hop increment for connection channel. | |
| sca[2:0] | 2:0 | Sleep Clock accuracy value. | |

## Connection parameter 2 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xF6 | 0x1EC | CONN_PARAM2 | RW | Connection parameter crc_init bits 24:7 exchanged in connect_request of this | 0x0000 |

| | | | | | |
|---|---|---|---|---|---|
| | | | | connection. The connection index register must be programmed with index of the connection, before reading the register. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| crc_init[23:8] | 15:0 | This field defines the upper two bytes (23:8) of the CRC initialization vector. | 0x0000 |

## Connection Update New Interval

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1D2 | 0x3A4 | CONN_UPDATE_NEW_INTERVAL | RW | The connection interval that will be effective after the connection update instant. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Conn_interval_new[15:0] | 15:0 | This register will have the new connection interval that the hardware will use after the connection update instant. Before the instant, the connection interval in the register CONN_INTERVAL will be used by hardware. | 0x0000 |

- Connection Update New Latency

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1D4 | 0x3A8 | CONN_UPDATE_NEW_LATENCY | RW | The slave latency that will be effective after the connection update instant. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Slave_latency_newl[15:0] | 15:0 | This register will have the new slave latency parameter that the hardware will use after the connection update instant. | 0x0000 |

| | | | |
|---|---|---|---|
| | | Before the instant, the connection interval in the register SLAVE_LATENCY will be used by hardware. | |

- Connection Update New Su To

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1D6 | 0x3AC | CONN_UPDATE_NEW_SU_TO | RW | The Supervision timeout that will be effective after the connection update instant. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Conn_so_to_new[15:0] | 15:0 | This register will have the new supervision timeout that the hardware will use after the connection update instant. Before the instant, the connection interval in the register SUP_TIMEOUT will be used by hardware. | 0x0000 |

- Connection Update New slaveLatency x connInterval value

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1D8 | 0x3B0 | CONN_UPDATE_NEW_SL_INTERVAL | RW | The (slaveLatency * connInterval) value that will be effective after the connection update instant. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| sl_conn_interval_new[15:0] | 15:0 | This register will have the new SL*CI value that the hardware will use after the connection update instant. Before the instant, the connection interval in the register SL_CONN_INTERVAL will be used by hardware. | 0x0000 |

## Window Widen for Interval register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xB0 | 0x160 | WINDOW_WIDEN_INTVL | RW | Window widening value based on connection interval of the connection. The connection index register must be programmed with index of the connection, before reading the register. | 0x000A |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:12 | Not used | |
| Window_widen | 11:0 | This value defines the increased listening time for the slave.<br>The windowWidening shall be smaller than ((connInterval/2)-T_IFS us)<br>This value is calculated by firmware based on the drift, the connection interval value. The value is the unit widening value for one connection interval duration. In case of slave latency, this value is accumulated till the next anchor point at which the slave will listen. | 0x000A |

## PDU response timer register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x502 | 0xA04 | PDU_RESP_TIMER | RW | PDU response timer register. This timer is used to monitor the time to get the response for the control procedures for which timeout rules are specified in the specification. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Pdu_resp_time_val | 15:0 | This register is loaded with the count value to monitor the time to get a response for the control PDU sent to a peer device.<br>Firmware starts the timer by issuing the command, RESP_TIMER_ON, after it has queued a control PDU for transmission that requires a response.<br>If a response is received, firmware stops and clears the timer by issuing the command RESP_TIMER_OFF.<br>If this timer expires, it results in hardware closing the connection and triggering a conn_closed interrupt.<br>The *discon_status* field in the Connection status register is set with the appropriate reason.<br>Units : Milliseconds.<br>Resolution : 1.25 ms | 0 |

## Next response timeout instant register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x504 | 0xA08 | NEXT_RESP_TIMER_EXP | RO | 16-bit internal reference clock value at which the next PDU response timeout event will occur on a connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Next_resp_timer_expire | 15:0 | This field defines the clock instant at which the next PDU response timeout event will occur on a connection.<br>This is with reference to the 16-bit internal reference clock. | 0x0000 |

## Next Supervision timeout instant register

| Addr | Addr | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| 16-bit | 32-bit | | | | |
|---|---|---|---|---|---|
| 0x506 | 0xA0C | NEXT_SUP_TO | RO | 16-bit internal reference clock value at which the next supervision timeout event will occur on a connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Next_timeout_instant | 15:0 | This field defines the clock instant at which the next connection supervision timeout event will occur on a connection.<br>This is with reference to the 16-bit internal reference clock. | 0x0000 |

## Data list SENT Status register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x94 | 0x128 | DATA_LIST_SENT_STATUS | WO | The register is used by firmware to indicate that a packet buffer is queued (loaded) with data for transmission. Firmware sets a SENT bit in hardware corresponding to the packet buffer queued with a packet for transmission. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:9 | Unused | 0 |
| Set/Clear | 8 | Used to set the SENT bit in hardware for the selected packet buffer.<br>1 – packet queued<br>When firmware has a packet to send, firmware first loads the next available packet buffer. Then the hardware SENT bit is set by writing 1 to this bit field along with the list_index field that identified the buffer index. This indicates that a packet has been queued in the data | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | buffer for sending. This packet is now ready to be transmitted.<br>The SENT bit in hardware is cleared by hardware only when it has received an acknowledgement from the remote device.<br>Firmware typically does not clear the bit. However, It only clears the bit on its own if it needs to 'flush' a packet from the buffer, without waiting to receive acknowledgement from the remote device, firmware clears BIT7 along with the list_index specified.<br>Note: This register has a different meaning in the Read-path | |
| List_index | 7:0 | Indicates the buffer index for which the SENT bit is being updated by firmware.<br>The default number of buffers in the IP is 5. The index range is 0-4. | 0 |

## Data list ACK update register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x96 | 0x12C | DATA_LIST_ACK_STATUS | WO | Clear ACK indication for the packet, as reported by link layer hardware. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:9 | Unused | 0x0000 |
| Set/clear | 8 | Firmware uses the field to clear the ACK bit in the hardware to indicate that the acknowledgement for the transmit packet has been received and processed by firmware.<br>Firmware clears the ACK bit in the hardware by writing in this register only after the | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | acknowledgement is processed successfully by firmware.<br>For clearing ack for a packet transmitted in fifo-index : '3', firmware will write '3' in the 'list-index' field and set this bit (BIT7) to 0.<br>This is the indication that the corresponding packet buffer identified by List-Index is cleared of previous transmission and can be re-used for another packet from now on.<br>The ACK bit in hardware is set by hardware when it has successfully transmitted a packet.<br>Note: This register has a different meaning in the Read-path | |
| List_index | 7:0 | Indicates the buffer index for which the ACK bit is being updated by firmware.<br>The default number of buffers in the IP is 5. The index range is 0-4. | 0 |

## Data list SENT status register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x94 | 0x128 | DATA_LIST_SENT_STATUS | RO | Status of SENT bit of all the transmit buffers available in the hardware. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:8 | Unused | 0x0000 |
| tx_sent | 7:0 | The bits in this field indicate the status of the SENT bit in the hardware for each packet buffer. The bit values are<br>1 – queued<br>0 – no packet / packet ack received by hardware | 0 |

| | | | |
|---|---|---|---|
| | | Example1: If the read value is : 0x03, then packets in buffer 0 and buffer 1 are in the queue to be transmitted. All the other FIFOs are empty or hardware has cleared them after receiving acknowledgement. | |

## Data list ACK update register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x96 | 0x12C | DATA_LIST_ACK_STATUS | RO | Status of ACK bit of all the transmit buffers available in the hardware. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:8 | Unused | 0x0000 |
| tx_ack | 7:0 | If a particular bit is set, then the packet in the selected buffer has been transmitted (at least once) by the hardware and hardware is waiting for acknowledgement.<br>Example1 : If the read value is : 0x03, then packets in FIFO-0 and FIFO-1 are acknowledged by the remote device. These acknowledgements are pending to be processed by firmware.<br>Example2 : If the read value is : 0x02, then packet FIFO-1 is acknowledged by the remote device. This acknowledgement is pending to be processed by firmware.<br>Note : This register has a different meaning in the Write-path. | 0 |

The SENT bit and ACK bit have to be taken together to understand the meaning of packet status. The table below describes how the two bits are sequentially updated by either hardware/firmware to complete one data transmission.

| SENT | ACK | Description |
|---|---|---|
| 0 | 0 | Buffer is empty. No packet is queued in the buffer |
| 1 | 0 | Packet is queued by firmware. |
| 1 | 1 | Packet is transmitted by hardware. Hardware is waiting for acknowledgement. |
| 0 | 1 | Hardware has received ACK. Firmware has not yet processed the ACK. |
| 0 | 0 | Firmware has processed the ack. The buffer is again empty. |

## Device Data List Status Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x290 | 0x520 | DEVICE_DATA_LIST_STATUS | RO | Status of data packets queued and sent. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:8 | Unused | 0x0000 |
| device_data_list_status | 7:0 | These bits the status of data pecked queued and sent at device level. If the particular bit is set to ‘1’ indicates that there either pending PDU in the queue or pending ACK to be cleared. Based on the status of this register FW will queue next PDU.<br><br>Note : This register is used only in shared connection tx_fifo. | 0 |

### Data list Index 0 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x98 | 0x130 | LIST_INDEX0 | WO | Reserved for future use. | 0x0000 |

### Data list Index 1 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x9A | 0x134 | LIST_INDEX1 | WO | Reserved for future use. | 0x0000 |

## Data buffer descriptor 0-7 register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x200 - 0x21E | 0x400- 0x43C | DATA_MEM_DESCRIPTOR0 - DATA_MEM_DESCRIPTOR15 | RW | Descriptor for packet stored in the each of the transmit buffer which includes the packet specific information like length and LLID. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| conn_handle | 15:8 | Unused. Reserved for future use. | 0x0 |
| Enc | 7 | Unused. Reserved for future use. | |
| Data_length | 6:2 | This field indicates the length of the data packet.<br>Range: 0x0 to 0x1F. | 0 |
| LLID | 1:0 | The LLID indicates whether the packet is an LL Data PDU or an LL Control PDU.<br>00b= Reserved.<br>01b=LL Data PDU: Continuation fragment of an L2CAP message or an Empty PDU.<br>10b=LL Data PDU: Start of an L@CAP message or a complete L2CAP message with no fragmentation.<br>11b=LL Control PDU. | |

## Feature Configuration register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x508 | 0xA10 | LLH_FEATURE_CONFIG | RW | Enabling/Disabling of different features implemented in connection. | 0x000A |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 7:2 | RFU | 0 |
| llf_sl_dsm_ww_ctrl | 3 | Control bit to enable or disable the wakeup delay when slave latency is enabled. | 1 |
| slave_latency_en_sts | 2 | Read Only . Firmware reads this bit to know the status of slave latency enable. | 0 |
| llf_sl_dsm_en | 1 | LLF assisted slave latency dsm feature is enabled by setting this bit.<br>When slave latency is enabled, this feature enables the slave to awaken out of DSM when it is necessary for the slave to receive a packet. | 1 |
| Quick_transmit | 0 | Quick transmit feature in slave latency is enabled by setting this bit.<br>When slave latency is enabled, this feature enables the slave to transmit in the immediate connection interval, in case required, instead of waiting till the end of slave latency | 0 |

## Adaptive Window Widening Config

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x50A | 0xA14 | AWW_CONFIG | RW | Enabling/Disabling of various AWW specific functions and AWW configurable parameters. | 0xE244 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| aww_error_tolerence_en | 15 | This bit enables/disables the access code bit error tolerance functionality.<br>1 – enable<br>0 - disable | 1 |
| aww_tolerence_threshold | 14:10 | This value sets the lower bound on tolerance of bit errors in access code to | 0x18 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | overlook AWW history recapture. Eg., 0x18 implies 32-24 = 8 bit errors are tolerable. | |
| aww_alg_auto_switch_en | 9:9 | This bit is used to enable/ disable the functionality of automatic switching between the AWW algorithms i.e The Conservative Mode and Greedy Mode.<br>1 – Enable<br>0 – Disable | 1 |
| aww_alg_sel | 8:8 | IF the AWW algorithm auto switch functionality is disabled, this bit is used to manually select the AWW algorithm to be used.<br>1 – Greedy Mode<br>0 – Conservative Mode | 0 |
| constancy_cnt_init_val | 7:4 | This value defines the number of connection events for which the adaptive window module checks if master anchor points variations fall within set threshold before switching from conservative mode to greedy mode.<br>Valid Range : (0x1,0xf) | 0x04 |
| Obs_ce_cnt_init_val | 3:0 | This value defines the number of connection events for which the adaptive window module performs measurements of master anchor point swing before it applies the optimized window in accordance with conservative mode aww algorithm.<br>Valid Range : (0x1,0xf) | 0x04 |

## Slave Window Adjustment

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x50C | 0xA18 | SLV_WIN_ADJ | RW | Programmable adjust value to add to the calculated window widen value. This allows the firmware to add flexibility to calculated value of drift - to compensate for any underestimated drift in the | 0x0010 |

| | | | | | |
|---|---|---|---|---|---|
| | | | | manufacturer specification of crystal drift. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:11 | Unused | 0x00 |
| Slv_win_adj | 10:0 | Window Adjust value. This value is added to the calculated slave window widening value to be used as final window widen value. | 0x10 |

## slaveLatency x connInterval value

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x50E | 0xA1C | SL_CONN_INTERVAL | RW | Programmable Register which holds the (slaveLatency * connInterval) value for the connection. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| sl_conn_interval_val | 15:0 | This field defines the (SL * CI) product for the ongoing connection. This value is used in calculation of next connection instant during slave latency.<br>Unit is 1.25ms | 0x0000 |

## Cumulative hop increment register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x25A | 0x4B4 | SL_CONN_HOP_INCREMENT | RW | This register holds the value of cumulative hop increment corresponding to the Slave latency. | 0x00 |

| Field | Bit | Description | Reset |
|---|---|---|---|

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Sl_conn_hop_increment | 5:0 | Firmware writes the cumulative hop increment value corresponding to the slave latency upon connection creation complete before enabling Slave latency.<br>Range of the value is 0 to 36. | 0x00 |

## Cumulative window widen register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x25C | 0x4B8 | SL_CONN_WINDOW_WIDEN | RW | This register holds the value of cumulative window widen value corresponding to the slave latency. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Sl_conn_window_widen | 15:0 | Firmware writes the cumulative window widen value corresponding to the slave latency upon connection creation complete before enabling Slave latency.<br>Unit is in microseconds. | 0x0000 |

## Connection Update New slave latency hop increment register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x25E | 0x4BC | CONN_UPDATE_NEW_SL_HOP_INCREMENT | RW | The (slaveLatency * hopIncrement) value that will be effective after the connection update instant. | 0x00 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Sl_hop_increment_new[5:0] | 5:0 | This register will have the new SL_New * hopIncrement value that the hardware will use after the connection update instant. Before the instant, the hop increment in | 0x00 |

| | | | | |
|---|---|---|---|---|
| | | the register SL_CONN_HOP_INCREMENT will be used by hardware.<br>Range of the value is 0 to 36. | | |

## Connection Update New slave latency window widen register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x260 | 0x4C0 | CONN_UPDATE_NEW_SL_WIN_WIDEN | RW | The cumulative window widen value corresponding to the new slave latency after the update instant. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Sl_window_widen_new[15:0] | 15:0 | The cumulative window widen value after the connection update instant. Before the instant, the window widen in the register SL_CONN_WINDOW_WIDEN will be used by hardware.<br>Unit is in microseconds. | 0x0000 |

## Previous connection instant register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x262 | 0x4C4 | PREVIOUS_CONN_INSTANT | RO | Reference BT clock value of the previous anchor point. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Previous_conn_instant | 15:0 | Read only register.<br>Holds the value of the reference BT clock value at the previous connection event that LLH participated. | 0x0000 |

## Previous Connection instant event count

| Addr | Addr | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| 16-bit | 32-bit | | | | |
|---|---|---|---|---|---|
| 0x26E | 0x4DC | PREVIOUS_CONN_CE_COUNT | RO | Connection event count of the previous anchor point. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| previous_conn_ce_count | 15:0 | Read only register.<br>Holds the value of the event counter at the previous connection event that LLH participated. | 0x0000 |

## Previous Connection channel

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x270 | 0x4E0 | PREVIOUS_CONN_CH | RO | Connection channel of the previous anchor point. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| previous_conn_ch | 15:0 | Read only register.<br>Holds the value of the channel at the previous connection event that LLH participated. | 0x0000 |

## Slave latency connection event counter increment register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x264 | 0x4C8 | CE_COUNT_INCREMENT_N | RW | This register holds the value of connection event count N. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Ce_count_increment_n | 15:0 | Firmware programs the value of connection event count N corresponding to the elapsed time (from the previous anchor point) and expected next anchor point (anchor | 0x0000 |

| | | | |
|---|---|---|---|
| | | point when it wants to exit slave latency). | |

## Slave latency connection interval increment register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x266 | 0x4CC | CONN_INTERVAL_INCREMENT_N | RW | This register holds the value of cumulative connection interval for the connection event count N. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Conn_interval_increment_n | 15:0 | Firmware writes the cumulative connection interval for the connection event count N corresponding to the elapsed time (from the previous anchor point) and expected next anchor point (anchor point when it wants to exit slave latency).<br>Unit is 1.25ms | 0x0000 |

## Slave latency hop increment register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x268 | 0x4D0 | CONN_HOP_INCREMENT_N | RW | This register holds the value of cumulative hop increment for the connection event count N. | 0x00 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Conn_hop_increment_n | 5:0 | Firmware writes the cumulative hop increment for the connection event count N corresponding to the elapsed time (from the previous anchor point) and expected next anchor point (anchor point when it wants to exit slave latency).<br>Range of the value is 0 to 36. | 0x00 |

## Slave latency window widen increment register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x26A | 0x4D4 | CONN_WINDOW_WIDEN_N | RW | This register holds the value of cumulative window widen for the connection event count N. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Conn_window_widen_n | 15:0 | Firmware writes the cumulative window widen for the connection event count N corresponding to the elapsed time (from the previous anchor point) and expected next anchor point (anchor point when it wants to exit slave latency).<br>Unit is in microseconds. | 0x0000 |

## Slave latency new connection instant register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x26C | 0x4D8 | ANCHOR_POINT_INCREMENT_N | RW | This register holds the value of the distance for connection event count N corresponding to the elapsed time. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Anchor_point_increment_n | 15:0 | Firmware write the value of the distance for the connection event count N corresponding to the elapsed time from the previous anchor point.<br>It calculate the distance as<br>(N * CI) – (((SL_CONN_WINDOW_WIDEN_N) slots) + 1)).<br>Unit is 0.625ms | 0x0000 |

| | | | | |
|---|---|---|---|---|
| | | LLH use this value to check the validity the instant passed for the new derived anchor point with reference to the PREVIOUS_INSTANT. | | |

## **LE Ping timer address register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x510 | 0xA20 | CONN_PING_TIMER_ADDR | RW | The register used to configure the LE Authenticated payload Timeout (LE APTO) which is the Maximum amount of time specified between packets authenticated by a MIC.<br>This value of ping timer is in the order of 10ms, valid range 0x1 ~ 0xFFFF | 0x0000 |

## **LE Ping connection timer offset

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x512 | 0xA24 | CONN_PING_TIMER_OFFSET | RW | The value of ping timer nearly expired offset in the order of 10ms, valid range 0x0 ~ 0xFFFF. This is the time period after which the ping timer nearly expired interrupt is generated. | 0x0000 |

## **LE Ping timer next expiry instant

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x514 | 0xA28 | CONN_PING_TIMER_NEXT_EXP | RO | The value of ping timer next expiry instant in the terms of native clock value (least 16 bit value of the 17 bit ping counter).<br>This together with CONN_PING_TIMER_NEXT_EXP_WRAP will provide the correct status of ping timer duration. | 0x0000 |

## **LE Ping timer next expiry wrap count

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x516 | 0xA2C | CONN_SEC_CURRENT_WRAP | RO | This register holds the current position of the Ping timer. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| RESERVED | 15:9 | RFU | 0x0 |
| CONN_SEC_NEAR_WRAP | 8:5 | This field provides the time offset of the nearly expired event from the authentication payload timeout event. This offset is in the order of 40959.375 ms and specifies the time offset after starting the ping timer the nearly expired event will be generated.<br>Time= N*40959.375 ms. | 0x0 |
| CONN_SEC_CURRENT_WRAP | 4:1 | This field provides the current position of the ping timer and the value is in the order of 40959.375 ms.<br>Time= N*40959.375 ms<br>For Example if the APTO configured in 655,350 ms and this field returns 10, it means another 6 more units are remaining for the APTO event to be generated. | 0x0 |
| WRAP_VALID | 0 | This field will be ‘1’ from nearly expired event to the authenticated payload timeout or till the next reload of the ping timer. | 0x0 |

## #Connection Arbiter Parameter register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x102 | 0x204 | CONN_ARB_PARAMS | RO | Register holds the highest priority request to the connection arbiter from the connection engines. | 0xF |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:4 | Not used | -- |
| priority_pointer | 3:0 | Pointer for the highest priority request to the connection arbiter. | 0xF |

## Conn_SUTO_CI_Ratio register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x104 | 0x208 | CONN_SUTO_CI_RATIO | RW | Firmware programs this register with connection supervision timeout to connection interval ratio at the time of connection creation/ connection update. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| RFU | 15:13 | Not used | 0x0 |
| conn_suto_ci_ratio[12:0] | 12:0 | This register will have the ratio of the connection supervision timeout to the connection interval as programmed by the firmware before a connection creation or a connection update. The value is used by hardware to update the priority of a connection link that is nearing connection timeout due to packet miss. | 0x0000 |

## Connection Priority Config register

| Addr | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x106 | 0x20C | CONN_PRIORITY_CNFG | RW | This register is used by the firmware to override the hardware priority and set the priority of each connection link in the connection arbiter. The value of Zero has the least priority. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| priority_sel | 15 | If this bit is set to '1' connection arbiter will use the firmware programmed priority set in this register for each connection engine. | 0 |
| RFU | 14:12 | Not used | 0x0 |
| fw_priority3 | 11:9 | Firmware programmed priority for connection engine 3. | 0x0 |
| fw_priority2 | 8:6 | Firmware programmed priority for connection engine 2. | 0x0 |
| fw_priority1 | 5:3 | Firmware programmed priority for connection engine 1. | 0x0 |
| fw_priority0 | 2:0 | Firmware programmed priority for connection engine 0. | 0x0 |

## Connection Update New SUP_TO to CI ratio

| Addr | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1DA | 0x3B4 | CONN_UPDT_NEW_SU_CI_RATIO | RW | The Supervision Timeout to conn interval ratio that will be effective after the connection update instant. Firmware programs this register along with other connection update parameter registers. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| RFU | 15:13 | Not used. | 0x0 |
| conn_suto_ci_ratio_new | 12:0 | This register will have the new supervision timeout to connection interval ratio that the hardware will use after the connection update instant. Before the instant, the value in the register CONN_SUTO_CI_RATIO will be used by hardware. | 0x0000 |

## #Slave Window Offset Full register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x1DC | 0x3B8 | SL_WIN_OFF_FULL | RW | This register is programmed | 0x0000 |

| | | | | | | |
|---|---|---|---|---|---|---|
| | | | | with the maximum possible window widen value by the firmware when dsm entry during slave latency feature is enabled. This value is used by the hardware to calculate the next ce instant being reported to firmware. | | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| RFU | 15:6 | Not used. | 0x0 |
| sl_window_off_full | 5:0 | Value of maximum possible window widen programmed by the firmware when slave latency dsm feature is enabled. | 0x0000 |

# # Connection RSSI register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset | |
|---|---|---|---|---|---|---|
| 0x518 | 0xA30 | CONN_RX_RSSI | RO | This connection register holds the RSSI value of the last good (empty/non-empty) packet received by the specific connection. | 0x0000 | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| conn_rx_rssi | 15:0 | RSSI during the last good packet received in the specific connection. | 0x0000 |

# Connection Rx Memory read enable register

| Addr | Addr | Register Name | RW | Description | Reset | |
|---|---|---|---|---|---|---|

*Table continues on the next page...*

| 16-bit | 32-bit | | | | | |
|---|---|---|---|---|---|---|
| 0x522 | 0xA44 | LLH_MEM_READ_ENABLE_CONTROL_REG | WO | This register is used by the firmware to control read access to the connection Rx memory. | 0x0000 | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:14 | Not Used | 0x0 |
| conn_rxmem_rd_ctrl | 0 | When this bit is '1', connection Rx memory is enabled. | 0 |

## Tx memory configuration register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x27A | 0x4F4 | TXMEM_CONFIG | RW | This register fields can be set to configure the size of the data PDUs. | 0x700 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| RFU | 15:12 | Reserved | 0x0 |
| Number_of_packets_minus_1 | 11:9 | Maximum Number of Data PDUs in Tx FIFO. | 0x03 |
| Max_data_pdu_size | 8:0 | Maximum data packet length. | 0x100 |

## Tx memory configuration register 2

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x27C | 0x4F8 | TXMEM_CONFIG_2 | RW | This register fields can be set to configure the base address of the Control PDU. | 0x300 |

| Field | Bit | Description | Reset |
|---|---|---|---|

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| RFU | 15:11 | Reserved | 0x0 |
| Max_total_data_size | 10:0 | Total size of Data PDUs.<br>i.e. Maximum Number of Data PDUs * Maximum Data Packet Length as configured in TXMEM_CONFIG register.<br>It is base address of first Control PDU. | 0x300 |

### 64.5.1.1.4 Test and Debug Registers

Test and Debug Register Descriptions for the Bluetooth Link Layer

DTM control register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xB8 | 0x170 | LE_RF_TEST_MODE | RW | LE Direct Test Mode (DTM) configuration and control register. Used to control the direct test mode (DTM) operation. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:10 | Reserved for future use | 0 |
| dtm_conttx_en | 13 | Write:<br>1 – To enable continuous transmit mode<br>0 – To disable continuous transmit mode | 0 |
| Reserved | 12:10 | Not Used | |

| Test_type | 6 | Mixed Info Field.<br>Read:<br>1 – Indicates DTM test ON<br>0 – Indicates DTM test OFF<br>Write:<br>1 – To enable continuous receive mode<br>0 – To disable continuous receive mode | 0 |
| Test_frequency[5:0] | 5:0 | N = (F – 2402) / 2<br>Range: 0x00 – 0x27. Frequency Range : 2402 MHz to 2480 MHz | 0 |

## DTM receive packet count register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xBA | 0x174 | DTM_RX_PKT_COUNT | RO | Count of the number of LE packets received when device is configured in receive test mode. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Rx_packet_count[15:0] | 15:0 | Number of packets received in receive test mode. | 0 |

## Connection channel test control register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xBC | 0x178 | CONN_TEST_CONTROL | RW | Connection test control register. To introduce test behavior in the operation of connection. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:8 | Reserved for future use | 0 |
| Nonempty_pdu_rxnack | 7 | NACK the received packet, if rx packet is a NON-EMPTY PDU.<br>• Always NACK (no acknowledgement)<br>0 - No change from normal behavior | 0 |
| Empty_pdu_rxnack | 6 | NACK received packet, if rx packet is an EMPTY PDU.<br>• Always NACK<br>0 - No change from normal behavior | 0 |
| Nonempty_pdu_retx | 5 | Retransmit previous transmitted non-empty PDU irrespective of received NESN (whether acknowledged or not).<br>1 – Always retransmit<br>0 – No change from normal behavior | 0 |
| empty_pdu_retx | 4 | Retransmit previous transmitted empty PDU irrespective of received NESN (whether acknowledged or not).<br>1 – Always retransmit<br>0 – No change from normal behavior | 0 |
| Nonempty_crc_err | 3 | Cause CRC field error in transmitted non-empty PDU (only).<br>1 – Causes CRC error<br>0 – no change from normal behavior | 0 |
| empty_crc_err | 2 | Cause CRC field error in transmitted empty PDU (only).<br>1 – Causes CRC error<br>0 – no change from normal behavior | 0 |
| Nonempty_acc_err | 1 | Causes Access address error in transmitted non-empty PDU.<br>1 – Causes access address error<br>0 – no change from normal behavior | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| empty_acc_err | 0 | Causes Access address error in transmitted empty PDU.<br>1 – Causes access address error<br>0 – no change from normal behavior | 0 |

## Advertising channel test control register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xBE | 0x17C | ADVCH_TEST_CONTROL | RW | Advertising channel test control register. To introduce advertising channel test control operation. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:7 | Reserved for future use | 0 |
| Scan_tx_hdr | 6 | Corrupt the tx header of SCAN_REQ packet<br>1 – corrupt the address<br>0 – no change | |
| Peer_addr_err | 5 | Corrupt the peer address field in the SCAN_REQ packet<br>1 – corrupt the address<br>0 – no change | 0 |
| Rcv_txaddr_err | 4 | Corrupt the received transmit address type indication<br>1 - corrupt the tx address type (invert the bit)<br>0 – no change | 0 |
| Scnrsp_tx_err | 3 | Introduce CRC error in scan response packet.<br>1 – corrupt CRC<br>0 – no change | 0 |
| Rx_crc_err | 2 | Receive packet CRC error indication.<br>1 – Indicate CRC error of received packet, irrespective of good/bad CRC<br>0 – No change from normal behavior | 0 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Tx_crc_err | 1 | Corrupt transmit packet CRC, irrespective of packet type.<br>• Corrupt CRC<br>0 – No change in normal behavior<br>This is done by corrupting the crc_init value. | 0 |
| Tx_acc_err | 0 | Corrupt transmit packet access address.<br>• Corrupt access address<br>0 – No change in normal behavior | 0 |

## DTM Error Count

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xC0 | 0x180 | DTM_CRC_ERR_COUNT | RO | Indicates number of packets received with CRC error in the DTM mode | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| dtm_crc_err_pkt_count | [15:0] | DTM CRC error packet count. Used for Debug purpose only. | 0 |

## DTM transmit packet count register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xC2 | 0x184 | DTM_TX_PKT_COUNT | RO | Count of the number of LE packets transmitted when device is configured in transmit test mode. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| tx_packet_count[15:0] | 15:0 | Number of packets transmitted in transmit test mode. Used for Debug purpose only. | 0 |

## Channel Address register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xC4 | 0x188 | CH_ADDR/ TXRX_HOP | RO | Contains value of the transmit and receive hop frequency | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| reserved | 15 | Reserved for future use | 0 |
| hop_ch_rx | [14:8] | Receive channel index. Channel index on which previous packet is received. | 0 |
| reserved | 7 | Reserved for future use | 0 |
| hop_ch_tx | [6:0] | Transmit channel index. Channel index on which previous packet is transmitted. | 0 |

## DTM Length register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xCE | 0x19C | LE_DTM_TEST_LEN | RW | LE Direct Test Mode (DTM) length register. Used to configure the payload length of direct test mode (DTM) operation. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:8 | Reserved for future use | 0 |
| dtm_len | 7:0 | 0x00-0xFF (except 0x3F) Length in bytes of payload data in each packet<br>0x3F – Continuous Transmit mode. | 0 |

## Divider Value Register for SCA

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0x500 | 0xA00 | DIV_VAL_ADDR | RW | This value will go to divide by N module to derive various sleep clock frequencies | 0x1F3C |

| Reference Clock | Divider Value | Output Sleep Frequency(KHz) | PPM | SCA | |
|---|---|---|---|---|---|
| | Decimal | | | | Hex |
| 16.384 KHz | 7808 | 1E80 | 16.39351 | 580.59674 | |
| 7809 | 1E81 | 16.39135 | 448.73375 | 0 | |
| 7810 | 1E82 | 16.38920 | 317.56129 | 0 | |
| 7811 | 1E83 | 16.38722 | 196.25739 | 1 | |
| 7812 | 1E84 | 16.38501 | 61.54619 | 4 | |
| 7813 | 1E85 | 16.38287 | -69.19713 | 4 | |
| 7814 | 1E86 | 16.38097 | -185.16635 | 1 | |
| 7815 | 1E87 | 16.37870 | -323.70446 | 0 | |
| 7816 | 1E88 | 16.37668 | -446.48984 | 0 | |
| 16 KHz | 7996 | 1F3C | 16.00811 | 507.13706 | |
| 7997 | 1F3D | 16.00610 | 380.94506 | 0 | |
| 7998 | 1F3E | 16.00414 | 258.94704 | 0 | |
| 7999 | 1F3F | 16.00221 | 137.93902 | 2 | |
| 8000 | 1F40 | 15.99992 | -4.79998 | 7 | |
| 8001 | 1F41 | 15.99786 | -133.74211 | 2 | |
| 8002 | 1F42 | 15.99585 | -259.13283 | 0 | |
| 8003 | 1F43 | 15.99392 | -380.01553 | 0 | |
| | 8004 | 1F44 | 15.99192 | -505.02482 | |

A macro ‘SCA_DRIFT “is used to select the clock source for the Sleep Clock.

When the SCA_DRIFT macro is enabled then the sleep clock source is derived from the 64MHz based on the register DIV_VAL_ADDR setting. Otherwise sleep clock source is the on board 32.768 KHz

From 64 MHz of RF clock either 16 KHz or 16.384 KHz clock is derived using DCM (Digital Clock Manager, clock multiplier by 2) and a clock divider (divide by N). 64 MHz clock is given to DCM and this multiplied clock of 128 MHz is given to divide by N module. With 64 MHz clock only, it was not possible to cover lower, middle and upper range of required SCA (0 to 7) that led to use a DCM to get a higher clock and desired SCA values.

Clock divider value is given into a Programmable Read/Write register DIV_VAL_ADDR, whose address is 0x500 for 16 bit address bus.

Config.xml file is having all power up configuration parameters for BlueLitE IP. This will be loaded into Hardware after Reset.

For the validation, In order to introduce SCA other than '0' which is by default configuration of BlueLitE IP, one has to change corresponding "sca" field in config.xml file also. E.g. if one has selected SCA of 4 from table 2 given, then DIV_VAL_ADDR has to be programmed with 0x1E84 for positive ~61 PPM or 0x1E85 for negative ~69 PPM and "sca" field in config.xml has to be updated with 0x04.

Whenever SCA value is chosen from sleep clock frequency of 16 KHz, at that time internal adjustment for sleep clock frequency is not required. For that "clock_config" field in config.xml has to be updated with 0xA020.

## DTM 2 wire UART *Baud rate configuration*

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x580 | 0xB00 | DTM_2WIRE_CONFIG | RW | This value will go to different baud rate generator module for DTM 2 wire UART. | 0x006F |

| Field | Bit | Description | Reset |
|---|---|---|---|
| dtm_2wire_baud_config | 15:0 | This value will be given to baud clock generator module. For different input clock frequency to LLH, this value will be different to generate corresponding baud clock as mentioned in below table. | 0x006F |

| Radio clock | Baud rate | Configuration Value |
|---|---|---|
| 26 MHz | 1200 | 0x2A3B |
| | 2400 | 0X151E |
| | 9600 | 0X0546 |
| | 14400 | 0X0384 |
| | 19200 | 0X02A1 |
| | 38400 | 0X0152 |
| | 57600 | 0X00E1 |
| | 115200 | 0X006F |
| 64 MHz | 1200 | 0X19FA |

*Table continues on the next page...*

| | | |
|---|---|---|
| | 2400 | 0X0CFE |
| | 9600 | 0X033E |
| | 14400 | 0X0229 |
| | 19200 | 0X019E |
| | 38400 | 0X00D0 |
| | 57600 | 0X008A |
| | 115200 | 0X0042 |

Note: For lec_top (LLH + PHY) environment input frequency is 64 MHz. Value mentioned on above table for 64 MHz is w.r.t 16 MHz because we divide 64 MHz value by 4 internally. This 16 MHz derived value is given as an input to LLH and used for further calculation.

## DTM Offset Configuration Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x118 | 0x230 | DTM_OFFSET_CONFIG | RW | Contains configurable parameters for DTM function enhancement request. | 0x012D |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:11 | Reserved for future use. | |
| dtm_offset_us_buffer | 10:1 | Represents TIFS value ‘150’ in the calculation of dtm offset. | 0x96 |
| dtm_offset_en | 0 | If set to 1, DTM offset enhancement is enabled.<br>If set to 0, DTM offset enhancement is disabled. | 0x1 |

- 

## DTM Transmit Packet Configuration Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x11A | 0x234 | DTM_TX_PKT_CONFIG | RW | Configures number of DTM packets to be transmitted when DTM Tx operation is triggered and automatically | 0x0000 |

| | | | | | |
|---|---|---|---|---|---|
| | | | | stops the DTM Tx operation after that many number of packets are transmitted. | |

| Field | Bit | Description | Reset |
|---|---|---|---|
| dtm_tx_pkt_config[15:0] | 15:0 | If this field value is non-zero, it represents number of DTM packets to be transmitted when dtm_start command is received. DTM Tx operation is automatically stopped when DTM Tx packet count equals to the configured value.<br>If this field value is zero, DTM continues to transmit packets till dtm_stop command is issued. | 0 |

## DTM Expected Receive Packet Length Register

- 

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x11C | 0x238 | DTM_EXP_RX_LEN | RW | Contains configurable parameters for DTM timeout feature. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:9 | Reserved for future use. | |
| dtm_exp_rx_length | 8:1 | Configured length value for DTM receiver. | 0x00 |
| dtm_exp_rx_len_en | 0 | If set to 1, DTM timeout feature is enabled.<br>If set to 0, DTM timeout feature is disabled. | 0x0 |

## Packet Payload Status Register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x11E | - | PKT_PAYLOAD_STATUS | RO | Contains CRC status and Payload length value of received packet. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:9 | Reserved for future use. | |
| crc_status | 8 | Contains the value of CRC status of the received packet. Updates each time when packet reception is over. | 0x0 |
| payload_length | 7:0 | Contains the value of payload length field. Updated each time when packet reception is over. | 0x00 |

## Packet RSSI Status Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x120 | - | PKT_RSSI_STATUS | RO | Contains RSSI value for the received packet. | 0x000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| pkt_rssi_status | 15:0 | Contains the RSSI value of the received packet. Updated each time when packet reception is over. | 0x0000 |

### 64.5.1.1.5 Interface Registers

Interface Register Descriptions for the Bluetooth Link Layer

Receive trigger control register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0XFC | 0X1F8 | RECEIVE_TRIG_CTRL | RW | Receivers trigger control register. The threshold value for access address match, the access match trigger timeout is programmed to this register by firmware. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| Acc_trigger_timeout | 15:8 | If access address match does not occur then within this time from the start of receive operation, the receive operation times out and stops. An internal counter value of 1usec resolution is continuously compared with the value programmed.<br>Max value :0Xff | 0 |
| tim_adj_trig | 7 | Not used –RFU | 0 |
| | 6 | RFU | |
| Acc_trigger_threshold | 5:0 | Access address match threshold value. Number of bits of access address that should match with the expected access address to trigger an access code match.<br>Max value : 32 (for 32-bit access address)<br>Lower values may be programmed for bad radios or channels but care must be taken to ensure there are no 'false' matches due to reduced number of bits required to match.<br>Note : BQB spec mandates this to be 32. So ensure that the standard versions have 32. For debugging or RF tuning, we can experiment with smaller values. | 0 |

## Transmit/Receive data delay Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xC8 | 0x190 | TX_RX_ON_DELAY | RW | Controls the delay in link layer from internal reference point, to start the transmit and receive operation. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Txon_delay[7:0] | 15:8 | Transmit delay – Delay from internal trigger of transmit to transmission of first bit on air. | 0x00 |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| | | It is used to control the T_IFS. The delay is in resolution of 1 microsecond. | |
| Rxon_delay[7:0] | 7:0 | Receive delay – Delay from start of receive to expected first bit of receive packet at the controller. Used to control the turn on time of radio to optimize on power. The delay is in resolution of 1 microsecond. | 0x00 |

## Transmit/receive synthesizer delay register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0xCC | 0x198 | TX_RX_SYNTH_DELAY | RW | Controls the link layer behavior after waiting for RF synthesizer settling time. The delay relates to the PLL settling time, from the trigger to start transmit or receive operation. The action to be taken at the expiry of this delay is specific to each radio (e.g. we may set an external control pin to the radio). | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Tx_synth_delay[7:0] | 15:8 | Transmit synthesizer delay – Delay from start of transmit to stabilization of PLL. This may be used if any radio specific operation needs to be performed after PLL stabilization before bit transmission. | 0x00 |
| Rx_synth_delay[7:0] | 7:0 | Receive synthesizer delay – Delay from start of receive to receiver synthesizer stability. | 0x00 |

## RSSI Register

| Addr 16-bit | Addr 32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|

*Table continues on the next page...*

| | | | | | |
|---|---|---|---|---|---|
| 0xD8 | 0x1B0 | RADIO_RSSI_READ | RO | Indicates the RSSI value read from the radio for the last packet received.<br>Mixed-info-field/register | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Rssi_data | 15:0 | Indicates the RSSI value read from the radio for the last packet received. The meaning is specific to the RF IC used.<br>Mixed-info-field/register | 0x0 |

## RF_ACTIVE_PERIOD register

| Addr<br>16-bit | Addr<br>32-bit | Register Name | RW | Description | Reset |
|---|---|---|---|---|---|
| 0x5A | 0x0B4 | rf_active_period | RW | Register to specify the time offset before the start of a transceiver operation (i.e., a Tx/Rx) at which "RF_ACTIVE" output signal shall be asserted by the LLH. The purpose of the RF_ACTIVE signal is to indicate to the host of any upcoming transceiver activity. The host may schedule not to do any power-intensive operations during this time to reduce the system peak power. The time offset is specified in the units of BT slots (625us). Note: RF_ACTIVE signal will be asserted at the specified time offset before a transceiver operation and remain asserted till the end of the operation. | 0x0000 |

| Field | Bit | Description | Reset |
|---|---|---|---|
| Reserved | 15:7 | RFU | xx |
| rf_active_polarity | 6 | Polarity bit for rf_active<br>0: active high<br>1: active low. | |

*Table continues on the next page...*

| | | | |
|---|---|---|---|
| rf_active_slots | 5:0 | Number of BT slots (625 us) in advance of the actual start of the slot (tx/Rx) to assert rf_active. ”rf_active” is always de-asserted when the value is 6’h0 (all zeros) and always asserted when the value is 6’h3F(all ones) Therefore the Min. value is .625ms<br>and the Max value is 62*. 625ms. | 0 |

## 64.5.1.1.6 Instruction Set

Instruction Set Description for the Bluetooth Link Layer

| Command | Opcode | Description |
|---|---|---|
| START_ADV | 0x40 | Start Advertiser operation.<br>The associated Advertiser configuration registers are programmed before the command is issued. |
| STOP_ADV | 0x41 | Stop advertiser operation. |
| START_SCAN | 0x42 | Start scanner operation.<br>The associated configuration registers must be programmed before the command is issued. |
| STOP_SCAN | 0x43 | Stop the scanner operation. |
| START_INIT | 0x44 | Start connection creation operation.<br>The associated configuration registers must be programmed before the command is issued. |
| STOP_INIT | 0x45 | Cancel connection creation operation. |
| DTM_TX_START | 0x46 | Start Direct Test Mode Transmit Test.<br>The associated configuration registers must be programmed before the command is issued. |
| DTM_RX_START | 0x47 | Start Direct Test Mode Receive Test.<br>The associated configuration registers must be programmed before the command is issued. |
| DTM_STOP | 0x48 | Stop Direct Test Mode. |
| UPDATE_CHAN_MAP | 0x4B | Update channel map for the connection. |
| UPDATE_CONN_INSTANT | 0x4C | Start connection update procedure for the connection. |
| PACKET_RECEIVED | 0x4D | Indicates a received connection packet is read by firmware from connection receive FIFO. |
| ENTER_DSM | 0x50 | Enter deep sleep mode. |

*Table continues on the next page...*

| | | |
|---|---|---|
| ENTER_SM | 0x51 | Enter sleep mode. |
| EXIT_SM | 0x52 | Exit sleep mode |
| ENC_CLK_ON | 0x53 | Turn on clock to encryption block |
| ENC_CLK_OFF | 0x54 | Turn off clock to encryption block |
| ADV_CLK_ON | 0x55 | Turn on clock to advertiser block in NAP mode. |
| ADV_CLK_OFF | 0x56 | Turn off clock to advertiser block in NAP mode. |
| SCAN_CLK_ON | 0x57 | Turn on clock to scanner block in NAP mode. |
| SCAN_CLK_OFF | 0x58 | Turn off clock to scanner block in NAP mode. |
| INIT_CLK_ON | 0x59 | Turn on clock to initiator block in NAP mode. |
| INIT_CLK_OFF | 0x5a | Turn off clock to initiator block in NAP mode. |
| CONN_CLK_ON | 0x5b | Turn on clock to connection block in NAP mode. |
| CONN_CLK_OFF | 0x5c | Turn off clock to connection block in NAP mode. |
| UPDATE_CONN | 0x68 | Update connection parameters. Deprecated. |
| RC_ANCHOR_POINT | 0x69 | Instruct LLH to check the validity of the set and recalculate the new connection anchor point parameter if valid. |
| ENTER_AUTO_DSM | 0x6A | Indicates CPU is idle. |
| KILL_CONN | 0x70 | Kill connection immediately. |
| KILL_CONN_AFTER_TX | 0x71 | Kill connection after a transmit operation is over. |
| RESET_US_COUNTER | 0xc3 | Reset microsecond counter |
| RESP_TIMER_ON | 0x72 | Start PDU response timer.<br><br>The PDU_RESP_TIMER register must be programmed with timeout value before issuing this command. |
| RESP_TIMER_OFF | 0x73 | Stop PDU response timer. |
| RESET_READ_PTR | 0x74 | Reset the white list memory read pointer to 0. |
| *CONN_PING_TIMER_ON | 0x75 | Start connection ping timer |
| *CONN_PING_TIMER_OFF | 0x76 | Stop connection ping timer |
| ENTER_DSM_SHUTDOWN | 0x77 | Enter deep sleep mode with shutdown |
| STORE_START | 0x78 | Firmware triggers the store process |
| RESTORE_START | 0x79 | Firmware triggers the restore process |
| DATA_RESTORE_ON | 0x7A | Firmware data restore enable |
| DATA_RESTORE_OFF | 0x7B | Firmware data restore disable |
| START_RPA_TIMER | 0x7C | Start Privacy RPA timer |
| STOP_RPA_TIMER | 0x7D | Stop Privacy RPA timer |
| START_RPA_GEN | 0x7E | Start RPA address generation |
| SOFT_RESET | 0x80 | Software reset. Resets all the hardware registers (except a few registers related to radio initialization). |
| LOAD_RAND_NUM | 0x8C | Load random seed to LFSR for RPA generation |

## 64.5.2 802.15.4 Link Layer Controller

### 64.5.2.1 Introduction

The 802.15.4 Link Layer Controller implements all hardware functionality of the 802.15.4 Link Layer.

### 64.5.2.2 Overview

The 802.15.4 Link Layer implementation is divided into software and hardware components. The 802.15.4 Link Layer Controller represents the hardware component of the link layer. Link Layer hardware functionality is further sub-divided into functional blocks. These blocks include:

- Packet Processor block.
- Sequence Manager block.
- Packet Storage block.
- Event Timer block.
- Interrupts block.
- Clear Channel Assessment/Energy Detect/Link Quality Indication block.
- Bit Streaming Mode block.

Together, these blocks implement and accelerate critical functions of the 802.15.4 Link Layer. The non-timing critical functions are implemented in software on a MCU.

### 64.5.2.3 Block Diagram

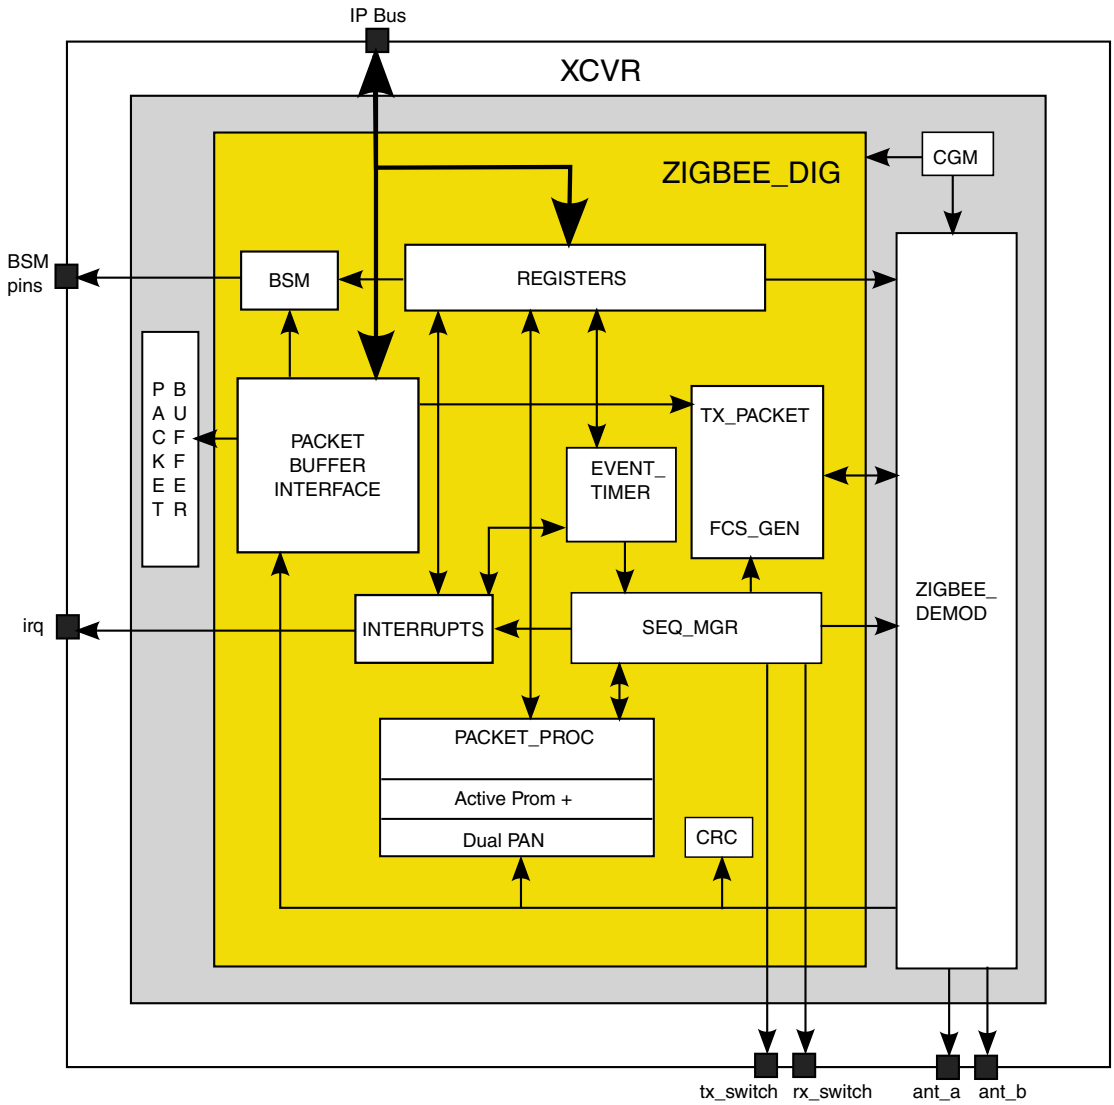

**Figure 64-138. 802.15.4 Link Layer Controller Block Diagram**

### 64.5.2.4 Functional Description

#### 64.5.2.4.1 Packet Processor

##### 64.5.2.4.1.1 Introduction

The 802.15.4 Packet Processor performs sophisticated hardware filtering of the incoming received packet, to determine whether the packet is both PHY- and MAC-compliant, whether the packet is addressed to this device, and if the device is a PAN Coordinator, whether a message is pending for the sending device. The packet processor greatly reduces the packet filtering burden on software, allowing software to tend to higher-layer tasks with a lower latency and smaller software footprint.

**Table 64-42. References**

#### *64.5.2.4.1.1.1 Overview*

The 802.15.4 Packet Processor performs aggressive hardware filtering of the incoming packet as it is being received, to increase battery life by not awakening the MCU to process packets which are non-compliant or not addressed to the device, or that violate the 802.15.4 MAC Frame structure. The advanced frame parsing enables the sequence manager to handle complex sequences, by, for example, determining whether a receive frame requires an acknowledge, and generating the Sequence Number for that acknowledge, so that the transmit/receive combination sequence can be executed without any MCU intervention. Finally, the packet processor includes a hardware accelerator that allows the device to handle a critical timing requirement that had been problematic for 8-bit MCU's in the past: the quick-turnaround requirement for an indirect queue-lookup to determine the correct response to an end device sending a data polling request. The packet processor contains a register-based table of end devices which have messages pending, allowing a single-cycle hardware table lookup to be performed, and a minimum-turnaround-time acknowledge packet to be sent to the end device without MCU intervention. The packet processor also includes support for Dual PAN mode, which allows the device to simultaneously reside on 2 networks, with 2 separate IEEE addesses. And the packet processor also supports Active Promiscuous mode, which allows address filtering rules to be bypassed, while still enabling the device to automatically acknowledge packets which are addressed to the device.

#### 64.5.2.4.1.1.2 Features

- Aggressive packet filtering to enable long, uninterrupted MCU sleep periods
- Fully compliant with both 2003 and 2006 versions of the 802.15.4 wireless standard
- Supports all Frame Types, including reserved types
- Supports all valid 802.15.4 Frame Lengths
- Enables auto-Tx Acknowledge frames (no MCU intervention) by parsing of Frame Control Field and Sequence Number
- Supports all Source and Destination Address modes, and also PAN ID Compression
- Supports Broadcast address for PAN ID and short address mode
- Supports “Promiscuous” mode, to receive all packets regardless of address- and rules-checking
- Allows Frame Type-specific filtering (e.g., reject all but Beacon frames)
- Supports SLOTTED and non-SLOTTED modes
- Includes special filtering rules for PAN Coordinator devices
- Enables minimum-turnaround TX-Acknowledge frames for data-polling requests by automatically determining message-pending status
- Assists MCU in locating pending messages in its indirect queue for data-polling end devices
- Assists MCU in determining if a poll request originated from a valid child end device
- Makes available to MCU detailed status of frames which fail address- or rules-checking
- Supports Dual PAN mode, allowing the device to exist on 2 PAN’s simultaneously
- Supports 2 IEEE addresses for the device
- Supports Active Promiscuous Mode
- Includes provisions to enable software support of 802.15.4e and 802.15.4-2015 frame types and versions

#### 64.5.2.4.1.1.3 Block diagram

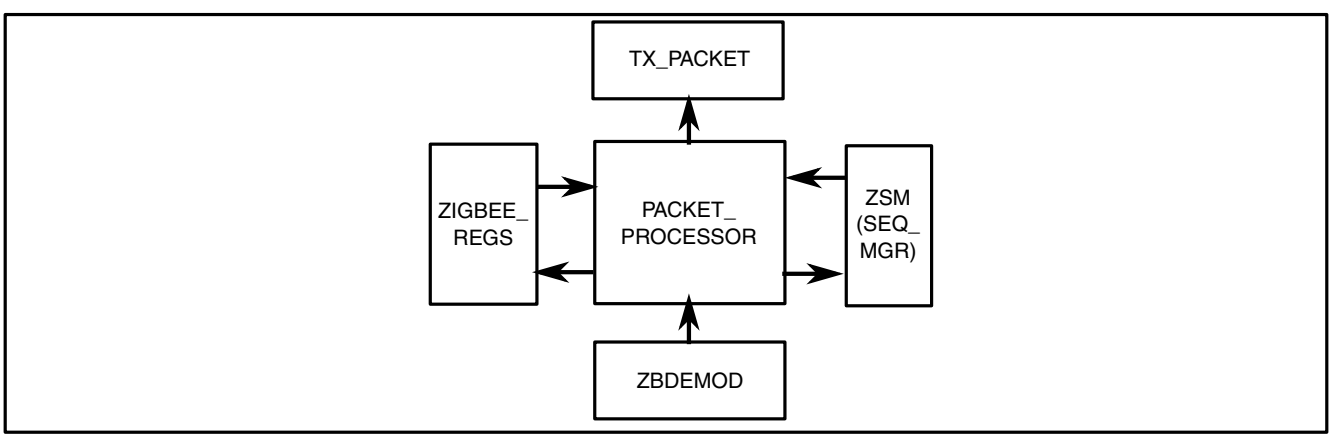

**Figure 64-139. Block diagram**

#### 64.5.2.4.1.2 Memory Map and register definition

Numerous registers exist to provide configuration and status for the 802.15.4 Packet Processor.

The memory-mapped registers which affect the Packet Processor are described in the table below.

| Field | R/W | Description |
|---|---|---|
| PI | r | Poll Indication:<br>1: the received packet was a data request, regardless of whether a source-address table-match occured, and regardless of whether source-adress matching is enabled (see SRCADDR_EN bit);<br>0: the received packet was not a data request<br>PI is a read-only bit. |
| SRCADDR | r | If Source Address Management is engaged, meaning at least one of the following bits is set:<br>• SAP0_EN<br>• SAA0_EN<br>• SAP1_EN<br>• SAA1_EN<br>then SRCADDR will be set to 1 if the packet just received is a poll request (PI=1), and at least one of the following conditions is met:<br>• SAP0_EN && SAP0_ADDR_PRESENT<br>• SAA0_EN && SAA0_ADDR_ABSENT<br>• SAP1_EN && SAP1_ADDR_PRESENT<br>• SAA1_EN && SAA1_ADDR_ABSENT<br>If SRCADDR=1, this indicates to SW that the Packet Processor has determined that an auto-TxACK frame must be transmitted with the FramePending subfield of the FrameControlField set to 1. HW will assemble and transmit this Ack packet.<br>If the above conditions are not met, SRCADDR will be cleared to 0. |
| SAP0_EN | rw | 1: Enables SAP0 Partition<br>0: Disables SAP0 Partition |
| SAA0_EN | rw | 1: Enables SAA0 Partition<br>0: Disables SAA0 Partition |
| SAP1_EN | rw | 1: Enables SAP1 Partition<br>0: Disables SAP1 Partition |
| SAA1_EN | rw | 1: Enables SAA1 Partition<br>0: Disables SAA1 Partition |
| SAA0_START[6:0] | rw | First Index of SAA0 partition. |
| SAP1_START[6:0] | rw | First Index of SAP1 partition. |
| SAA1_START[6:0] | rw | First Index of SAA1 partition. |
| SAM_CHECKSUM[15:0] | | Software-computed source address checksum, to be installed into a table index |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| SAM_INDEX[6:0] | | Contains the table index to be enabled or invalidated. Software must ensure that the index is within the range of the desired partition. |
| SAM_INDEX_WR | w | For 32-bit writes, SAM_INDEX_WR must be set to indicate that the table entry specified by SAM_INDEX[6:0] is to be written; if SAM_INDEX_WR=0, the table entry is not written, but the SAM_INDEX[6:0] register is updated. For 8-bit writes, this bit is ignored. |
| SAM_INDEX_EN | w | Enable the index selected by SAM_INDEX[6:0] for searching. |
| SAM_INDEX_INV | w | Invalidate the index selected by SAM_INDEX[6:0] |
| FIND_FREE_IDX | w | After modifying Valid bits (enabling or invalidating), write this bit to 1 to force HW to update the “First Free Index” registers to account for the changed Valid bits. This HW update process takes 4us. SW can poll SAM_BUSY to determine when the table update is complete. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate. |
| SAM_BUSY | r | HW is in the process of updating the Source Address table, either in response to a poll indication from the packet processor, or due to SW setting FIND_FREE_IDX=1. In the latter case, SW should poll SAM_BUSY until low before accessing the “First Free Index” registers. Read-only bit. |
| INVALIDATE_ALL | w | Writing a 1 to this bit clears all 128 Valid bits. Invalidates the entire table. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate. |
| SAP0_1ST_FREE_IDX[6:0] | r | First non-enabled (invalid) index in the SAP0 partition. Read-only. |
| SAA0_1ST_FREE_IDX[6:0] | r | First non-enabled (invalid) index in the SAA0 partition. Read-only. |
| SAP1_1ST_FREE_IDX[6:0] | r | First non-enabled (invalid) index in the SAP1 partition. Read-only. |
| SAA1_1ST_FREE_IDX[6:0] | r | First non-enabled (invalid) index in the SAA1 partition. Read-only |
| PROMISCUOUS | rw | Bypasses most packet filtering.<br>1: all packet filtering except frame length checking (FrameLength>=5 and FrameLength<=127) is bypassed.<br>0: normal mode<br>**Note:** Promiscuous Mode is not intended for Sequence TR with RXACKRQD=1 (auto-RXACK mode), because the contents of auto-RXACK packets are not stored in the Packet Buffer. If auto-RXACK packets are to be stored in the PB, use ACTIVE_PROMISCUOUS instead. |
| PANCORDNTR0 | rw | Device is a PAN Coordinator on PAN0. Allows device to receive packets with no destination address, if Source PAN ID matches. |
| MACPANID0[15:0] | rw | MAC PAN ID for PAN0. The packet processor compares the incoming packet's Destination PAN ID against the contents of this register to determine if the packet is addressed to this device; or if the incoming packet is a Beacon frame, the packet processor compares the incoming packet Source PAN ID against this register. Also, if PANCORDNTR0=1, and the incoming packet has no Destination Address field, and if the incoming packet is a Data or MAC Command frame, the packet processor compares the incoming packet Source PAN ID against this register. |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| MACSHORTADDRS0[15:0] | rw | MAC Short Address for PAN0, for 16-bit destination addressing mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device. |
| MACLONGADDRS0[63:0] | rw | MAC Long Address for PAN0, for 64-bit destination addression mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device. |
| BEACON_FT | rw | 1: Beacon frame type enabled.<br>0: reject all Beacon frames |
| ACK_FT | rw | 1: Acknowledge frame type enabled.<br>0: reject all Acknowledge frames |
| DATA_FT | rw | 1: Data frame type enabled.<br>0: reject all Data frames |
| CMD_FT | rw | 1: MAC Command frame type enabled.<br>0: reject all MAC Command frames |
| LLDN_FT | rw | 1: LLDN frame type enabled (Frame Type 4).<br>0: reject all MAC Command frames |
| MULTIPURPOSE_FT | rw | 1: MULTIPURPOSE frame type enabled (Frame Type 5).<br>0: reject all MAC Command frames |
| EXTENDED_FT | rw | 1: EXTENDED frame type enabled (Frame Type 7).<br>0: reject all MAC Command frames |
| NS_FT | rw | 1: Not-specified (reserved) frame type enabled. No packet filtering is performed, except for frame length checking (FrameLength>=5 and FrameLength<=127).<br>0: reject all reserved frame types |
| EXTENDED_FCS_CHK | rw | Verify FCS on Frame Type Extended<br>1: Packet Processor will check FCS at end-of-packet based on packet length derived from PHR, for Frame Type EXTENDED<br>0: Packet Processor will not check FCS for Frame Type EXTENDED (default) |
| ACTIVE_PROMISCUOUS | rw | 1: Provide Data Indication on all received packets under the same rules which apply in PROMISCUOUS mode, however acknowledge those packets under rules which apply in non-PROMISCUOUS mode<br>0: normal operation (Default) |
| FRM_VER_FILTER[3:0] | rw | The incoming packet's Frame Control Field is parsed to obtain the FrameVersion subfield, and that value is compared against this register, in accordance with the following:<br>xxx1: Accept received packets with FrameVersion=00<br>xx1x: Accept received packets with FrameVersion=01<br>x1xx: Accept received packets with FrameVersion=10<br>1xxx: Accept received packets with FrameVersion=11<br>These filtering rules apply to Beacon, Acknowledge, Data, and MAC Command Frame Types, since these frame types require a 2-octet Frame Control Field which embeds a 2-bit FrameVersion subfield. |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | Later frame types introduced in the 802.15.4e addendum (LLDN, Multipurpose) don't guarantee a FrameVersion subfield with the original meaning, so these filtering rules do not apply to these frame types. See registers LLDN_FT and MULTIPURPOSE_FT.<br>For Acknowledge frames, FrameVersion bits are ignored by the Packet Processor, irrespective of FRM_VER_FILTER. |
| MACPANID1[15:0] | rw | MAC PAN ID for PAN1. The packet processor compares the incoming packet's Destination PAN ID against the contents of this register to determine if the packet is addressed to this device; or if the incoming packet is a Beacon frame, the packet processor compares the incoming packet Source PAN ID against this register. Also, if PANCORDNTR1=1, and the incoming packet has no Destination Address field, and if the incoming packet is a Data or MAC Command frame, the packet processor compares the incoming packet Source PAN ID against this register. |
| MACSHORTADDRS1[15:0] | rw | MAC Short Address for PAN1, for 16-bit destination addressing mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device. |
| MACLONGADDRS1[63:0] | rw | MAC Long Address for PAN1, for 64-bit destination addression mode. The packet processor compares the incoming packet's Destination Address against the contents of this register to determine if the packet is addressed to this device. |
| ACTIVE_NETWORK | rw | Selects the PAN on which to transceive, by activating a PAN parameter set (PAN0 or PAN1). In Manual Dual PAN mode (or Single PAN mode), this bit selects the active PAN parameter set (channel and addressing parameters) which governs all autosequences. In Auto Dual PAN mode, this bit selects the PAN on which to begin transceiving, latched at the point at which DUAL_PAN_DWELL register is written.<br>1: Select PAN1<br>0: Select PAN0 (Default) |
| DUAL_PAN_AUTO | rw | Activates automatic Dual PAN operating mode. In this mode, PAN-switching is controlled by hardware at a pre-programmed rate, determined by DUAL_PAN_DWELL.<br>1: Auto Dual PAN Mode<br>0: Manual Dual PAN mode (or Single PAN mode). Default.<br>Whenever DUAL_PAN_AUTO=0, CURRENT_NETWORK=ACTIVE_NETWORK at all times. <tr><td>11</td><td>50ms</td><td>50ms - 3.2seconds</td></tr>
</table>
<br>A write to DUAL_PAN_DWELL also causes the value of ACTIVE_NETWORK to get latched into the hardware. This latched value will be the starting point for the automatic dual-pan mode (i.e., start on PAN0 or on PAN1). The starting value takes effect immediately (if sequence is underway and DUAL_PAN_AUTO=1), or is otherwise delayed until sequence starts and DUAL_PAN_AUTO=1.</td></tr>
<tr><td>DUAL_PAN_REMAIN[5:0]</td><td></td><td>This read-only register indicates time remaining before next PAN switch in auto Dual PAN mode. The units for this register, depend on the PRESCALER setting (bits [1:0]) in the DUAL_PAN_DWELL register, according to the following table:<br><br>
<table>
<tr><th>DUAL_PAN_DWELL PRESCALER</th><th>DUAL_PAN_REMAIN UNITS</th></tr>
<tr><td>00</td><td>0.5ms</td></tr>
<tr><td>01</td><td>2.5ms</td></tr>
<tr><td>10</td><td>10ms</td></tr>
<tr><td>11</td><td>50ms</td></tr>
</table>
<br>The readback value indicates that between N-1 and N timebase units remain until the next PAN switch. For example, a DUAL_PAN_REMAIN readback value of 3, with a DUAL_PAN_DWELL PRESCALER setting of 2 (10ms), indicates that between 20ms (2*10ms) and 30ms (3*10ms), remain until the next automatic PAN switch.</td></tr>
<tr><td>RECD_ON_PAN0</td><td>r</td><td>Indicates the packet which was just received, was received on PAN0.<br><br>In Dual PAN mode operating on 2 different channels, RECD_ON_PAN0 will be set if CURRENT_NETWORK=0 when the packet was received, regardless of FILTERFAIL status.</td></tr>
</table>

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN0 will be set only if a valid packet was received on PAN0 (PAN0's FILTERFAIL_FLAG is deasserted). |
| RECD_ON_PAN1 | r | Indicates the packet which was just received, was received on PAN1.<br>In Dual PAN mode operating on 2 different channels, RECD_ON_PAN1 will be set if CURRENT_NETWORK=1 when the packet was received, regardless of FILTERFAIL status.<br>In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN1 will be set only if a valid packet was received on PAN1 (PAN1's FILTERFAIL_FLAG is deasserted). |
| FILTERFAIL_CODE[9:0] | r | Status of packet processor filtering. For incoming packets which have been rejected by the packet processor, FILTERFAIL_CODE will indicate which violated packet-filtering rule(s) led to the rejection. This is intended for debug only. The contents of this register are valid at the FILTERFAIL_IRQ interrupt. The packet processor maintains 2 independent copies of FILTERFAIL_CODE[9:0], one for each PAN. When reading this register, software can select for which PAN the FILTERFAIL_CODE applies, using the FILTERFAIL_PAN_SEL bit. See Appendix A. |
| FILTERFAIL_PAN_SEL | rw | 1: FILTERFAIL_CODE[9:0] will report the FILTERFAIL status of PAN1<br>0: FILTERFAIL_CODE[9:0] will report the FILTERFAIL status of PAN0 |
| LENIENCY[39:0] | rw | The LENIENCY register allows individual packet filtering rules to be overriden, on a rule-by-rule basis. In other words, a specific packet filtering rule, such as an address-mode check, which would result in an incoming packet being rejected, can be overridden by setting the corresponding bit in the LENIENCY register, which would then result in the packet being accepted. This is similar to PROMISCUOUS mode, except that it allows checks to be overridden individually. This will facilitate debug, and potentially allow the device to communicate with devices which may not be 100% MAC-compliant. The mapping of LENIENCY register bits to rules is shown in Appendix B of this document. |

#### 64.5.2.4.1.3 Functional Description

The packet processor is responsible for receiving symbols from the demodulator, combining them into octets, assembling the octets into packets, filtering the packets in compliance with the 802.15.4 wireless MAC standard, and storing the packets into the Packet Buffer (Packet RAM).

The packet processor parses the incoming packets on-the-fly to determine:

1. whether the packet is MAC-compliant, and if it is,
2. whether the packet is addressed to the end device.

The packet processor performs aggressive filtering on incoming packets, in order to reduce unnecessary MCU wake-ups, to allow longer MCU sleep durations, and to provide sufficient hardware automation so as to enable complex sequences to be executed by the sequence manager. The packet processor also includes hardware support for Dual PAN operation (allowing the device to reside on two networks simultaneously), and for Active Promiscuous mode (allowing the device to receive all packets, but acknowledging only those addressed to the device).

The 802.15.4 packet processor also includes functionality to allow a critical-timing requirement to be met, which in the past has been problematic for low-MIPS 802.15.4 receiving devices: the ability of a coordinator device to respond to a MAC Command data request from an end device, with an Acknowledge frame containing a FramePending bit accurately reflecting the presence of a message for the end device in the coordinator's indirect queue, or the absence of the end device in the coordinator's neighbor table, within the prescribed 192us window. This functionality is described in more detail in the Source Address Matching section.

#### *64.5.2.4.1.3.1 Packet Filtering Background*

The packet processor parses packets to verify compliance with the 802.15.4 MAC frame format. The basic MAC frame format is shown in the figure below.

<table>
<tr><td>Octets: 2</td><td>1</td><td>0/2</td><td>0/2/8</td><td>0/2</td><td>0/2/8</td><td>0/5/6/10/ 14</td><td>variable</td><td>2</td></tr>
<tr><td rowspan="2">Frame Control</td><td rowspan="2">Sequence Number</td><td>Destination PAN Identifier</td><td>Destination Address</td><td>Source PAN Identifier</td><td>Source Address</td><td rowspan="2">Auxiliary Security Header</td><td rowspan="2">Frame Payload</td><td rowspan="2">FCS</td></tr>
<tr><td colspan="4">Addressing fields</td></tr>
<tr><td colspan="7">MHR</td><td>MAC Payload</td><td>MFR</td></tr>
</table>

**Figure 64-140. MAC Frame Format**

The packet processor parses the incoming octets on the fly, as they are received. The Frame Control Field, two octets in length, contains subfields which encode "instructions" on how to parse the remainder of the MHR (MAC Header). The structure of the Frame Control Field is shown in the figure below.

| Bits: 0–2 | 3 | 4 | 5 | 6 | 7–9 | 10–11 | 12–13 | 14–15 |
|---|---|---|---|---|---|---|---|---|
| Frame Type | Security Enabled | Frame Pending | Ack. Request | PAN ID Compression | Reserved | Dest. Addressing Mode | Frame Version | Source Addressing Mode |

**Figure 64-141. Frame Control Field**

The packet processor utilizes the Frame Control Fields subfields in the following manner:

| FCF Subfield | Utilization by Packet Processor |
|---|---|
| FrameType | Interprets the remaining MHR as specific to Beacon, Ack, Data, Command, or Reserved frame types. Each frame type has a unique MHR structure, and so different parsing rules apply. |
| SecurityEnabled | If SecurityEnabled=1 and FrameVersion>0 (frame versions 2006 and later), an Auxiliary Security Header field will be present in the MHR and will need to be further parsed by the packet processor if this is a MAC Command frame (see Section Source Address Management below). There is no other use of SecurityEnabled by the packet processor. |
| FramePending | ignored by packet processor |
| Ack. Request | will be copied into the **pp_ack_request** signal to the sequence manager. An auto-TxAck frame will follow the incoming receive frame if necessary conditions are met |
| PAN ID Compression | used for addressing mode rules-checking and addressing field parsing. |
| Reserved | ignored by packet processor |
| Destination Addressing Mode | used for addressing mode rules-checking and addressing field parsing |
| FrameVersion | For Beacon, Data, and MAC Command frames, FrameVersion is checked against the allowed frame versions according to FRM_VER_FILTER<br>For Acknowledge frames, FrameVersion is ignored.<br>If SecurityEnabled=1 and FrameVersion>0 (frame versions 2006 and later), an Auxiliary Security Header field will be present in the MHR and the MHR will need to be further parsed by the packet processor if this is a MAC Command frame (see Section Source Address Management). |
| Source Addressing Mode | used for addressing mode rules-checking and addressing field parsing |

The Packet Processor parses the FrameType field of the Frame Control Field per the following table:

| Frame type value $b_2$ $b_1$ $b_0$ | Description |
|---|---|
| 000 | Beacon |
| 001 | Data |
| 010 | Acknowledgment |
| 011 | MAC command |
| 100–111 | Reserved |

**Figure 64-142. Frame Type Field**

Directly following the Frame Control Field is the Sequence Number field. The Sequence Number field of the MHR is captured by the packet processor. If an auto-TxAck frame follows the incoming receive frame, the captured Sequence Number will be copied to the transmitted Acknowledge packet, and the Packet Processor will insert FrameVersion=00 into the Frame Control Field of the transmitted frame, regardless of the received FrameVersion subfield of the original frame.

The Addressing Fields follow the Sequence Number. The format of the Addressing Fields depends upon the Source and Destination Addressing Mode subfields of the Frame Control Field. The Addressing Modes are defined in the table below:

| Addressing mode value $b_1$ $b_0$ | Description |
|---|---|
| 00 | PAN identifier and address fields are not present. |
| 01 | Reserved. |
| 10 | Address field contains a 16-bit short address. |
| 11 | Address field contains a 64-bit extended address. |

**Figure 64-143. Addressing Mode Fields**

The packet processor uses these Source and Destination Address Modes shown above, to extract the Source PAN ID and Address (if present), and the Destination PAN ID and Address (if present), from the MHR, according to the table below:

| FrameType | Destination Addressing Mode | Source Addressing Mode | PanID-Compression | Addressing Fields |
|---|---|---|---|---|
| Acknowledge only<br>(reject all other frame types) | 0 | 0 | 0 | None |
| Data or Command<br>(reject Ack and Beacon frames) | 2 or 3 | 0 | 0 | DstPanID + DstAddr |
| Beacon (all devices), or<br>Data or Command (PAN Coord Only)<br>(reject Ack frames) | 0 | 2 or 3 | 0 | SrcPanID + SrcAddr |
| Data or Command<br>(reject Ack and Beacon frames) | 2 or 3 | 2 or 3 | 0 | DstPanID + DstAddr + SrcPanId + SrcAddr |
| Reject all frames<br>(Illegal as per Section 7.2.2.1.5) | 0 | 0 | 1 | - |
| Reject all frames<br>(Illegal as per Section 7.2.2.1.5) | 2 or 3 | 0 | 1 | - |
| Reject all frames<br>(Illegal as per Section 7.2.2.1.5) | 0 | 2 or 3 | 1 | - |
| Data or Command<br>(reject Ack or Beacon frames) | 2 or 3 | 2 or 3 | 1 | DstPanID + DstAddr + SrcAddr |
| Reject all frames<br>(Illegal as per Section 7.2.2.1.6) | 1 | - | - | - |
| Reject all frames<br>(Illegal as per Section 7.2.2.1.8) | - | 1 | - | - |

The Source PAN ID and Address, and Destination PAN ID and Address, extracted by the packet processor, are then checked against the MACPANID, MACSHORTADDRS, and MACLONGADDRS register settings, depending on the FrameType of the incoming packet, to determine:

1. Is the addressing mode combination valid for this frame type?
2. Do the address fields indicate that the packet is indeed addressed to the end device?

The details on how the packet processor answers those 2 questions, are described in the following sections.

#### *64.5.2.4.1.3.2 Packet Filtering Detail*

The figure below is a high-level representation of the packet filtering performed by the 802.15.4 packet processor. The sections which follow provide more detail on the packet filter implementation.

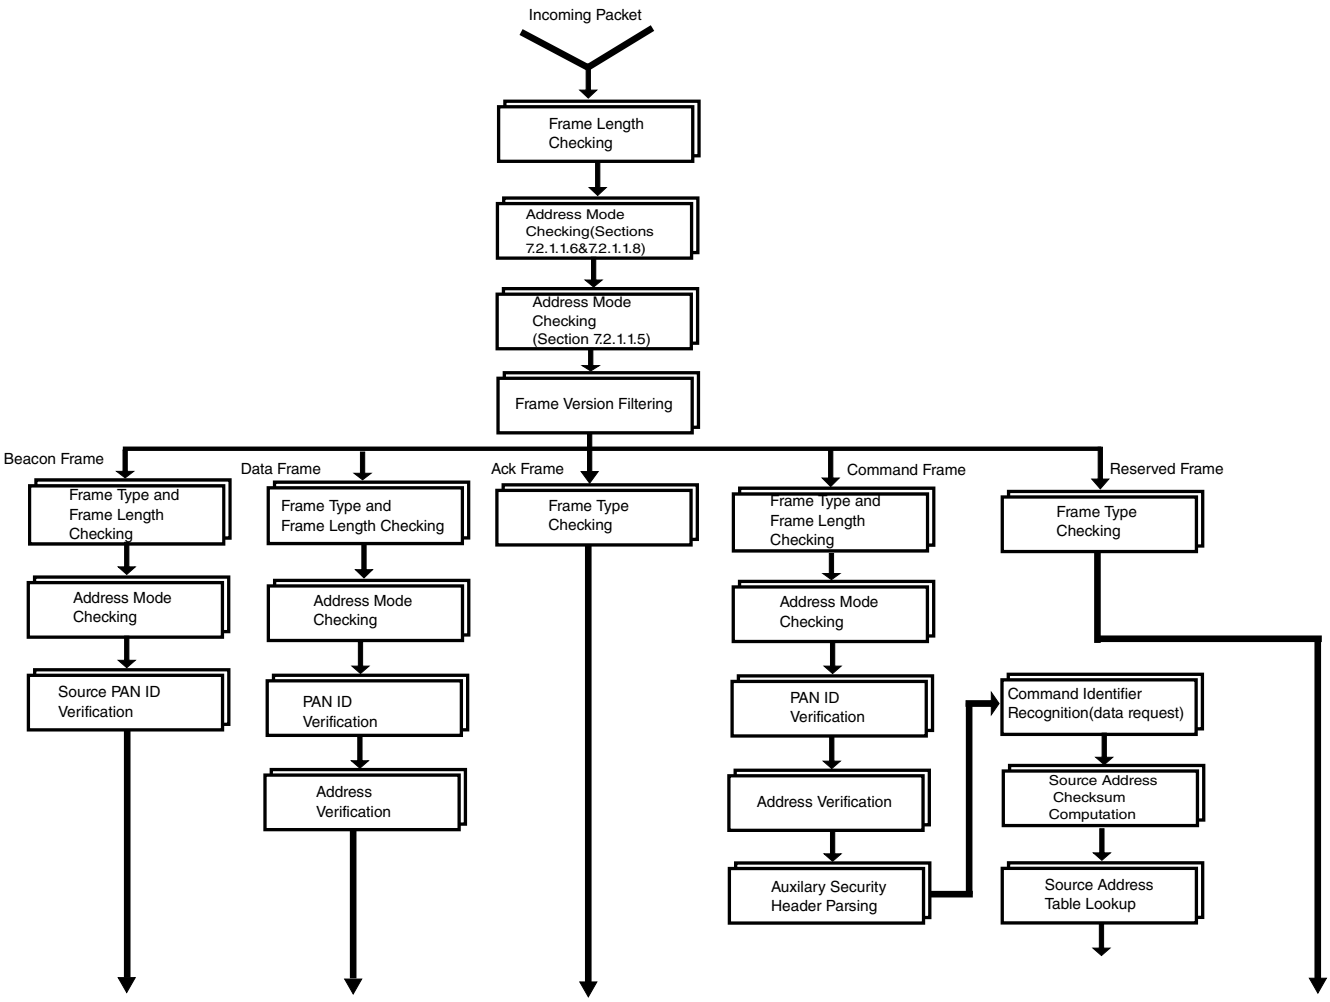

**Figure 64-144. Packet Filtering Flow Diagram**

## First-Stage Packet Filtering

The first stage of packet filtering examines the incoming packet, and implements basic rule-checking, based on the 2006 version of the 802.15.4 standard, and is applied to *all* frame types. First stage rule-checking is described in the table below:

| | Filtering Step | Description |
|---|---|---|
| 1 | Frame Length Checking | Check that all frames are at least 5 octets long (minimum frame length required by the standard), and no longer than 127 octets long (maximum frame length allowed by the standard). |
| 2 | Address Mode Checking (Sections 7.2.1.1.6 and 7.2.1.1.8) | Check that neither Source nor Destination Address Mode set to 1 (illegal addressing mode) |
| 3 | Address Mode Checking (Section 7.2.1.1.5) | Check for PAN ID Compression enabled, with either Source or Destination Address Mode set to 0 (illegal addressing mode) |
| 4 | FrameVersion Checking | Check that incoming packet's Frame Version is allowed based on FRM_VER_FILTER setting. (FRM_VER_FILTER is a programmable register, see Register Descriptions Section). |

Packets which pass first stage filtering, proceed to the second stage of packet filtering, which is *frame type-specific* filtering. Packets which fail initial rule checking are marked as rejected.

## Second-Stage Packet Filtering

The second stage of packet filtering is *frame type-specific*. Different variations of the MAC Header (MHR) apply to different frame types, so different parsing mechanisms apply to each.

**Note:** In the following section, the following references are to register bits; see Register Description Section for register descriptions: BEACON_FT, ACK_FT, DATA_FT, CMD_FT, NS_FT, PANCORDNTR, MACPANID, MACSHORTADDRS, and MACLONGADDRS.

1) For Beacon frames, these are the basic filtering steps:

- Check that Beacon frames are enabled by software (BEACON_FT)
- Check that FrameLength >= 9
- Check for illegal combinations of PAN ID Compression and Source/Destination Address Modes
- Verify the Source PAN ID matches MACPANID, or that MACPANID = 0xffff.

2) For Acknowledge frames, these are the basic filtering steps:

- Check that Ack frames are enabled by software (ACK_FT)
- If Sequence TR is active and RXACKRQD = 1, check the received Sequence Number matches the transmitted Sequence Number; FrameVersion bits are ignored, as per section 7.2.2.3.1 of the 802.15.4 standard.

**Note**: It is recommended to use Sequence TR to receive Acknowledge frames, not Sequence R. See Chapter ZSM Sequence Manager, Section Sequence TR (Transmit/ Receive).

3) For Data frames, these are the basic filtering steps:

- Check that Data frames are enabled by software (DATA_FT)
- Check that FrameLength >= 9
- Check for illegal combinations of Source and Destination Address Modes
- If PANCORDNTR=0, check for missing Destination Address field or present Source Address field
- If no Destination Address field (PANCORDNTR=1 only), check Source PAN ID matches MACPANID
- If Destination Address present, check Destination PAN ID matches MACPANID or broadcast (0xffff)
- If Short Destination Address field, check address matches MACSHORTADDRS or broadcast (0xffff)
- If Long Destination Address field, check address matches MACLONGADDRS.

4) For MAC Command frames, these are the basic filtering steps:

- Check that Command frames are enabled by software (CMD_FT)
- Check that FrameLength >= 9
- Check for illegal combinations of Source and Destination Address Modes
- If PANCORDNTR=0, check for missing Destination Address field or present Source Address field
- If no Destination Address field (PANCORDNTR=1 only), check Source PAN ID matches MACPANID
- If no Destination Address field (PANCORDNTR=1 only), capture Source PAN ID and Source Address for later use
- If Destination Address present, check Destination PAN ID matches MACPANID or broadcast (0xffff)
- If Short Destination Address field, check address matches MACSHORTADDRS or broadcast (0xffff)
- If Long Destination Address field, check address matches MACLONGADDRS.
- At end of the addressing field, if incoming packet's FrameVersion=0 or SecurityEnabled=0, capture the next octet (Command Identifier)
- At end of the addressing field, if incoming packet's FrameVersion!=0 and SecurityEnabled=1, parse the Auxiliary Security Header, then capture the next octet (Command Identifier)
- If Command Identifier indicates the MAC Command is a data request, compute a "Source Address Checksum" to uniquely identify the sending device.

#### *64.5.2.4.1.3.3 Source Address Management*

The 802.15.4 wireless MAC standard envisions a scenario whereby an end device may interrogate a coordinator as to whether the coordinator is storing data (i.e., a pending message) for the end device. The situation arises in a beacon-enabled network, when a coordinator includes in its transmitted beacon frame the MAC address of the end device in its “Pending Address Fields”. The “Pending Address Fields” are part of the required MAC payload of the beacon frame. The “Pending Address Fields” contain a list of end device addresses for which messages are pending. In this scenario, an end device which finds its address included in the “Pending Address Fields” of the received beacon frame, must respond to the beacon (coordinator) with a MAC Command of type “data request”. Alternatively, in non-beacon-enabled networks, an end device may periodically wake up and “poll” a coordinator, to determine if a message is pending for the end device. In either case, the coordinator stores messages for its end devices in its “indirect queue”. The coordinator must respond to an incoming MAC Command data request (which *must* have AckRequest=1 in its Frame Control Field), with an Acknowledge frame containing a FramePending subfield indicating the presence (or absence) of a message for the requesting end device, in the coordinator’s indirect queue. For a coordinator built around a low-MIPS MCU, a significant amount of MCU time is typically required, simply to ascertain whether a given end device has a message pending or not; the indirect queue can be quite large, and for 8-bit MCU’s, the queue must be searched byte-by-byte. This makes it difficult, or impossible, for an underpowered MCU to establish frame-pending status within the 192us RX-to-TX turnaround time required by the standard.

Also, coordinators may include, in software, a “Neighbor Table”, the contents of which consist of all the end devices with which the coordinator is in communication. The neighbor table requires periodic maintenance by coordinator (parent) software, as end devices (children) come and go within the network, join different parents, or simply never return. Child tables have limited capacity and parents need to create space for new devices that may show up. A timeout mechanism is the only way that can guarantee that child tables will eventually be cleaned up. Coordinator software must “age out” end devices with which there has not been recent communication. In order for an end device to refresh its status within its parent’s Neighbor Table, the end device may periodically send a “keepalive” message in the form of a MAC Data Poll Request. Upon receipt of such a poll request, the parent must search its neighbor table to determine if the source address of the end device is a valid table entry. If the end device exists in the table, an Acknowledgment packet must be transmitted to the end device, with the FramePending subfield set to 0, and coordinator software resets that end device’s timeout counter; if the child is not present in the table, an Acknowledgment packet must be transmitted to the end device, with the FramePending subfield set to 1, and the parent device will follow up by transmitting a “Leave Packet” to the end device, instructing the end device to sever its child status with the parent. The end device may opt to rejoin at a later time. Due to the

size of the parent's Neighbor table, the search a child's source address can be time consuming, and may not always be possible within the 192us RX-to-TX turnaround time required by the standard.

To alleviate both of these problems, the 802.15.4 packet processor includes hardware acceleration to expedite the source address table search, greatly relieving the software bottleneck during the critical 192us turnaround time. The table search acceleration consists of 2 components: 1) a search for the *presence* of a specific end device's source address, which expedites the process of determining whether a message is pending for the device; and 2) a search for the *absence* of a specific end device's source address, which expedites the process of determining whether the end device is a valid child of the parent.

The packet processor maintains a register table (128 deep, 16-bit wide). The table is divided into multiple partitions, one to perform the "Source Address Present" (SAP) search, and another to perform the "Source Address Absent" (SAA) search. In the SAP partition of the table, coordinator software will store the address of end devices for which it has a message pending; in the SAA partition of the table, coordinator software will store the address of end devices for which it is the parent. To reduce area, the address information is stored in a "compressed" format. Software compresses the address information, and stores it into the table partitions, during a non-critical time. Then, when the coordinator's packet processor receives a MAC Command data request, it extracts the source address information from the incoming packet, and compresses it using the *same* compression algorithm used by software to populate the source address table. The packet processor performs 2 steps simultaneously:

1. it compares the just-received, compressed source address information, or "checksum", against all of the enabled entries in the SAP partition of the table. If a match is found in the SAP partition, the packet processor *asserts* the **rx_frame_pending** signal to the transmit block (TX_PACKET), so that an auto-TxAck packet can be sent to the requesting end device, with the FramePending subfield set to 1, indicating that the end device has a message pending in the coordinator's indirect queue. A message packet from the coordinator to the end device will follow.
2. it compares the just-received, compressed source address information, or "checksum", against all of the enabled entries in the SAA partition of the table. If *no* match is found in the SAA partition, the packet processor *asserts* the **rx_frame_pending** signal to the transmit block (TX_PACKET), so that an auto-TxAck packet can be sent to the requesting end device, with the FramePending subfield set to 1, indicating that the end device is not a valid child of this parent, and a "Leave Packet" from the coordinator to the end device, will follow.

If neither condition is met, i.e, there is no address match in the SAP partition, and a positive match in the SAA partition, the packet processor *deasserts* the **rx_frame_pending** signal, so that an auto-TxAck packet can be sent indicating to the end device that it has no data pending, and that it remains a valid child of this parent; the end device may then deactivate its receiver immediately. For the packet processor, the entire table lookup occurs in 128 clock cycles, once the last source address octet has been received. The SAP and SAA lookups are performed simultaneously. The checksum is also computed on-the-fly by hardware as the source address octets are received, taking no more than 1 clock cycle per octet. Finally, table-search status is reported to the MCU:

1. after the packet processor completes its SAP table search, the status bit SAP0_ADDR_PRESENT will be set to 1 if a match is found in the SAP partition, and the table index which matched will be indicated in the SAP0_MATCH[6:0] register, to further assist software in locating the relevant message within its indirect queue; if no match is found in the SAP partition, the status bit SAP0_ADDR_PRESENT will be set to 0.
2. after the packet processor completes its SAA table search, the status bit SAA0_ADDR_ABSENT will be set to 1 if *no* match is found in the SAA partition; if a positive match is found in the SAA partition, the status bit SAA0_ADDR_ABSENT will be set to 0, and the table index which matched will be indicated in the SAA0_MATCH[6:0] register, to further assist software in locating the child device within its neighbor table.

Both features, SAP and SAA acceleration, are optional, and functionally independent. Coordinator software can elect to enable both, either, or neither feature. The control bit SAP0_EN enables SAP acceleration. The control bit SAA0_EN enables SAA acceleration. If either feature is disabled, that table partition (SAP or SAA) is not searched, and so is not a factor in determining FramePending status for the transmitted Acknowledge frame. If *both* features are disabled, FramePending status defaults to software control, and merely tracks the state of the ACK_FRM_PND register bit; in this case software must manage FramePending status for all auto-TxAck frames.

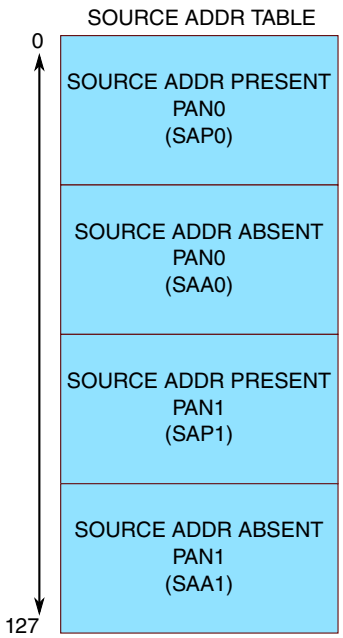
Software can also take direct control of FramePending status for the next auto-TxAck frame at any time (regardless of whether SAP or SAA acceleration is enabled), by setting the ACK_FRM_PND_CTRL bit; in this case, hardware FramePending status will track the state of ACK_FRM_PND.

In order to support Dual PAN mode, a device could theoretically be a PAN Coordinator on both networks. Thus, a coordinator device may need to maintain distinct message pending lists and/or neighbor tables for the 2 PANs. Accordingly, the packet processor further subdivides the Source Address Management table into 4, instead of 2, partitions:

1. SAP0: Source Address Present Partition for PAN0
2. SAA0: Source Address Absent Partition for PAN0

3. SAP1: Source Address Present Partition for PAN1
4. SAA1: Source Address Absent Partition for PAN1

### SOURCE ADDRESS TABLE PARTITIONS



Four register control bits enable each partition individually. If a partition is enabled, and a MAC poll request is received on the corresponding PAN (e.g. SAP0 or SAA0 partitions on PAN0), then the partition is searched by the packet processor, looking for a source address match (or absence), and the result of the search affects the FramePending status; if a partition is disabled, the partition is not searched, and will not influence FramePending status. The register bits are described in the table below.

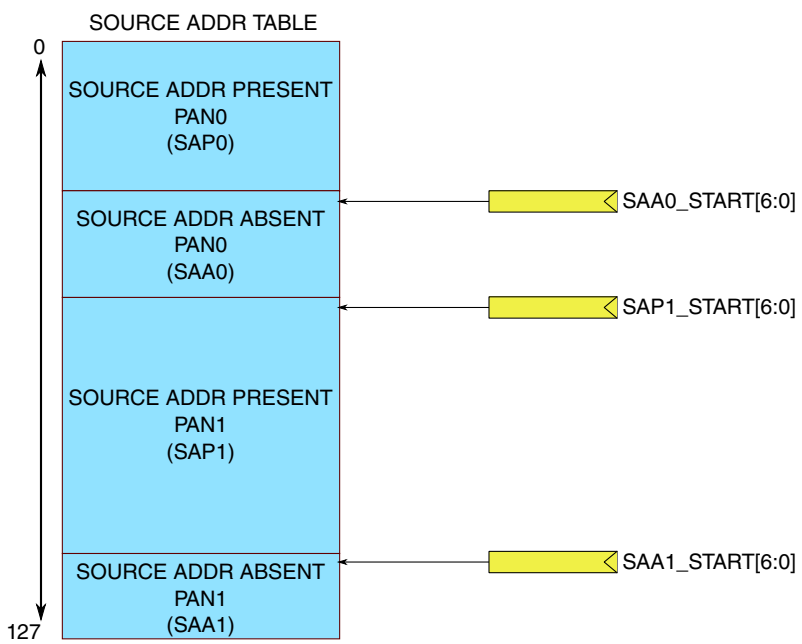
| REGISTER NAME | DESCRIPTION |
|---|---|
| SAP0_EN | Enables SAP0 Partition |
| SAA0_EN | Enables SAA0 Partition |
| SAP1_EN | Enables SAP1 Partition |
| SAA1_EN | Enables SAA1 Partition |

For maximum flexibility in supporting all combinations of message-pending status, neighbor-table status, and dual PAN mode, the dividing-line between all the partitions is fully programmable. The SAP0 partition always starts at table index 0. Three registers control the starting point for the other 3 partitions. The starting point is defined the first table index (0-127) of that partition. The registers are described below, along with some software restrictions to ensure table consistency.

| REGISTER NAME | DESCRIPTION | RESTRICTIONS |
|---|---|---|
| SAA0_START[6:0] | First Index of SAA0 partition. | If SAA0_START=0, then there is no SAP0 partition (SAP0_EN should be set to 0) |
| SAP1_START[6:0] | First Index of SAP1 partition. | Software must ensure that:<br>**SAP1_START ≥ SAA0_START**<br>If SAP1_START = SAA0_START, then there is no SAA0 partition (SAA0_EN should be set to 0) |
| SAA1_START[6:0] | First Index of SAA1 partition. | Software must ensure that:<br>**SAA1_START ≥ SAP1_START**<br>If SAA1_START = SAP1_START, then there is no SAP1 partition (SAP1_EN should be set to 0) |

A diagram which depicts one example of how the dividing-line registers affect partitioning of the table, is shown below.

### SOURCE ADDRESS TABLE PARTITIONS -- NON-EQUAL SIZES (EXAMPLE)



Each table partition consists of one or more indices, which can be used to store source address checksums. The first index for any partition, is defined by the aforementioned *PARTITION*_START[6:0] register, where *PARTITION*_ is one of {SAP0, SAP1, SAA0, SAA1}. The last index for any partition, is defined by the next higher partition's *PARTITION*_START[6:0] register, minus 1. When populating the table with source address information, software must be sure to select an index that is within the defined range for the partition. For example, when installing a checksum in the SAP1 partition:

$$SAP1_START \leq Selected_Index \leq (SAA1_START - 1)$$

To populate the table partitions, a 7-bit register SAM_INDEX[6:0] is provided, as well as a “index enable bit”, and a “index invalidate” bit. A 16-bit SAM_CHECKSUM[15:0] is provided, into which software will write the computed checksum. Installing a checksum into any partition is referred to as “Enabling an Index”, and removing a checksum from any partition is referred to as “Invalidating an Index”. A description of the registers is provided in the following table:

| REGISTER NAME | DESCRIPTION |
|---|---|
| SAM_CHECKSUM[15:0] | Software-computed source address checksum, to be installed into a table index |
| SAM_INDEX[6:0] | Contains the table index to be enabled or invalidated. Software must ensure that the index is within the range of the desired partition. |
| SAM_INDEX_WR | For 32-bit writes, this must be set to indicate that the table entry specified by SAM_INDEX[6:0] is to be written; if SAM_INDEX_WR=0, the table entry is not written, but the SAM_INDEX[6:0] register is updated. For 8-bit writes, this bit is ignored. |
| SAM_INDEX_EN | Enable the index selected by SAM_INDEX[6:0] for searching. |
| SAM_INDEX_INV | Invalidate the index selected by SAM_INDEX[6:0] |
| FIND_FREE_IDX | After modifying Valid bits (enabling or invalidating), write this bit to 1 to force HW to update the “First Free Index” registers to account for the changed Valid bits. This HW update process takes 4us. SW can poll SAM_BUSY to determine when the table update is complete. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate. |
| SAM_BUSY | HW is in the process of updating the Source Address table, either in response to a poll indication from the packet processor, or due to SW setting FIND_FREE_IDX=1. In the latter case, SW should poll SAM_BUSY until low before accessing the “First Free Index” registers. Read-only bit. |
| INVALIDATE_ALL | Writing a 1 to this bit clears all 128 Valid bits. Invalidates the entire table. Write-only bit. Writing 0 to this bit has no effect. Readback value is indeterminate. |

All the index-control registers reside within a single 32-bit word, so that a single 32-bit write can store a new checksum in the table, and simultaneously enable, or invalidate, the index. For 32-bit writes, SAM_INDEX_WR must be set to 1 to cause the SAM_CHECKSUM[15:0] to be loaded into the table at the address specified by SAM_INDEX[6:0]. For 32-bit reads, it is necessary first to update SAM_INDEX[6:0] to the desired table index, if it is not already set to the desired index; this requires a write to SAM_INDEX[6:0] with SAM_INDEX_WR=0, so as to not update the table contents. Then, a subsequent 32-bit read will return the table contents at the desired index.

For systems that don't support 32-bit writes, the register fields should be written in the following order:

1. SAM_INDEX[6:0]
2. SAM_CHECKSUM (the 2 bytes can be written in either order)
3. SAM_INDEX_EN (to enable), or SAM_INDEX_INV (to invalidate)

During operation, when a packet is received and the packet processor searches the table for a source address match, only enabled indices within each partition are searched. Invalidated indices are ignored.

To assist software in finding an available index to store the next source address checksum, the packet processor makes available the following 4 read-only registers:

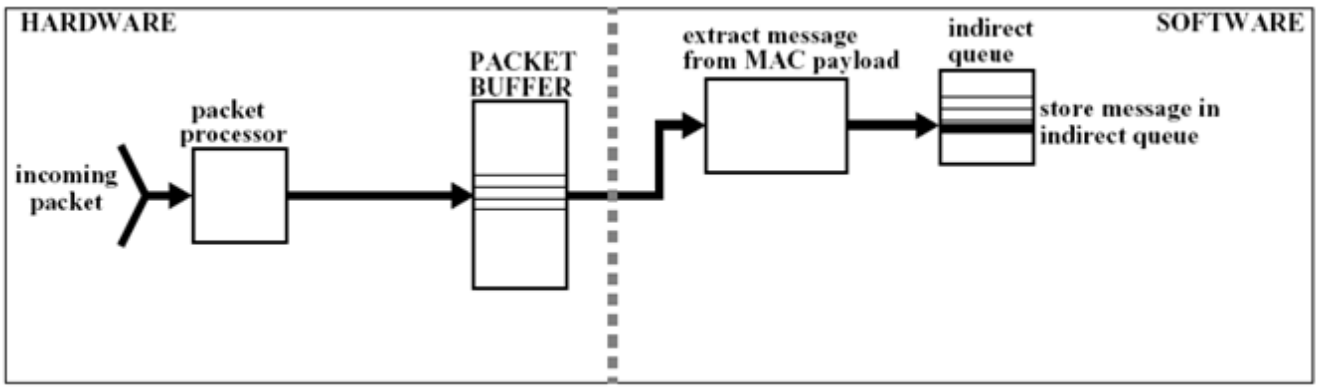
| REGISTER NAME | DESCRIPTION |
|---|---|
| SAP0_1ST_FREE_IDX[6:0] | First non-enabled (invalid) index in the SAP0 partition |
| SAA0_1ST_FREE_IDX[6:0] | First non-enabled (invalid) index in the SAA0 partition |
| SAP1_1ST_FREE_IDX[6:0] | First non-enabled (invalid) index in the SAP1 partition |
| SAA1_1ST_FREE_IDX[6:0] | First non-enabled (invalid) index in the SAA1 partition |

## Operational Use

The following flow description illustrates how hardware and software interact to utilize the Source Addressing Management feature to facilitate pending-message handling and neighbor table management. This flow assumes both SAP and SAA acceleration are enabled, and Dual PAN mode is in effect. There are 11 sequential steps.

### Step 1: Message Packet Reception, Extracting the Message, Indirect Queue Management

A message (data frame) is received by a coordinator. The message is received from one end device, and is intended for another end device. The coordinator's packet processor receives the packet, and stores it in the packet buffer. Coordinator software downloads the packet data from the packet buffer, extracts the message from the MAC payload, and stores the message in its indirect queue.



### Step 2: Software computes address checksum

Coordinator software also extracts the destination information (Destination PANID and Destination Address), from the data packet stored in the packet buffer. Software uses this information to compute a 16-bit checksum. This checksum uniquely identifies the sending device, with a high degree of reliability. The checksum is computed according to the following rules:

| Destination Addressing Mode | Rule |
|---|---|
| Mode 2 (short address) | Checksum = (Destination PAN ID + DstAddr[15:0]) % 65536 |
| Mode 3 (long address) | Checksum = (Destination PAN ID + DstAddr[15:0]) % 65536<br>Checksum = (Checksum + DstAddr[31:16]) % 65536<br>Checksum = (Checksum + DstAddr[47:32]) % 65536<br>Checksum = (Checksum + DstAddr[63:48]) % 65536 |

### Step 3: Software populates the address table

Coordinator software chooses an index in the Source Address Table in which it will store the just-computed checksum. If the data packet was received on PAN0, an index in the SAP0 partition should be chosen. Software may consult the register SAP0_1ST_FREE_IDX[6:0] to find the first available index in this partition. If the data packet was received on PAN1, an index in the SAP1 partition should be chosen. Software may consult the register SAP1_1ST_FREE_IDX[6:0] to find the first available index in this partition.

If an index is chosen which is already valid, software should first invalidate the index with the following procedure:

1. Set SAM_INDEX[6:0] to the selected index
2. Set SAM_INDEX_EN=0 and SAM_INDEX_INV=1

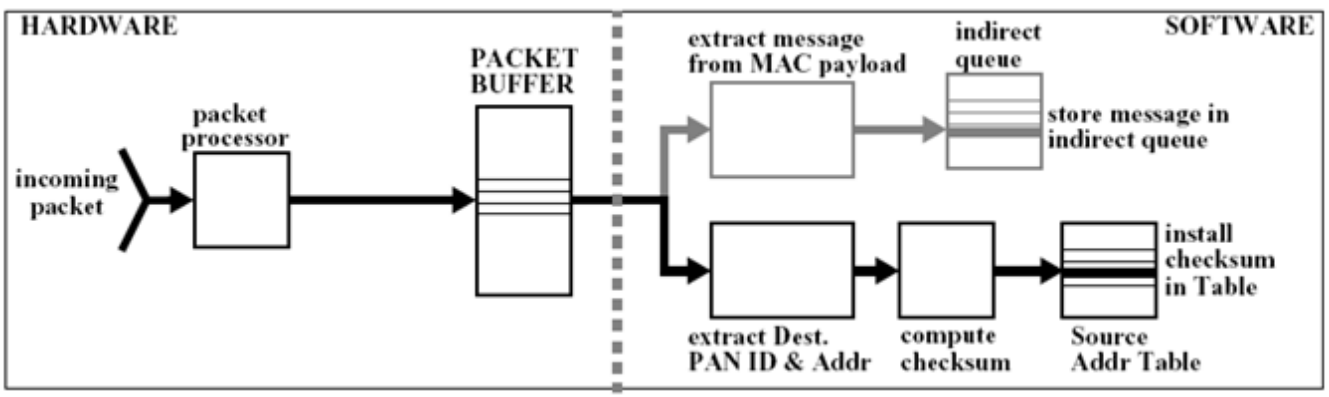
These steps can be performed in a single, 32-bit register write.

To install the source address checksum into the index and enable the index, the following procedure should be used:

1. Program SAM_CHECKSUM[15:0] to the computed checksum
2. Set SAM_INDEX[6:0] to the selected index
3. Set SAM_INDEX_EN=1 and SAM_INDEX_INV=0

These steps can be performed in a single, 32-bit register write.

The index is now enabled, and the packet processor will include it in its search when the next MAC Poll Request is received.



### Step 4: Incoming Poll request, Packet Processor parses the Auxiliary Security Header

An incoming packet is received. The packet processor performs routine packet filtering. After determining that the packet is type ‘MAC Command’, the packet processor must perform additional packet parsing in order to locate the packet’s Command Frame Identifier. This is the octet that distinguishes this commandas being of type “data request”, from other MAC Command types. For the packet processor, this extra parsing is more complex, because the Command Frame Identifier is part of the MAC payload; this is theonly scenario where the packet processor is required to parse the payload. This is further complicated bythe fact that the revision 2006 (and subsequent) of the 802.15.4 wireless MAC standard, includes a variable-length “Auxiliary Security Header”, prior to the MAC payload. This header is only present for FrameVersion > 0, and SecurityEnabled = 1. The packet processor must conditionally parse this header in order to locate the start of the MAC payload, where the Command Frame Identifier is located.The packet processor uses 2 subfields of the Frame Control Field to parse the Auxiliary Security Header (A.S.H.): FrameVersion, and SecurityEnabled. The packet processor parses the Auxiliary Security Header (A.S.H.) according to the following table:

| Length of Auxiliary Security Header (Octets) | SecurityEnabled (Frame Control Field) | FrameVersion (Frame Control Field) | KeyIdentifierMode (Security Control Field) | Remarks |
|---|---|---|---|---|
| **0** | 0 | 00 or 01 | - | If !SecurityEnabled, no ASH regardless of FrameVersion |
| **0** | 1 | 00 | 0 | If packet is 2003-compliant, no ASH |
| **5**<br>Security Control (1 octet) +<br>Frame Counter (4 octet) | 1 | 01 | 0x00 | ASH present. Length of ASH computed by HW. |
| **6**<br>Security Control (1 octet) +<br>Frame Counter (4 octet) +<br>Key Identifier (1 octet) | 1 | 01 | 0x01 | ASH present. Length of ASH computed by HW. |
| **10**<br>Security Control (1 octet) +<br>Frame Counter (4 octet) +<br>Key Identifier (5 octet) | 1 | 01 | 0x2 | ASH present. Length of ASH computed by HW. |
| **14**<br>Security Control (1 octet) +<br>Frame Counter (4 octet) +<br>Key Identifier (9 octet) | 1 | 01 | 0x3 | ASH present. Length of ASH computed by HW. |
| - | - | 10 or 11 | - | HW will handle these FrameVersion's indentically to FrameVersion 01 |

The contents of the A.S.H. are irrelevant to the packet processor; only its length is important. This is because the octet which immediately follows the A.S.H. is the Command Frame Identifier. This is all the packet processor needs to know.

## Step 5: Hardware extracts the Command Frame Identifier

After parsing the A.S.H. (if present), the next octet in the MAC payload, in accordance with the 802.15.4 standard, is the Command Frame Identifier.

| Command frame identifier | Command name | RFD | | Subclause |
|---|---|---|---|---|
| | | Tx | Rx | |
| 0x01 | Association request | X | | 5.3.1 |
| 0x02 | Association response | | X | 5.3.2 |
| 0x03 | Disassociation notification | X | X | 5.3.3 |
| 0x04 | Data request | X | | 5.3.4 |
| 0x05 | PAN ID conflict notification | X | | 5.3.5 |
| 0x06 | Orphan notification | X | | 5.3.6 |
| 0x07 | Beacon request | | | 5.3.7 |
| 0x08 | Coordinator realignment | | X | 5.3.8 |
| 0x09 | GTS request | | | 5.3.9 |
| 0x0a–0xff | Reserved | | | — |

The packet processor checks to see if the Command Frame Identifier = 0x4. If it is not, packet processing for this frame is complete, the remainder of the packet is received, without inspection by the packet processor, and is stored the packet buffer. If the Command Frame Identifier = 0x4, then this is a data request, and assuming the prior rules-checking and address-checking on this packet have already passed, then the Source Address Matching function will be applied to this packet, continuing in STEP 6.

### Step 6: Hardware Computes the Source Address Checksum

The packet processor uses the received Source PAN ID and Source Address for this packet to compute a 16-bit Source Address checksum. This checksum uses precisely the same algorithm that software uses to compute its Address checksum (see STEP 2), except that the *Source* PAN ID and address are used, rather than the Destination PAN ID and address. This checksum uniquely identifies the sending device, with a high degree of reliability. Note if the incoming packet's Frame Control Field has the PANIDCompression subfield asserted, the packet processor will substitute "Destination PAN ID" for "Source PAN ID" in the computation, since Source PAN ID will not be present under these circumstances.

### Step 7: Hardware performs "Source Address Present" Table Search

If the MAC poll request was received on PAN0, and SAP0_EN=1 to enable searches of the PAN0 “Source Address Present” partition, the packet processor uses its Source Address checksum to look for a match in the SAP0 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If a single table match is found (i.e., 1 software-computed checksum in SAP0 partition matches the hardware-computed checksum for the incoming packet), this means that there is a message for this requestor in the coordinator’s message queue. For a SAP0 match, the packet processor takes these 2 steps:

1. Set SAP0_ADDR_PRESENT=1
2. Set SAP0_MATCH[6:0] to the index which matched

If multiple table matches are found (i.e., more than 1 software-computed checksum in the SAP0 partition matches the hardware-computed checksum for the incoming packet), this means that there are multiple messages for this requestor in the coordinator’s message queue. In this case, the packet processor takes the same steps as for a single match, with the SAP0_MATCH[6:0] register being set to the lowest-value matching index (i.e., the smallest number) within the SAP0 partition.

If no source address match is found in the SAP0 table search, the packet processor will set SAP0_ADDR_PRESENT=0.

If, on the other hand, the MAC poll request was received on PAN1, and SAP1_EN=1 to enable searches of the PAN1 “Source Address Present” partition, the packet processor uses its Source Address checksum to look for a match in the SAP1 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If a single table match is found (i.e., 1 software-computed checksum in SAP1 partition matches the hardware-computed checksum for the incoming packet), this means that there is a message for this requestor in the coordinator’s message queue. For a SAP1 match, the packet processor takes these 2 steps:

1. Set SAP1_ADDR_PRESENT=1
2. Set SAP1_MATCH [6:0] to the index which matched

If multiple table matches are found (i.e., more than 1 software-computed checksum in the SAP1 partition matches the hardware-computed checksum for the incoming packet), this means that there are multiple messages for this requestor in the coordinator’s message queue. In this case, the packet processor takes the same steps as for a single match, with the SAP1_MATCH[6:0] register being set to the lowest-value matching index (i.e., the smallest number) within the SAP1 partition.

If no source address match is found in the SAP1 table search, the packet processor will set SAP1_ADDR_PRESENT=0.

### Step 8: Hardware performs "Source Address Absent" Table Search

If the MAC poll request was received on PAN0, and SAA0_EN=1 to enable searches of the PAN0 "Source Address Absent" partition, the packet processor uses its Source Address checksum to look for a match in the SAA0 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If one (or more) table match is found (i.e., a software-computed checksum in SAA0 partition matches the hardware-computed checksum for the incoming packet), this means that the end device which sent the poll request is a valid child of this parent. For a SAA0 match, the packet processor takes these 2 steps:

1. Set SAA0_ADDR_ABSENT=0
2. Set SAA0_MATCH[6:0] to the first index which matched

If *no* source address match is found in the SAA0 table search, the packet processor will set SAA0_ADDR_ABSENT=1.

If, on the other hand, the MAC poll request was received on PAN1, and SAA1_EN=1 to enable searches of the PAN1 "Source Address Absent" partition, the packet processor uses its Source Address checksum to look for a match in the SAA1 partition of the table. Only table entries that are enabled, are compared against (see STEP 3); table indices which are not enabled, are ignored in the search.

If one (or more) table match is found (i.e., a software-computed checksum in SAA1 partition matches the hardware-computed checksum for the incoming packet), this means that the end device which sent the poll request is a valid child of this parent. For a SAA1 match, the packet processor takes these 2 steps:

1. Set SAA1_ADDR_ABSENT=0
2. Set SAA1_MATCH[6:0] to the first index which matched

If *no* source address match is found in the SAA1 table search, the packet processor will set SAA0_ADDR_ABSENT=1.

### Step 9: Hardware determines FramePending status

The packet processor maintains an internal flag called **rx_frame_pending**, which is sent to the TX_PACKET block after every received packet, to directly control the state of the FramePending subfield of the Frame Control Field in the upcoming auto-TxAck frame (if enabled with AUTOACK=1).

If the Source Address Management feature is completely disabled, i.e.,

SAP0_EN = SAA0_EN = SAP1_EN = SAA1_EN = 0

then the packet processor will set the **rx_frame_pending flag** to the value of the ACK_FRM_PND register, putting the state of FramePending under direct software control.

Otherwise, if *any* of the following conditions are met, the packet processor will set its **rx_frame_pending** flag to 1:

1. The MAC Poll Request was received on PAN0, SAP0_EN=1, and SAP0_ADDR_PRESENT=1
2. The MAC Poll Request was received on PAN1, SAP1_EN=1, and SAP1_ADDR_PRESENT=1
3. The MAC Poll Request was received on PAN0, SAA0_EN=1, and SAA0_ADDR_ABSENT=1
4. The MAC Poll Request was received on PAN1, SAA1_EN=1, and SAA1_ADDR_ABSENT=1

If none of the conditions are met, **rx_frame_pending** flag will be set to 0.

### Step 10: Receive interrupt RXIRQ

The packet processor receives the remainder of the packet, and verifies the FCS. Assuming the CRC check passes, the RXIRQ interrupt is issued. In the coordinator software's RXIRQ Interrupt Service Routine, software can determine if the received packet was a MAC Poll Request by reading the PI bit of the IRQSTS register. If PI=0, the received packet was not a poll request, and no action relating to Source Address Matching need be taken.

Otherwise, if *either* SAP0_ADDR_PRESENT=1 or SAP1_ADDR_PRESENT=1, an auto-TxAck packet is being sent with the FramePending subfield set to 1, so software should follow up by constructing a data packet (or packets) for the requesting end device, with a payload consisting of the message for this device which had been stored in the coordinator's indirect queue.

Also, if *either* SAA0_ADDR_ABSENT=1 or SAA1_ADDR_ABSENT=1, an auto-TxAck packet is being sent with the FramePending subfield set to 1, so software should follow up by constructing a “Leave Message” for the requesting end device.

### Step 11: Software disables the spent index

In the final step, coordinator software must disable (invalidate) the index which was just used to locate and send the stored message to the requesting end device. To disable the index:

1. Set SAM_INDEX[6:0] to the selected index
2. Set SAM_INDEX_EN=0 and SAM_INDEX_INV=1

At this point, the disabled index is now an available table entry, which can be used to install a new Address checksum for another message in the indirect queue.

#### *64.5.2.4.1.3.4 Dual PAN Mode*

In the past, radio transceivers designed for 802.15.4 applications allow a device to associate to one and only one PAN (Personal Area Network), at any given time. The Packet Processor includes hardware support for a device to reside on two networks simultaneously. In optional Dual PAN mode, the device will alternate between the 2 PAN’s, under hardware or software control. Hardware support for Dual PAN operation consists of 2 sets of PAN and IEEE addresses for the device, 2 different channels (one for each PAN), a programmable timer to automatically switch PAN’s (including on-the-fly channel-changing) without software intervention, control bits to configure and enable Dual PAN mode, and read-only bits to monitor status in Dual PAN mode. A device can be configured to be a PAN Coordinator on either network, both networks, or neither.

For the purpose of defining a "PAN" in the context of Dual PAN mode, two sets of network parameters are maintained. In this document, "PAN0" and "PAN1" will be used to refer to the 2 PAN’s. Each parameter set uniquely identifies a PAN for Dual PAN mode. These parameters are:

| PAN0 | PAN1 |
|---|---|
| CHANNEL_NUM0 | CHANNEL_NUM1 |
| MACPANID0 (16-bit register) | MACPANID1 (16-bit register) |
| MACSHORTADDRS0 (16-bit register) | MACSHORTADDRS1 (16-bit register) |
| MACLONGADDRS0 (64-bit registers) | MACLONGADDRS1 (64-bit registers) |
| PANCORDNTR0 (1-bit register) | PANCORDNTR1 (1-bit register) |

During device initialization, if Dual PAN mode is to be utilized, software will program both parameters sets, to configure the hardware for operation on two networks.

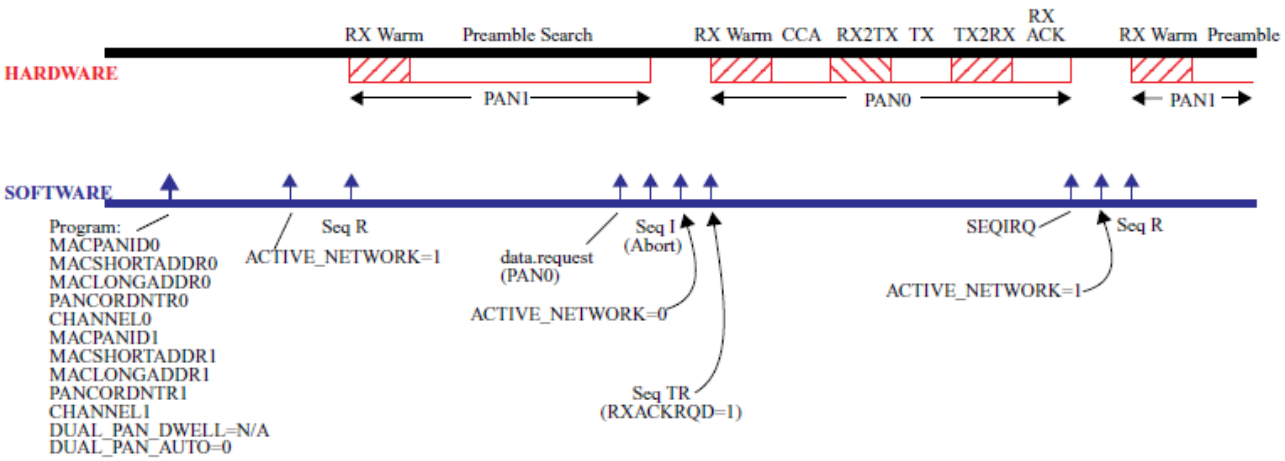
Two modes are available for Dual PAN operation: manual and automatic.

## Manual Dual PAN

In manual Dual PAN mode, software controls which PAN is selected for transmission and reception, at all times. Software populates both PAN network parameter-set registers listed above. Software then selects a PAN to begin transmission or reception. A single control bit **ACTIVE_NETWORK**, selects the PAN. To select PAN0, **ACTIVE_NETWORK** should be set to 0; to select PAN1, **ACTIVE_NETWORK** should be set to 1. Software then initiates an autosequence by writing the appropriate value to XCVSEQ (PHY_CTRL1 Register). At any point, software can elect to switch to the alternate PAN. To do so, software aborts the sequence (if one is active) by writing XCVSEQ=IDLE. Software then toggles **ACTIVE_NETWORK**, and restarts a new sequence with XCVSEQ. Software is responsible for aborting and initiating sequences. Hardware is responsible for warming up the transceiver on the selected channel (CHANNEL_NUM0 or CHANNEL_NUM1), and performing address-filtering on the selected network's address parameters (PANCORDNTR, MacPanID, Short Address, and/or IEEE address). Software overhead is significantly reduced in this mode, since there is no need to re-program all of the the PAN-select registers every time the PAN is toggled in Dual PAN mode; only a single bit (**ACTIVE_NETWORK**) need be written. For manual Dual PAN operation, **DUAL_PAN_AUTO** should be set to 0.

The following diagram depicts Dual PAN operation in manual mode. In this example, software populates both PAN parameters sets during initialization. In this example, software elects to initiate packet reception on PAN1, so **ACTIVE_NETWORK** is set to 1. Software initiates the Sequence R by writing to XCVSEQ. Hardware warms up the receiver on CHANNEL_NUM1 and enters preamble-search. In this example, no packet is received, but a data request from higher-level software requires a switch to PAN0. Software responds by aborting the reception by writing Sequence I to XCVSEQ. Software then sets **ACTIVE_NETWORK** to 0 to select PAN0. In the example, software initiates a Sequence TR. Hardware warms up the receiver for CCA on CHANNEL_NUM0, performs CCA (channel is idle), warms down the receiver, and warms up the transmitter on CHANNEL_NUM0, transmits the requested packet, warms down the transmitter and warms up the receiver again (as per the autosequence) on CHANNEL_NUM0, to receive the acknowledge packet. The acknowledge packet is received and the autosequence completes successfully with RXIRQ and SEQIRQ. Software elects to resume packet reception on PAN1 (which was in progress before the data request). Software toggles **ACTIVE_NETWORK** back to 1, and re-initiates Sequence R.

**DUAL PAN MANUAL MODE**



## Auto Dual PAN

In automatic Dual PAN mode, hardware is responsible for alternating the selected PAN, at a pre-programmed interval. Software programs a "PAN dwell time", which determines the amount of time during which the hardware will receive on a given PAN. This is done by programming the **DUAL_PAN_DWELL** register. Software sets the **DUAL_PAN_AUTO** bit to 1 for automatic Dual PAN operation, and sets **ACTIVE_NETWORK** to correspond to the PAN on which it desires packet reception to begin. Software then initiates a Sequence R. Hardware warms up the receiver on the selected PAN, and begins preamble search. When the dwell time expires, assuming preamble and SFD have not been detected, hardware will switch to the alternate PAN. This includes an on-the-fly channel change. Once switched to the alternate PAN, hardware will use the address filtering parameters (PANCORDNTR, MacPanID, Short Address, and/or IEEE address) programmed for the alternate PAN. Once the dwell time expires on the alternate PAN, assuming preamble and SFD have not been detected, hardware will switch back to the original PAN. This process will repeat indefinitely, until one of the following occurs:

1. A packet is successfully received (address match and CRC valid).
2. Software aborts the Sequence R
3. A TMR3 RX timeout, which automatically aborts the Sequence R
4. A PLL unlock automatically aborts the Sequence R (if unlock aborting is enabled)

If the hardware PAN dwell timer expires *during* a packet reception (i.e., preamble and SFD have been detected during a Sequence R), the PAN-switch will be delayed until the packet is completely received. If the packet is received successfully (address match and

CRC valid), the receive sequence will terminate with RXIRQ and SEQIRQ (if an auto-Acknowledge was requested and enabled, the sequence will complete after the Acknowledge packet was transmitted, and TXIRQ will also be set, in addition to RXIRQ and SEQIRQ); the PAN switch will occur at this point, after the Sequence has returned to IDLE.

If the received packet fails FCS (CRC check), or, if the packet was not intended for the device (address mismatch), the hardware will toggle the PAN, and return to preamble-search on the new PAN.

If the hardware PAN dwell timer expires during a state *other* than RX preamble search during Sequence R (i.e., if expiration occurs during TX, CCA, ED, Sequence TR, or any warmup or transitional state), PAN-switch will be delayed until either:

1. Preamble Search state is reached during a Sequence R (not Sequence TR)

2. Sequence returns to IDLE.

At any point, software can elect to interrupt the automatic Dual PAN operation, by aborting the sequence with a XCVSEQ=IDLE, and the setting the **DUAL_PAN_AUTO** bit to 0. In response, hardware will freeze the current state of the dwell timer, and capture the currently-selected PAN, so that hardware-controlled PAN alternation can resume where it left off, later. Software can then tend to that tasks that caused the Dual PAN interruption. When software wants to resume Dual PAN operation, it then sets **DUAL_PAN_AUTO**=1, and re-initiates Sequence R. Hardware will resume the dwell timer from the point it was frozen earlier, on the same PAN, and will warmup the receiver to receive on the PAN which was being monitored before the interruption. Hardware will dwell on that PAN until the timer expires, and then switch PAN's (assuming no preamble and SFD detected, subject to the conditions listed above). Software can always determine the selected PAN at any time, in any mode, by reading **CURRENT_NETWORK** bit. If **DUAL_PAN_AUTO**=0, then **CURRENT_NETWORK** = **ACTIVE_NETWORK**. If **DUAL_PAN_AUTO**=1, then **CURRENT_NETWORK** is controlled by hardware.

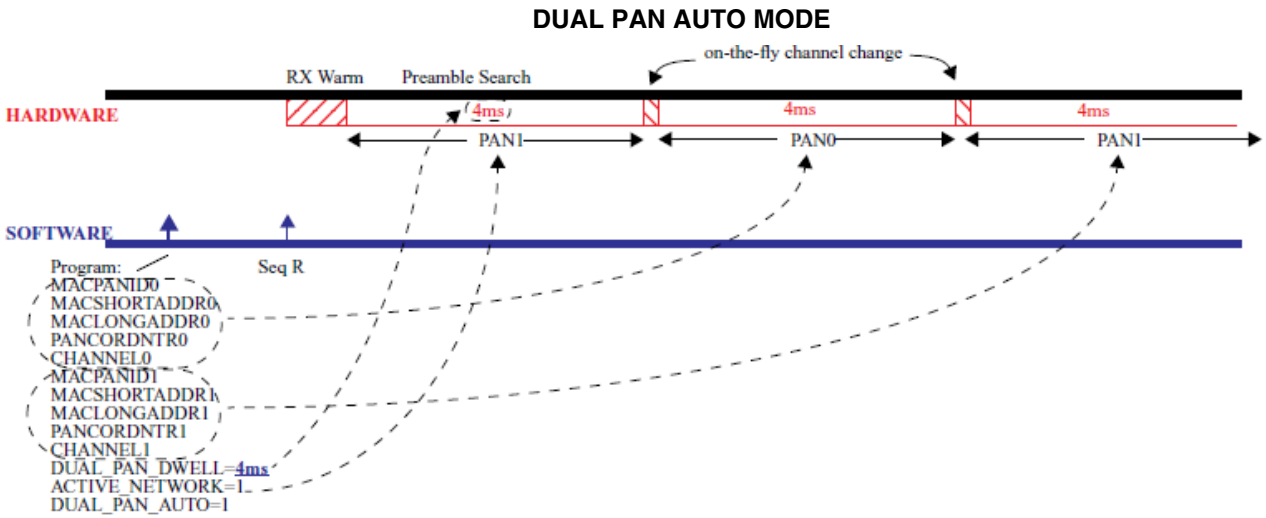
To initiate auto Dual PAN operation for the first time, or to reset the dwell timer to its programmed value and allow software to select the initial PAN for auto Dual PAN operation, software should program the desired initial PAN to **ACTIVE_NETWORK** (0 for PAN0, 1 for PAN1), and then program the desired dwell time into the **DUAL_PAN_DWELL** register. Hardware always responds to a write to **DUAL_PAN_DWELL**, by resetting the dwell timer to its programmed value, and selecting the initial PAN for auto Dual PAN operation, based on the state of **ACTIVE_NETWORK**. A write to **DUAL_PAN_DWELL**, always re-initilizes the DWELL TIMER to the programmed value. If a write to **DUAL_PAN_DWELL** occurs during an autosequence, the DWELL TIMER will begin counting down immediately. If a

write to **DUAL_PAN_DWELL** occurs when there is no autosequence underway, the DWELL TIMER will not begin counting until the next autosequence begins; it will begin counting at the start of the autosequence warmup. Under all circumstances, **DUAL_PAN_AUTO** must be asserted to allow the DWELL TIMER to count. If **DUAL_PAN_AUTO**=0, the DWELL TIMER will freeze and hold its state, until **DUAL_PAN_AUTO**=1. However, a write to **DUAL_PAN_DWELL** will still initialize the DWELL TIMER to its programmed value, regardless of the state of **DUAL_PAN_AUTO**.

At any point during auto Dual PAN mode, software can ascertain the PAN currently being serviced by hardware, by reading the **CURRENT_NETWORK** bit. Software can also determine the time-remaining in the current dwell, by reading the **DUAL_PAN_REMAIN** Register.

In auto Dual PAN mode, software retains responsibility for initiating and aborting sequences. There is no provision for hardware-initiated sequences. TMR2 may be used to initiate an autosequence at a future time. TMR3 may be used as an RX hardware-abort mechanism.

The following diagram depicts Dual PAN operation in automatic mode. In this example, software populates both PAN parameters sets during initialization. In this example, software wants to initiate packet reception in auto Dual PAN mode, on PAN1, so **ACTIVE_NETWORK** is set to 1. For auto Dual PAN operation, software programs the desired PAN-switching interval into **DUAL_PAN_DWELL** register, in this case, 4ms. Software initiates the Sequence R by writing to XCVSEQ. The dwell timer begins counting as soon as the receiver warmup begins. Hardware warms up the receiver on CHANNEL_NUM1 (since PAN1 was selected as the initial PAN in this example), and begins preamble search. If a packet is received during this interval, hardware applies PAN1 address filtering. In this example, no preamble is detected at the point at which the dwell timer expires. So, at this point, hardware executes a PAN-switch to PAN0. which includes an on-the-fly channel change. The on-the-fly channel change requires approximately 93us and no preamble detection is possible during this "blind spot". (For more details on how the hardware executes the Dual PAN on-the-fly channel change, see Chapter ZSM Sequence Manager, Section Dual PAN Mode.) After the PAN switch, hardware resumes preamble search on CHANNEL_NUM0, and applies PAN0 address filtering if a packet is received. In this example, no preamble is detected at the point at which the dwell timer expires. So, at this point, hardware performs a PAN-switch back to PAN1. And so on and so forth.



## Two-PAN-one-channel

A special case occurs if a device is operating in Dual PAN mode (either Auto or Manual mode), and both PAN's occupy the same channel; in other words, CHANNEL_NUM0=CHANNEL_NUM1. In this case, hardware will detect this condition automatically, and apply both sets of address-filtering parameters simultaneously. Hardware will provide Data Indication if the received packet matches either the PAN0 address parameter set {**MACPANID0, MACSHORTADDRS0, MACLONGADDRS0, PANCORDNTR0**}, or the PAN1 address parameter set {**MACPANID1, MACSHORTADDRS1, MACLONGADDRS1, PANCORDNTR1**}. At Data Indication, two status bits can be queried by software to quickly determine on which PAN the packet was received, **RECD_ON_PAN0** or **RECD_ON_PAN1**. In the "Two-PAN-one-channel" scenario, it is possible for a packet to satisfy both sets of addressing parameters (PAN0 and PAN1). When this happens, both **RECD_ON_PAN0** and **RECD_ON_PAN1** will be set. In the "Two-PAN-one-channel" scenario, the **CURRENT_NETWORK** bit should be ignored, since both networks are simultaneously active.

If Dual PAN mode is not to be utilized, **ACTIVE_NETWORK** should be maintained at 0 (default) to select the PAN0 parameters for transceiving. In single PAN operation, the PAN1 parameter registers need not be programmed, and can be used as scratchpad. CHANNEL_NUM1 should not be programmed, and should instead be left in its default state, if Dual PAN mode is not in use.

## Dual PAN Channel Override

In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to do that, by designating one of the two PAN channels to use the transceiver's set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers – integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the 802.15.4 mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1. This is referred to as "Dual PAN Channel Override". For more details on this feature, see Chapter ZSM Sequence Manager, Section Dual PAN Channel Override.

#### *64.5.2.4.1.3.5 Active Promiscuous Mode*

**Functional description**

The 802.15.4 Wireless Medium Access Control (MAC) and Physical Layer (PHY) Specifications for Low-Rate Wireless Personal Area Networks (WPANs) defines the following behavior for Promiscuous Mode operation:

> "In promiscuous mode, the MAC sublayer shall pass all frames received after the first filter directly to the upper layers without applying any more filtering or processing."

Where first level filtering is described as:

> "For the first level of filtering, the MAC sublayer shall discard all received frames that do not contain a correct value in their FCS field in the MFR (see 7.2.1.9)"

Promiscuous mode allows a device to receive and process all 802.15.4 frames which pass FCS check (CRC), regardless of whether or not they are addressed to the device. This allows a device to receive and process all valid traffic on a network. In Promiscuous mode, the Packet Processor will provide a Data Indication on all such packets. This capability allows a simple network sniffer to be constructed, which can display comprehensive packet data for all packets transmitted on a network within receiving range of the device.

Since a device operating in promiscuous mode is designed to do so discreetly, automatic acknowledgement of all received packets is inhibited, regardless of the state of the Ack Request field in the Frame Control Field of the received packet; otherwise, the sniffing device would be acknowledging received frames for which it was not the addressee.

The Packet Processor features an "Active Promiscuous Mode". In this mode, the Packet Processor will process packets according to the same rules that it applies to Promiscuous mode, except that it will automatically transmit an acknowledgement packet *for frames*

*that are addressed to the device*. In other words, in Active Promiscuous mode, if the received frame meets all the address and packet filtering requirements that would have applied in non-promiscuous mode, an acknowledgement packet will be transmitted; a Data Indication will still be provided for all valid packets (those which pass FCS check). Note that all existing packet processor rules governing transmission of acknowledge packets, are still in effect; i.e., AUTOACK bit of the PHY_CTRL1 Register must be set to 1, and the Ack Request field in the Frame Control Field of the received packet must be set to 1.

The Packet Processor can be also programmed to provide a Data Indication for packets which fail FCS check, by setting CRC_MSK=0. Received packets which fail FCS check are never acknowledged, under any circumstances.

## Special Handling for Broadcast Packets

Special rules apply to received packets which contain a broadcast PAN Identifier (0xffff), and/or a broadcast short address (0xffff). According to the 802.15.4 standard,

> “For valid frames that are not broadcast, if the Frame Type subfield indicates a data or MAC command frame and the Acknowledgment Request subfield of the Frame Control field is set to one, the MAC sublayer shall send an acknowledgment frame."

An exception is made for received packets which contain a broadcast PAN Identifier, and a long address which matches the device’s IEEE address. Such packets are acknowledged, because the IEEE address uniquely identifies the device, regardless of PAN. This special case will apply also in Active Promiscuous mode; such packets will be acknowledged. The following diagram describes the packet processor’s "acknowledgement decision" for all permutations of broadcast indicators in the received packet’s addressing fields.

ACKNOWLEDGE-ON-BROADCAST (ALL PERMUTATIONS)

| DESTINATION ADDRESS MODE | PAN ID = !BROADCAST<br>DSTADDR = !BROADCAST | PAN ID = !BROADCAST<br>DSTADDR = BROADCAST | PAN ID = BROADCAST<br>DSTADDR = BROADCAST | PAN ID = BROADCAST<br>DSTADDR = !BROADCAST |
|---|---|---|---|---|
| SHORT | ACK | NO ACK | NO ACK | NO ACK |
| LONG | ACK | | | ACK |

## Special Handling for Broadcast Packets

The Packet Processor features an autosequence to automatically receive, and verify, Acknowledge Frames after a Transmit frame has been sent by the device. This is accomplished by programming a Sequence TR with RXACKRQD=1. During normal operation, these receive Acknowledge Frames are not stored in the Packet Buffer. They are merely checked for matching Sequence Number and Frame Version, with a Data Indication issued for a valid match on both. In Active Promiscuous Mode, receive Acknowledge frames *will* be stored into the Packet Buffer, just like any other received frame. This saves software from having to re-construct the contents of the Acknowledge packet, from the contents of the packet which was originally transmitted. Ordinary Promiscuous Mode should therefore not be used with Sequence TR with RXACKRQD=1. Use Active Promiscuous instead.

#### *64.5.2.4.1.3.6 Provisions to Enable Software Support for 802.15.4e and 802.15.4-2015*

Addendum 802.15.4e to the 802.15.4-2011 standard introduces 3 new variations on the 802.15.4 MAC Frame Structure:

1. FrameVersion=2 (Frame Types: Beacon, Acknowledge, Data, and MAC Command)
2. LLDN Frame Type
3. Multipurpose Frame Type

In addition, the 802.15.4-2015 revision to the standard introduces a new Frame Type: Extended (Frame Type = 0b111).

All three of the “4e-compliant packets”, as well as the Extended Frame Type, modify the format and definition of the Frame Control Field in such a way as to render parsing of the MHR by the packet processor impossible, without major upgrades to the hardware. For example, the packet processor hardware does not support 8-bit (simple) addressing, nor Sequence Number Suppression.

As in interim solution, provisions have been added to the packet processor to allow these new packet variations to be recognized and conditionally admitted (Data Indication to software). Three new Frame Type control bits, and a modification of the Frame Version Filtering bits, are included in the Packet Processor, and affect hardware packet parsing as indicated in the following table:

| REGISTER | DEFINITION |
|---|---|
| FRM_VER_FILTER[3:0] | Frame Version selector. The incoming packet's Frame Control Field is parsed to obtain the FrameVersion subfield, and that value is compared against this register, in accordance with the following:<br><br>xxx1: Accept received packets with FrameVersion=00<br>xx1x: Accept received packets with FrameVersion=01<br>x1xx: Accept received packets with FrameVersion=10<br>1xxx: Accept received packets with FrameVersion=11<br><br>These filtering rules apply to Beacon, Acknowledge, Data, and MAC Command Frame Types, since these frame types require a 2-octet Frame Control Field which embeds a 2-bit FrameVersion subfield. Later frame types introduced in the 802.15.4e addendum (LLDN, Multipurpose) don’t guarantee a FrameVersion subfield with the original meaning, so these filtering rules do not apply to those frame types. See registers LLDN_FT and MULTIPURPOSE_FT. |
| LLDN_FT | 1: LLDN frame type enabled (Frame Type 4)<br>0: reject all LLDN frames |
| MULTIPURPOSE_FT | 1: Multipurpose frame type enabled (Frame Type 5)<br>0: reject all Multipurpose frames |
| EXTENDED_FT | 1: Extended frame type enabled (Frame Type 7)<br>0: reject all Extended frames |

The Extended Frame Type does not comply with the General MAC Frame Format, which is shown in the following diagram:

| Octets: 1/2 | 0/1 | 0/2 | 0/2/8 | 0/2 | 0/2/8 | variable | variable | | variable | 2/4 |
|---|---|---|---|---|---|---|---|---|---|---|
| Frame Control | Sequence Number | Destination PAN Identifier | Destination Address | Source PAN Identifier | Source Address | Auxiliary Security Header | Information Elements (IE) | | Frame Payload | FCS |
| | | Addressing fields | | | | | Header IEs | Payload IEs | | |
| MHR | | | | | | | MAC Payload | | | MFR |

Figure 86—General MAC frame format

**Figure 64-145. General MAC Frame Format**

Instead, the Extended Frame has its own unique format, which is shown in the following diagram:

| Bits: 0-2 | 3-5 | variable |
|---|---|---|
| Frame Type | Extended Frame Type | Extended Frame Payload |

Figure 105—Extended frame format

**Figure 64-146. Extended Frame Format**

Because the Extended Frame Payload, which is not defined in the 802.15.4-2015 revision to the standard, would be intended to contain and fully specify the FCS, the Packet Processor will not be able to verify FCS on received packets with Frame Type Extended. FCS checking will need to be implemented in software.

**Note:** If the EXTENDED_FT bit is set to enable Data Indication on packets of Frame Type Extended, software should expect a substantial increase in the frequency of notifications, as a consequence of the lack of hardware verification of FCS, which will have implications for software workload as well as power consumption in the SoC.

When the packet processor receives any of the 4e-compliant frames, if the corresponding control bit is set, the hardware will skip Stage 2 filtering, and merely verify FCS. If FCS passes, the packet processor will notify software of the packet, without inspection of the addressing fields or payload. For such packets, software will be responsible for parsing the MHR and payload sections of the frame. If the corresponding control bit is not set, the packet processor will reject the received packet and there will be no Data Indication.

When the packet processor receives a packet of Frame Type Extended, if the EXTENDED_FT bit is set, the hardware will skip Stage 2 filtering, and after the entire packet is received, the packet processor will merely notify software of the packet, without inspection of the Extended Frame Type bits or the Extended Frame Payload. For such packets, software will be responsible for parsing the Extended Frame Type and the Extended Frame Payload sections of the frame. If the corresponding control bit is not set, the packet processor will reject the received packet and there will be no Data Indication.

Like all existing frames prior to 802.15.4e and 802.15.4-2015, a received frame may require an acknowledgement. In the case of the new 802.15.4e and 802.15.4-2015 frames, the required timing for the acknowledge frame transmission, has been modified. The acknowledgement no longer immediately follows the packet reception. For this reason, upon reception of any of these 4e-compliant 2015-compliant packets, the packet processor will cancel any auto-ACK transmission, regardless of the state of the PHY_CTRL[AUTOACK] bit and AR field of the received packet's Frame Control Field. Software will be responsible for constructing the acknowledgment packet and transmitting it at the appropriate time using a Sequence T.

To help expedite software processsing of the 4e- and 2015-compliant Frame Types and Versions, additional status bits have been added to the 802.15.4 register set, which are described in the following table:

| STATUS BIT | RESIDES IN REGISTER | DEFINITION |
|---|---|---|
| ENH_PKT_STATUS | IRQSTS | 1: The last packet received was 4e- or 2015-compliant (SW should query the RX_FRAME_FILTER register for additional status bits)<br>0: The last packet received was neither 4e- nor 2015-compliant |
| BEACON_FV2_RECD | RX_FRAME_FILTER | 1: The last packet received was a FrameType Beacon with FrameVersion 2<br>0: The last packet received was not a FrameType Beacon with FrameVersion 2 |
| DATA_FV2_RECD | RX_FRAME_FILTER | 1: The last packet received was a FrameType Data with FrameVersion 2<br>0: The last packet received was not a FrameType Data with FrameVersion 2 |
| ACK_FV2_RECD | RX_FRAME_FILTER | 1: The last packet received was a FrameType Acknowledge with FrameVersion 2<br>0: The last packet received was not a FrameType Acknowledge with FrameVersion 2 |
| CMD_FV2_RECD | RX_FRAME_FILTER | 1: The last packet received was a FrameType MAC Command with FrameVersion 2<br>0: The last packet received was not a FrameType MAC Command with FrameVersion 2 |
| LLDN_RECD | RX_FRAME_FILTER | 1: The last packet received was a FrameType LLDN<br>0: The last packet received was not a FrameType LLDN |

*Table continues on the next page...*

| | | |
|---|---|---|
| MULTIPURPOSE_RECD | RX_FRAME_FILTER | 1: The last packet received was a FrameType Multipurpose with FrameVersion 2<br>0: The last packet received was not a FrameType Multipurpose |
| EXTENDED_RECD | RX_FRAME_FILTER | 1: The last packet received was a FrameType Extended<br>0: The last packet received was not a FrameType Extended |

The new status bits are mapped into the 802.15.4 Address space as shown in the diagram below:

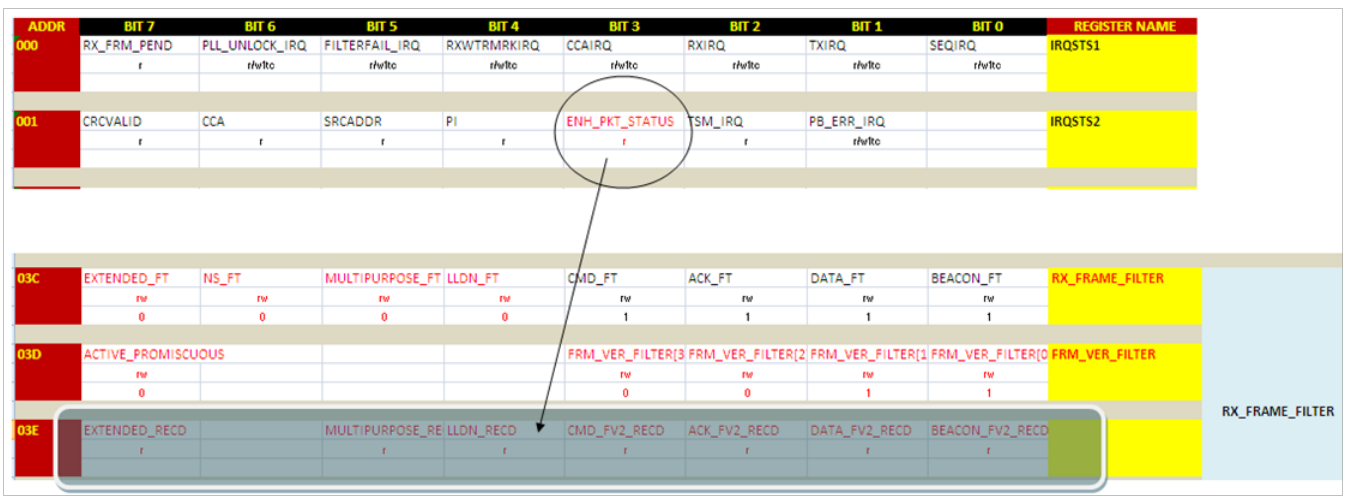


**Figure 64-147. Enhanced Packet Status Bits**

#### *64.5.2.4.1.3.7 Clocks*

Packet Processor is a fully synchronous module. It has a single clock input **clk_250khz**. The clock frequency, 250KHz, is the 802.15.4 bit rate. This clock input is driven by a divide-down of the RF Oscillator, generated in the CRM (Clocks and Resets module). The Packet Processor has no asynchronous interfaces.

#### *64.5.2.4.1.3.8 Reset*

The Packet Processor has a single, active-low, asynchronous reset input: **rst_b** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

#### *64.5.2.4.1.3.9 Interrupts*

The Packet Processor does not generate any interrupts.

*64.5.2.4.1.3.10 Appendix A*

## FILTERFAIL CODES

A description of the FILTERFAIL codes can be found in the following table.

| FILTERFAIL CODE BIT | REASON FOR FILTERFAIL |
|---|---|
| [0] | Fails Stage 1 Frame Length Checking (FL < 5 or FL > MAXFRAMELENGTH)<br>**Note:** FL < 3 will not generate an SFD, so this bit will not be set |
| [1] | Fails Stage 1 Section 7.2.1.1.6 or Section 7.2.1.1.8 Checking (DST_ADDR_MODE or SRC_ADDR_MODE = 1) |
| [2] | Fails Stage 1 Section 7.2.1.1.5 Checking (Illegal PAN_ID_COMPRESSION Usage) |
| [3] | Fails Stage 1 Frame Version Checking |
| [4] | Fails Stage 2 Auto-RxAck Checking (Illegal Ack Frame Format in Sequence TR) |
| [5] | Fails Stage 2 Frame Type Checking (Incorrect Frame Filter Bit setting) |
| [6] | Fails Stage 2 Frame Length Checking (Illegal Beacon, Data, or Cmd FL) |
| [7] | Fails Stage 2 Addressing Mode Checking (Illegal Addressing Mode for Beacon, Data, OR Cmd) |
| [8] | Fails Stage 2 Sequence Number Matching (Sequence TR Only) |
| [9] | Fails Stage 2 PAN ID or Address Checking (Beacon, Data, or Cmd) |

*64.5.2.4.1.3.11 Appendix B*

## LENIENCY BITS

The Packet Processor performs filtering on all received packets, in order to determine whether the packet is intended for the device. The packet filtering is based on rules. In case any of the packet filtering rules need to be overriden, a 40-bit "leniency register" has been provided. When the leniency register is programmed to its default value (0), all hardware packet filtering rules are in effect, and if an incoming packet violates any rule, a "Filter Fail" will occur (packet will be rejected). When a given leniency register bit is asserted, the packet filtering rule assigned to that bit will not be in effect, and if any incoming packet violates that rule (but no other rules), then a "Filter Fail" will not occur, the packet will not be rejected, the packet will be treated as "intended for the device", and software will be notified of the incoming packet. The table below shows the assignment of leniency bits to packet filtering rules.

| LENIENCY BIT | PACKET FILTERING RULE OVERRIDDEN |
|---|---|
| leniency[0] | Override Stage 1 Frame Length Checking (FL < 5 or FL > MAXFRAMELENGTH) |
| leniency[1] | Override Stage 1 Section 7.2.1.1.6 Checking (DST_ADDR_MODE = 1) |
| leniency[2] | Override Stage 1 Section 7.2.1.1.8 Checking (SRC_ADDR_MODE = 1) |
| leniency[3] | Override Stage 1 Section 7.2.1.1.5 Checking (Illegal PAN_ID_COMPRESSION Usage) |

*Table continues on the next page...*

| LENIENCY BIT | PACKET FILTERING RULE OVERRIDDEN |
|---|---|
| leniency[4] | Override Stage 2 Auto-RxAck Checking (Illegal Ack Frame Format in Sequence TR) |
| leniency[5] | Override Stage 2 Frame Length Checking (Illegal Beacon, Data, or Cmd FL) |
| leniency[6] | Override Stage 2 Beacon Frame Address Mode Violations |
| leniency[7] | Override Stage 2 Data Frame Address Mode Violations |
| leniency[8] | Override Stage 2 MAC Command Frame Address Mode Violations |
| leniency[9] | Override Stage 2 Sequence Number Matching |
| leniency[10] | Override Stage 2 Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_SHORT (Beacon Only) |
| leniency[11] | Override Stage 2 Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_SHORT (Data and MAC Command Only) |
| leniency[12] | Override Stage 2 Dst PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_NONE (Data and MAC Command Only) |
| leniency[13] | Override Stage 2 Dst Short Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_NONE (Data and MAC Command Only) |
| leniency[14] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Beacon Only) |
| leniency[15] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[16] | Override Stage 2 Dst Short Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_SHORT/PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[17] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Beacon Only) |
| leniency[18] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESS ION (Data and MAC Command Only) |
| leniency[19] | Override Stage 2 Dst Addr Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[20] | Override Stage 2 Src PAN ID Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Beacon Only) |
| leniency[21] | Override Stage 2 Src PAN ID Filter for DST_ADDR_MODE_NONE/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[22] | Override Stage 2 Dst PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_NONE (Data and MAC Command Only) |
| leniency[23] | Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_NONE (Data and MAC Command Only) |
| leniency[24] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ PAN_ID_COMPRESSION (Beacon Only) |
| leniency[25] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[26] | Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_SHORT/ SRC_ADDR_MODE_LONG/PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[27] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Beacon Only) |
| leniency[28] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ PAN_ID_COMPRESSION (Data and Mac Command Only) |
| leniency[29] | Override Stage 2 Dst Long Addr Filter for DST_ADDR_MODE_LONG/ SRC_ADDR_MODE_SHORT/PAN_ID_COMPRESSION (Data and Mac Command Only) |

*Table continues on the next page...*

| LENIENCY BIT | PACKET FILTERING RULE OVERRIDDEN |
|---|---|
| leniency[30] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Beacon Only) |
| leniency[31] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[32] | Override Stage 2 Short Addr Filter for DST_ADDR_MODE_SHORT/SRC_ADDR_MODE_LONG/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[33] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Beacon Only) |
| leniency[34] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSI ON (Data and MAC Command Only) |
| leniency[35] | Override Stage 2 Long Addr Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_SHORT/ NO_PAN_ID_COMPRESSION (Data and MAC Command Only) |
| leniency[36] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_LONG (Beacon Only) |
| leniency[37] | Override Stage 2 PAN ID Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_LONG (Data and MAC Command Only) |
| leniency[38] | Override Stage 2 Long Addr Filter for DST_ADDR_MODE_LONG/SRC_ADDR_MODE_LONG (Data and MAC Command Only) |
| leniency[39] | Allow an auto-TxAck frame to be sent, after a receive frame which has all of the following parameters:<br>1. Destination PAN ID = Broadcast (0xFFFF)<br>2. Destination Address = !Broadcast (not 0xFFFF)<br>3. Destination Address Mode = Short<br><br>Nominally, the SEQ_MGR inhibits auto-TxAck on such frames. |

## 64.5.2.4.2 Sequence Manager

### 64.5.2.4.2.1 Introduction

This Section describes the 802.15.4 Sequence Manager.

#### *64.5.2.4.2.1.1 Overview*

The 802.15.4 Sequence Manager (ZSM) is a hardware state machine which controls the timing of all transmit, receive, and CCA operations for the 802.15.4 Link Layer. The ZSM manages high-level 802.15.4 required timing (autosequences), and interfaces directly with a lower-level, protocol-neutral sequence manager called the Transceiver Sequence Manager (TSM), which manages the direct control of the digital, analog, and RF components of the 2.4GHz transceiver. See the TSM Chapter for more details.

For each digital and analog element in the 2.4GHz transceiver, the ZSM and TSM operate seamlessly and collaboratively, to perform some or all of the following functions:

- activation
- deactivation

- initialization
- mode transitions
- initiating calibration routines
- clock enabling and disabling
- interrupt triggering and status generation

Designed into the ZSM are a variety of complex sequences, called autosequences, which are sequential concatentations of simpler, building-block sequences. The hardware autosequences provide the following advantages:

- smaller SW memory footprint: HW automates operations previously done by SW
- increases MCU sleep times, reducing current consumption
- handles timing-critical sequences (rx-to-tx), e.g., data-polling, not possible in SW

Sequences can be initiated by software directly, or alternatively, can be initiated automatically at the expiration of a hardware timer. The general parameters of the sequences can be programmed by software prior to initiating the sequences. Such parameters allow software to select, for example:

- whether CCA is required ahead of a transmit sequence
- whether an automatic Ack frame should be transmitted after a receive sequence
- slotted vs. unslotted mode
- type of CCA (e.g., Energy Detect, CCA Mode 2)
- whether the device is a PAN Coordinator or not
- whether the device resides on 2 networks simultaneously (Dual PAN mode)

The ZSM also includes support for Dual PAN Mode, and Active Promiscuous Mode.

#### *64.5.2.4.2.1.2 Features*

- Supports complex sequences
- Unburdens software by automating many transceiver operations
- Data-polling accelerator hardware enables critical-timing sequences
- Includes Continuous CCA for low-latency-transmit applications
- Includes capability to conditionally perform CCA prior to every transmit operation
- Includes capability to conditionally transmit an Ack frame after every receive operation
- Supports software- or timer-initiated sequences
- Fully supports 2003 and 2006 versions of the 802.15.4 standard
- Supports slotted and unslotted modes
- Supports beacon-enabled and non-beacon-enabled networks
- Supports orderly transceiver shutdown on PLL unlock event
- Increases software visibility by making SEQ_STATE state readable

- Supports Dual PAN Mode, including on-the-fly channel changing
- Supports Active Promiscuous Mode

#### *64.5.2.4.2.1.3 Modes and operations*

The ZSM controls, coordinates, and automates all 802.15.4 transceiver operations within the 2.4GHz radio. Software selects the desired sequence, sets the general parameters, and (optionally) configures a hardware timer to trigger the sequence at a precise time in the future. Subsequently, the MCU can enter a low-power state, or tend to other activities, while the sequence manager state machine conducts the programmed transceiver operations. When the sequence completes, an interrupt alerts the MCU. At this point the MCU can check the completion status of the sequence, download received data from the packet buffer, and then prepare the next sequence. Sequences can be simple transceiver operations. For example, transmit one frame, or, perform a CCA on a channel. Alternatively, the sequence manager supports complex sequences, which use simple operations as building blocks, strung together in a back-to-back fashion, with precise timing intervals between operations. For example, a “TR” sequence calls for a transmit frame followed by a receive frame. For complex sequences, interrupts can optionally be generated at the completion of each stage of the sequence, providing greater visibility for the MCU into the timeline of the sequence. Software can determine the precise state of the sequence manager state machine at any time. Software can opt to abort a sequence at any time; when this happens, the sequence manager will return to its IDLE state in an orderly fashion.

#### *64.5.2.4.2.1.4 Block diagram*

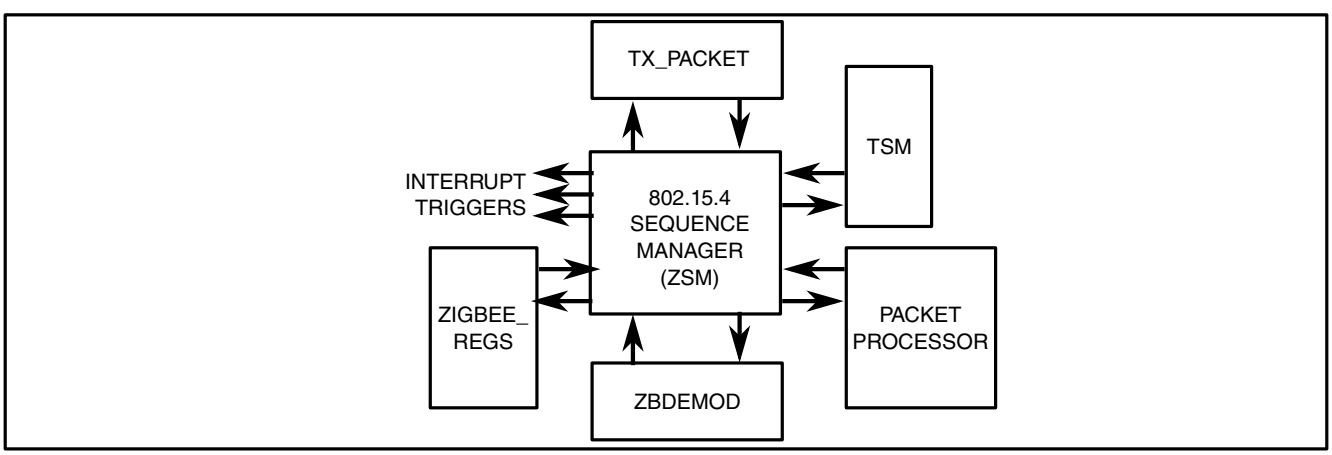

**Figure 64-148. Block diagram**

### 64.5.2.4.2.2 Memory Map and register definition

Numerous registers exist to provide configuration and status for the 802.15.4 Sequence Manager. See table below.

<table>
<tr><th>Field</th><th>R/W</th><th>Description</th></tr>
<tr><td>XCVSEQ</td><td>rw</td><td>The Transceiver Sequence Selector register selects a sequence for the sequence manager to execute. Sequence initiation can be immediate, or scheduled (see TMRTRIGEN). A write of XCVSEQ=IDLE will abort any ongoing sequence. A write of XCVSEQ=IDLE must always be performed after a sequence is complete, and before a new sequence is programmed. Any write to XCVSEQ other than XCVSEQ=IDLE during an ongoing sequence, shall be ignored. The mapping of XCVSEQ to sequence types is as follows:
<table>
<tr><th>XCVSEQ</th><th>SEQUENCE</th><th>DESCRIPTION</th></tr>
<tr><td>0</td><td>I</td><td>IDLE</td></tr>
<tr><td>1</td><td>R</td><td>RECEIVE</td></tr>
<tr><td>2</td><td>T</td><td>TRANSMIT</td></tr>
<tr><td>3</td><td>C</td><td>CCA</td></tr>
<tr><td>4</td><td>TR</td><td>TRANSMIT/RECEIVE</td></tr>
<tr><td>5</td><td>CCCA</td><td>CONTINUOUS CCA</td></tr>
</table></td></tr>
<tr><td>TMRTRIGEN</td><td>rw</td><td>Timer2 Trigger Enable.<br>1: allow timer TC2 (or TC2') to initiate a preprogrammed sequence (see XCVSEQ register).<br>0: programmed sequence initiates immediately upon write to XCVSEQ.</td></tr>
<tr><td>CCABFRTX</td><td>rw</td><td>CCA Before TX. Applies only to Sequences T and TR, ignored during all other sequences.<br>1: at least one CCA measurement is required prior to the transmit operation (see also SLOTTED).<br>0: no CCA required, transmit operation begins immediately.</td></tr>
<tr><td>SLOTTED</td><td>rw</td><td>Slotted Mode, for beacon-enabled networks. Applies only to Sequences T, TR, and R, ignored during all other sequences. Used, in concert with CCABFRTX, to determine how many CCA measurements are required prior to a transmit operation. Also used during R sequence to determine whether the ensuing transmit acknowledge frame (if any) needs to be synchronized to a backoff slot boundary.</td></tr>
<tr><td>RXACKRQD</td><td>rw</td><td>Receive Acknowledge Frame required. Applies only to Sequence TR, ignored during all other sequences.<br>1: A receive Ack frame follows the transmit frame.<br>0: An ordinary receive frame (not an Ack frame) follows the transmit frame.</td></tr>
<tr><td>AUTOACK</td><td>rw</td><td>Auto Acknowledge Enable. Applies only to Sequence R and Sequence TR, ignored during other sequences.</td></tr>
</table>

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | 1: sequence manager will follow a receive frame with an automatic hardware-generated Tx Ack frame, assuming other necessary conditions are met.<br>0: sequence manager will not follow a receive frame with a Tx Ack frame, under any conditions; the sequence will terminate after the receive frame. |
| CRC_MSK | rw | CRC Mask.<br>1: sequence manager requires CRCVALID=1 at the end of the received frame in order for the receive operation to complete successfully; if CRCVALID=0, sequence manager will return to preamble-detect mode after the last octet of the frame has been received.<br>0: sequence manager ignores CRCVALID and considers the receive operation complete after the last octet of the frame has been received. |
| PROMISCUOUS | rw | Prevents auto-TxAck on received packets<br>1: promiscuous mode, no auto-TxAck<br>0: auto-TxAck allowed, depending on other conditions. |
| CCATYPE[1:0] | rw | Clear Channel Assessment Type. Selects one of four possible functions for CCA or ED, per below. (See Chapter CCA/ED/LQI for more details).<br>00: ENERGY DETECT<br>01: CCA MODE 1<br>10: CCA MODE 2<br>11: CCA MODE 3 |
| TC3TMOUT | rw | 1: Allow a TMR3 timeout to abort any RX operation<br>0: Don't allow a TMR3 timeout to abort any RX operation<br>See Appendix A for more details on how autosequences are affected by a TMR3 timeout |
| SEQ_STATE[4:0] | r | This read-only register reflects realtime 802.15.4 Sequence Manager (ZSM) state |
| ACTIVE_PROMISCUOUS | rw | 1: Provide Data Indication on all received packets under the same rules which apply in PROMISCUOUS mode, however acknowledge those packets under rules which apply in non-PROMISCUOUS mode<br>0: normal operation (Default) |
| ACTIVE_NETWORK | rw | Selects the PAN on which to transceive, by activating a PAN parameter set (PAN0 or PAN1). In Manual Dual PAN mode (or Single PAN mode), this bit selects the active PAN parameter set (channel and addressing parameters) which governs all autosequences. In Auto Dual PAN mode, this bit selects the PAN on which to begin transceiving, latched at the point at which DUAL_PAN_DWELL register is written.<br>1: Select PAN1<br>0: Select PAN0 (Default) |
| DUAL_PAN_AUTO | rw | Activates automatic Dual PAN operating mode. In this mode, PAN-switching is controlled by hardware at a pre-programmed rate, determined by DUAL_PAN_DWELL.<br>1: Auto Dual PAN Mode |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | The readback value indicates that between N-1 and N timebase units remain until the next PAN switch. For example, a DUAL_PAN_REMAIN readback value of 3, with a DUAL_PAN_DWELL PRESCALER setting of 2 (10ms), indicates that between 20ms (2*10ms) and 30ms (3*10ms), remain until the next automatic PAN switch. |
| RECD_ON_PAN0 | r | Indicates the packet which was just received, was received on PAN0.<br>In Dual PAN mode operating on 2 different channels, RECD_ON_PAN0 will be set if CURRENT_NETWORK=0 when the packet was received, regardless of FILTERFAIL status.<br>In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN0 will be set only if a valid packet was received on PAN0 (PAN0's FILTERFAIL_FLAG is deasserted). |
| RECD_ON_PAN1 | r | Indicates the packet which was just received, was received on PAN1.<br>In Dual PAN mode operating on 2 different channels, RECD_ON_PAN1 will be set if CURRENT_NETWORK=1 when the packet was received, regardless of FILTERFAIL status.<br>In DUAL PAN mode operating with same channel on both networks, CURRENT_NETWORK will be ignored and RECD_ON_PAN1 will be set only if a valid packet was received on PAN1 (PAN1's FILTERFAIL_FLAG is deasserted). |
| ACKDELAY[5:0] | rw | Provides a fine-tune adjustment of the time delay between Rx warmdown and the beginning of Tx warmup for an Tx Acknowledge packet. ACKDELAY register will apply to both SLOTTED and UNSLOTTED TxAck, but only to TxAck (not T sequences). This is a two's complement value. The minimum permissible value is -19 (0x2D). Values less than -19 will lead to unexpected results.<br>Resolution = 2us.<br>Range = +/- 62us.<br>Default = 0x0.<br>Max ACKDELAY = 0x1F.<br>Min ACKDELAY = 0x2d. |
| TXDELAY[5:0] | rw | Provides a fine-tune adjustment of the time delay between post-CCA Rx warm-down and the beginning of Tx warm-up for an Tx (non-Ack) packet. TXDELAY register will apply in both SLOTTED and UNSLOTTED modes, but only to T sequences (e.g., T, TR, and T(R) ), not TxAck operations. This is a two's complement value. The minimum permissible value is -19 (0x2D). Values less than -19 will lead to unexpected results.<br>Resolution = 2us.<br>Range = +/- 62us.<br>Default = 0x0.<br>Max TXDELAY = 0x1F.<br>Min TXDELAY = 0x2d |
| CLR_NEW_SEQ_INHIBIT | rw | when asserted, overrides the automatic hardware locking of the programmed XCVSEQ while an autosequence is underway. Asserting this feature will allow software to change the programmed |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| | | autosequence “on-the-fly”, without aborting and returning to idle between sequences. Overriding the hardware lockout of XCVSEQ should be used with caution, since the Sequence Manager is not designed (or verified) for manual state transitions between one type of autosequence and other (i.e., Sequence T -> Sequence R). |
| NO_RX_RECYCLE | rw | when asserted, prevents the Sequence Manager from automatically re-starting the receiver when a packet is received which results in a FilterFail or CRC failure. Normally, the Sequence Manager jumps to the RX_CYC state, and then resumes from there with a new Rx warmup, in search of a new packet. When this bit is set, the Sequence Manager will instead return to idle state, and issue a SEQIRQ, after a FilterFail or CRC failure. |
| LATCH_PREAMBLE | rw | 1: Make PREAMBLE_DET and SFD_DET bits of PHY_STS Register “sticky”, i.e.,occurrences of preamble and SFD detection are latched and held until the start of the next autosequence<br>0: Don’t make PREAMBLE_DET and SFD_DET bits of PHY_STS Register “sticky”, i.e, these status bits reflect the realtime, dynamic state of preamble_detect and sfd_detect. (default) |
| XCVSEQ_ACTUAL[2:0] | r | indicates the programmed sequence that has been recognized by the Sequence Manager.<br>Takes into account the fact that sequence-change commands from software are ignored<br>while a sequence is underway (see new_seq_inhibit bit). Read-only bits. |
| SEQ_IDLE | r | when asserted, indicates that the Sequence Manager is in its idle state. Read-only bit. |
| NEW_SEQ_INHIBIT | r | when asserted, indicates that a new programmed autosequence has commenced (TMR2 match has occurred if TMRTRIGEN=1). Once this bit is asserted, software is blocked from commanding any new autosequences (other than Sequence I to abort the current sequence), until the current sequence completes. Hardware will ignore a sequence-change command from software while this bit is asserted. Hardware will automatically deassert this bit once the sequence completes. Read-only bit. |
| RX_TIMEOUT_PENDING | r | when asserted, indicates that a TMR3 timeout (RX timeout) flag has been set by Hardware, but the Sequence Manager has not yet aborted because an RX operation is not currently underway. This would be the case, for example, during a Sequence TR, if a TMR3 timeout were to occur during the transmit operation of this sequence; the sequence would not be aborted by Hardware until the receive operation begins. This bit will always be 0 if TC3TMOUT=0. Read-only bit. |
| RX_MODE | r | indicates that an RX operation is in progress. CCA and ED operations are considered RX operations. Read-only bit. |
| TMR2_SEQ_TRIG_ARMED | r | when asserted, indicates that TMR2 has been programmed and is armed to trigger a new autosequence, when Sequence Manager timer-triggering mode is selected (i.e., TMRTRIGEN=1). When timer-triggering mode is selected, TMR2 must be re-programmed (using either T2CMP or T2), in advance of each new sequence. Once TMR2 is programmed, this bit will be asserted, and will remain asserted until the new sequence commences (at TMR2 match). Hardware will deassert this bit when the new sequence starts. When TMRTRIGEN=0, this bit should be ignored. Read-only bit. |

*Table continues on the next page...*

| Field | R/W | Description |
|---|---|---|
| SW_ABORTED | r | when asserted, indicates that the autosequence has terminated due to an Software abort. Software can abort any programmed autosequence by writing Sequence I to XCVSEQ. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| TC3_ABORTED | r | when asserted, indicates that the autosequence has terminated due to an TC3 (TMR3) timeout during a receive operation. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| PLL_ABORTED | r | when asserted, indicates that the autosequence has terminated due to an PLL unlock event. This bit is valid at the SEQIRQ interrupt. Hardware will maintain this bit asserted until the next autosequence commences. Read-only bit. |
| CCCA_BUSY_CNT[5:0] | r | For Sequence CCCA mode only, this register indicates the number of “busy” CCA attempts which occurred during the autosequence, before the channel was detected to be idle. This register can also be read in real-time (during the autosequence) to determine how many busy CCA attempts have occurred to that point. The register saturates at 63 (i.e, if there are more than 63 busy attempts, the register will continue to read 63). This register is automatically cleared to zero by hardware when the next autosequence commences. Read-only register. |
| SEQ_T_STATUS[5:0] | r | Status of the just-completed (or ongoing) Sequence T or Sequence TR autosequence. This register is valid at all times during, and after, the Sequence T or Sequence TR. Not valid for other types of autosequences. This is a read-only register. The bits of this register map to status, according to the following table:<br>[0] 1st CCA complete (CCABFRTX=1)<br>[1] 2nd CCA complete (SLOTTED=1)<br>[2] Tx operation complete<br>[3] Rx Rec ycle occurred (Sequence TR only)<br>[4] Rx operation complete (Sequence TR only)<br>[5] TxAck operation complete(Sequence TR only) |
| CONTINUOUS_EN | rw | Enable Continuous TX or RX mode (testmode). See Appendix B. |
| SLOT_PRELOAD[7:0] | rw | This register represents the number that gets loaded into the slot_timer at SFD detect, which ultimately determines when the next slot boundary will occur. Due to processing delays within the analog front-end and digital modem, the point at which SFD is detected by the modem, is delayed relative to over-the-air timing. Since this timing may not be known prior to until actual silicon, and since this is such a critical timing parameter for slotted operations, it has been made programmable. The default value is 0x74. This timing parameter is critical for the Sequence R autosequence in slotted mode, when an automatic TxAck is required. |

### 64.5.2.4.2.3 Functional description

This section describes the supported sequences in more detail. All sequences can be initiated by software directly (instantaneously) by writing the desired sequence to the XCVSEQ register, with the TMRTRIGEN bit deasserted. Alternatively, software can

schedule the initiation of a sequence at a precise time in the future, by programming the desired start time into the T2CMP (or T2PRIMECMP) timer compare register, and setting the TMRTRIGEN bit. The XCVSEQ register field is writable and readable, so software can read this register to determine which sequence it had programmed earlier. After the sequence completes (SEQIRQ interrupt), software should set the XCVSEQ to IDLE (0x0), before initiating a new sequence. If the sequence-complete interrupt (SEQIRQ) is masked, software can determine when the sequence is complete by polling the SEQ_STATE register, until it returns to SEQ_IDLE (0x0). While a sequence is ongoing, software can abort the sequence at any time by writing IDLE (0x0) to XCVSEQ; the sequence manager state machine will respond with an orderly return to the SEQ_IDLE state, and a SEQIRQ will be generated. While a sequence is underway, software should not attempt to change XCVSEQ (other than aborting the sequence as previously described); the sequence manager will ignore all mid-sequence attempts to change XCVSEQ. As mentioned previously, software should write the IDLE value to XCVSEQ before changing sequences. If TMR2 triggering is enabled (TMRTRIGEN=1), after the scheduled sequence is automatically launched at TMR2 match, and then completes, software must re-arm TMR2 triggering by writing to either T2CMP, or T2PRIMECMP. At least the LS byte of one of these registers must be written to re-arm. This hardware interlock is designed to prevent the inadvertent re-triggering of sequences, which would otherwise occur after the 24-bit Event Timer rolls over.

The supported sequences are shown in the following table.

**Table 64-43. Supported Sequences**

| XCVSEQ | Sequence | Description |
|---|---|---|
| 0 | I | Idle |
| 1 | R | Receive Sequence<br>- conditionally followed by a TxAck |
| 2 | T | Transmit Sequence |
| 3 | C | Standalone CCA |
| 4 | TR | Transmit /Receive Sequence<br>- transmit unconditionally followed by either an R or RxAck |
| 5 | CCCA | Continuous CCA<br>- sequence completes when channel is idle |
| 6 | Reserved | |
| 7 | Reserved | |

All sequences can be aborted by a PLL unlock detection. The unlock detection is qualified by the sequence manager; in other words, an unlock detection during the early stages of the PLL warmup is expected, and is not allowed to abort the sequence at that

point. The primary rationale for the PLL unlock abort, is to prevent transmission on an incorrect, or unstable, frequency during a transmit operation, or to increase battery life by not prolonging a receive or CCA operation that is bound to fail. Software can disable the PLL unlock auto-abort. See Sequence Aborting.

#### *64.5.2.4.2.3.1 Supported Sequences*

##### *64.5.2.4.2.3.1.1 Sequence I (Idle)*

When the IDLE value is written to XCVSEQ, the sequence manager goes to its SEQ_IDLE state. If not already in SEQ_IDLE, the sequence manager executes an orderly warmdown to return to SEQ_IDLE. A SEQIRQ interrupt is then issued. Writing IDLE value to XCVSEQ is the proper way to abort a sequence.

When a sequence is aborted in this way (called a software abort), the SW_ABORTED bit of the ABORT_STS register in 802.15.4 space, will become set. This bit will be self-cleared at the start of the next autosequence.

##### *64.5.2.4.2.3.1.2 Sequence R (Receive)*

Sequence R is the basic receive sequence. Sequence R can be used to receive all types of 802.15.4 PHY- and MAC-compliant frames, including reserved frame types. However, reception of Acknowledge frames is not recommended using Sequence R. This is because reception of an Acknowledge frame, usually follows a transmitted frame, with a designated Sequence Number, so that the received Acknowledge frame can be verified for the matching Sequence Number. In a standalone Sequence R, there is no Sequence Number to verify against, so any Acknowledge frame is merely transferred to the Packet Buffer. (Note: the appropriate way to receive Acknowledge frames is with Sequence TR, with the RXACKRQD bit asserted). Using Sequence R, *all* frames which pass frame-filtering rules and CRC check, are transferred to the Packet Buffer.

The basic execution of a successful Sequence R is as follows:

- MCU writes TC2 compare value to the desired initiation time, and sets TMRTRIGEN (optional)
- MCU writes XCVSEQ=R
- Wait for TC2 match (if TMRTRIGEN=1)
- SEQ_MGR executes RxWarmup
- Preamble Detected
- SFD Detected
- FrameLength octet received, transferred to Packet Buffer
- *N* additional octets received (*N* = FrameLength), transferred to Packet Buffer. *Note if (FrameLength > 127), then N = 127.*
- If frame-filtering rules and CRC check pass:

- ---> RXIRQ interrupt issued
- ---> SEQ_MGR executes RxWarmdown
- ---> If received Frame Control Field indicates AckRequest=1
- ---- ---> SEQ_MGR executes TxWarmup
- ---- ---> an Ack frame is transmitted using the received Sequence Number
- ---- ---> SEQ_MGR executes TxWarmdown
- SEQIRQ interrupt issued

When Sequence R is initiated, the ZSM sequence manager warms up the receiver (analog and digital elements), via the TSM (Transceiver Sequence Manager). After warmup is complete, timer TMR3 can be enabled as a “bracketing” timer (software option). If a TMR3 timer match occurs, and software has asserted the TC3TMOUT bit, the sequence manager will warm down the receiver and return to SEQ_IDLE state. Assuming no TMR3 timeout, reception proceeds in preamble-search mode. Once a preamble is detected, reception continues in SFD-search mode. At this point, the sequence manager’s slot timer is activated. This is because a slotted “transmit acknowledge” frame (TxAck) may be required later in this sequence. The slot timer is loaded with the following value (in us):

Slot Timer Preload = 160 + TXWARMUPTIME + (2*ACKDELAY).

The 160 term arises because, at the point of SFD detection, we are exactly 10 symbols into the backoff slot, and the symbol period is 16us. The slot timer will count up and eventually rollover at 319, to 0. (There are 320us in a backoff slot). The receiver receives the next octet (FrameLength). Starting with this octet, and continuing through the remainder of the frame, each octet that is received is transferred to Packet Buffer. After each octet is transferred to Packet Buffer, the Packet Buffer address is incremented by 1. The next 2 octets (Frame Control Field) are then received, which are parsed to obtain the AckRequest field, and the FrameVersion field. The next octet is then received (SequenceNumber), and stored. The remainder of the frame, determined by FrameLength, is then received. As the octets are received, the packet data is parsed and subjected to packet-filtering rules (see Chapter Packet Processor). If any of the packet-filtering rules fail, or if the CRC check on the FCS field fails, the sequence manager will return the receiver to preamble-search mode, after the last octet has been received and transferred to Packet Buffer. Assuming the packet-filtering rules and CRC pass, an interrupt (RXIRQ) is issued to the MCU. At this point, the sequence manager must determine if a TxAck is required. A TxAck is required if the following 3 conditions are all met:

- AUTOACK=1 (register bit)
- PROMISCUOUS=0 (register bit)
- The received FrameControlField has AckRequest=1

If these conditions are met, and SLOTTED mode is not in effect, the sequence manager loads its TxAck timer with the following value (in us):

TxAck Timer Preload = 192 - TXWARMUPTIME - 2*ACKDELAY

The 192us is the non-slotted RX-to-TX turnaround requirement in the 802.15.4 standard. The TXWARMUPTIME takes into account the fact that the TxAck timer must expire early for the Tx warmup to be complete at exactly the 192us point. The ACKDELAY is a signed, fine-tune adjustment to the TxAck transmission time (+/- 62us).

If SLOTTED mode is in effect, the slot timer was previously loaded (at SFD detect), but the sequence manager needs to determine how much time is left in the current backoff slot. If less than 192us remain, the sequence manager must wait an *additional* backoff slot before initiating the Ack transmission. So it sets a flag indicating it must allow the slot counter to rollover an additional iteration.

Finally, at TxAck timer expiration (in non-SLOTTED mode), or at the qualified rollover of the slot timer (in SLOTTED mode), a Tx warmup is initiated. The conclusion of the Tx warmup will coincide precisely with a backoff slot boundary if SLOTTED mode is in effect. The sequence manager will then initiate the transmission of the Ack frame. The entire Ack frame will be built up by hardware; the Packet Buffer is not used for the auto-TxAck feature. The hardware will insert the following parameters into the Ack frame's Frame Control Field:

**Table 64-44. Frame Control Field for Hardware-generated Auto-TxAck Frame**

| FCF Field | Value |
|---|---|
| FrameType | Acknowledge |
| SecurityEnabled | 0 |
| FramePending | Determined by the Packet Processor.<br>(see Packet Processor Chapter, Source Address Management.) |
| AckRequest | 0 |
| PanIDCompression | 0 |
| Reserved (bits 7-9) | 000 |
| DstAddrMode | 0 |
| FrameVersion | 0 |
| SrcAddrMode | 0 |

The Sequence Number for the Ack packet, will be the Sequence Number obtained from the previously received frame.

After the Ack frame has been transmitted, the sequence manager will issue a TXIRQ interrupt, and then perform a Tx warmdown. Finally, a SEQIRQ interrupt will be issued, and the sequence manager returns to SEQ_IDLE state.

#### *64.5.2.4.2.3.1.3 Sequence T (Transmit)*

Sequence T is the basic, standalone transmit sequence. Sequence T can be used to transmit all types of 802.15.4 PHY- and MAC-compliant frames. However, transmission of Acknowledge frames is not recommended using Sequence T. This is because transmission of an Acknowledge frame, usually follows a received frame, with a designated Sequence Number. The ZSM sequence manager automates the transmission of an Ack frame which follows a received frame, using Sequence R with the AUTOACK bit asserted. This is the recommended method for transmitting an Ack frame. This is especially beneficial, because the transmitted Ack frame octets are generated by hardware, and so no setup of a transmit packet in Packet Buffer, is required. However, sequence manager hardware does not prohibit Ack frames using Sequence T.

Sequence T allows for the insertion of 1 or 2 CCA (clear channel assessment) measurements prior to transmission, to ensure that the selected channel is idle. The CCA-before-TX feature is governed by two register bits, CCABFRTX and SLOTTED. All CCA measurements must indicate channel-idle, in order for the sequence manager to proceed to transmission; if the channel is determined by CCA to be busy, the sequence

manager will terminate the sequence without a transmission. The number of CCA measurements attempted by the sequence manager, and the timing of the measurements, is shown in the following table.

**Table 64-45. Timing of CCA Operations for Sequence T**

| CCABFRTX | SLOTTED | Number of CCA measurements | Timing of Initiation of CCA measurement #1 | Timing of Initiation of CCA measurement #2 | Timing of First Bit of Transmitted Frame (assumes channel idle) |
|---|---|---|---|---|---|
| 0 | X | 0 | - | - | Immediately follows TxWarmup |
| 1 | 0 | 1 | Immediately follows RxWarmup | - | Immediately follows RxWarmdown and TxWarmup |
| 1 | 1 | 2 | Immediately follows RxWarmup | 320us after Initiation of CCA measurement #1 | 320us after Initiation of CCA measurement #2 |

Any CCA mode can be used for Sequence T and Sequence TR (CCA Modes 1, 2, and 3 are available. See Chapter CCA/ED/LQI). Software must configure the CCATYPE bits prior to initiating the autosequence, to select the CCA Mode.

The basic execution of a successful Sequence T is as follows:

- MCU writes TC2 compare value to the desired initiation time, and sets TMRTRIGEN (optional)
- MCU sets CCABFRTX if one or more CCA's are required prior to transmit
- MCU sets SLOTTED if in slotted mode (2 CCA's will be attempted)
- MCU writes XCVSEQ=T
- Wait for TC2 match (if TMRTRIGEN=1)
- If CCABFRTX=1 :
- ---> SEQ_MGR executes RxWarmup
- ---> SEQ_MGR initiates CCA measurement (takes 128us)
- ---> if CCA indicates channel busy, sequence terminates, CCAIRQ & SEQIRQ issued
- ---> otherwise, if CCA indicates channel idle:
- ---- ---> if SLOTTED=0, SEQ_MGR executes a RxWarmdown, followed by a TxWarmup
- ---- ---> if SLOTTED=1, SEQ_MGR initiates a 2nd CCA, 320us after initiating 1st CCA.
- ---- ---> if SLOTTED=1, and channel busy, sequence terminates, CCAIRQ & SEQIRQ issued

- ---- ---> if SLOTTED=1, and channel idle, SEQ_MGR executes a RxWarmdown, followed by a TxWarmup
- if SLOTTED=1, SEQ_MGR waits until 320us elapse after 2nd CCA initiation
- SEQ_MGR executes TxWarmup
- Preamble transmitted
- SFD transmitted
- FrameLength octet is obtained from Packet Buffer Address 0, and transmitted
- CRC engine is reset
- *N* additional octets are obtained from Packet Buffer and transmitted (*N* = FrameLength - 2)
- Each octet that is transmitted, is shifted through the CRC engine
- After *N*th octet transmitted, FCS is available from CRC engine.
- FCS lower octet transmitted
- FCS upper octet transmitted
- SEQ_MGR issues TXIRQ
- SEQ_MGR executes TxWarmdown
- SEQ_MGR issues SEQIRQ

When Sequence T is initiated, the sequence manager first must determine if one or more CCA measurements are required. If CCABFRTX bit is asserted, the sequence manager warms up the receiver (analog and digital elements), via the TSM (Transceiver Sequence Manager). Immediately after the conclusion of the warmup, a CCA measurement is initiated. The CCA measurement takes 128us. If CCA indicates the channel is busy, the sequence manager warms down the receiver, issues CCAIRQ and SEQIRQ interrupts, and terminates the sequence. If, however, CCA indicates the channel is idle, the sequence manager inspects the SLOTTED bit to determine what to do next. If the SLOTTED bit is clear, the sequence manager issues a CCAIRQ interrupt, and then executes a warmdown of the receiver. If, however, the SLOTTED bit is set, the sequence manager does not issue a CCAIRQ interrupt; instead, the sequence manager initiates a second CCA measurement, precisely 320us after the initiation of the first CCA. This 320us interval is timed by the slot timer, which had been preloaded with 320 (microseconds) at the instant that Rx warmup was complete. At the conclusion of the second CCA, the sequence manager issues a CCAIRQ. If the second CCA indicates the channel is busy, the sequence manager warms down the receiver, issues a SEQIRQ interrupt, and terminates the sequence. If, however, CCA indicates the channel is idle, the sequence manager executes a warmdown of the receiver. Prior to executing the warmdown, the sequence manager reloads the slot timer, in order to precisely schedule the ensuing transmission. This time, the slot timer is loaded with a smaller value, in order to account for the fact that the timer must expire early in order to trigger the Tx warmup, which must complete at precisely the next backoff slot boundary. Thus, this time the slot timer is preloaded with:

Slot Timer Preload = 320 - TXWARMUPTIME + (2*TXDELAY).

The 320us is the duration of the backoff slot. The TXWARMUPTIME takes into account the fact that the TxAck timer must expire early for the Tx warmup to be complete at exactly the 320us point. The TXDELAY is a signed, fine-tune adjustment to the TxAck transmission time (+/- 62us).

If the SLOTTED bit is asserted, once the slot timer expires, the sequence manager executes a Tx warmup. The conclusion of this warmup coincides with the backoff slot boundary. If the SLOTTED bit is deasserted, the sequence manager does not wait for the slot timer, and instead executes a Tx warmup immediately after the Rx warmdown.

At this point, the sequence manager begins the transmit operation. The preamble and SFD are transmitted first. The preamble and SFD octets are generated by hardware, and are not included in the Packet Buffer. Then, the FrameLength octet is obtained from the Packet Buffer (address 0), and the buffer address pointer is incremented by one. The FrameLength octet is transmitted. The CRC engine is reset at this point. The FrameLength octet is used to determine how many more octets remain in the Packet Buffer. The number of remaining octets is:

Number of octets remaining in Tx buffer = FrameLength - 2

This is because the final 2 octets of the transmit frame constitute the FCS (Frame Check Sequence), and this value is hardware-computed. Thus, FCS is not part of the Tx buffer. Each of the octets in the Tx buffer is transmitted, and simultaneously shifted through CRC, to generate the FCS field. Once the Tx buffer is drained and all of its octets transmitted, the 2 FCS octets are transmitted, starting with the least significant octet. At this point, the transmit operation is complete. The sequence manager issues a TXIRQ interrupt. The sequence manager then executes a complete Tx warmdown, and follows up with a SEQIRQ interrupt. The sequence manager returns to SEQ_IDLE state.

#### *64.5.2.4.2.3.1.4 Sequence C (CCA)*

Sequence C is the standalone CCA sequence. During Sequence C, the sequence manager executes a Clear Channel Assessment (CCA). The result of the CCA measurement is reported back to software in the CCA bit of the IRQSTS2 Register. The CCA bit indicates either a busy channel (1), or an idle channel (0).

The basic execution of a Sequence C is as follows:

- MCU writes TC2 compare value to the desired initiation time, and sets TMRTRIGEN (optional)
- MCU writes XCVSEQ=C
- Wait for TC2 match (if TMRTRIGEN=1)
- SEQ_MGR asserts one of {**cca1_en, cca2_en, cca3_en, ed_en** } to CCA_DIG
- SEQ_MGR executes RxWarmup, via Transceiver Sequence Manager
- SEQ_MGR initiates CCA measurement by asserting **rx_cca_en** to CCA_DIG
- SEQ_MGR waits for CCA to complete

- CCA bit is set to the CCA status (1=busy 0=idle)
- CCAIRQ interrupt issued
- SEQ_MGR executes RxWarmdown
- SEQIRQ interrupt issued

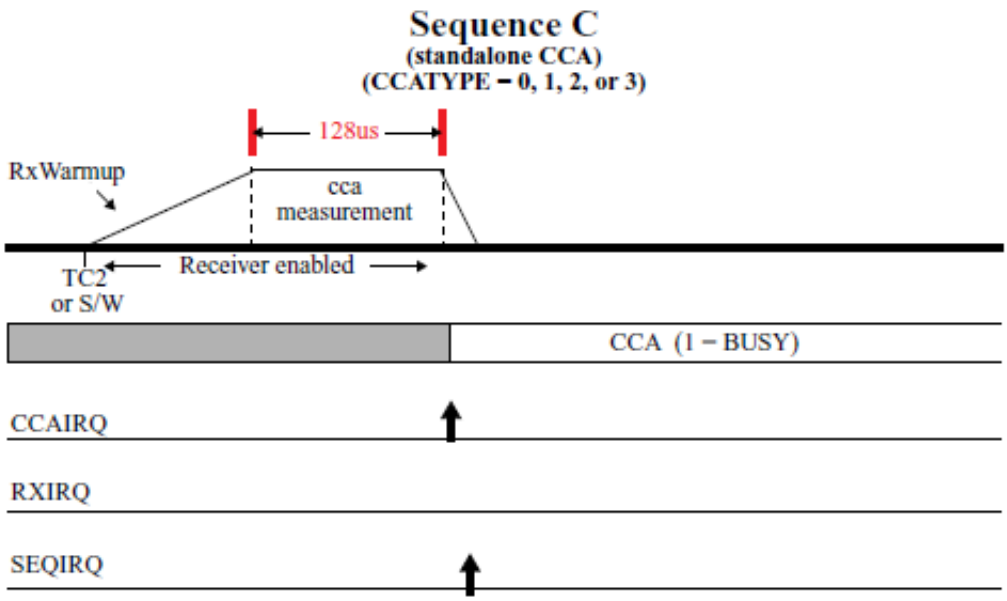
When Sequence C is initiated, the sequence manager asserts one of 4 control signals to CCA_DIG, based on which CCA or ED mode is programmed into CCATYPE[1:0]. The mapping of CCATYPE[1:0] to control signal is shown in the following table:

| CCATYPE[1:0] | CCA_DIG CONTROL SIGNAL |
|---|---|
| 00 | ed_en |
| 01 | cca1_en |
| 10 | cca2_en |
| 11 | cca3_en |

The asserted control signal will remain asserted for the duration of the Sequence C. The sequence manager warms up the receiver (analog and digital elements), via the Transceiver Sequence Manager (TSM). The TC3 “bracketing” timer has no effect on the sequence manager during Sequence C, so it cannot abort the sequence. At the competion of the warmup, the sequence manager intiates the CCA by asserting the **rx_cca_en** signal to CCA_DIG. While CCA is enabled, the CCA_DIG measures and averages the energy or signal on the channel. At the completion of the CCA process, the CCA bit is set to the status of the channel (idle or busy). The CCAIRQ is issued, the receiver is warmed down, the SEQIRQ is issued, and the sequence manager returns to SEQ_IDLE state.

Any CCATYPE setting may be used for Sequence C.

## Sequence C Timing Diagrams



#### *64.5.2.4.2.3.1.5 Sequence TR (Transmit/Receive)*

Sequence TR is a combination Transmit/Receive sequence. The sequence is executed as a concatenation of 1 transmit operation followed by 1 receive operation, with a minimum TX-to-RX turnaround time in between. There are 2 permutations of Sequence TR, depending on the RXACKRQD bit. For both permutations, the Sequence T which constitutes the first half of a Sequence TR, is identical to the standalone Sequence T (XCVSEQ=2). This means that the transmit operation can be slotted or unslotted, and can be preceded by 1 or 2 CCA measurements, depending on the state of the CCABFRTX and SLOTTED bits.

If RXACKRQD=0, then Sequence TR is executed as a Sequence T followed by a Sequence R, with a minimum TX-to-RX turnaround time in between. The Sequence R, which constitutes the second half of the Sequence TR, is identical to the standalone Sequence R (XCVSEQ=1). This means that the receive operation can be followed by an automatic, hardware-generated transmit Acknowledge frame, if all the necessary conditions are met. As with basic Sequence R, data for a successful receive operation is always transferred to Packet Buffer.

If RXACKRQD=1, then Sequence TR is executed as a Sequence T followed by a Receive-Acknowledge-Only frame. This type of receive operation is special, and not the same as a standalone Sequence R. The Ack-only receive operation filters all incoming frames, looking only for an Acknowledge frame whose Sequence Number matches the Sequence Number which was transmitted in the Sequence T portion of the sequence. All

non-matching frames are discarded, and after each non-matching frame, the sequence manager will return the receiver to preamble-detect mode. This receive operation will continue until the matching Ack frame is received. Since this is a Receive-Acknowledge-Only operation, and not a Sequence R, there will be no receive octets transferred to Packet Buffer (an exception is made if ACTIVE_PROMISCUOUS=1; if so, all receive octets are transferred to the Packet Buffer, even for the Receive-Acknowledge-Only frame). The sequence will end with a RXIRQ interrupt, which indicates that the matching Ack frame was successfully received.

Needless to say, if during the transmit operation of a Sequence TR, an Acknowledge frame is being requested of the receiving end device (Frame Control Field: AckRequest=1), then Sequence TR with RXACKRQD=1 is the appropriate procedure. (Using Sequence TR with *RXACKREQ=0* is *not* recommended for this scenario, since there is no Sequence Number matching.)

Conversely, if during the transmit operation of a Sequence TR, an Acknowledge frame is *not* being requested of the receiving end device (Frame Control Field: AckRequest=0), then Sequence TR with RXACKRQD=1 should *never* be used, since a receive acknowledge frame will not be forthcoming. Instead, use Sequence TR with RXACKRQD=0, or simply Sequence T, if no followup receive frame is expected.

### *64.5.2.4.2.3.1.6 Sequence CCCA (Continuous CCA)*

Sequence CCCA is the Continuous CCA sequence. This sequence is designed to accommodate situations where channel availability may be infrequent, or low-duty-cycle, and a device needs to be able to transmit at the earliest available opportunity. During Sequence CCCA, the sequence manager repeats CCA measurements continuously until a channel-idle condition is found. The interval between the end of one CCA measurement, and the start of the next, is 63us. The actual interval between consecutive CCA measurements (i.e., from measurement-start to measurement-start), in the CCCA sequence, is 193us. After each CCA iteration, the CCA bit (IRQSTS2 Register) is set to the result of the measurement. As long as the CCA bit is high (busy) at the end of the iteration, the sequence manager will initiate a new measurement. Unlike Sequence C (standalone CCA), there is no CCAIRQ interrupt generated at the end of each CCA

measurement, until the channel-idle condition is detected, at which point CCAIRQ is issued. The SLOTTED bit has no effect on this sequence. A Sequence CCCA will be aborted by the ZSM Sequence Manager if a TMR3 match occurs, and TC3TMOUT=1. CCA Modes 1, 2, or 3, can be used for Continuous CCA.

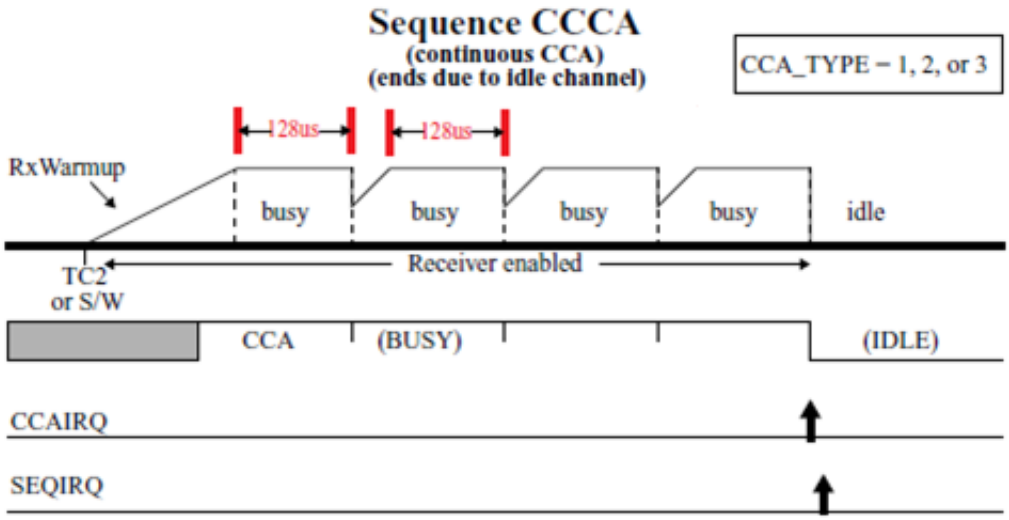
The basic execution of a Sequence CCCA is as follows:

- MCU writes TC2 compare value to the desired initiation time, and sets TMRTRIGEN (optional)
- MCU writes XCVSEQ=CCCA
- Wait for TC2 match (if TMRTRIGEN=1)
- SEQ_MGR asserts one of {**cca1_en, cca2_en, cca3_en** } to CCA_DIG
- SEQ_MGR executes RxWarmup
- SEQ_MGR initiates CCA measurement by asserting **rx_cca_en** to CCA_DIG
- SEQ_MGR waits for CCA to complete
- CCA bit is set to the CCA status (1=busy 0=idle)
- If CCA=1, initiate a new CCA measurement immediately and repeat the previous 4 steps
- If CCA=0, CCAIRQ is issued
- SEQ_MGR executes RxWarmdown
- SEQIRQ interrupt issued

**Note:** The CCA bit (IRQSTS2 register) may change dynamically during the CCA measurement, and are only considered valid (and sampled by the Sequence Manager), at the end of the CCA measurement; therefore the user should not continuously poll CCA during CCCA and be expecting continuously-valid results

**Note:** The user can continuously monitor progress of the Sequence CCCA by reading the CCCA_BUSY_CNT register.

## Sequence CCCA Timing Diagrams

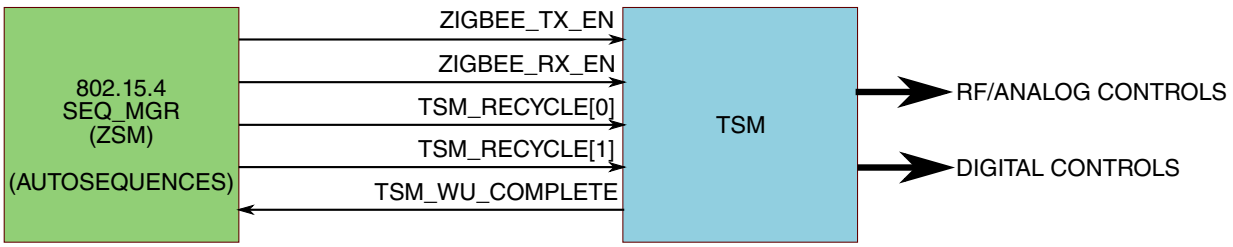


#### *64.5.2.4.2.3.2 ZSM/TSM Interaction*

The 802.15.4 Sequence Manager (ZSM) controls high-level autosequence timing, but offloads low level warmup and warmdown tasks to a dedicated, protocol-neutral Transceiver Sequence Manager, or TSM (see TSM Chapter). The ZSM initiates high-level functions, such as a CCA measurement operation or a transmit acknowledge operation, by commanding the TSM to execute an RX warmup, a TX warmup, a RX warmdown, a TX warmdown, or an RX recycle. Based on these commands, TSM generates the precise timing to control all of the digital, analog, and RF components of the TX and RX chains. The TSM is fully programmable, allowing all of the enabling and control signals to the transceiver components to be independently scheduled with 1us precision. TSM also allows all enable and control signals to be optionally overridden at any time, giving software complete control of each transceiver block, and ultimately the entire warmup/warmdown process if desired.

The ZSM and TSM sequence managers operate on the same clock domain, and both have 1us resolution. The TSM is fully programmable, while the ZSM is largely hardwired, with a few key exceptions. In the ZSM/TSM relationship, ZSM is the master and TSM is the slave. The key ZSM/TSM interface signaling is shown below:

**ZSM/TSM INTERFACE SIGNALS**



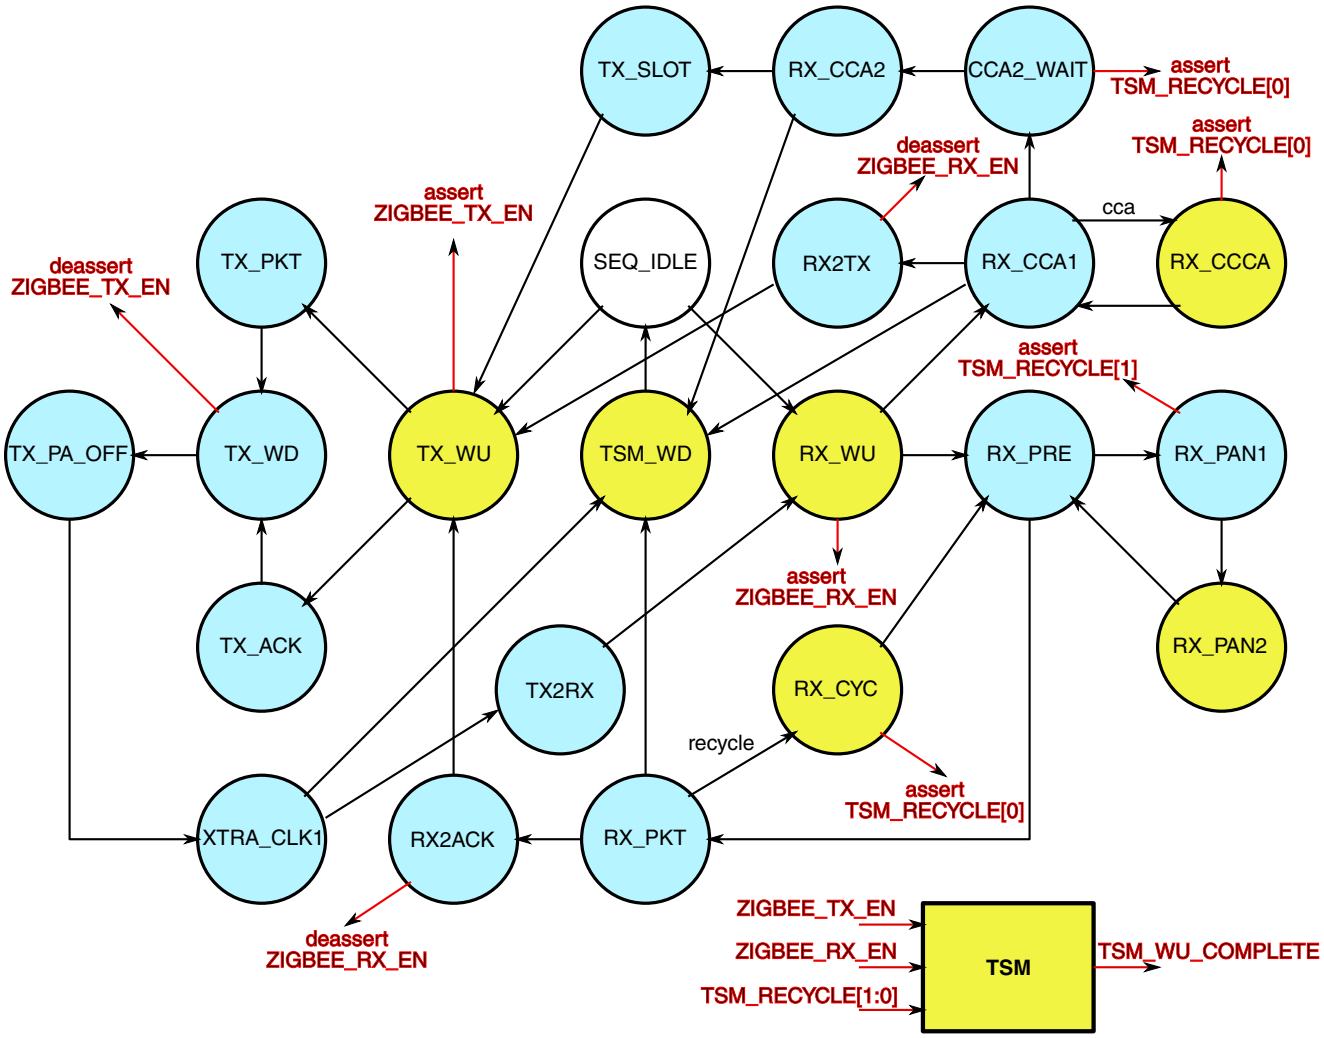
A description of the interface signals is provided in the table below.

| ZSM/TSM INTERFACE SIGNAL | DESCRIPTION |
|---|---|
| ZIGBEE_TX_EN | A low-to-high transition initiates a TSM TX warmup, starting 1us after the transition. A high-to-low transition initiates a TSM TX warmdown, starting 1us after the transition. |
| ZIGBEE_RX_EN | A low-to-high transition initiates a TSM RX warmup, starting 1us after the transition. A high-to-low transition initiates a TSM RX warmdown, starting 1us after the transition. |
| TSM_RECYCLE[0] | This signal asserts in the ZSM RX_CYC state, and causes the TSM to jump from its “ON” phase, back to a point in the TSM RX warmup determined by the TSM’s RECYCLE_COUNT0[7:0] register in XCVR space. This process is used to execute an RX recycle. This signal is also asserted in the ZSM RX_CCCA state, with the same response by the TSM. This process is used to re-initialize the CCA function during Continuous CCA (CCCA) operations. |
| TSM_RECYCLE[1] | This signal asserts in the ZSM RX_PAN1 state, and causes the TSM to jump from its “ON” phase, back to a point in the TSM RX warmup determined by the TSM’s RECYCLE_COUNT1[7:0] register in XCVR space. This process is used to re-initialize the PLL digital on a new RF channel, during a Dual PAN mode on-the-fly channel change. |
| TSM_WU_COMPLETE | For the ZSM states which assert ZIGBEE_TX_EN or ZIGBEE_RX_EN, this 1us-wide signal from the TSM indicates that the warmup is complete, and the ZSM is now free to advance to its next state. The TSM_WU_COMPLETE is asserted 1us before the actual end of sequence, which is determined by the END_OF_TX_WU[7:0] register for TX warmup, and the END_OF_RX_WARMUP[7:0] register for RX warmup. |

#### *64.5.2.4.2.3.3 ZSM State Diagram*

A ZSM state diagram is shown below. The states in yellow, are ZSM states which require interaction with the TSM. For example, a TSM control signal is asserted or deasserted, and/or a wait for warmup-complete from TSM is required; the assertions of the TSM control signals are shown in red. The states in blue have no interaction with TSM, so the timing of these states, and the transitions between such states, are governed by the ZSM itself.

## 802.15.4 SEQUENCE MANAGER AND TSM INTERACTION



Each ZSM state is represented in the hardware by a 5-bit state vector. The ZSM state can be monitored at any time by way of the read-only SEQ_STATE[4:0] register in 802.15.4 space. The mapping of ZSM state names to state vectors is shown in the table below:

| ZSM STATE | VECTOR |
|---|---|
| SEQ_IDLE | 0x00 |
| RX_WU | 0x10 |
| RX_PRE | 0x14 |
| RX_PKT | 0x15 |
| RX2ACK | 0x16 |
| RX_CYC | 0x17 |
| RX_PAN1 | 0x1D |
| RX_PAN2 | 0x1E |
| RX_CCA1 | 0x18 |

*Table continues on the next page...*

| ZSM STATE | VECTOR |

#### *64.5.2.4.2.3.5 Dual PAN Mode*

## Dual PAN On-the-fly Channel Change

The 802.15.4 Sequence Manager (ZSM) supports Dual PAN mode, which allows the device to reside on 2 networks simultaneously, switching back and forth between the 2 networks under software, or hardware control. (See Packet Processor Chapter, Section Dual PAN Mode for more details on Dual PAN mode).

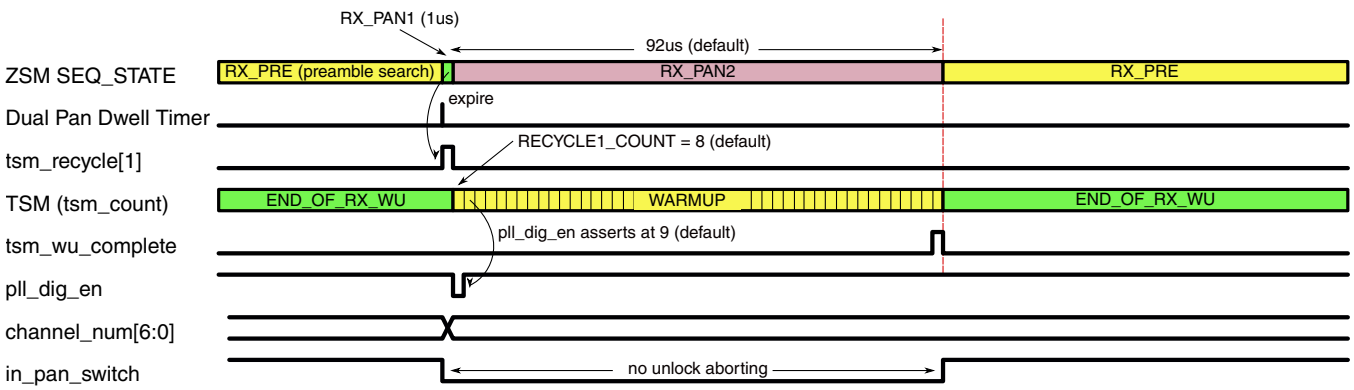
In Automatic Dual PAN Mode, the device must switch from one network to another under hardware control, at a software-programmed rate. Since the 2 networks often occupy different channels (frequencies), the sequence manager supports an “on-the-fly channel change”, whereby, during a Sequence R, in preamble-search state (RX_PRE), the sequence manager will request the TSM to toggle **pll_dig_en** and switch to a new RF channel, wait out a PLL settling time, and then resume preamble search on the new channel. The entire on-the-fly channel change consumes 93us (based on default TSM programming), and consumes 2 ZSM states. The first state (RX_PAN1) issues **tsm_recycle[1]** to the TSM, which causes TSM to jump from its “ON” phase, back to the tsm_count value which is programmed into the RECYCLE_COUNT1[7:0] register in XCVR space. Based on the default programming for RECYCLE1_COUNT, along with the default programming for the TSM timing registers, this TSM recycle will cause the TSM to jump back to the point 1us before **pll_dig_en** is asserted, resulting in a 1us-long deassertion of **pll_dig_en**. The TSM will resume counting from that point, which will re-assert **pll_dig_en**, and the ZSM will simultaneously select the alternate Dual Pan channel. Meanwhile, the ZSM will advance to RX_PAN2 state and wait there pending **tsm_wu_complete** from the TSM. The TSM will resume counting until it once again until it reaches END_OF_RX_WU[7:0], and then will return to its ON phase. At the end of the TSM RX warmup, TSM will issue **tsm_wu_complete** to ZSM, which will return ZSM to RX_PRE (preamble search) state.

Normally, during RX sequences, the PLL is monitored for unlock conditions, and if such an unlock were to occur, the ZSM would abort the RX sequence by deasserting ZIGBEE_RX_EN to TSM. During RX_PAN1 and RX_PAN2 states, ZSM asserts

**in_pan_switch** to the transceiver, which indicates that PLL unlock detection should be temporarily suspended while the channel change and subsequent PLL re-lock takes place. Once the ZSM transitions from RX_PAN2 state back to RX_PRE, ZSM will deassert **in_pan_switch** to resume PLL unlock monitoring.

As mentioned, the entire on-the-fly channel change consumes 93us, based on default TSM programming. This 93us represents a short “blind spot” during which preamble detection can’t occur, while the device switches from one RF frequency to another. See diagram below.

**ZSM DUAL PAN ON-THE-FLY CHANNEL CHANGE**



## Dual PAN Channel Override

When using Dual PAN mode, the channels are assigned to the 2 PAN’s by programming the CHANNEL_NUM0[6:0] and CHANNEL_NUM1[6:0] registers in 802.15.4 space. This method allows a channel number, from 11 to 26, to be programmed into each register, and the channel number is processed downstream into the necessary Integer, Numerator, and Denominator components, required to generate the correct RF frequencies (see PLL Digital Chapter).

In Dual PAN mode, in case there is a need to generate a frequency which may be offset from the 16 prescribed 5MHz-spaced channels, to, for example, avoid interference on one of the Dual PAN channels, a method has been provided to do that, by designating one of the two PAN channels to use the transceiver’s set of direct frequency-programming registers, instead of CHANNEL_NUMx. Programming the direct frequency-programming registers – integer, numerator, and denominator, allows an RF frequency to be selected with much more precision than the 5MHz granularity of the 802.15.4 mapped-channel registers, CHANNEL_NUM0 and CHANNEL_NUM1.

Two bits have been provided in 802.15.4 space to realize this feature: ZB_DP_CHAN_OVRD_SEL and ZB_DP_CHAN_OVRD_EN. When ZB_DP_CHAN_OVRD_EN=1, this enables one of the Dual PAN channels to use the direct frequency programming. The ZB_DP_CHAN_OVRD_SEL bit determines *which* channel uses the direct programming, according to the following table:

| ZB_DP_CHAN_OVRD_EN | ZB_DP_CHAN_OVRD_SEL | PAN0 Frequency Determined by … | PAN1 Frequency Determined by … |
|---|---|---|---|
| 0 | X | CHANNEL_NUM0[6:0] | CHANNEL_NUM1[6:0] |
| 1 | 0 | DIRECT FREQUENCY PROGRAMMING | CHANNEL_NUM1[6:0] |
| 1 | 1 | CHANNEL_NUM0[6:0] | DIRECT FREQUENCY PROGRAMMING |

Direct Frequency Programming is accomplished by setting the PLL's Integer, Numerator, and Denominator registers to the appropriate values for the desired RF frequency. These registers are in XCVR address space, and are shown in the following table:

| DIRECT FREQUENCY PROGRAMMING PARAMETER | REGISTER NAME (XCVR SPACE) | REGISTER MNEMONIC |
|---|---|---|
| Integer | LPM_INTG[6:0] | PLL_LP_SDM_CTRL1 |
| Numerator | LPM_NUM[27:0] | PLL_LP_SDM_CTRL2 |
| Denominator | LPM_DENOM[27:0] | PLL_LP_SDM_CTRL3 |

See the PLL Digital Chapter for RF frequency programming details.

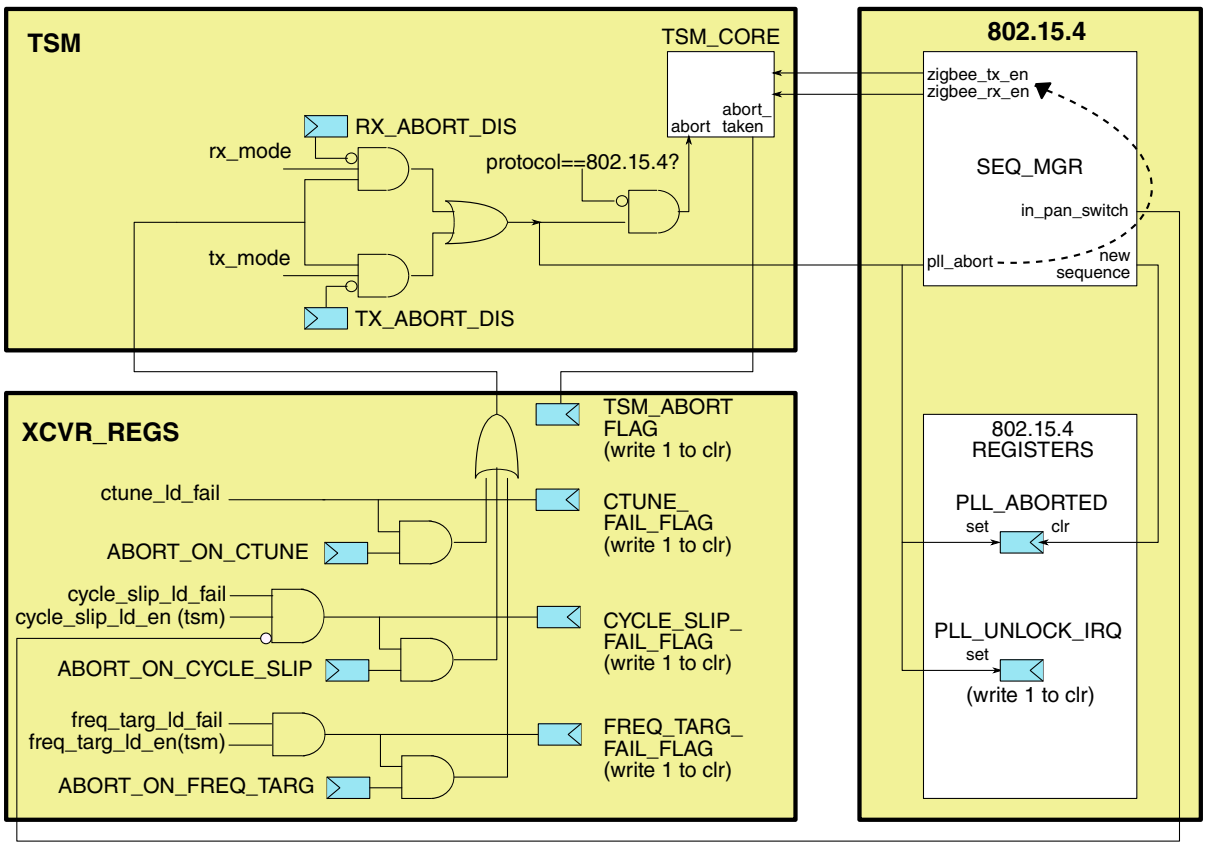
In Dual PAN automatic mode, if ZB_DP_CHAN_OVRD_EN=1, when the hardware switches to the PAN selected by ZB_DP_CHAN_OVRD_SEL as a direct-programming channel, the CHANNEL_NUMx[6:0] register is ignored and the directly programmed frequency is used instead; when the hardware switches back to the other channel, the CHANNEL_NUMx[6:0] register is used once again.

#### *64.5.2.4.2.3.6 Sequence Aborting*

All 802.15.4 sequences can be aborted by a PLL unlock detection. The unlock detection is qualified by the ZSM sequence manager; in other words, an unlock condition during the early stages of the PLL warmup is expected, and is not allowed to abort the sequence at that point. The primary rationale for the PLL unlock abort is to prevent transmission on an incorrect, or unstable, frequency during a transmit operation, or to increase battery life by not prolonging a receive or CCA operation that is bound to fail. Software can disable the PLL unlock auto-abort.

When a PLL unlock event occurs during a 802.15.4 autosequence, the TSM's abort facilities are not used, to allow the ZSM to handle the unlock condition directly, as shown in the following diagram:

**802.15.4 PLL UNLOCK HANDLING**



The combined-abort signal is blocked from reaching the TSM, and instead is routed to the 802.15.4 Sequence Manager (ZSM). This is due to the fact that the ZSM already includes abort-handling logic, which is being re-used from previous Freescale/NXP 802.15.4 products. Keeping the unlock handling intact, facilitates the porting of software from one NXP 802.15.4 product to the next.

For 802.15.4, the logic which determines which ZSM states allow aborting, is designed into the ZSM state machine. Not all states require an abort-on-unlock. When an unlock event occurs during a ZSM state that requires an abort, the ZSM will deassert its initiating signal to TSM (zigbee_tx_en or zigbee_rx_en), which results in a de facto abort, similar to a TSM-generated abort. For a ZSM abort, the PLL_UNLOCK_IRQ bit will become set, as will the PLL_ABORTED bit. The PLL_UNLOCK_IRQ bit is of type write-1-to-clear, and resides in the IRQSTS1 register of 802.15.4 space. The PLL_ABORTED bit is a read-only bit, and resides in the ABORT_STS register of 802.15.4 space; it will self-clear at the start of the next autosequence.

#### *64.5.2.4.2.3.7 Clocks*

The ZSM sequence manager use 2 clocks.

The main clock is **seq_mgr_clk**. This clock establishes the sequence manager timebase (1us), and runs the sequence manager state machine and auxiliary timers.

A secondary clock is "**ck",** which is a gated 32mhz clock from the reference oscillator. This clock is used only for low-latency processing of a few incoming signals, such as the issuing of XCVSEQ sequence commands through the IPS bus interface, which can occur at a rate faster than 1us.

The **seq_mgr_clk** and **ck** derive from the same 32MHz source. Thus, these 2 clocks are in the same clock domain, and will be balanced (skew-controlled) during clock-tree synthesis. The **seq_mgr_clk** will be generated in the CRM. All inputs to the sequence manager are also in this same clock domain, including all the TSM interface signals, and the IPS bus-based control registers; there are no clock-domain-crossings or asynchronous interfaces in the ZSM sequence manager.

#### *64.5.2.4.2.3.8 Reset*

The 802.15.4 Sequence Manager has a single, active-low, asynchronous reset input: **rst_b** . At integration, this reset should be tied to the master reset for the entire transceiver. There are no special reset requirements.

#### *64.5.2.4.2.3.9 Interrupts*

The 802.15.4 Sequence Manager generates 4 interrupt "triggers":

1. rxirq_trig
2. txirq_trig
3. ccairq_trig
4. filterfail_irq_trig

These triggers are not a direct interrupts to the MCU, but are used to set individual 802.15.4 Interrupt Status bits to become 4 of the 12 802.15.4 Link Layer interrupt sources which, if enabled, will result in the 802.15.4 interrupt **ipi_int_zigbee** being asserted to the MCU. These 4 interrupt triggers will assert the 802.15.4 Interrupt Status Bits RXIRQ, TXIRQ, CCAIRQ, and FILTERFAIL_IRQ, respectively. All of these Interrupt Status Bits reside in the IRQSTS1 register of 802.15.4 Address Space. See Section Interrupts for more details on how the 802.15.4 Link Layer interrupt sources are consolidated into a single MCU interrupt line.

*64.5.2.4.2.3.10 Appendix A*

## Effect of Timer TMR3 on Sequence Manager

Timer TMR3 can be used as a “bracketing” timer, to abort certain sequences after a software-determined timeout period. This timeout mechanism is enabled by setting the TC3TMOUT bit to 1. If TC3TMOUT=0, then the abort mechanism is disabled, and timer TMR3 functions merely as a software timer.

Timer TMR3’s hardware-abort functions are summarized in the following table.

**Table 64-46. TMR3 Hardware Abort Functions**

| SEQUENCE | TC3TMOUT=0 | TC3TMOUT=1 |
|---|---|---|
| I | S/W timer | S/W timer |
| R | S/W timer | Abort sequence |
| T | S/W timer | S/W timer |
| C | S/W timer | S/W timer |
| TR | S/W timer | Abort sequence, (during receive operation only) |
| CCCA | S/W timer | Abort sequence |

*64.5.2.4.2.3.11 Appendix B*

## Continuous TX and RX Modes

Setting the bit CONTINUOUS_EN enables continuous transmission or reception, determined by which type of sequence is subsequently activated using the XCVSEQ register (i.e., Sequence T or Sequence R). Continuous TX and RX modes are designed to be used in tandem; i.e., two communicating devices, one serving as a continuous transmitter, and the other serving as a continuous receiver. The CONTINUOUS_EN resides in the SEQ_MGR_CTRL register of 802.15.4 address space. A description of the continuous TX and RX modes follows:

## Continuous TX Mode

Continuous TX mode instructs the Sequence Manager to stay in a transmitting state forever (TX_PKT state), rather than shutting down the sequence after the 802.15.4 packet has been transmitted. In Continuous TX mode, data to be transmitted must be pre-established in the Packet Buffer prior to initiating a Sequence T. In Continuous TX mode, the first byte of the Packet Buffer determines the length of the buffer, in bytes. In this mode, when the end of the buffer is reached, instead of transmitting FCS (CRC bytes),

the TX modem circles back to the 2nd byte of the buffer (the byte after the length byte), and re-transmits the remainder of the buffer again, and this repeats continuously, until one of the following events occurs:

1) CONTINUOUS_EN is deasserted by SW

2) SW aborts the Sequence T by writing Sequence I to XCVSEQ

3) An PLL Unlock occurs, aborting the Sequence

To prepare for Continuous TX mode, the following steps should be taken:

1) Write the “length” byte to the first byte of the Packet Buffer

2) Write the remaining Packet Buffer contents (a total of “length” bytes)

3) Assert the CONTINUOUS_EN bit

4) Start the Transmit Sequence by writing Sequence T to XCVSEQ.

After Continuous TX mode has been entered, the SEQ_STATE register can be monitored to verify the Sequence Manager has reached the TX_PKT state, and remains in this state.

## Continuous RX Mode
